Results: 107 subjects were recruited (G1: 31, G2:31, G3:21, G4:24). Any lesion: SLE patients 74.7%, HS 41.67%; p 0.002. Synovitis: G1: 64.52%, G2: 51.61%, G3: 45%, G4: 20.83%; p 0.013. Erosions: G1: 29.03%; G2: 54.84%, G3: 47.62%; G4: 25%; p 0.066. Bone marrow edema: G1: 29.03%, G2: 22.58%, G3: 19.05%, G4: 0.0%; p 0.046. Tenosynovitis: G1: 38.71%; G2: 25.81%, G3: 14.29%, G4: 0.0%; p 0.005. Peritendonitis: G1: 12.90%; G2: 3.23%, G3: 0.0%, G: 0.0%; p 0.07.

Conclusion: SLE patients have a high prevalence of inflammatory musculoskeletal alterations by contrasted MRI, even if asymptomatic. Not only tenosynovitis but peritendonitis is also present.

AB0487 SJÖGREN SYNDROME: DESCRIPTIVE AND COMPARATIVE STUDY OF PRIMITIVE AND ASSOCIATED FORMS

S. Skhiri[1], A. Baya Chatti[1], W. Ben Yahia[1], A. Atig[1], N. Ghannouchi[1]. *[1]Farhat Hached Hospital, Internal Medecine, Sousse, Tunisia*

Background: Sjögren syndrome (SS) is an autoimmune disease (AID) characterized by a dysfunction of the exocrine glands (mainly salivary and tear glands). It is responsible for xerostomia and xerophtalmia as well as systemic manifestations that may affect multiple organs. This syndrome comes in two forms: primary when it is isolated (pSS) and associated (aSS) when it is in association with another AID whether it is specific of organs or not. These two entities have different particularities, requiring explorations and adapted treatments. Few studies have taken interest in determining them.

Objectives: The objective of this study was to compare the various clinical and evolutionary manifestations of these two forms.

Methods: We conducted a retrospective analytical study over a period of 33 years. All patients with SS based on ACR 2012 and/or ACR/EULAR classification

criteria were included. Epidemiological, clinical, para-clinical, therapeutic and disease course characteristics in both groups (pSS and aSS) were described and compared.

Results: One hundred and forty-five patients were included. Sixty-three (43.4%) had pSS and 82 (56.5%) had aSS. The pSS group consisted of 58 women (92%) and five men (8%) with a mean age at diagnosis of 51.9 ±15.3 years. Seventy-eight women (95%) and four men (5%) with a mean age at diagnosis of 45.4±16.2 years had a SS. The most common AADs associated with the latter were SLE (39%) and RA (18.3%). The comparison of the two groups concluded that the mean age at the time of diagnosis was significantly higher in patients with pSS (p= 0.01). Glandular involvement was almost constant in both groups. Joint involvement, skin involvement and Raynaud's syndrome were significantly more common in the aSS group (p< 0.01; < 0.001 and 0.02 respectively). Central neurological involvement was significantly more common in the pSS group (p=0.04). The other clinical manifestations were comparable in both groups. Comparison of biological abnormalities between pSS and aSS showed a statistically higher frequency of leukopenia (p=0.04), lymphopenia (p <0.001), Antinuclear antibodies (p=0.001), anti SSA antibodies (p=0.003), rheumatoid factor (p < 0.001) and anti CCP antibodies (p<0.001) in aSS. Synthetic antimalarial drugs, corticosteroids and immunosuppressive treatment were significantly more prescribed for aSS (p= 0.003, p < 0.001 and p=0.02 respectively). After a mean of follow up of 3 ±4.5 years for the pSS and 4 ±4.5 years for the aSS. No cases of lymphoma were observed in both groups.

Conclusion: Differentiating between pSS and aSS is crucial in order to establish an early diagnosis and ensure adequate management and a better prognosis. Larger-scale studies appear to be needed to optimize management.

AB0488 THE UTILITY OF ERYTHROCYTE SEDIMENTATION RATE, C-REACTIVE PROTEIN, AND PROCALCITONIN IN DETECTING INFECTIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A DIAGNOSTIC TEST ACCURACY REVIEW

S. Bruera[1], M. Ventura[1], S. Agarwal[1], M. A. Lopez-Olivo[2]. [1]*Baylor College of Medicine, Section of Immunology, Allergy, and Rheumatology, Houston, United States of America;* [2]*The University of Texas MD Anderson Cancer Center, Health Services Research, Houston, United States of America*

Background: Patients with systemic lupus erythematosus (SLE) are at an increased risk of hospitalization for flares or infections. In practice, diagnosing SLE flares versus infection can be challenging as both present with similar signs and symptoms. Strategies are needed to help differentiate between infections and SLE flares in hospitalized patients. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and procalcitonin (PCT) are commonly used to aid in the diagnosis of infection in hospitalized patients, however, their utility in SLE is unclear.

Objectives: To summarize the evidence about accuracy of ESR, CRP, and PCT in diagnosing infection in hospitalized patients with SLE.

Methods: We searched five databases until April 2021. We included studies published in English investigating levels of ESR, CRP, or PCT on adults hospitalized with a diagnosis of SLE comparing infection versus non-infection. We excluded studies with no clinical data, inadequate data to perform analysis, different conditions, and not relevant study types (such as case reports, other reviews). We also excluded studies with overlapping data (e.g., abstracts that are later published as full-text articles). We used the Quality Assessment of Diagnostic Studies to assess for bias and applicability. We obtained pooled sensitivities and specificities from studies that used similar cut-offs. We also generated mean differences for ESR, CRP, and PCT in infection versus non-infection hospitalized SLE patients.

Results: We included 26 studies in our analysis. Most studies had an unclear or high risk of bias. Most patients from both infection and non-infection groups were women aged from 27-40 years. The definitions for infection were heterogenous but mainly included positive culture or biochemical testing, suggestive imaging, response to antibiotics, or obvious signs/symptoms (such as purulence). The CRP had a pooled sensitivity of 0.75 (95%CI 0.57-0.94) and specificity of 0.72 (0.59-0.85), PCT had a pooled sensitivity of 0.68 (95% CI 0.0.59-0.77) and specificity of 0.75 (0.59-0.90), and for ESR pooled estimates were not calculated due to insufficient data but sensitivity ranged from 50 to 69.8 and specificity from 38.5 to 55.6. Modifying cut-offs improved sensitivities and specificities (see Table 1). The ESR, CRP, and PCT mean differences were all greater in infection groups versus non-infection (10.1, 95% CI 3.2-17.0; 46.8, 95% CI 36.5-57.0; 0.53, 95% CI 0.26-0.80; respectively).

Conclusion: Our study showed that although ESR, CRP, and PCT mean values are increased in hospitalized infected SLE patients compared to patients with no infection, the included studies used varying cut-offs for sensitivities and specificities and definitions for infection decreasing the uncertainty on the results and making the clinical usefulness of these biomarkers unclear. Our findings at this time do not support the widespread use of these biochemical markers in SLE patients and highlight the need that more research is needed to investigate the use of these markers in this patient population.

Table 1. Pooled sensitivity and specificities of CRP and PCT

	Studies (n)	Sensitivity (95% CI)	Specificity (95% CI)
CRP			
CRP < 10	3	0.68 (0.48-0.89)	0.70 (0.62-0.77)
CRP > 10	2	0.91 (0.86-0.97)	0.87 (0.81-0.93)
Overall	5	0.75 (0.57-0.94)	0.72 (0.59-0.85)
Procalcitonin			
PCT > 0.2	3	0.66 (0.50-0.81)	0.84 (0.76-0.92)
PCT < 0.2	3	0.70 (0.61-0.80)	0.61 (0.53-0.69)
Overall	6	0.68 (0.59-0.77)	0.75 (0.59-0.90)

AB0489 ORGANIC DAMAGE MEASURED BY SDI IN A LONG-FOLLOW-UP SLE COHORT

J. Álvarez Troncoso[1], Á. Robles Marhuenda[1], R. Sorriguieta Torre[1], S. Carrasco Molina[1], C. Soto Abánades[1], A. Noblejas Mozo[1], E. Martínez Robles[1], C. Sánchez Díaz[1], J. J. Rios[1]. [1]*Hospital Universitario La Paz, Autoimmune Diseases Unit. Internal Medicine Department, Madrid, Spain*

Background: SLICC Damage Index (SDI) index was designed to reflect accrual damage in patients with systemic lupus erythematosus (SLE). It reflects an irreversible change, unrelated to inflammatory activity, that has occurred since the diagnosis of SLE, verified by clinical assessment, and has been present for at least 6 months.

Objectives: Our objective is to determine the factors associated with higher mean SDI and SDI≥1 in patients with SLE in a long-follow-up cohort.

Methods: Single-centre retrospective observational study of SDI in SLE in a Spanish Lupus Cohort (HAPLES cohort: single-center cohort designed for the prospective evaluation of cardiac involvement in SLE). We included 219 SLE patients but 9 were excluded from the study because they did not fulfill the EULAR/ACR 2019 classification criteria.

Results: Two hundred and ten patients with a mean age at diagnosis of 35.3 years (89.1% women) were analyzed. The mean follow-up time was 15.4 years. Mean SDI was 2.21 (range 0-26). The majority (70,9%) of patients presented an SDI≥1. However, an SDI≥1 was more frequent with longer follow-up (p=0.034): 23.8% in ≤5 years vs 74% in ≥10 years. The mean SDI increases over time (follow-up) (p<0.001): in patients with <5 years since diagnosis is 1.16, between 5-10 years 2.14 and in >10 years of follow-up 2.47. A positive correlation was also found between mean SDI and age (p<0.001), hypertension (p<0.001), diabetes (p=0.004), dyslipidemia (p<0.001), obesity (p=0.045), thrombosis (p<0.001), serositis (p=0.005), renal involvement (p=0.012), neurolupus (p<0.001), cardiac involvement (p<0.001) and antiphospholipid antibodies (aPLs) (p=0.002). A negative (protective) correlation was only found with antimalarials (p=0.002). Patients with SDI=0 (no damage) vs. SDI≥1 (any damage) were compared (Table 1) to evaluate the risk factors of presenting some irreversible accrual damage in the follow-up.

Table 1. Damage accrual measured by SDI (SDI=0 vs SDI≥1)

	SDI=0	SDI≥1	p value	OR (IC95%)
Female sex (%)	88.71 %	88.51 %	p=0.967	
Late onset SLE (≥50 years) (%)	6.45 %	23.65 %	p=0.003	3.43 (1.41-8.32)
Obesity (%)	6.45 %	16.89 %	p=0.045	2.83 (1.07-7.48)
Hypertension (%)	24,19 %	53.38 %	p<0.001	2.21 (1.27-3.86)
Diabetes (%)	1.61 %	7.43 %	p=0.097	
Dyslipidemia (%)	22.58 %	45.27 %	p=0.002	1.96 (1.10-3.47)
Thrombosis (%)	3.23 %	18.24 %	p=0.004	6.00 (1.71-21.01)
Serositis (%)	12.90 %	27.03 %	p=0.026	2.08 (1.01-4.26)
Neurolupus (%)	8.06 %	25.00 %	p=0.005	3.12 (1.35-7.26)
Glomerulonephritis (%)	14.52 %	24.32 %	p=0.114	
Cardiac involvement (%)	15.52 %	54.86 %	p<0.001	3.67 (1.95-6.92)
DNAds+ (%)	56.45 %	63.51 %	p=0.338	
Anti-Sm (%)	12.90 %	14.86 %	p=0.711	
Anti-Ro (%)	29.03 %	25.68 %	p=0.616	
Anti-RNP (%)	11.29%	8.11%	p=0.463	
Antiphospholipid antibodies (%)	25.81 %	54.05 %	p<0.001	2.16 (1.25-3.75)
LLDAS (%)	56.14 %	63.51 %	p=0.331	
DORIS (%)	41.38%	48.65%	p=0.347	
Prednisone (or equivalent) >7.5	2.94 %	12.93 %	p=0.019	4.33 (1.20-15.67)
Antimalarials	90.16 %	79.73 %	p=0.022	0.43 (0.17-1.09)
Conventional DMARDs (%)	37.70%	47.97%	p=0.175	
Belimumab (%)	1.64%	5.41%	p=0.223	
Death (%)	0.00 %	2.03 %	p=0.259	

Conclusion: SDI in our SLE-cohort was correlated with age, vascular risk factors, severe organ involvement, aPLs and steroid use. Only antimalarials were associated with a lower mean SDI. SDI increases significantly with longer follow-up time, especially after the fifth year of follow-up. Prevention and early treatment of the aforementioned risk factors could avoid irreversible organ accrual damage in lupus.

AB0490 INFLAMMATORY MUSCULOSKELETAL ABNORMALITIES BY CONTRAST ENHANCED MRI SHOW A SPECIFIC PROFILE IN SLE PATIENTS

P. Corzo Garcia[1], A. Agustí Claramunt[2], I. Garcia-Duitama[2], I. Carrión Barberà[3], S. Marsico[2], J. Monfort[3], T. C. Salman Monte[3]. *[1]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; [2]Hospital del Mar, Radiology, Barcelona, Spain; [3]Hospital del Mar, Rheumatology, Barcelona, Spain*

Background: Joint involvement in SLE is the most frequent manifestation and often it is the first clinical symptom. Despite this, it is not well characterised and demographic, serological and clinicotherapeutic correlations have not been well stablished[1].

Objectives: We aim to determinate if there is a demographic, clinic or serological profile related to inflammatory joint involvement of hand and/or wrist (sinovitis, bone marrow edema, erosions, tenosynovitis or peritendonitis) confirmed by contrasted MRI in SLE patients.

Methods: Consecutive SLE patients fulfilling SLICC criteria both symptomatic and asymptomatic for joint involvement were recruited. Contrasted MRI of non-dominant hand/wrist was performed for joint and tendon evaluation. Sociodemographic, clinicotherapeutic and serological data were collected and statistically analysed along with each MRI abnormality.

Results: 83 subjects were recruited. Erosions and synovitis were more frequent at advanced age (55±12.61 vs 45.06±12.18 years, p 0.001 and 52.78±12.99 vs 44.95±12.49 years, p 0.011). Synovitis is less frequent in patients with renal involvement (6.7% vs 24.3%, p 0.031). No other SLE organ-specific involvement showed statistical correlation. Neither SLE related autoantibodies (ANA, DNAds, Sm, RNP, Ro, La, antiphospholipid), complement fractions, ESR nor CRP correlated with MRI lesions, except for erosions which showed lower DNAds titers (15.94±49.56 vs. 27.23±62.41, p 0.008). Patients with bone marrow edema received more methotrexate (25% vs 6.3%, p 0.033), and those with erosions and peritendonitis received less mycophenolate (5.6% vs 22.9%, p 0.034; y 0% vs 12.8%, p 0.026). Peritendonitis was the only alteration related to higher SLEDAI (7±2.45 vs 3.64±3.34, p 0.018). None of the musculoskeletal abnormalities correlated with accrual damage.

Conclusion: SLE patients with joint and/or tendon abnormalities confirmed by MRI are usually older and have less renal involvement, receiving more methotrexate and less mycophenolate than those who do not show musculoskeletal involvement.

AB0491 MUSCULOSKELETAL INVOLVEMENT, CONFIRMED BY CONTRAST ENHANCED MRI, CONTRIBUTES TO A WORSE HEALTH-RELATED QUALITY OF LIFE IN SLE PATIENTS

P. Corzo Garcia[1], I. Carrión Barberà[2], I. Garcia-Duitama[3], A. Agustí Claramunt[3], S. Marsico[3], J. Monfort[2], T. C. Salman Monte[2]. *[1]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; [2]Hospital del Mar, Rheumatology, Barcelona, Spain; [3]Hospital del Mar, Radiology, Barcelona, Spain*

Background: Joint involvement in SLE is the most frequent manifestation, despite this, its impact on health-related quality of life (HRQoL) has not been well stablished in these patients[1]. Pain, fatigue and functional disability contribute to HRQoL related to SLE[2].

Objectives: We aim to study the relation between joint and tendon involvement confirmed by contrasted MRI and these patient related outcomes (PRO).

Methods: Consecutive SLE patients fulfilling SLICC criteria both symptomatic and asymptomatic for joint involvement were recruited. Gadolinium-enhanced MRI of non-dominant hand/wrist was performed in all subjects for joint and tendon evaluation. Different PRO: numeric scale (NE) of pain (0-10) and fatigue (0-3), Health Assessment Questionnaire (HAQ) and Fatigue Severity Scale (FSS-9) were collected and statistically analysed along with each MRI abnormality.

Results: 83 subjects were recruited. Patients with synovitis, tenosynovitis, peritendonitis and bone marrow edema reported higher values in pain NE (6.03±2.57 vs 4.26±2.49, p 0.005; 6.56±1.95 vs 4.76±2.75, p 0.017; 8.80±1.30 vs 4.95±2.55, p 0.001; 6.47±2.62 vs 4.83±2.58, p 0.026); patients with synovitis reported higher values in fatigue EN (2.32±0.82 vs 1.91±0.84, p 0.035) and patients with tenosynovitis showed worse FSS-9 (61.50±1.73 vs 45.70±16.80, p 0.015) versus patients who did not show these abnormalities by MRI. Patients with synovitis and peritendonitis had a worse HAQ (1.14±0.69 vs 0.75±0.65, p 0.031; 1.69±0.07 vs 0.90±0.69, p 0.018).

Conclusion: SLE patients with joint and/or tendon involvement confirmed by contrast enhanced MRI have a worse HRQoL measured by pain, fatigue and functional disability.

AB0492 INTESTINAL MICROBIOLOGICAL DISORDER CLOSELY ASSOCIATED WITH PERIPHERAL LYMPHOCYTE SUBSETS AND CYTOKINES IN SYSTEMIC LUPUS ERYTHEMATOSUS.

R. Zhao[1,2,3], S. X. Zhang[1,2,3], J. Qiao[1,2,3], S. Song[1,2,3], T. Cheng[1,2,3], X. Li[1]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Shanxi Medical University, Key Laboratory of Cellular Physiology, Taiyuan, China*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by widespread inflammation and tissue damage in multiple organs[1]. Microbiome is one of environmental factors that has been suggested to contribute to the occurrence and development of SLE[2].

Objectives: This study aims to the understanding of the pathogenesis of SLE from the perspective of intestinal microorganisms and investigate the associations between flora and peripheral lymphocyte subpopulations and cytokines in SLE patients.

Methods: Fecal samples were collected from 96 patients with SLE, and 96 sex- and age-matched healthy controls (HCs). The gut microbiota were investigated via 16s rRNA sequencing and the peripheral T lymphocyte subsets of these participants were assessed by flow cytometry. Indicators of disease activity such as erythrocyte sedimentation rate (ESR), C-reaction protein (CRP), complement C3 and C4 were recorded. Differential abundance analysis was carried out using the edgeR algorithm. The Wilcoxon rank-sum test was used to compare alpha diversity indices, bacterial abundances, and the F/B ratio between groups. R (version 4.0.1) was used for comparative statistics, and pearson's correlation analysis was used to assess the correlations between the relative abundances of bacterial genera and serum levels of ESR, CRP, C3 and C4 in the samples; correlations with $p < 0.05$ were considered significant.

Results: The alpha estimators of richness (ACE and Chao 1) were significantly reduced in SLE feces samples compared with those of HCs ($p < 0.0001$). Bacterial diversity estimators, including the Shannon ($p < 0.001$) and Simpson's ($p < 0.01$) indices, were also significantly lower in SLE (Figure 1A-D). The microbial community structures of the SLE and HCs could be separated by unweighted UnFrac-based principal coordinates analysis (PCoA) ($R = 0.186$, and $p = 0.001$; Figure 1E). Significant differences in gut microbiota composition between SLE and HCs were found using the edgeR algorithm. Compared with HCs, 24 species of flora were discovered to be distinctly different($p < 0.05$). Moreover, there was a significant positive correlation between Tregs and Corynebacterium

(p < 0.05), CD8+T and Corynebacterium (p < 0.05), CD4+T and Corynebacterium (p < 0.05), T and Corynebacterium (p < 0.05), Th1 and Escherichia–Shigella (p < 0.01), Th2 and Dielma (P<0.001) as well as Eubacterium eligens group (p < 0.05), NK and Faecalibacterium (p < 0.01). as well as Corynebacterium (p < 0.001), IL-6 and Coprococcus (p < 0.05), IL-10 and Eubacterium eligens group (p < 0.001) as well as Veillonella (p < 0.05). and Lachnospira (p < 0.01). As for clinical disease measures, there were positive correlations between CRP and Eubacterium ventriosum (p < 0.05). and Coprococcus (p < 0.05), C4 and the abundance of Corynebacterium (p < 0.05) (Figure 1**F**).

Conclusion: Patients with gut dysbiosis that mainly characterized by reduced the diversity and impaired abundance of the intestinal flora. Abnormality of T cell subsets and cytokines, especially the level of CD4+T, CD8+T, NK, Treg, Th, IL-6 and IL-10 cells contributes to the occurrence and progression of SLE, which may be related to the disturbance of gut microbiota. The discovery of the associated intestinal microbiota of SLE may provide a new idea for treatment.

AB0493 FACTORS ASSOCIATED WITH SUICIDAL IDEATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME PATIENTS

A. Borisova[1,2], T. Lisitsyna[2], D. Veltishchev[1], T. Reshetnyak[2], O. Seravina[1], O. Kovalevskaya[2], F. Cheldieva[2]. *[1]Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Mental Disorders in Patients with Somatic Deseases, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, Thromboinflammation, Moscow, Russian Federation*

Background: Suicidal ideations in systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) patients are associated with stress related depressive and anxiety disorders and can lead to higher mortality rates.

Objectives: To describe the rates and potential causes of suicidal ideations in SLE and APS patients.

Methods: 159 patients (62 with SLE, 49 with SLE and secondary APS, 48 with primary APS (PAPS)), mostly women (120 (75,5%)), were consecutively enrolled in the study. The mean (M±SD) age was 37,5±12,2 years. SLE activity was measured by SLEDAI. Suicidal ideations and mental disorders were detected by psychiatrist in semi-structured interview. The severity of mental disorders was measured with MADRS, HADS, PHQ9, PSS10, and quality of life with EQ-5D, LupusQoL.

Results: The majority of patients had mental disorders (149 (93.7%)) with a predominance of anxiety and depressive spectrum (143 (89.9%)). Anxiety and depressive disorders in remission were diagnosed in 7 (4.40%) patients. Suicidal ideations in the past were revealed in 20 (12,6%) patients: in SLE - 9 (14,5%), SLE + APS - 8 (16,3%), PAPS - 3 (6,25%); suicidal attempt – in 1 (0,63%) patient with SLE + APS; autoaggressive behavior – in 11 (6,92%) patients (mainly presented as discontinuation of treatment in 10 (6,29%) patients): 6 (9,68%) - SLE, 4 (8,16%) - SLE + APS, 1 (2,08%) - PAPS. Current suicidal ideations were found in 16 (10,1%) patients: SLE - 5 (8,06%), SLE + APS - 5 (10,2%), PAPS - 6 (12,5%). The patients with suicidal ideations had higher depression (according to MADRS, HADS, PHQ-9) and anxiety (according to HADS) severity, they also presented with higher rates of stress perception (PSS-10) and poorer life quality (EQ-5D, LupusQol). The APS duration was significantly longer in patients with suicidal ideations; no differences in activity, severity and duration of SLE or steroid therapy were found, but SLE patients with current suicidal ideations compared to patients without them were 2 times more likely to receive rituximab (Table 1).

Table 1. Description of patients with/without suicidal ideations.

Characteristic, Me [25%; 75%] M±SD	With current suicidal ideations (n=16)		Without current suicidal ideations (n=143)		
	n	%	n	%	p
SLE	5	31,3	57	40,2	n/s
SLE+APS	5	31,3	44	30,9	n/s
APS	6	37,4	41	28,9	n/s
SLE duration, months	156,0 [132,0; 216,0]		84,0 [24,0; 68,0]		n/s
APS duration, months	228,0 [204,0; 348,0]		120,0 [48,0; 180,0]		0,001
MADRS	27,0 [14,5; 31,5]		13,0 [8,0; 18,0]		0,0001
HAM-A	18,5 [10,5; 25,5]		15,0 [10,0; 21,0]		n/s
HADS:					
-depression	7,0 [3,0; 9,0]		3,0 [1,0; 6,0]		0,009
-anxiety	9,0 [5,0; 14,0]		6,0 [3,0; 9,0]		0,04
PHQ-9	12,0 [8,0; 15,0]		6,0 [3,0; 12,0]		0,02
PSS-10	32,7±8,73		27,6±6,50		0,006
EQ-5D	0,56±0,29		0,72±0,22		0,009
Lupus Qol	113,7±24,9		132,0±25,8		0,02
Methylprednisolone intake:					
-Current dose, mg/day	10,0 [0; 22,5]		10,0 [5,0; 15,0]		n/s
-Cumulative dose, g	16,9 [0,9; 61,2]		7,2 [0; 28,9]		n/s
Rituximab treatment	5	31,2	26	18,2	n/s

Conclusion: Suicidal ideations in SLE/ APS patients are mainly caused by anxiety-depressive spectrum disorders provoked by stress factors, no associations with the duration, activity and manifestations of the rheumatic diseases were found. Timely identification and therapy of depressive and anxiety spectrum disorders can prevent suicidal ideations and possible poor outcomes.

AB0494 COMPARISON OF CUTANEOUS SILENT PERIOD PARAMETERS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME WITH THE HEALTHY POPULATION

G. Yolcu[1], K. Abacar[2], O. Kenis-Coskun[1], N. Inanc[2], E. Karadag-Saygi[1], O. H. Gunduz[3]. *[1]Marmara University, Physical Medicine and Rehabilitation, Istanbul, Turkey; [2]Marmara University, Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [3]Marmara University, Physical Medicine and Rehabilitation, Division of Pain Medicine, Istanbul, Turkey*

Background: Neurological involvement has a great importance in the clinical spectrum of primary Sjögren's syndrome (pSS) (1). The presence of small fiber neuropathy (SFN), which cannot be detected in routine electrophysiological examinations, causes the peripheral nervous system involvement to be underestimated in the course of the disease and causes pain-related symptoms in patients that cannot be explained by routine examinations (2). Various methods can be used in the detection of SFN, and cutaneous silent period (CSP) measurement is gaining popularity recently due to its non-invasiveness and practical application (3).

Objectives: Evaluating SFN involvement in patients with pSS using CSP and evaluating its relationship with clinical parameters.

Methods: Patients with a diagnosis of pSS followed in the rheumatology outpatient clinic and healthy volunteers demographically homogeneous with the patient group were included in the study. The CSP responses were recorded over the abductor pollicis brevis muscle in the upper extremity of all participants. The latency and duration values of the responses were obtained. In patient group, EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), Hospital Anxiety and Depression Scale (HADS), Short Form-36 (SF-36) questionnaire, Leeds Assessment of Neuropathic Symptoms and Signs (LANSS) and Central Sensitization Inventory (CSI) were applied for the evaluation of symptom severity, mood, quality of life, presence of neuropathic pain and central sensitization, respectively. Comparison of CSP parameters between patients with pSS and healthy volunteers was determined as the primary outcome measure. The secondary outcome measure was the relationship between CSP parameters and ESSPRI, HADS, SF-36, LANSS and CSI scores.
Results: A total of 36 patients and 36 healthy controls were included in the final analyses. There was no significant difference between the two groups in terms of demographic data. The mean CSP latency was significantly longer in patients with a mean of 78.18 (±7.51) when compared to controls with a mean of 67.91 (±6.41) (95% CI: 6.98- 13.55, p<0.001). Mean CSP duration was also significantly shorter in patients with a mean of 33.40 (±6.93) (95% CI: 9.57 -15.31, p<0.001). There were no significant differences in CSP parameters (latency and duration, respectively) according to patients' neuropathic pain or central sensitization profile (p>0.05 for all analyses). There were significant correlations of CSP parameters with ESSPRI dryness (r=0.469, p=0.004; r=-0.553, p<0.001), fatigue (r=0.42, p=0.011; r=-0.505, p=0.002), pain (r=0.428, p=0.009; r=-0.57, p<0.001) subscores and mean ESSPRI score (r=0.631, p<0.001; r=-0.749, p<0.001). Significant correlations were not found between CSP parameters and SF-36 scores, other than CSP duration and "pain" subscore (r=-0.395, p=0.017). When the other correlations were investigated there were no significant correlations other than CSP duration and the HADS anxiety score (r=-0.201, p=0.02).
Conclusion: As an indicator of CSP measurement, SFN is more common in patients with pSS than in the healthy population. The association with important clinical symptoms of the disease course such as dryness, fatigue, pain and anxiety highlights the importance of detecting small fiber neuropathy.

AB0495 SERUM AND URINE GALECTIN-9, IP-10 AND SIGLEC-1 AS BIOMARKERS OF DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Mirioglu[1,2,3,4], S. Çınar[2,3], O. Uludag[1], E. Gurel[1], S. Varelci[1], Y. Ozluk[5], I. Kilicaslan[5], Y. Yalçınkaya[1], H. Yazici[6], A. Gül[1], M. Inanc[1], B. Artim-Esen[1]. *[1]Istanbul University Istanbul School of Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul University, Graduate School of Health Sciences, Istanbul, Turkey; [3]Istanbul University Aziz Sancar Institute of Experimental Medicine, Department of Immunology, Istanbul, Turkey; [4]Bezmialem Vakif University School of Medicine, Division of Nephrology, Istanbul, Turkey; [5]Istanbul University Istanbul School of Medicine, Department of Pathology, Istanbul, Turkey; [6]Istanbul University Istanbul School of Medicine, Division of Nephrology, Istanbul, Turkey*

Background: Galectin-9, interferon-inducible protein-10 (IP-10) and sialoadhesin (SIGLEC-1) are proteins associated with interferon signature, and considered as potential biomarkers reflecting disease activity in patients with systemic lupus erythematosus (SLE).
Objectives: In this study, we aimed to investigate the association of serum and urine levels of galectin-9, IP-10 and SIGLEC-1 with disease activity in patients with SLE.
Methods: Sixty-three patients with active SLE (31 renal and 32 extrarenal) were included in the study. Thirty inactive patients with SLE (15 renal and 15 extrarenal) and 32 healthy volunteers were selected as control groups. Serum (s) and urine (u) levels of galectin-9, IP-10 and SIGLEC-1 were tested using ELISA. Urine levels of biomarkers were normalized by urine creatinine.
Results: Groups were comparable with regard to sex and age distribution. Of 125 participants, 102 (81.6%) were female and median age was 33 (28-44.5) years. Proliferative lupus nephritis (LN) (class III/III+V and IV/IV+V) were found in 22 patients with active renal SLE (70.9%), while 6 patients (19.3%) had pure class V and 3 (9.7%) had class II LN. Levels of sIP-10, uIP-10, sGalectin-9 and uSIGLEC-1 were significantly higher in the active SLE group compared to the inactive SLE group (sIP-10 p=0.046, uIP-10 p<0.001, sGalectin-9 p=0.031 and uSIGLEC-1 p=0.006); however, no differences were detected in the comparison of uGalectin-9 and sSIGLEC-1 between the groups (uGalectin-9 p=0.180 and sSIGLEC-1 p=0.699) (Table 1). Serum and urine levels of galectin-9, IP-10 and SIGLEC-1 did not differ between patients with active renal and extrarenal SLE. Levels of sIP-10, uIP-10 and uSIGLEC-1 were correlated with SLE Disease Activity Index (SLEDAI). Serum and urine levels of all biomarkers were re-tested in 41 of 63 patients (65%) with active SLE after a median treatment of 8 (5-22.5) months. At the time of the second tests, there was a significant decrease in disease activity as measured by SLEDAI [2 (0-4)] compared to the time of the first tests [10 (6-15.5)]. Comparison of sGalectin-9 levels between the serum at the time of active disease and remission showed a very significant decline (p<0.001) as shown in Figure 1. uGalectin-9, sIP-10 and uSIGLEC-1 also decreased after treatment; however, the difference was not statistically significant.

Table 1. Serum and urine levels of biomarkers across study groups.

Biomarker	Active SLE (n=63)	Inactive SLE (n=30)	Healthy Control (n=32)
sGalectin-9 (ng/ml)	11.73 (7.52-14.15)	8.66 (7.51-10.02)	5.61 (4.56-6.6)
sIP-10 (pg/ml)	279.4 (147.5-430.3)	173.4 (142.2-247.9)	74.3 (58.8-103)
sSIGLEC-1 (pg/ml)	181.2 (157.8-213.9)	182.5 (169.9-203.1)	258.3 (179-602)
uGalectin-9 (ng/ml)	8.83 (4.07-18.11)	11.54 (7.03-15.07)	10.63 (5.55-17.4)
uIP-10 (pg/ml)	34.4 (15.9-73,9)	20.8 (9.9-53.3)	12.2 (1.8-25.7)
uSIGLEC-1 (pg/ml)	321 (236.3-370.9)	297.6 (247.7-371)	290 (205.1-323.5)
uGalectin-9 (ng/mgCre)	15.50 (9.60-32.05)	11.41 (8.78-19.54)	13.57 (11.27-22.08)
uIP-10 (pg/mgCre)	73.4 (40.9-136.9)	26.1 (18.1-55.1)	16.4 (5-32.5)
uSIGLEC-1 (pg/mgCre)	619.6 (389.4-1056.5)	393.2 (248.6-715.8)	425.6 (264.7-925.9)

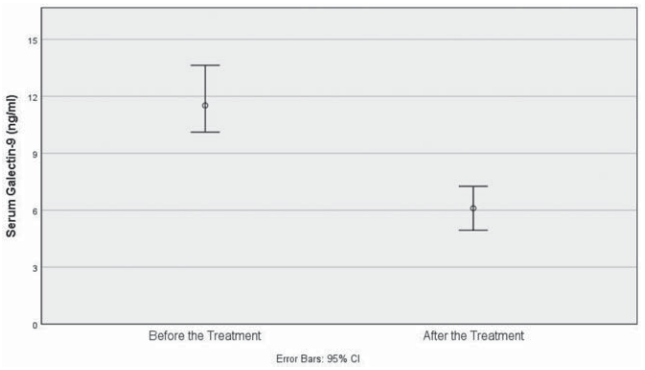

Figure 1. Serum levels of galectin-9 before and after the treatment in 41 patients with active SLE.

Conclusion: sIP-10, uIP-10, sGalectin-9 and uSIGLEC-1 are associated with disease activity in SLE. None is able to discriminate active renal from active extrarenal disease. sGalectin-9 may be a valuable biomarker to monitor response after treatment for active disease (Funded by Scientific Research Projects Coordination Unit of Istanbul University. Project number: TSA-2019-34218).

AB0496 SHOULD ANTIBODIES TO DOMAIN I B2-GLYCOPROTEIN 1 BE INVESTIGATED IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME (APS) AND SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)?

F. Cheldieva[1,2,3], T. Reshetnyak[1,2], M. Cherkasova[3], S. Glukhova[4], A. Lila[2,4], E. Nasonov[4]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [2]Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [4]V.A. Nasonova Research Institute of Rheumatology, Department of Rheumatology, Moscow, Russian Federation*

Background: The role of antiphospholipid antibodies (aPL) not included in the International Classification Criteria for the verification of APS continues to be discussed.
Objectives: To determine the clinical significance of IgG antibody for domain 1 β_2-glycoprotein 1 (IgG-aβ_2-GP1-D1) in patients with APS and SLE.
Methods: The study included 187 patients: 52 - with primary APS (PAPS), 12 - with probable APS (proAPS), 59 - with SLE+APS, and 64 - with SLE without APS. The comparison group included 49 patients with various rheumatic diseases (thrombosis without aPL (n=7), rheumatoid arthritis (RA) (n=10), Behcet's disease (BD) (n=15), systemic sclerosis (SSD) (n=12), pregnant women (n=2),

polymyositis (n=2) and Buerger's endarteritis (n=1)) and a control group of 100 relatively healthy people. IgG/IgM-antibodies to cardiolipin (aCL) and IgG/IgM-aβ_2-GP1 were determined by ELISA, and IgG-aβ_2-GP1-D1 - by chemiluminescence assay (CMA) in all patients and controls.

Results: IgG-aβ_2-GP1-D1 was detected in 37 (71%) of 52 patients with primary APS (PAPS), in 6 (50%) of 12 patients with probable APS (proAPS), in 42 (71%) of 59 patients with SLE+APS, in 17 (26%) of 64 patients with SLE, in 1 (2%) of comparison group and in none of control group. IgG-aβ_2-GP1-D1 was significantly associated with PAPS and SLE+APS compared with patients with SLE (P=0,0002 and P=0,0001, respectively). IgG-aβ_2-GP1-D1 levels were significantly higher in patients with PAPS, proAPS, SLE+APS, and SLE compared to control group (P < 0,000001, 0,03, < 0,000001, and 0,02, respectively). IgG-aβ_2-GP1-D1 levels were significantly higher in patients with PAPS and SLE+APS compared to patients with SLE (P = 0,001 and P = 0,000005, respectively) and patients from the comparison group (P < 0,05). The frequence of IgG-aβ_2-GP1-D1 positivity was associated with both thrombosis and obstetric pathology - the risk of developing clinical manifestations of APS was 9,69 and 4,19 times higher, respectively. A reliable correlation between antibodies to IgG-aβ_2-GP1-D1 and arterial thrombosis can be traced. Obstetric pathology was detected in 32 of 37 women with a history of pregnancy and all were with IgG-aβ_2-GP1-D1, versus 21 of 32 with negative IgG-aβ_2-GP1-D1 (χ2=4,19; P=0,04). Eclampsia/preeclampsia and fetoplacental insufficiency in history was in 19 of 37 women with IgG-aβ_2-GP1-D1, versus 7 of 32 with obstetric pathology but no IgG-aβ_2-GP1-D1 (χ 2=6,35; P=0,01). The incidence of obstetric pathology was significantly associated with the presence of IgG-aβ_2-GP1-D1 compared to women without these antibodies. Isolated IgG-aβ_2-GP1-D1 positivity was reported in 13 (19%) of 70 aPL-negative patients. Obstetric pathology was present in all 6 (100%) women who had pregnancy in their disease course, and thrombosis in 7 (53%) of 13 patients. Sensitivity and specificity of IgG-aβ_2-GP1-D1 depending on APS and its clinical manifestations are presented in the Table 1.

Table 1. ***Sensitivity and specificity of IgG-aβ2-GP1-D1***

	Thrombosis	*Obstetric pathology*	*Diagnosis of APS*
Sensitivity (%)	63	58	71
Specificity (%)	83	92	87

Conclusion: The frequency of IgG-aβ_2-GP1-D1 positivity was higher in patients with APS compared to patients with SLE without aPL, comparison group and controls (P < 0,05). In 19% of cases, isolated IgG-aβ_2-GP1-D1 positivity was observed. Positive IgG-aβ_2-GP1-D1 levels were significantly associated with thrombotic complications and with obstetric pathology (χ2=8,84; P=0,002 and χ2=6,35; P=0,01). Specificity of IgG-aβ_2-GP1-D1 for APS and its clinical manifestations (thrombosis and obstetric pathology) was higher than sensitivity.

The study was performed at the V.A. Nasonova Research Institute of Rheumatology within the framework of the fundamental topic FURS-2022-003.

AB0497

IMMUNOLOGICAL DISEASE ACTIVITY PARAMETERS AT CONCEPTION ARE RISK FACTORS FOR PRETERM BIRTH AND LOW BIRTH WEIGHT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

H. Shimada[1], R. Wakiya[1], S. Nakashima[1], M. Kato[1], T. Miyagi[1], K. Sugihara[1], R. Mino[1], M. Mizusaki[1], T. Kameda[1], H. Dobashi[1]. *[1]Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan*

Background: Women with systemic lupus erythematosus (SLE) are known to have more difficulty in achieving a successful pregnancy than healthy women. They have a higher risk for adverse pregnancy outcomes (APOs) including preterm birth (PB), low birth weight (LBW). (1,2). Many reports revealed that these APOs are related to uncontrolled high disease activity (3,4). Therefore, it is important for SLE women who hope to conceive to control disease activity strictly. However, it is not clear to what extent disease activity should be strictly controlled, including serum parameters such as complement levels and anti-dsDNA antibodies.

Objectives: The purpose of this study was to determine whether disease activity parameters at conception could be a risk factor for PB or LBW among APOs in patients with SLE.

Methods: Disease activity parameters including SLEDAI score, LLDAS achievement rate, serum complement levels (C3, C4, CH50), and anti-dsDNA antibody titer were retrospectively collected from medical records. We then collected information related to each APOs (PB and LBW), and analyzed the association with disease activity parameters.

Results: The subjects were 60 pregnancies of 45 patients. As for a comprehensive disease activity index at conception, SLEDAI score or the rate of LLDAS achievement became risk factors for PB (both of p<0.01, Table 1), and SLEDAI score was also a risk factor for LBW (P=0.04, Table 1). Analysis of immunological disease activity parameters showed that low C3 or high titer of anti-dsDNA antibody were risk factors for PB (P=0.03 and 0.01, respectively, Table 1). In the logistic regression analysis of PB, the cut-off levels of C3 and anti-dsDNA antibody were 62 mg/dl and 5.4 IU/ml, respectively (Figure 1 **[1]-A, [1]-D**). The risk of PB was significantly higher in the cases with low serum C3 and high anti-dsDNA antibody titer at conception (P=0.02). Similarly, low C3 or CH50 were risk factors for LBW (P=0.02 and 0.03, respectively, Table 1). Logistic regression analysis for LBW showed the cut-off level of C3 as 87 mg/dl, and CH50 as 41.8 IU/ml (Figure 1 **[2]-A, [2]-C**). Cases with low C3 and low CH50 were at higher risk for LBW (P=0.03).

Table 1. Association between disease activity parameters and PB or LBW

	Preterm birth (PB)			Low birth weight (LBW)		
	PB (+) (n = 14)	PB (-) (n = 46)	P value	LBW (+) (n = 23)	LBW (-) (n = 37)	P value
Achievement of LLDAS, n (%)##	5 (41.7)	30 (71.4)	0.09	12 (63.2)	23 (65.7)	1.00
Achievement of LLDAS without a glucocorticoid dose, n (%)##	5 (41.7)	37 (88.1)	< 0.01*	13 (68.4)	29 (82.9)	0.31
SLEDAI score#	3.5±2.9	1.1±1.3	<0.01*	2.3±2.1	1.3±2.0	0.04*
C3, mg/dl#	77.3±19.0	94.7±21.2	0.03*	80.5±16.3	96.7±22.7	0.02*
C4, mg/dl#	16.1±9.0	19.2±6.3	0.16	17.6±6.3	19.1±7.4	0.56
CH50, IU/ml#	37.3±10.6	41.1±8.5	0.17	36.5±6.6	42.2±9.7	0.03*
Anti-dsDNA antibody, IU/ml#	32.5±68.5	5.5±11.1	0.01*	20.7±55.8	7.0±12.2	0.34

(Values are presented as mean ± standard deviation or number (%). #Wilcoxon rank sum test; ##Fisher's exact test; *P < 0.05.)

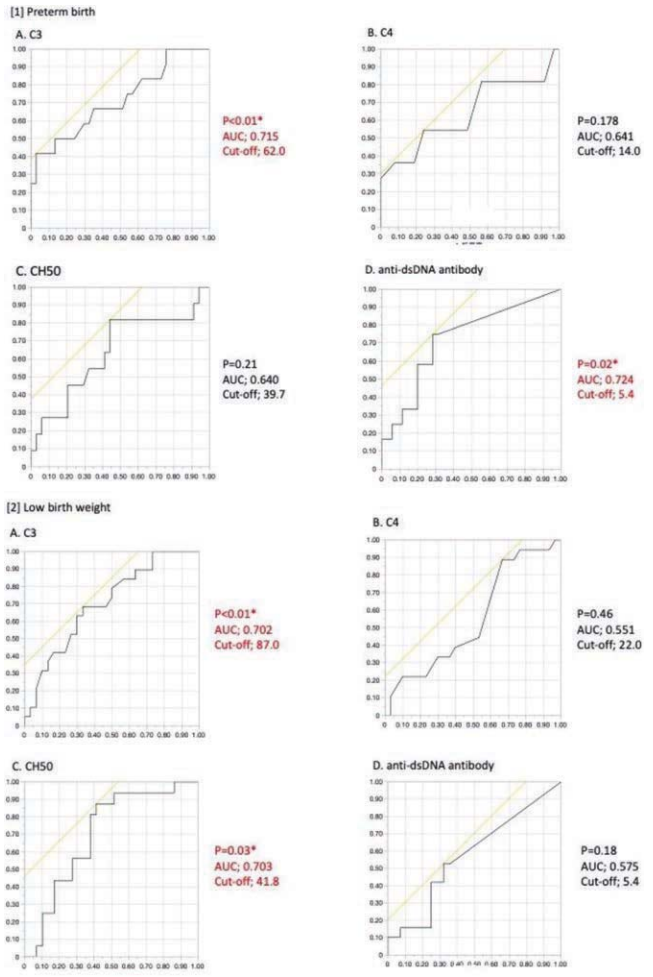

Figure 1. Logistic regression analysis of cut-off value of PB and LBW for C3, C4, CH50 and anti-dsDNA antibody. (ROC curves based on logistic regression analysis of cut-off levels for disease activity parameters, including C3, C4, CH50, and anti-dsDNA antibody titer. [1] showed ROC curves for PB, and [2] showed those for LBW.)

Conclusion: We revealed that disease activity parameters of SLE at conception are strongly associated with negative pregnancy outcomes; PB and LBW. These include low serum C3 and CH50 levels and high anti-dsDNA antibody

titers. In particular, low serum complement is a risk factor for both PB and LBW. Therefore, it is important to strictly control these disease activity parameters at conception in women with SLE.

AB0498 CONCENTRATIONS OF ADVANCED GLYCATION END PRODUCTS (AGES) CORRELATE WITH INDEXES OF ACTIVITY AND DAMAGE ACCRUAL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE).

I. Carrión Barberà[1], L. Triginer[2], L. Tío[2], C. Pérez[1], L. Polino[1], J. Llorente Onaindia[2], A. Ribes[2], E. Beltrán[1], A. Pros[1], M. Ciria Recasens[1], J. Monfort[1], T. C. Salman Monte[1]. *[1]Hospital del Mar, Rheumatology, Barcelona, Spain; [2]IMIM, Rheumatology, Barcelona, Spain*

Background: It has been postulated that AGES could have a relevant role as inducers in the chronic inflammatory pathway present in various diseases[1]; among them, in immune-mediated diseases such as SLE, as well as that its concentration could be related to some parameters of the disease such as activity [2] or accumulated damage [3], showing studies discrepant results to date.
Objectives: To describe correlations between the concentrations of AGEs measured by cutaneous autofluorescence and various parameters related to the disease in a population of SLE patients.
Methods: AGE concentrations were measured by skin autofluorescence (Age Reader Mu Connect from Diagnoptics Technologies BV) in 66 SLE Caucasian patients and correlations with demographic and clinical data were analyzed, after adjusting for age, smoking and corticosteroids as possible confounding factors, according to previous data. Previous validation studies have shown that skin autofluorescence is strongly related to AGE levels in skin biopsies[4]. The indices were analyzed both as quantitative and categorized variables according to previously established categories or to medians/tertiles/quartiles depending on the distribution of the variable in our population.

Results: Table 1 shows some descriptive characteristics of our cohort. There were clinically and statistically significant differences in the values of AGEs according to the patient's SLEDAI and SLICC. Specifically, it was observed that AGEs' values in the population with severe activity according to SLEDAI was 0.61 (95% CI 0.85-2.046; p=0.045) points > than in those in remission (p=0.045); as well as AGEs' values in patients with SLICC ≥1 was 1.23 (95% CI 0.49-1.98; p=0.030) points > than in the group without cumulative damage. In all the models, the values of AGEs increased significantly with age, smoking and current treatment with corticosteroids, except for the model including the SLICC variable. Interactions in said model were explored, and it was observed that the concentration of AGES depended on the interaction between the value of SLICC and the intake of corticosteroids, so that differences were only observed between SLICC groups in those who took corticosteroids.
Conclusion: A correlation with elevated values of AGEs was observed in those SLE patients with higher scores in the indexes of activity (SLEDAI) and damage accrual (SLICC). The fact that the differences in SLICC are only observed in those patients treated with corticosteroids suggests that, maybe, only the accumulated damage related to taking corticosteroids could be mediated by AGEs.

AB0499 LYMPHOID ORGANIZATION IN LUPUS NEPHRITIS: EVALUATING POSSIBLEAUTO ANTIGENS

V. A. Pacucci[1], F. R. Spinelli[1], C. Garufi[1], F. Ceccarelli[1], S. Colafrancesco[1], M. Leopizzi[2], C. Alessandri[1], F. Conti[1]on behalf of Lupus Clinic, Sapienza University of Roma. *[1]Sapienza University of Rome, Rheumatology Unit; Department of Clinical, Internal, Anaesthesiologic and Cardiovascular Sciences, Roma, Italy; [2]Sapienza University of Rome, Pathology Unit, Department of Radiological, Oncological, Pathological Sciences, Roma, Italy*

Background: Lupus nephritis (LN) represent one of the most frequent organ manifestations and one the major cause of morbidity in Systemic Lupus Erythematosus (SLE) patients. Tubule-interstitial infiltrate (TII) represents an independent prognostic factors of renal outcome[1].
Objectives: The aim of the study was to evaluate the inflammatory infiltrates organization in kidney biopsies obtained from LN patients and to investigate possible autoantigens for in situ immune response.
Methods: Paraffin embedded kidney specimens collected since 2017 from SLE patients who underwent a renal biopsy for diagnostic purpose were re-evaluated[2]. Clinical, laboratory and histological data were collected in a standardized, computerized and electronically filled form, including demographics and past medical history. Disease activity was assessed by using SLEDAI-2K and remission in response to therapy was defined as a score 0 of renal item of the SLEDAI[3]. The cellular infiltrate were assessed by hematoxylin-eosin and by immunohistochemistry with a staining of sequential sections for monoclonal antibodies to CD3, CD20, CD21. Staining for detections of LL-37, vimentin and citrulline was made[4]. Serological levels of CXCL13 and anti-vimentin antibodies (AVAs) were evaluated in a subgroup of patients.
Results: Eighteen paraffin embedded renal specimens with TII, from LN patients were re-evaluated (F:M = 17:1, median age at biopsy-SD years 37-23; median disease duration at date of biopsy-IQR 3-4 years). A histo-morphologic grading score was performed based on the total count of TI lymphocytes and the presence of ectopic lymphoid structures-ELSs (grade 3-G3) (Figure 1). A correlation was found between G3 structures and the absence of renal remission with conventional immunosuppressive therapy (P=0.0026). Samples with G3 foci showed significantly higher intensity of LL37 (P=0.013) and LL37 co-localization (P=0.006) compared to the other lymphocytic infiltrates. No correlation was found among the intensity of vimentin and citrulline and the grade of lymphoid aggregates. A statistically significant inverse correlation between AVAs serum levels and response to therapy was found (P=0.0048). Moreover, higher level of AVAs and CXCL13 were found in patients with G3 structures. To note, two patients underwent anti-CD20 therapy but renal remission was achieved only in the patients displaying G3 structure.

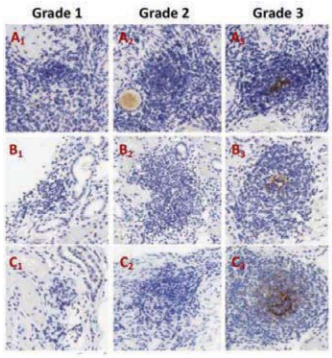

Figure 1. Characterization of the lymphocytic infiltrate and histo- morphologic grading of renal specimens from three patients with lupus nephritis (LN). Renal specimens (3 µm thick) from LN patients were stained for detection of CD21+ follicular dendritic cells (**A3, B3, C3**). Displayed are representative examples of grade 1 (**A1, B1, C1;** cellular aggregates with 10–50 lymphocytes,), found in 12 of the 18 LN patients (66.7%); grade 2 (**A2, B2, C2;** 50 lymphocytes) identified in 10 of the 18 patients (55.6%); and grade 3 (**A3, B3, C3**; > 50 lymphocytes, with ELS) foci, observed in 6 of the 18 patients (33.4%). (Original magnification x50)

Figure 1.

Conclusion: The study demonstrated that tubule-interstitium involvement is associated with the presence of lymphoid aggregation and poor renal outcome. For the first time we demonstrated that patients with G3 structures had a significant decreased response to immunosuppressant conventional therapies compared to those without ELSs. These results suggest a possible phatogenetic, prognostic and therapeutical role of lymphocytic aggregates. In addiction, LL37, thus NETosis, could have a possible role in inducing the formation of lymphocytic structures. Moreover, patients with a G3 foci showed high serological levels of AVAs and CXCL13, thus, promoting their possible role as circulating biomarkers of the presence of ELSs.

AB0500 THE LEVEL OF PERIPHERAL BLOOD LYMPHOCYTE SUBSETS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS WITH RESPIRATORY TRACT INFECTION AND ITS CLINICAL SIGNIFICANCE

J. Q. Zhang[1], S. X. Zhang[1], J. Qiao[1], M. T. Qiu[1], X. Li[1]. *[1]The Second Hospital of Shanxi Medical University, Rheumatology,Taiyuan, China*

Background: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disorder. Infections are a most common cause of morbidity and mortality in this patient population[1] and at least 50% of patients with SLE are suffered with infections during the course of their disease [2]. Lymphocytes and Natural killer (NK) cells play an important role in the occurrence and development of SLE[3]. In this study, peripheral blood lymphocyte subsets were detected in these patients, providing reference for early diagnosis and treatment of SLE patients with respiratory tract infection.

Objectives: To analyze the detection level and clinical significance of peripheral blood lymphocyte subsets in patients with SLE with respiratory tract infection.

Methods: A total of 333 SLE patients with no recent infection, 95 SLE patients with respiratory tract infection, and 132 healthy individuals matched in age and sex were enrolled in the second Hospital of Shanxi Medical University from July 2014 to December 2016. The characteristics of lymphocyte subsets in the three groups were compared and receiver operating characteristic (ROC) curves were drawn to analyze the predictive value of lymphocyte subsets in SLE patients with respiratory tract infection.

Results: The counts of T, B, CD4 + T, CD8 + T, NK, Th1, Th2, Th17 and Tregs in SLE non-infection group and SLE infection group were [(1094.235 ± 574.495) / (702.781 ± 432.152), t= -7.169, P < 0.001], [(208.338 ± 210.448) / (177.55 ± 170.256), t = -1.306, P = 0.192], [(503.382 ± 303.498) / (304.075 ± 215.497), t = -7.168, P < 0.001], [(536.705 ± 344.218) / (358.034 ± 235.234), t = -5.802, P < 0.001], [(113.898 ± 101.48) / (61.768 ± 50.127), t = -6.831, P < 0.001], [(86.268 ± 89.081) / (47.92 ± 54.174), t = -3.367, P = 0.001], [(11.363 ± 9.834) / (6.628 ± 6.434), t = -3.622, P < 0.001], [(9.537 ± 10.12) / (5.346 ± 4.731), t = -3.646, P < 0.001], [(25.736 ± 27.013) / (20.78 ± 28.083), t =-1.037,P=0.301] (Figure 1).The above indexes in SLE infection group were lower than those in SLE non-infection groups. When lymphocyte subsets predict pulmonary infection in SLE, the AUC value of CD4 + count is the highest, and the cut-off is 387/ µ l(Table 1). The sensitivity and specificity of predicting SLE pulmonary infection were 75.8% and 38.6%(Figure 2).

Table 1. Predictive value of peripheral blood lymphocyte subsets in SLE complicated with respiratory tract infection

					Susceptibility	Specificity
Indicator	AUC	P value	Jordan index	cut-off	(%)	(%)
B	0.569	0.040	83.9950	0.183	0.421	0.238
CD4	0.714	<0.001	0.372	387	0.758	0.386
CD8	0.682	<0.001	0.325	405	0.726	0.401
CD4+ T /CD8+ T	0.569	0.041	0.000	0.785	0.537	0.370
NK	0.687	<0.001	0.309	82.5	0.768	0.460

Conclusion: The absolute number of these subsets in infected SLE patients is significantly lower than that in uninfected patients, which indicates that the low absolute number of these cells can be used as an indicator of high infection risk in SLE patients. CD4 + T lymphocytes and NK cells in patients with respiratory tract infection are significantly lower, and can play a certain predictive value for SLE respiratory tract infection to a certain extent.

AB0501 COMPREHENSIVE ASSESSMENT OF PATIENTS WITH SUSPECTED SJÖGREN'S SYNDROME: 5-YEAR RESULTS OF A MULTIDISCIPLINARY SJÖGREN'S SYNDROME CLINIC

V. C Romão[1,2], M. J. Sousa Bandeira[1,2], M. Silvério-António[1,2], R. Simão[3], J. Pinto[4], A. I. Gonçalves[4], M. J. Gonçalves[1,2], A. L. Martins[3], P. José[4], G. Coutinho[3], L. Morena Bueno Silva[1], M. Brito Lança[2], R. Esteves Marques[4], C. Macieira[1], N. Khmelinskii[1,2], W. Rodrigues[4], F. Salvado[3], J. E. Fonseca[1,2]. *[1]Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon Academic Medical Centre, Rheumatology Department, Lisbon, Portugal; [2]Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Rheumatology Research Unit, Lisbon, Portugal; [3]Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon Academic Medical Centre, Stomatology Department, Lisbon, Portugal;*

[4]Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon Academic Medical Centre, Ophthalmology Department, Lisbon, Portugal

Background: Primary Sjögren's syndrome (pSS) is a systemic rheumatic disease that affects several organ systems, most frequently the ocular, oral and musculoskeletal domains. Multidisciplinary care is thus crucial in the optimal management of SS patients.
Objectives: To report the clinical impact of a Multidisciplinary SS Clinic (MSSC) over a 5-year period.
Methods: We prospectively included patients assessed in the MSSC from September 2015 to October 2020. All patients had a full clinical evaluation, including disease-related questionnaires, specialized oral/ocular assessment, salivary gland biopsy (SGB) and ultrasound (SGUS), tear and salivary flow and ocular staining scores. We compared the results of patient-reported outcomes, comprehensive clinical assessments and specialized complementary exams in patients with pSS and other diagnoses.
Results: 445 patients (96% women, mean age 57±14 years) with sicca symptoms underwent complete multidisciplinary evaluation. Patients were most frequently referred from Rheumatology (91%), but also from Stomatology (5%), Ophthalmology (2%), Internal Medicine (1%) and other medical specialties (1%). Most patients were diagnosed with pSS (n=221; 50%), followed by non-Sjögren sicca syndrome (nSSS, n=134; 30%), secondary SS (sSS, n=60; 13%) and undifferentiated connective tissue disease (n=30; 7%). Positive sicca tests were present in 217/385 patients (56%): unstimulated whole salivary flow (UWSF) ≤0.1ml/min in 84/317 (27%); Schirmer's test ≤5mm/5min in 163/354 (46%); van Bijsterveld score ≥4 in 42/349 (12%); Ocular Staining Score (OSS) ≥5 in 36/343 (11%). Subjective complaints assessed by the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), the EULAR Sicca Score (ESS), the Profile of Fatigue and Discomfort - Sicca Symptoms Inventory (PROFAD-SSI), the Xerostomia Inventory (XI), and the Ocular Surface Disease Index (OSDI) did not differ between patients with pSS and other diagnoses. However, objective dryness measures such as UWSF (31vs20%, p=0.028), Schirmer's test (51vs40%, p=0.040) and OSS (14vs7%, p=0.048) were significantly associated with pSS. A positive SGB (focus score≥1) was seen in 48% of patients with a clinical diagnosis of pSS (p<0.001 vs. other diagnoses), with a mean focus score of 1.1±1.6. Instead, 94% of patients with nSSS had grade 0-1 biopsies. Mean SGUS scores (p=0.006) and the frequency of moderate/severe changes (p<0.001) were higher in pSS patients.
Conclusion: Multidisciplinary evaluation was crucial in the assessment of patients with similar sicca complaints and in the management of ocular/oral/systemic involvement. Objective measurements and specialized complementary exams greatly contribute to establishing or confirming the diagnosis of pSS.

AB0502 STRESS AS POTENTIAL PATHOGENIC FACTOR IN PRIMARY SJOGREN'S SYNDROME.

M. Jaskólska[1], D. Jaskólski[2], M. Ziętkiewicz[1], A. Viti[3], Z. Zdrojewski[1]. [1]Medical University of Gdańsk, Department of Internal Medicine, Connective Tissue Diseases and Geriatrics, Gdańsk, Poland; [2]Medical University of Gdańsk, II Department of Orthopedics and Traumatology, Gdańsk, Poland; [3]University of Naples Federico II, Medical Faculty, Naples, Italy

Background: Sjogren's Syndrome (SS) is a common autoimmunological disorder characterized by infiltration of exocrine glands by autoreactive immune cells that lead to the disease's two most common symptoms — dry eyes and a dry mouth, also known as sicca syndrome. The etiopathogenesis considers the coexistence of genetic predisposition and environmental factors, such as viral infections or sex hormones imbalance.
Objectives: The aim of the study was to determine whether major stressful life events are also risk factors for developing SS.
Methods: We performed a matched case-control study. Cases were patients with an established diagnosis of primary SS (pSS) within the previous five years. Controls were patients with osteoarthritis in whom systemic connective tissue disease has been ruled out. Data on major stressful life events were collected using the modified Holmes-Rahe stress scale. Data were collected for the period of the year before the disease onset.
Results: 100 patients were enrolled in the study (pSS group = 50, control group = 50), mean age was 55.8±10.4 years for pSS and 61.3±9.59 years for control group, in both groups 96 % of patients were female. pSS patients had significantly higher total score on Holmes-Rahe stress scale within the preceding 1 year before the onset of disease symptoms than control group (pSS group = 152±66.3 vs control group = 50±54.6; p<0.001). In pSS group 50 % of patients reported the subjective impression that the symptoms were caused by stress, while in control group it was 12 % (p<0.001). The most frequently mentioned life events in the pSS group were divorce or marital separation, death or change in health of family member and stress related to work.
Conclusion: Patients with pSS are significantly more likely to have had a major stressful life event within the preceding 1 year before the disease onset. The relationship between stress and the occurrence of many diseases and their exacerbations is well documented, especially within autoimmune diseases. Stress is a ubiquitous problem these days, therefore it is of fundamental importance to understand the biological mechanisms underlying its influence on the development of diseases. It is crucial to properly recognize the stressful situation in the patient's life and undertake appropriate interventions in order to prevent health consequences.

AB0503 CLINICAL AND SEROLOGICAL DIFFERENCES BETWEEN CAUCASIAN AND LATIN AMERICAN SLE PATIENTS IN A MULTIETHNIC SPANISH SINGLE-CENTRE COHORT

J. Álvarez Troncoso[1], Á. Robles Marhuenda[1], R. Sorriguieta Torre[1], C. Soto Abánades[1], A. Noblejas Mozo[1], E. Martínez Robles[1], C. Sánchez Díaz[1], J. J. Rios[1]. [1]Hospital Universitario La Paz, Autoimmune Diseases Unit. Internal Medicine Department, Madrid, Spain

Background: Systemic lupus erythematosus (SLE) is a highly heterogeneous systemic autoimmune disease with multiorgan manifestations. There are

Table 1. Caucasian vs. Latin American SLE patients

	Caucasian	Latin American	p-value	Odds ratio (IC95%)
Serositis (%)	22.58 %	26.32 %	p=0.712	
Skin involvement (%)	65.59 %	52.63 %	p=0.261	
Arthritis (%)	24.32 %	52.63 %	p=0.008	2.39 (1.06-5.38)
AIHA (%)	0.00 %	5.26 %	p=0.002	28.69 (1.13-728.60)
Lymphopenia (%)	34.95 %	52.63 %	p=0.084	
Immune thrombocytopenia (%)	4.30 %	10.53 %	p=0.230	
Neurolupus (%)	20.97 %	10.53 %	p=0.278	
Glomerulonephritis (%)	18.82 %	42.11 %	p=0.018	2.51 (1.05-6.02)
ESRD (%)	3.76 %	15.79 %	p=0.020	4.20 (1.01-17.58)
Low C3 (%)	54.30 %	89.47 %	p=0.003	1.65 (0.82-3.31)
Low C4 (%)	49.46 %	84.21 %	p=0.004	1.70 (0.84-3.46)
Low vitamin D (%)	11.29 %	26.32 %	p=0.061	2.33 (0.79-6.89)
High DNAds (%)	61.29 %	63.16 %	p=0.404	
Anti-Sm (%)	12.37 %	36.84 %	p=0.004	2.98 (1.13-7.85)
Anti-Ro (%)	26.34 %	31.58 %	p=0.624	
Anti-RNP (%)	8.06 %	21.05 %	p=0.063	2.61 (0.79-8.66)
Anti-histones (%)	4.30 %	21.05 %	p=0.003	4.89 (1.35-17.77)
Antiphospholipid antibodies (%)	45.16 %	42.11 %	p=0.799	
Steroids (%)	88.71 %	94.74 %	p=0.419	
Antimalarials (%)	94.05 %	89.47 %	p=0.436	
SLEDAI≥6 (%)	34.41%	26.32%	p=0.477	
SDI ≥1 (%)	70.43 %	68.42 %	p=0.855	
LLDAS (%)	60.99 %	66.67 %	p=0.637	
DORIS (%)	48.09 %	38.89 %	p=0.456	
Death (%)	1.61 %	0.00 %	p=0.577	

disparities in its manifestations conditioned by sex, age of onset, and serological characteristics. The ethnic origin of the patients may be a conditioning factor for different organic manifestations, immunological markers, and outcomes.

Objectives: Our objective was to evaluate the clinical and serological differences in Caucasian vs. Latin American patients in a multiethnic Spanish single-center SLE cohort.

Methods: Single-centre retrospective observational study from a Spanish Lupus Cohort of adult SLE patients fulfilling the 2019 EULAR/ACR Classification Criteria. Only patients of Caucasian or Latin American origin were included.

Results: The study included 205 patients: 186 (90.7%) Caucasian and 19 (9.3%) Latin American. The mean age at diagnosis was 35.5 years. The female/male ratio was 9:1 in the Caucasian group and 19:1 in the Latin American group (ns). Serous and cutaneous involvement was similar between groups. The presence of arthralgia was also similar (ns) but there were statistically significant differences with the presence of arthritis (p=0.008). Severe hematologic manifestations were also more frequent in Latin American patients but only statistically significant for autoimmune hemolytic anemia (AIHA). Lupus nephritis and end-stage renal disease (ESRD) were two-fold and four-fold more common in Latin American patients. Among the immunological findings: hypocomplementemia, Anti-Sm, and anti-histones were differential markers between the two groups. Anti-RNP was also more frequent in the Latin American group (ns). Regarding treatments, there were no relevant differences between steroids and antimalarials. There were also no disparities in outcomes measured by activity (SLEDAI), cumulative damage (SDI), low activity (LLDAS), remission (DORIS), or death in our cohort.

Conclusion: In our multiethnic Spanish single-center cohort, SLE patients of Latin American origin had a higher frequency of arthritis, glomerulonephritis, and AIHA. They also presented a higher frequency of hypocomplementemia, anti-Sm, and anti-histones at the immunological level. However, these clinical and serological differences did not correlate with outcomes of activity, damage, remission, or mortality. Future studies are needed to assess the definitive effect of ethnicity on SLE.

AB0504 DOES THE PRESENCE OF ANTIPHOSPHOLIPID ANTIBODIES AFFECT THE PROGRESSION OF RENAL FAILURE IN PATIENTS WITH LUPUS NEPHROPATHY? LONG-TERM OBSERVATION

E. Łyś[1], D. Suszek[1], M. Majdan[1]. [1]*Medical University of Lublin, Rheumatology and Connective Tissue Diseases, Lublin, Poland*

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disorder with various clinical manifestations and diverse courses. Lupus nephropathy (LN) is observed in 30-50% of patients with SLE. 10% of patients with LN will develop renal failure (RF). Antiphospholipid antibodies (aPLs) are known for their pro-thrombotic action. According to the literature data, the presence of aPLs can lead to the development of thrombotic microangiopathy and may influence the progression of RF among patients with LN.

Objectives: The study aims to assess the influence of the presence of aPLs on the course and the progression of LN in long-term observation.

Methods: We conducted a retrospective analysis of the medical history of 34 patients (pts) with SLE and confirmed lupus nephropathy who are under the constant, long-term care of a rheumatology center. The kidney function (creatinine, estimated glomerular filtration rate; eGFR) was assessed at the beginning of the observation and after approximately 7-10 years.

The presence of antiphospholipid antibodies (anticardiolipin antibodies IgG or IgM, anti-beta-2-glycoprotein-I antibodies IgG or IgM, lupus anticoagulants) was taken into consideration. The progression of RF was compared between the pts groups with positive and negative aPLs test results.

Results: A total of 34 patients (median age at the end of follow-up was 50 years; range 24-82) were included. The majority of patients were female (88.2%). Of these patients, 8 (23.5%) had a positive tests for aPLs many times in their medical history. Considering the progression of RF among patients with positive aPLs, significant statistical differences were observed (p <0,01). Moreover, a statistically significant effect of aCL (p <0.03) and antibodies directed against anti-beta2 glycoprotein I (p <0.04) on the reduction of eGFR in the course of the disease was observed.

Conclusion: The presence of aPLs is associated with the risk of the deterioration of kidney function in patients with LN. It affects the decrease of eGFR and an increase of the concentration of creatinine in the blood.

AB0505 RISK OF SYSTEMIC LUPUS ERYTHEMATOSUS FLARES ACCORDING TO THE POSITIVITY OF AUTOANTIBODIES

O. C. Kwon[1], M. C. Park[1]. [1]*Yonsei University College of Medicine, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by excessive production of pathogenic autoantibodies. A variety of autoantibodies can be detected in patients with SLE. Presence of particular autoantibody is known to be associated with specific manifestations of SLE: anti-double-stranded DNA antibody (anti-dsDNA Ab) with renal involvement and overall disease activity, anti-Sm Ab with renal involvement, anti-Ro Ab with cutaneous lupus and neonatal lupus, anti-La Ab with cutaneous lupus and neonatal lupus, and anti-U1RNP Ab with Raynaud's phenomenon and pulmonary hypertension. However, little is known about the association between positivity of each autoantibody and risk of SLE flare.

Objectives: We aimed to assess the risk of SLE flare according to the positivity of various autoantibodies.

Methods: A total of 228 patients with SLE who fulfilled the 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE were included. SLE flare was defined as an increase of SLE disease activity index-2000 (SLEDAI-2K) of more than 4 points and/or hospitalization for SLE and/or augmentation of SLE therapy. The occurrence of flare was retrospectively reviewed from the date of SLE diagnosis to the date of last follow-up. Multivariable Cox regression analysis was conducted to estimate the hazard ratio (HR) and 95% confidence interval (CI) of SLE flare, according to the positivity of autoantibodies. Multivariable model was adjusted for sex, age at SLE diagnosis, positivity of other autoantibodies, SLEDAI-2K at diagnosis, use of immunosuppressants.

Results: Among the 228 patients, flare occurred in 179 (78.5 %) patients during 635.0 person-years of follow-up (incidence rate: 28.2/100 person-years). Of the 179 flares, 92 were severe flares (necessitating use of glucocorticoid dose > 20mg of prednisolone or equivalent, and/or addition of immunusuppressants), whereas 87 were mild-to-moderate flares (necessitating use of glucocorticoid dose < 20mg of prednisolone or equivalent, and no addition of immunosuppressants). In the multivariable Cox regression analysis, anti-dsDNA Ab positivity (adjusted HR 1.46, 95% CI 1.04–2.05, p = 0.031) and anti-Sm antibody positivity (adjusted HR 1.73, 95% CI 1.16–2.59, p = 0.007) were significantly associated with a higher risk of SLE flares.

Conclusion: Patients with SLE who are positive for anti-dsDNA Ab or anti-Sm Ab at diagnosis have a higher risk of SLE flare during the course of their disease. Careful monitoring of disease activity and prompt adjustment of therapy accordingly could be helpful in these patients.

REFERENCES: Not applicable.

Table 1. Risk of flares according to the positivity of each autoantibodies

	Univariable analysis		Multivariable analysis[a]	
	Unadjusted HR (95% CI)	P value	Adjusted HR (95% CI)	P value
Anti-dsDNA antibody positivity	1.47 (1.09–1.99)	0.011	1.46 (1.04–2.05)	0.031
Anti-Sm antibody positivity	1.52 (1.12–2.07)	0.008	1.73 (1.16–2.59)	0.007
Anti-Ro antibody positivity	1.19 (0.88–1.61)	0.252	1.04 (0.71–1.52)	0.836
Anti-La antibody positivity	1.24 (0.89–1.74)	0.211	1.26 (0.83–1.92)	0.278
Anti-U1RNP antibody positivity	1.19 (0.89–1.60)	0.250	0.83 (0.57–1.21)	0.332

AB0506

PRELIMINARY STUDY ON IMBALANCE BETWEEN TH17 AND REGULATORY T CELLS IN ANTIPHOSPHOLIPID SYNDROME

H. Yan[1], B. C. Li[1], R. Su[1], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Antiphospholipid syndrome (APS) is a typical autoimmune disease, which can be classified into primary antiphospholipid syndrome (PAPS) and secondary antiphospholipid syndrome (SAPS) based on the presence or not of other autoimmune diseases. Disorders of peripheral blood lymphocyte and CD4+T cell subsets, especially Th17 and Treg cell subsets, may be involved in the pathogenesis of APS.

Objectives: To investigate the differences of peripheral blood lymphocyte and CD4+T cell subsets between patients with primary and secondary antiphospholipid syndrome and healthy controls, and to evaluate the correlation of antiphospholipid antibody titers and Th17/Treg values in PAPS and SAPS groups, as well as the correlation of cytokines and clinical characteristics in APS patients.

Methods: A total of 67 APS patients (12 PAPS patients, 55 SAPS patients) and 40 healthy controls were enrolled in this study. Retrospectively collected clinical and laboratory data of these patients. The absolute numbers of peripheral blood lymphocyte subsets and CD4+ T cell subsets were detected by flow cytometry, and serum cytokine levels were detected by flow cytometry bead array.

Results: Compared with healthy control group, the absolute values of T [689.26 vs. 1239.00, $p < 0.001$], B (104.69 vs. 177.50, $p < 0.001$), NK (98.97 vs. 300.00, $p < 0.001$) and CD4+T (330.16 vs. 628.50, $p < 0.001$) cells in SAPS group were decreased. While only the NK cells (151.30 vs. 300.00, $p = 0.002$) in the PAPS group were lower than that in healthy control group. However, the absolute values of T (1295.41 vs. 689.26, $p = 0.001$), B (184.44 vs. 104.69, $p = 0.012$), NK (151.30 vs. 98.97, $p = 0.023$) and CD4+T cells (698.34 vs. 330.16, $p = 0.002$) in PAPS group were significantly higher than those in SAPS group. For CD4+T cell subsets, PAPS patients and SAPS patients showed the same trend compared with healthy controls, showing increased Th1(111.50 vs. 23.47, p=0.002 and 71.43 vs. 23.47, p=0.001, respectively), decreased Th2(6.97vs.12.43, p=0.037 and 2.49 vs. 12.43, $p < 0.001$, respectively) and, more importantly, decreased Treg (18.77 vs. 29.53, p=0.031 and 12.01 vs. 29.53, $p < 0.001$, respectively), with increased Th17/Treg ratio (0.39 vs. 0.17, p=0.001 and 0.42 vs. 0.17, $p < 0.001$, respectively). Meanwhile, Th2(6.97 vs. 2.46, $p = 0.006$), Th17 (8.42 vs. 4.00, $p = 0.042$) and Treg (18.77 vs. 12.01, $p = 0.020$) cells in PAPS group were higher than those in SAPS group. As for the correlation study, we concluded that both aCL (r=0.6061, p=0.0405) and aβ2GPI (r=0.6900, p=0.0158) were positively correlated to Th17/Treg ratio in PAPS group. In addition, for APS patients, IL-2 (r=-0.420, p=0.010), IL-4 (r=-0.392, p=0.016), IL-10 (r=-0.331, p=-0.046), IL-17 (r=-0.479, p=0.006), and IFN-γ (r=-0.339, p=0.040) were negatively correlated with titers of aCL. And IL-6 is also associated with ESR (r=0.469, p=0.004) and CRP (r=0.670, $p < 0.001$).

Conclusion: Whether PAPS or SAPS patients, detection and balancing of lymphocyte and CD4+T subsets, especially Th17 and Treg subsets, may help correct immune disorders. Of course, the immune function of primary and secondary APS patients is not completely consistent, at least in terms of immune cells. Also, the role of cytokines in the pathogenesis of APS should not be ignored.

IMPACT OF CAFFEINE CONSUMPTION ON ENDOTHELIAL PROGENITOR CELLS SURVIVAL IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

V. Orefice[1], F. Ceccarelli[1], C. Barbati[1], E. Putro[1], C. Pirone[1], F. R. Spinelli[1], C. Alessandri[1], F. Conti[1]. [1]*Lupus Clinic, Rheumatology Unit, Sapienza University of Rome, Italy, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, 00161, Italy*

Background: Circulating endothelial progenitor cells (EPCs) are widely demonstrated biomarkers of endothelial function. Their frequency and function varied in systemic lupus erythematosus (SLE) patients, with a significant association with subclinical atherosclerosis[1]. Caffeine, one of the most widely consumed products in the world, seems to interact with multiple components of the immune system by acting as a non-specific phosphodiesterase inhibitor, and it seems to be able to activate autophagy[2-3]. In terms of cardiovascular disease (CVD), data from the literature showed a U-shaped association between habitual coffee intake and CVD[4]. In this view, Spyridopoulos et al. demonstrated a significant improvement in endothelial cells and EPCs migration after coffee consumption in coronary artery disease both in mouse models and in patients[5]. Finally, we demonstrated the impact of caffeine on SLE disease activity, in terms of SLEDAI2k values and

serum cytokine levels. Moreover, patients with a low caffeine intake seemed to have a more severe disease phenotype[6].

Objectives: The aim of this study was to evaluate the role of caffeine intake on endothelial function in SLE patients, by assessing its effect on number and function of EPCs both *ex vivo* in SLE patients and *in vitro* in healthy donors (HD) treated with SLE sera.

Methods: We performed a cross-sectional study enrolling consecutive SLE patients (revised 1997 ACR criteria), referring to the Sapienza Lupus Clinic. Patients with history of traditional CV risks factors were excluded. Caffeine intake was evaluated using a 7-day food frequency questionnaire. At the end of questionnaire filling circulating EPCs were detected by using a flow cytometry analysis defined as CD34+KDR+ cells. Subsequently, EPCs pooled from 6 HD were co-cultured with caffeine at 0.5 mM and 1 mM with and without SLE sera. After 7 days, we evaluated the cells morphology and the ability to form colonies. Moreover, we analyzed for the percentage of annexin V-positive (AV) apoptotic cells by flow cytometry analysis and for levels of autophagy and apoptotic markers LC3-II, p62 and Bcl2 by western blot.

Results: We enrolled 31 SLE patients (F:M 30:1, median age 43 years, IQR 18; median disease duration 144 months, IQR 180). The median intake of caffeine was 166 mg/day (IQR 194). We found a EPCs median percentage of 0.03% (IQR 0.04) observing a positive correlation between caffeine intake and EPCs percentage (p=0.03, r=0.4). Moving on *in vitro* experiments, after 7 days of cell cultures, HD EPCs treated with SLE sera and caffeine showed an improvement in morphology and in number of EPCs-CFU in comparison with those incubated with SLE sera without caffeine (p=0.0003). Moreover, the colonies treated with SLE sera were poorly organized in comparison with HD; the addition of caffeine restored the colony structure. After treated HD-EPCs with SLE sera we observed an increase in AV positive cells and p62 and LC3-II values and a reduction of Bcl2 values; the addition of caffeine was able to significantly reduce AV positive cells and p62 and LC3-II values and to significantly increased Bcl2 values, without any significant differences between caffeine 0.5 mM and 1 mM treatment (Figure 1A-D).

Conclusion: Our data demonstrated the ability of caffeine in increasing the number of circulating EPCs in SLE patients. Moreover, *in vitro* experiments seem to suggest a protective role of caffeine on EPCs survival and vitality through the promotion of autophagy and the inhibition of apoptosis.

AB0508 RISK FACTORS FOR DEVELOPMENT OF ATHEROSCLEROSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

T. Panafidina[1], T. Popkova[1], L. Kondrateva[1], Y. Gorbunova[1], E. Nasonov[2].
[1]V.A.Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation; [2]V.A.Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation

Background: Systemic lupus erythematosus (SLE) has been strongly linked to accelerated atherosclerosis and increased cardiovascular morbidity and mortality.

Objectives: The goal is to evaluate the traditional cardiovascular risk factors (TRF), intima-media wall thickness (IMT) and cardiovascular events (CVE) in SLE patients as compared to the same-nationality populations.

Methods: This cross-sectional study included 227pts (69% females, aged 35,6±0,7years) with SLE according to SLICC/ACR 2012 criteria, attending a routine visit at our Clinic between February 2018 and February 2020. Carotid plaques were assessed by ultrasound (US). Disease duration was 132,9±7,7months, SLEDAI 2K–9,4±0,5, SLICC/DI–1,89±0,13 score. Briefly, 90% had a history of joint involvement, 72%-hematological involvement, 70%-nephritis, 67%-serositis, 64%-skin lesions, 48%-neuropsychiatric involvement. Out of them 82%pts were on prednisone therapy at 17,3±1,0mg/day, 41%–on HCQ, 22%-immunosuppressants. Forty-one (18%) patients were diagnosed with SLE for the first time and were not receiving therapy at the time of enrollment. Concomitant antiphospholipid syndrome (APS) had 24% of SLEpts: 80% of SLE+APSpts had venous thrombosis, 43%-arterial, 56%-obstetric pathology. The control group (healthy donors) was matched by age and gender (n=99, 79% females, aged 36,2±0,8years).

Results: Patients with SLE compared to controls had a higher incidence of hypertension (52% and 21%,p<0,001), triglyceride concentrations (1,60±0,07 and 0,89±0,09mmol/l,p<0,001), lower levels of high-density lipoprotein (HDL) cholesterol (1,20±0,03 and 1,40±0,04mmol/l,p<0,01) and a higher number of TRF (2,40±0,08 and 2,01±0,13,p<0,05). Following carotid US assessment, atherosclerotic plaques (IMT≥1,5 mm) occurred in 24% of SLEpts versus 5% of controls,p<0,001. SLEpts had hazard ratio (HR) of carotid plaques of 5,22 (95%CI 1,95-13,99). Clinical manifestations of atherosclerosis (CVE) were reported in 19% of SLEpts vs 2% of controls, p<0,001. Out of them coronary artery disease (CAD) was in 13% vs 2%, p=0,002, myocardial infarction (MI)-in 5% vs 1%, p>0,05, stroke – 7% vs 1%, p>0,05. SLEpts had HR of CVE of 9,16 (95%CI 2,26-37,09), of CAD - 6,54 (95%CI 1,59-26,84). In SLEpts carotid plaques were more common than in controls at the age of 30-49 years, p<0,05; clinical manifestations of atherosclerosis occurred after 40 years: CAD - at 40-49 years, stroke - >50 years, p<0,05. No differences were found in other age groups. Patients were found to correlate CVE with age (r=0,384,p<0,001), male gender (r=0,361,p<0,001), hypertension (r=0,227,p<0,001), body mass index (BMI) (r=0,180,p=0,007), number of TRF (r=0,247,p<0,001), SLE duration (r=0,317,p=0,001), SLICC/DI (r=0,273,p<0,001), steroid use duration (r=0,255,p<0,001) and cumulative prednisolone dose (r=0,163,p<0,05).

Conclusion: The frequency of CVE (CAD, MI) and carotid plaques is higher in patients with SLE than in controls. In patients, CAD and carotid plaques were detected more frequently at the age of 30-49 years than in controls. Hypertension, hypertriglyceridemia and low HDL are the most common TRF in young SLE patients. In SLE, not only TRF and their number are associated with CVE, but also SLE duration, SLICC/DI, steroid use duration and cumulative dose.

AB0509

AGREEMENT BETWEEN LABIAL BIOPSIES AND THE OMERACT GREY-SCALE ULTRASOUND SCORING SYSTEM FOR SALIVARY GLANDS IN A SINGLE-CENTER COHORT OF PATIENTS WITH SUSPECTED SJÖGREN'S SYNDROME

V. Fana[1], N. Surlemont Schmidt[1], U. Møller Døhn[1], S. Krabbe[2], L. Terslev[1]. [1]*Copenhagen Center for Arthritis Research, Rigshospitalet, Center for Rheumatology and Spine Diseases, Glostrup, Denmark;* [2]*Herlev Hospital, Department of Radiology, Herlev, Denmark*

Background: Ultrasound is a promising non-invasive tool in the evaluation of the salivary glands for parenchymal changes related to Sjögrens Syndrome (SS). The OMERACT Ultrasound Grey-scale (GS) Scoring System for SS has been shown to have good sensitivity and excellent specificity for fulfilling the SS classification criteria, when a GS ≥2 in at least 1 gland was considered indicative of SS (1), however others have suggested pathology in at least 2 glands is required (2). Systematic use of ultrasound might reduce the need for labial biopsies if US findings are in agreement with biopsies.
Objectives: To assess the agreement between labial biopsy results and salivary gland ultrasound findings in patients suspected of SS.
Methods: Patients referred to our department with a suspicion of SS from 2017-2021, scheduled for a diagnostic labial biopsy were recruited. All underwent GS ultrasound of the parotid and submandibular glands bilaterally prior to clinical exam, Schirmer's test, unstimulated salivary flow, blood samples including autoantibody analysis. Still images of the four glands were scored 0-3 using a previously developed ultrasound atlas (1) of the OMERACT ultrasound scoring system for SS (2,3). All biopsies were evaluated by a pathologist and focus score ≥1 was considered indicative of SS. Two different ultrasound scores for SS were tested: US-score ≥2 in at least 1 gland and US-score ≥2 in at least 2 glands. Descriptive statistics were used. In these analyses, we used labial biopsy as reference standard.
Results: 103 patients were included and 44 were clinically diagnosed with SS of which 42 (95%) fulfilled the 2016 ACR/EULAR classification criteria and 33 (75%) had positive labial biopsy. Demographics are shown in Table 1.

Table 1. Demographics

	All patients, n=103
Gender, n=females (%)	89 (86)
Age, mean ± SD	55 ± 15.9
Symptoms > 2 years, n=patients (%)	51 (50)
Symptoms < 2 years, ≥ 1 year, n= patients (%)	28 (27)
Symptoms < 1 year, n= patients (%)	24 (23)
Biopsy with focus score ≥ 1, n= patients (%)	32 (31)
US with ≥ 1 gland score ≥ 2, n=patients (%)	36 (35)
US with ≥2 glands score ≥ 2, n= patients (%)	31 (30)
SSA positive (%)	39 (38)
SSB positive (%)	9 (9)
ANA positive (%)	42 (41)
Sialometry positive (%)	67 (65)
Schirmer's test positive (%)	32 (31)

The sensitivity of ultrasound score ≥2 in at least 1 gland was 0.69 and the specificity 0.80. The positive predictive (PPV) and negative predictive values (NPV) were 0.61 and 0.85, respectively. Applying ultrasound score ≥2 in at least 2 glands did not improve specificity (0.83), PPV (0.61) or NPV (0.82) whereas sensitivity dropped to 0.59. The agreement between biopsies and ultrasound for SS is shown Figure 1.

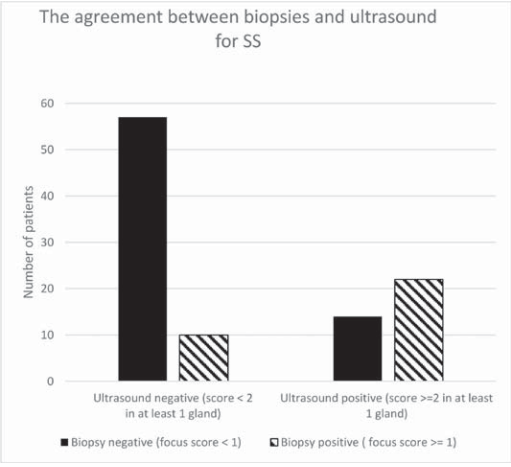

Figure 1

Conclusion: In patients with suspected SS, we found good agreement between US of salivary glands and subsequent labial biopsy. US of salivary glands seems useful in the diagnosis and classification of SS, but labial biopsies may still be needed in select cases.

IMMUNOPHENOTYPIC RECLASSIFICATION OF ANA ASSOCIATED AUTOIMMUNE DISEASE: PRELIMINARY ANALYSIS OF FLOW CYTOMETRIC DATA IN A MULTI-DISEASE COHORT.

J. Arnold[1,2], L. M. Carter[1,2], M. Y. MD Yusof[1,2], Z. Wigston[1,2], S. U. Hassan[1,2], K. Dutton[1,2], S. Dass[1,2], A. Psarras[1,2], E. Vital[1,2]. [1]*University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom;* [2]*Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: The heterogeneity within the connective tissue disease patient cohort is not adequately reflected by current diagnostic labels(1,2). An immunophenotypic classification may be more appropriate for targeting therapy and basket therapeutic trials. DEFINITION is a multi-disease cohort (n=300) containing multiple clinical and immune datasets.
Objectives: To perform preliminary clustering analysis using the flow cytometric dataset from DEFINITION.
Methods: 142 patients with comprehensive flow cytometry data available were selected from the DEFINITION cohort. Highly sensitive flow cytometry was used to identify 7 B cell, T cell, NK cell and monocyte subsets and tetherin/SIGLEC1 expression on each subset.
ANA and ENA titres were assessed via the Bioplex assay. Demographic and clinical data was obtained from the DEFINITION cohort. Multiple classification algorithms were applied to flow cytometry data using R. Including K-means, hierachical, model-based and partitioning around medioids (PAM). Output clusters were retrospectively compared to their legacy diagnoses and serology.
Results: In the first 142 patients, PAM identified 3 clusters with memberships of 45, 49 and 48 patients respectively (Table 1).

Table 1. Key legacy diagnoses and ENA positivity for the identified clusters.

Diagnosis	Total	Cluster 1	Cluster 2	Cluster 3	P value
SLE	57	22	10	25	>0.01

Chromatin	29	10	8	11	0.68
Ribosomal P	4	1	1	2	0.78

Cluster 1 (**UCTD/CD3+ dominant**) was characterised by a higher proportion of UCTD patients (27%) and larger populations of CD3+ T cells and NK bright cells. Cluster 2 (**SSc dominant/Tetherin low**) was characterised by a higher population of systemic sclerosis (SSc) patients (10%) and a lower proportion of SLE patients (20%). High levels of classical and non-classical monocytes were demonstrated alongside low plasmablast populations and low SIGLEC1/Tetherin expression. Cluster 3 (**SLE/pSS high, Ro/Tetherin high**) included a higher proportion of SLE and primary Sjogren's syndrome (pSS) patients (52% and 19%). This cluster showed larger plasmablast numbers and higher SIGLEC1/Tetherin expression. Serologically this cluster had higher levels of Ro60, Ro52, Sm-RNP and La positivity. There were statistically significant differences in Ro60, Ro52, La, and Sm antibody positivity between the 3 clusters. Significant differences in CD19+CD27+ memory B cell tetherin expression and CD14+CD16- classical monocyte SIGLEC1 expression were observed (both

p < 0.05). A significant difference in SLE distribution was noted between the clusters (p < 0.01).

Conclusion: This preliminary study identified of a flow cytometric dataset identified 3 immunophenotypically distinct subgroups, each comprised of multiple legacy diagnoses within spectrum of ANA+ disease. Future work will evaluate other datasets within the full cohort with a view to conduct basket trials in the baskets defined.

Background: Many activity indices have been developed for Systemic Lupus Erythematosus. However, they present important limitations due to the multi-organ compromise. The SLEDAI score and its different versions are widely used in daily practice and in clinical research. Diogo Jesus et al (2018) developed the SLE-DAS (Systemic Lupus Erythematosus Disease Activity Score), that include 17 items, 4 of them continuous. SLE-DAS assesses disease activity in the 28 previous days using an online calculator, with clinical characteristics non-evaluated by SLEDAI. It showed greater precision to measure disease activity, greater sensitivity to detect clinically significant changes and better performance to predict accumulated damage than SLEDAI. It has not yet been validated in Argentina.

Objectives: To determine the validity of the SLE-DAS score in a population of patients with SLE from Argentina.

Methods: A multicenter observational study was conducted. Outpatients and hospitalized patients with SLE from 9 Argentinian centers were included between July to August 2021. Socio-demographic and disease variables were studied and SLE activity was measured by physician's global assessment (PGA), SLEDAI 2K and SLE-DAS. The disease activity categories used for SLE-DAS were: remission ≤2.08; mild activity >2.08 to 7.10, moderate and severe activity >7.10. For SLEDAI 2K, remission was considered 0, mild activity 1 to 5, moderate 6 to 10, high 11 to 19, very high >20 points. To determine construct validity and criterion validity, SLEDAI 2K and PGA were used as the gold standard and correlation between scores was analyzed with the Pearson and Spearman correlation coefficient. Sensitivity and specificity of the points that define each of the activity levels were established by ROC curves to determine the discriminative capacity of SLE-DAS.

Results: A multicenter observational study was conducted. Outpatients and hospitalized patients with SLE from 9 Argentinian centers were included between July to August 2021. Socio-demographic and disease variables were studied and SLE activity was measured by physician's global assessment (PGA), SLEDAI 2K and SLE-DAS. The disease activity categories used for SLE-DAS were: remission ≤2.08; mild activity >2.08 to 7.10, moderate and severe activity >7.10. For SLEDAI 2K, remission was considered 0, mild activity 1 to 5, moderate 6 to 10, high 11 to 19, very high >20 points. To determine construct validity and criterion validity, SLEDAI 2K and PGA were used as the gold standard and correlation between scores was analyzed with the Pearson and Spearman correlation coefficient. Sensitivity and specificity of the points that define each of the activity levels were established by ROC curves to determine the discriminative capacity of SLE-DAS.

Conclusion: In this population of lupus patients from Argentina, the SLE-DAS allowed to discriminate between remission and disease activity, being a useful and practical tool.

AB0512 COMPARATIONS OF SALIVARY GLAND ULTRASONOGRAPHY FINDINGS IN PRIMARY SJOGREN'S SYNDROME VS TYPE 2 DIABETES MELLITUS

A. Kahveci[1], A. Gümüştepe[1], Ş. Ataman[1]. *[1]Ankara University, Division of Rheumatology, Ankara, Turkey*

Background: Primary Sjogren syndrome (pSS) is a chronic autoimmune disease that mainly affects the exocrine glands [1]. Type 2 diabetes mellitus (DM) is also autoimmune disease involving not only the pancreas but also salivary glands. In both diseases, sicca symptoms due to different mechanisms were common [1, 2]. The use of salivary gland ultrasonography (SGUS) has become widespread in the diagnosis and follow-up of pSS [3, 4]. In DM, fewer US-based studies have shown abnormalities in the major salivary glands [2].

Objectives: This study aimed to compare the SGUS findings in patients with pSS and DM patients with sicca symptoms and to examine the relationship between these findings with clinical and laboratory parameters.

Methods: In this study, 32 patients with pSS and 28 DM patients with sicca symptoms (not meet ACR/EULAR pSS criteria) were included. Demographic data and patient characteristics were obtained from medical records. Physical examination was assessed by a rheumatologist. In all patients, bilateral parotid and submandibular gland US was performed by a blind another rheumatologist, using the Hocevar and the Outcome Measures in Rheumatology (OMERACT) scoring system. Clinic and ultrasonographic variables were compared between groups. The association between SGUS score and disease duration was analyzed by correlation analysis.

Results: Patients with pSS presented higher SGUS scores than patients with DM significantly (the Hocevar total score; 20.93(±9.65) vs 3.82(±3.71); p<0.05, the OMERACT total score; 5.96(±2.30) vs 2.07(±1.65); p<0.05, respectively). In patients with pSS, the submandibular gland scores higher than the parotid gland scores while in patients with DM showed higher parotid gland scores. Other demographic data is shown in Table 1. In pSS patients, the Hocevar and the OMERACT total SGUS scores were significantly correlated with disease duration (r=0.584, p<0.01 vs r=0.518, p<0.01, respectively). This correlation was not found in patients with DM (Figure 1).

Table 1. Demograpfic data and salivary gland ultrasonography scores in pSS and diabetic patients

	pSS patients(n=32)	DM patients with sicca(n=28)
Age, mean(±SD)	53.90(±9,70)	52.25(±7.65)
Disease duration, mean(±SD)	7.68(±4.01)	8.46(±6.31)
First symptom, n(%)		
Sicca	5(15.62%)	4(14.28%)
Non-sicca	23(71.87%)	20(71.42%)
Parotitis, n(%)	7(21.87%)	2(7.14%)[a]
Anti-Ro positivity, n(%)	22(68.75%)	0(0.0%)[a]
Unstimulated saliva flow rate ≤0.1 ml/m, n(%)	28(87.5%)	13(46.42%)[a]
Schirmer's test≤5 mm/5 m in at least one eye, n(%)	30(93.75%)	8(28.57%)[a]
The Hocevar total SGUS score, mean(±SD)	20.93(±9.65)	3.82(±3.71)[a]
right parotid	4.62(±2.73)	1.25(±1.17)[a]
left parotid	4.34(±2.57)	1.25(±1.08)[a]
right submandibular	6.06(±3.07)	0.67(±0.41)[a]
left submandibular	6.31(±2.95)	0.64(±0.43)[a]
The OMERACT total SGUS score,(mean(±SD)	5.96(±2.30)	2.07(±1.65)[a]
right parotid	1,28(±0.77)	0,71(±0.59)[a]
left parotid	1,21(±0.65)	0,78(±0.62)[a]
right submandibular	1,68(±0.82)	0,44(±0.25)[a]
left submandibular	1,78(±0.83)	0,47(±0.32)[a]

[a] *p<0.05*

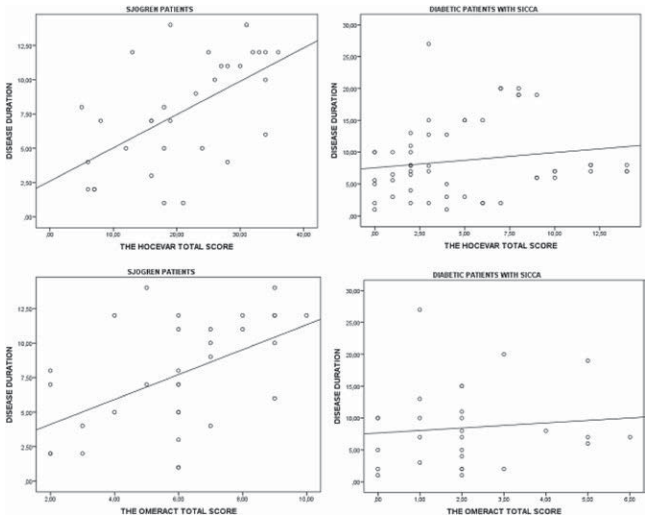

Figure 1. Correlation between SGUS scores and disease duratin in two groups

Conclusion: This study demonstrated that the major salivary gland involvement was more severe, submandibular gland dominant and correlated with disease duration in pSS. Contrarily, in patients with DM, it was mild compared to pSS, parotid dominant and uncorrelated with disease duration.

AB0513 COVID-19 PREVENTION IN PATIENTS WITH MODERATE-TO-SEVERE LUPUS DURING THE PANDEMIC: RESULTS FROM THE BILAG-BIOLOGICS REGISTER (BILAG-BR)

S. Dyball[1], M. Rodziewicz[1], E. Sutton[1], B. Parker[2,3], I. N. Bruce[1,2,3]on behalf of BILAG-BR. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [2]NIHR Manchester Biomedical Research Unit, Centre for Musculoskeletal Research, Manchester, United Kingdom; [3]Manchester University NHS FT,The Kellgren Centre for Rheumatology, Manchester, United Kingdom*

Background: There have been concerns over the susceptibility of SLE patients to severe COVID-19 illness since the beginning of the pandemic, and many patients were assigned 'clinically extremely vulnerable' according to the UK's shielding guidance issued in March 2020. Here we report on vaccination and shielding behaviours of a moderate-to-severe SLE cohort with high immunosuppressant burden.

Objectives: To review the shielding behaviours, and the safety and tolerability of COVID-19 vaccines in a real-world cohort of patients with moderate to severe SLE.

Methods: The British Isles Lupus Assessment Group Biologics Registry (BILAG-BR) is a national prospective registry of lupus patients from the UK (2010-21). Patients from the BILAG-BR were invited to complete a paper or online questionnaire which consisted of 17 questions to assess their self-reported shielding behaviour, vaccination status, and any adverse responses following COVID-19 vaccination. Questionnaires were completed between 9th Oct 2021 and 7th Jan 2022. Responses were linked with data collected in the BILAG-BR.

Results: Data were collected from the first 202/1268 patients (186 [92.1%] women) to respond, with a median age of 51 (IQR 38-61) years from 37 UK centres. The majority of patients were Caucasian (78.1%, 150/192). Previous therapy included rituximab (165, 81.7%), belimumab (33, 16.3%) and cyclophosphamide (54, 26.7%). In the past 12 months, over two thirds of patients (138, 68.3%) had received oral prednisolone (current dose median 5mg [IQR 5-8mg, range 2-40mg] daily), and almost a third had received parental steroids (60, 29.7%).

Shielding was reported in the first national lockdown (March-June 2020) by 93.6% (189/202) of patients, and of those in employment at the time, over half (58/100) were unable to work from home. The vast majority of patients complied with the UK government guidance (97.0%, 196/202) and did not socialise with other households indoors during this time period. Fifty-four percent of patients (109/202) reported attending a hospital or GP appointment during the first lockdown, and 24/202 (11.9%) reported regular appointments. During the first lockdown, 13/109 (11.9%) patients reported receiving rituximab infusions and 9/109 (8.3%) belimumab infusions.

Ninety-seven percent (196/202) had received at least 1 COVID-19 vaccination (Oxford AstraZeneca 95/146, 65.1%; Pfizer/ BioNTech 50/146, 34.3%). Approximately half of patients (54.2%, 104/192) reported an adverse reaction to the vaccine (both vaccine doses in 45 (23.9%) patients). The majority of these included lethargy/ flu-like symptoms (82, 78.8%) or local site reactions (32, 30.8%). Six (3.0%) patients reported a lupus flare and 3 (1.5%) patients reported a hospital attendance due to vaccine side effects.

Conclusion: In this cohort of moderate-to-severe SLE patients there was strong engagement with UK shielding guidance, however only half of patients attended a GP or hospital appointment during the earliest peak of the pandemic, highlighting disruptions to routine clinical care. There was high uptake of COVID-19 vaccination, which whilst generally well tolerated in this cohort, may be temporally associated with a flare, albeit in only a small number of patients. We recognise it may be difficult to distinguish between vaccine adverse events and lupus flares in patients with SLE, therefore this may be an overestimation. Of note, three patients reported a hospital attendance post-vaccination which warrants further investigation.

AB0514 EXPRESSION OF IMMUNITY-RELATED GTPASE FAMILY M PROTEIN (IRGM) SNPS AMONG EGYPTIAN LUPUS PATIENTS

M. Behiry[1], B. M Medhat[2], S. S. Ashour[3], D. Dorgham[2], A. Badr[3], A. Yamany[1]. *[1]Faculty Of Medicine, Cairo University, Internal Medicine, Giza, Egypt; [2]Faculty Of Medicine, Cairo University, Rheumatology and Rehabilitation, Giza, Egypt; [3]Faculty Of Medicine, Cairo University, Biochemistry, Giza, Egypt*

Background: Of determinants that drives systemic lupus erythematosus (SLE) triggering and development is autophagy, Immunity-related GTPase family M protein (IRGM) was shown to be linked with immune -mediated diseases.

Objectives: Aim of the current study is to assess whether IRGM-autophagy gene polymorphism has a role in SLE susceptibility among Egyptian population and its relation to diverse clinical manifestations particularly lupus nephritis.

Methods: A cohort where total of 200 subjects (100SLE patients who fulfilling according to 2012 SLICC criteria and 100 controls) were enrolled. All patients underwent a thorough medical history and clinical examination. Lupus activity was evaluated by SLEDAI-2K score. Two single-nucleotide polymorphisms (SNPs) (rs10065172 & rs4958846) were genotyped. Genotypes and Alleles analysis were conducted to compare between cases and controls as well as on the stratification analysis of presence or absence of lupus nephritis

Results: Among selected SNPs of IRGM, no association was considered between both SNPs and SLE susceptibility. For rs10065172, the major expressed genotype was CC (61% and 71%) (Adj OR= 2.9, 95%= 0.545-15.5) followed by TC (34 % and 27%) (Adj OR= 1.985, 95%= 0.357-11.041) in cases and controls respectively. For rs 4958847 AA and AG were comparably expressed in case (43% &39%) and control (41%&43%) with (Adj OR= 1.073, 95%= 0.483-2.382) and (Adj OR= 1.24, 95%= 0.557- 2.763) respectively. Additionally, no relation between both SNPs with gender, lupus nephritis, disease activity, or disease duration.

Table 1. SNPs of rs 10065172, rs 4958847 genotypes and allele frequencies for cases and controls.

IRGM[a] 10065172	Case N (%)	Control N (%)	p value unadjusted OR		p value Adjusted OR		95th CI
TT	5(5)	2(2)	0.445	0.388	0.252		
TC	34(34)	27(27)	0.261	0.707	0.433	1.985	0.357-11.041
CC	61(61)	71(71)	0.161	1.525	0.211	2.9	0.545-15.5
IRGM4958847							
GG	18(18)	16(16)	0.849	0.93	0.835		
AG	39(39)	43(43)	0.565	1.1	0.598	1.24	0.557-2.763
AA	43(43)	41(41)	0.744	0.921	0.863	1.073	0.483-2.382

a IRGM: Immunity-related GTPase family M protein

Conclusion: IRGM SNPs (rs10065172 and rs4958846) is not associated with SLE susceptibility in this Egyptian cohort that necessitates further research to evaluate more the impact of IRGM autophagy-related gene on lupus.

AB0515 CARDIOVASCULAR RISK FACTORS ASSESSMENT AND CONTROL IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Torcato Cartaxo[1], N. Carreira[2,3], L. Duarte[2,3], M. Terenas[4], C. Mota[3], P. Gaspar[2,5]on behalf of Hospital of Santa Maria Immune-mediated Disease Group. *[1]Hospital Fernando Fonseca, Internal Medicine, Amadora, Portugal; [2]Hospital de Santa Maria, Internal Medicine Department II, Lisboa, Portugal; [3]Faculty of Medicine, University of Lisbon, Internal Medicine II University Clinic, Lisboa, Portugal; [4]Hospital de Santa Maria, Emergency Department, Lisboa, Portugal; [5]Instituto de Medicina Molecular (IMM), Cellular Immunology Lab, Lisboa, Portugal*

Background: Systemic lupus erythematosus (SLE) is an independent risk factor for cardiovascular disease (1). Studies reporting how cardiovascular risk factors (CVRF) are assessed in clinical practice are scarce.

Objectives: To describe the prevalence of CVRF and characterize the assessment and control of dyslipidaemia and high blood pressure (HBP) in SLE patients.

Methods: Cross-sectional study of all adult SLE patients (SLICC 2012 criteria) followed in a dedicated clinic in 2019. Patients with less than one year of follow-up or less than three in-person visits were excluded. LDL-cholesterol control was defined as desirable (<115mg/dL), ideal (<100mg/dL), and according to the SCORE risk (2) (low, <115mg/dL; moderate, <115mg/dL; high, <100mg/dL; very high, <70mg/dL). Blood pressure (BP) control was defined as desirable (systolic BP [SBP]/ diastolic BP [DBP]<140/90mmHg) and ideal (SBP/DBP<130/80mmHg). Data are shown as number (%) and median (interquartile range [IQR]) for categorical and continuous variables respectively. We used statistical tests as needed.

Results: Among 82 SLE patients followed in 2019, 65 met the inclusion criteria (89% female; median age, 52 years; median disease duration, 15 years; median follow-up, 8 years). The median SLEDAI-2K was 2 (0 - 4). Most patients were on hydroxychloroquine (88%), 43% were on steroids and 31% on other immunosuppressants. Dyslipidaemia was present in 62% of patients, followed by HBP (51%), obesity (n = 9,14%) and diabetes mellitus (n = 4, 6%). Once-a-year CVRF assessment in the five years prior to the study was low: lipid profile (LP) - 25% among all patients (33% of patients with dyslipidaemia); BP - 9% of all patients (15% of patients with HBP) (Table 1). In the study year, LP was assessed in 69% of all patients and in 85% (34/40) of patients with known dyslipidaemia, with a median LDL-cholesterol of 96 (128 – 74) mg/dL. Thirty-five (35/40, 88%) patients were under statins and the LP control was desirable, ideal and in line with the SCORE risk in 56%, 53% and 56% of patients, respectively. In the study year, BP was assessed in 32% of all patients and in 39% (13/33) of patients with known HBP, of whom 94% were under antihypertensive drugs. Among these patients (n=13), 69% had desirable and 23% ideal BP control. Steroid treatment regimen prevalence as well as disease activity as measured by the SLEDAI-2K was similar between patients who had LP and BP assessed and controlled compared to those who did not (all $p>0.05$).

Table 1. Prevalence of diagnosis, clinical recognition, drug prescription and control of HBP and dyslipidaemia.

		Total (n = 65)	Subgroup by disease
HBP, n (%)			**33 (51)**
Clinical assessment	2019	21 (32)	13 (39)
	Annual	6 (9)	5 (15)
Under treatment		31 (48)	31 (94)
Control *	Desirable	17 (81)	9 (69)
	Ideal	10 (48)	3 (23)
SBP / DBP, mmHg		130 (134–120) / 77 (80–70)	134 (141–130) / 80 (87–75)
Dyslipidaemia, n (%)			**40 (62)**
Clinical assessment	2019	45 (69)	34 (85)
	Annual	16 (25)	13 (33)
Under treatment		35 (54)	35 (88)
Control *	Desirable	29 (64)	19 (56)
	Ideal	24 (53)	18 (53)
	According to SCORE	28 (62)	19 (56)
LDL, mg/dL		97 (124–74)	96 (128–74)

*Calculated from the clinical assessment number for each group.

Conclusion: LP was the most frequently evaluated CVRF but only about one third of patients had their BP measured. Despite treatment, dyslipidaemia and BP control are suboptimal.

AB0516 IN-HOSPITAL MORTALITY IN YOUNG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND ASSOCIATED CLINICAL FEATURES

S. Bowman[1], S. Bruera[2], S. Agarwal[2]. *[1]Baylor College of Medicine, Internal Medicine, Houston, United States of America; [2]Baylor College of Medicine, Section of Immunology, Allergy and Rheumatology, Houston, United States of America*

Background: Patients with systemic lupus erythematosus (SLE) are three times more likely to die from any cause as compared to patients without SLE.[1] This is largely driven by cardiovascular disease, malignancy, and an increased risk of infection. Alarmingly, recent studies have shown that younger patients with SLE are particularly vulnerable to all-cause mortality.[1] However, there is a paucity in knowledge about patient characteristics and specific etiologies of mortality in this population that needs to be described in order to implement strategies to improve outcomes in younger patients with SLE.

Objectives: To identify disease characteristics and etiologies of mortality in young patients with SLE that died while hospitalized.

Methods: A retrospective chart review of a multi-institutional publicly funded health system in Texas, USA was performed. Deceased patients aged 18-49 with a 2019 EULAR/ACR diagnosis of SLE were identified from 2012 to 2021. Patients with mixed connective tissue disease, missing records, or cardiac arrest in the emergency room that did not have a clear etiology of death were excluded. Data was extracted from the electronic medical records by two independent reviewers to determine the most likely cause of death. If there was any discrepancy between the reviewers, this would be resolved by a third-party reviewer. Baseline demographics, disease activity by the SLE disease activity index (SLEDAI), medications, and reasons for prednisone administration were collected.

Results: Twenty- six patients with SLE (age range 22 to 48) that died in the hospital were identified. The most common cause of death was infection (58%) followed by lupus activity (15%). Of those that died of infection, all but one was on a two-month average dose of prednisone ≥10mg. Furthermore, the majority of patients (71%) that were on prednisone doses of ≥10mg had not undergone a prednisone taper within two months (i.e. were on a consistent dose). This was because of either persistent disease activity or poor follow-up.

Conclusion: To our knowledge, this is the first study to describe characteristics of young patients with SLE that died during hospitalization. Our findings show that young patients with SLE primarily die from infection while on increased doses of corticosteroids that have not been tapered. Further research is warranted to determine association and causality of these findings with mortality. Practitioners should remain vigilant and continue to taper steroids as able as this may be a potential source of mortality in young patients with SLE.

AB0517 IMPAIRED INTESTINAL BARRIER FUNCTION IN SLE MEASURED BY SERUM ZONULIN

J. An[1], Y. Wang[1], R. Fan[1], X. R. Hu[1], Y. Q. Liu[1], F. Zhang[1], J. Chen[1].
[1]The Second Hospital of Shanxi Medical University, the Department of Rheumatology, Taiyuan, China

Background: Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease characterized with the secretion of normal autoantibodies, which leads to the involvement of multiple organs. Several observations have showed that the breakdown of immune tolerance was involved in the pathogenesis of SLE, especially the imbalance of Th17/Treg [1], but the mechanism of the impaired immune tolerance is unknown yet. Numerous researches support that intestinal mucosal barrier is an upstream mechanism leading to impaired immune balance [2]. However, the relationship between intestinal mucosal barrier and SLE is little known.
Objectives: To measure the expression of serum zonulin to assess and compare the function of intestinal mucosal barrier in patients with SLE and healthy adults, and to explore the role of intestinal mucosal barrier in the pathogenesis and development of SLE.
Methods: 20 patients with SLE who hospitalized at the Second Hospital of Shanxi Medical University and 10 age and gender-matched healthy adults were enrolled in this study. We collected the blood sample of the patients and healthy controls to examine the function of intestinal mucosal barrier and the absolute number of Th17 and Treg cells. The level of serum zonulin was measured by ELISA to assess the function of intestinal mucosal barrier. The absolute number of Th17 cells and Treg cells was detected by flow cytometry. Disease activity indicators of patients with SLE were collected from laboratory including erythrocyte sedimentation rate (ESR, mm/h), complement 3(C3, g/l) and anti-dsDNA (IU/ml). Then we compared the expression of serum zonulin between the patients and healthy controls and analyzed the correlation of serum zonulin with Th17 cells, Treg cells and disease activity.
Results: The level of serum zonulin of SLE group were significantly higher than that of healthy control group ($p<0.05$). And the expression of serum zonulin was positively correlated with the level of ESR ($r=0.491$, $p=0.033$) and anti-dsDNA, but was negatively correlated with C3 ($r=-0.519$, $p=0.018$). And the expression of serum zonulin was not correlated with the absolute number of Th17 cells and Treg cells ($P>0.05$), but Th17 cells showed a trend of increasing with the increase of zonulin, while Treg cells showed a trend of decreasing with the increase of zonulin.
Conclusion: The results here showed that the level of serum zonulin,a marker of the intestinal mucosal barrier function,was up-regulated in patients with SLE, and the higher level of serum zonulin was positively correlated with the disease activity of SLE, which indicated that impaired intestinal mucosal barrier function in SLE played an important role in the development of the disease.

Table 1. A summary of baseline demographics of all enrolled patients and healthy controls

	HC(n=10)	SLE(n=20)	P value
Age(years)	44.1±18.8	42±12.384	P=0.76
Sex(male/female)	2/8	2/18	P=0.47

Results are expressed as the mean ± standard error. Normally distributed continuous variables were analyzed by the independent-samples Student's t-test.

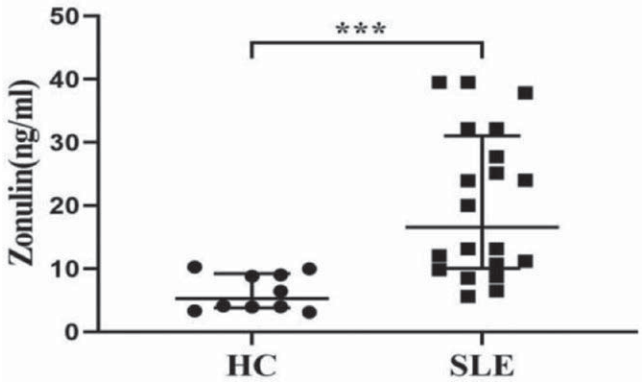

Figure 1. The difference of the expression of serum Zonulin in patients with SLE and healthy controls. Statistical analyses were performed by the Mann-Whitney U test.(***P<0.001)

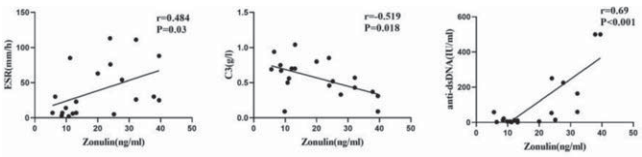

Figure 2. The correlation of disease activity with the level of serum Zonulin.Statistical analyses were performed by the Spearman correlation analysis.

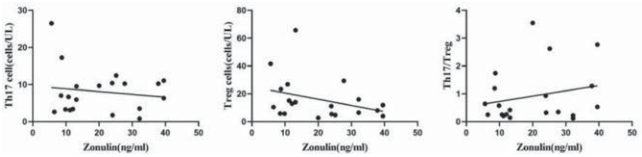

Figure 3. The correlation of disease activity with the level of serum Zonulin. Statistical analyses were performed by the Spearman correlation analysis.

AB0518 OBESITY PARADOX IN SLE PATIENTS LOWER BMI TRADUCES TO HIGHER DISEASE ACTIVITY.

M. A. Balderas-Palacios[1], D. Á. Galarza-Delgado[1], I. J. Colunga-Pedraza[1], J. R. Azpiri-López[2], A. N. Garza-Cisneros[1], A. Garcia-Heredia[1], A. B. Rodriguez-Romero[1], N. Guajardo-Jauregui[1], A. Cárdenas[1]. *[1]Hospital Universitario Dr. José Eleuterio González, Reumathology, Monterrey, Mexico; [2]Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*

Background: Cachexia plays an important role in rheumatoid arthritis (RA), due to its chronic inflammatory process characterized by decreased muscular mass with preservation or increase of fat that occurs in 1-13% of the RA population. A decreased BMI has a paradoxical relationship with disease activity, with an increase in disease activity and mortality (1). Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by the production of nuclear autoantibodies that can form immune complexes and cause inflammation of multiple organs. Cardiovascular events and mortality are nearly twice as high in patients with SLE as in the general population. (2)
Objectives: To determine the relationship between BMI and disease activity in patients with SLE.
Methods: A cross-sectional, observational study was conducted in which a group of 58 patients with SLE were included and their level of disease activity was determined using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and BMI. Distribution was assessed with the Kolmogorov-Smirnov test. Descriptive analysis using measures of central tendency. Correlation between BMI and SLEDAI with Pearson's test. A p value <0.05 was considered statistically significant.

Results: The mean age of SLE patients was 35.4 ± 12.11 years, rest of demographic characteristics in Table 1. Pearson's test showed a correlation between BMI and disease activity (r= -0.304, p= 0.020) Image 1. Multivariate analysis found that a decrease in BMI is independently associated with an increase in disease activity assessed by SLEDAI (B= -0.411, 95% CI= -0.819- -0.003, p=0.049).

Table 1. Demographic characteristics

	SLE n=58
Female n (%)	54 (93.0)
Age, years, mean ± SD	35.4 ± 12.1
DM n (%)	2 (3.4)
AH n (%)	12 (20.6)
DLP n (%)	4 (6.8)
Obesity n (%)	4 (6.8)
SLEDAI mean ± SD	8.06 ± 6.4
ANA positivity n (%)	47 (81.0)
BMI mean ± SD	25.0 ± 4.9

DM; Diabetes Mellitus, AH; Arterial Hypertension, DLP; Dyslipidemia, SLEDAI; Systemic Lupus Erythematosus Disease Activity Index, ANA; Anti-Nuclear Antibodies, BMI; Body Mass Index.

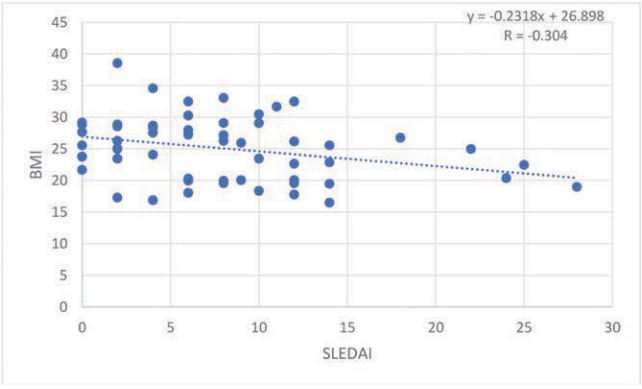

Figure 1. Correlation between BMI and SLEDAI.

Conclusion: The results show an inverse relationship between BMI and disease activity in patients with SLE. Further studies with a larger number of patients should be performed.

AB0519 ELECTROCARDIOGRAPHIC ALTERATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND CONTROLS.

M. A. Balderas-Palacios[1], J. R. Azpiri-López[2], D. Á. Galarza-Delgado[1], I. J. Colunga-Pedraza[1], A. N. Garza-Cisneros[1], A. Garcia-Heredia[1], N. Guajardo-Jauregui[1], A. B. Rodriguez-Romero[1], A. Cárdenas[1]. *[1]Hospital Universitario Dr. José Eleuterio González, Reumathology, Monterrey, Mexico; [2]Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with a high prevalence worldwide. Patients with SLE have a higher frequency of developing cardiovascular disease than the general population. There is little evidence on conduction abnormalities and arrhythmias in patients with SLE(1).
Objectives: The aim of this study is to compare electrocardiogram alterations in patients with SLE and a control group.
Methods: A cross-sectional, observational, comparative study was performed. A total of 70 patients with SLE, and 70 controls matched for age (± 5 years) and gender were recruited. An electrocardiogram was performed in all study subjects. Kolmogorov-Smirnov test was used for distribution analysis. Comparisons were performed by Chi-square test for qualitative variables and Student's t-test or Mann Whitney U test for quantitative variables. A p value <0.05 was considered statistically significant.
Results: In electrocardiogram findings, a significant difference was found in QRS segment duration (84.00 vs 89.50 ms, p=0.012), QT segment duration (397.01 vs 384.44 ms, p=0.016) and heart rate (68.60 vs 74.77, p=0.03) (Table 1).

Table 1. ECG comparison between SLE and controls.

Characteristics	Pacientes with SLE (n=70)	Controls (n=70)	*P*
Age (years), median (p25-p75)	35.0 (25.0-50.2)	35.0 (22.7-50.2)	NS
Female, n (%)	63 (90)	64 (91.4)	NS
QRS (ms), median (p25-p75)	89.50 (84.75-95.50)	84.00 (80.00-90.00)	0.012
QT (ms), mean ± SD	384.44 ± 30.84	397.01 ± 30.21	0.016
HR (Bpm), mean ± SD	74.77 ± 12.93	68.60 ± 11.25	0.003

ECG; electrocardiogram, SLE; systemic lupus erythematosus, NS; not significant, HR; heart rate, MS; milliseconds, BPM; beats per minute.

Conclusion: The results suggest that patients with SLE have increased QRS segment, increased heart rate and decreased QT segment duration, which may be related to disturbances of the conduction system.

AB0520 ASSOCIATION BETWEEN LEFT VENTRICULAR MASS INDEX AND BODY WEIGHT IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

A. N. Garza-Cisneros[1], D. Á. Galarza-Delgado[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], M. A. Balderas-Palacios[1], A. Garcia-Heredia[2], N. Guajardo-Jauregui[1], A. B. Rodriguez-Romero[1], A. Cárdenas[1]. *[1]Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico; [2]Universidad Autónoma de Nuevo León, Hospital "Dr. José Eleuterio González", Cardiology, Monterrey, Mexico*

Background: Rheumatoid cachexia is a clinical spectrum of rheumatoid arthritis in which individuals present increased inflammatory activity, more aggressive joint destruction, and worse cardiovascular prognosis (1). Systemic lupus erythematosus (SLE) is a chronic, inflammatory, autoimmune disease in which there is a high cardiovascular mortality rate (2). Currently, the cachexia phenomenon in SLE patients has not been studied.
Objectives: To correlate body weight with left ventricular (LV) indexed mass in SLE patients.
Methods: This was a cross-sectional study that included a total of 34 patients aged ≥18 years with a diagnosis of SLE according to EULAR/ACR 2019 criteria. Patients with a personal pathological history of cardiovascular disease (myocardial infarction, stroke, or peripheral arterial disease) and pregnancy were excluded. Three certified cardiologists performed a transthoracic echocardiogram in each patient, assessing relative wall thickness, and indexed LV mass. The distribution was assessed with Kolmogorov-Smirnov. Correlations between weight and echocardiographic parameters with Spearman-rho coefficient. A value of p<0.05 was considered statistically significant.
Results: Most patients were female (94.1%), with a mean age of 33.29±9.91. Of the total patients 2 (5.88%) had Type 2 Diabetes Mellitus, 2 (5.88%) hypertension, 1 (2.94%) dyslipidemia, 3 (8.82%) obesity, and 6 (17.64%) smoking. Spearman-rho coefficient showed a significant negative correlation between LV indexed mass and body weight of SLE patients (rho=-0.411, *p*=0.016) (Figure 1).

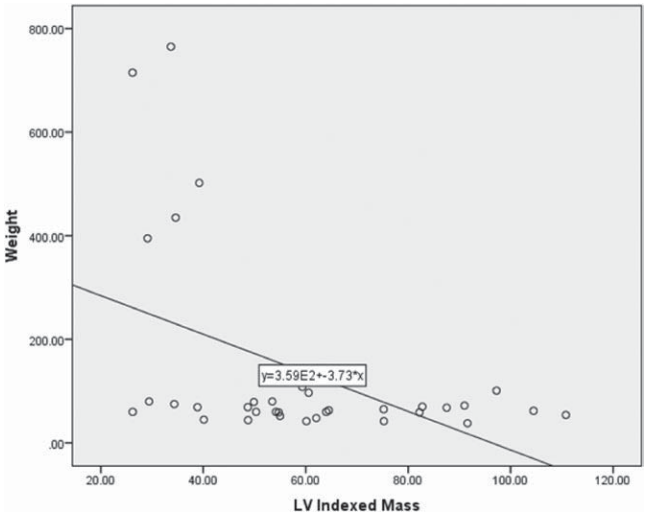

Figure 1. Spearman rho correlation between weight and LV indexed mass.

Conclusion: There is a negative correlation between body weight and LV indexed mass in SLE patients, this suggests that a lower body weight may be related to higher LV mass, which may result in LV hypertrophy and increased cardiovascular morbidity and mortality.

AB0521 PERICARDITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS: CHARACTERISTICS, MANAGEMENT, EVOLUTION AND PREDICTIVE FACTORS FOR RELAPSE. A MONOCENTRIC RETROSPECTIVE STUDY.

M. Lemeu[1], O. Lairez[2], S. Faguer[3], G. Pugnet[4], G. Moulis[1], L. Alric[4], A. Huart[3], D. Ribes[3], M. L. Piel-Julian[1], A. Constantin[5], D. Chauveau[3], L. Sailler[1]. *[1]Hôpital Purpan, Internal Medecine, Toulouse, France; [2]Hospital Rangueil, Cardiology, Toulouse, France; [3]Hospital Rangueil, Nephrology, Toulouse, France; [4]Hospital Rangueil, Internal Medecine, Toulouse, France; [5]Hôpital Purpan, Rheumatology, Toulouse, France*

Background: Pericarditis is frequent in Systemic Lupus Erythematosus (SLE) and usually benign. Dedicated studies are scarce. However, recurrences can lead to repeated steroid prescriptions and further immunosuppression. The best management, including the potential benefit of colchicine, remains to be determined.

Objectives: The aim of this study was to describe management, evolution over time and risk factor for relapse in SLE pericarditis in our University Hospital Center.

Methods: Cases were retrospectively collected among hospital discharge data (coding code "SLE" and "pericarditis"), from January 1997 to December 2019. All SLE cases met the ACR/EULAR 2019 classification criteria. Pericarditis cases met ESC 2015 diagnosis criteria. Patients with conditions other than lupus known to cause pericarditis were excluded as well as patients with myocarditis. A minimal follow-up of one year after pericarditis diagnosis was mandatory. Relapse-free survival was described using an actuarial survival model.

Results: Among 103 patients identified in the database, 29 patients (women: n=25, mean age 30 +/- 13 years) were included. Median follow-up was 7 years [range: 1-22].

Description of first episodes: 31% (n= 9) were inaugural of SLE; otherwise, median time elapsed since SLE diagnosis was 65 months [1.7-400]. Fifty-five percent (n=16) of first episodes occurred during a multi-systemic lupus flare. Median SLEDAI-2K was 9 [range: 4-30l. Clinical symptoms and signs were typical chest pain (93%, n=27), dyspnea (55%, n=16); pericardial rub (31%, n=9), fever (38%, n=11). EKG was abnormal in 59% of the cases (n= 17). When present, 79% of effusions (n=17/22) were circumferential, 82% (n= 18/22) were mild to moderate (<20mm), and 25% (n=7) were dry pericarditis. Two Cardiovascular Magnetic Resonance imaging were performed and were pathological.

Biological data showed always high CRP levels (65mg [range: 7-460]), high-titer anti-DNA (79%, n=19) but few patients had low complement levels (C3 21% (n=4/19), C4 26%(n=5/19)).

Prescribed drugs were non-steroidal anti-inflammatory drugs/acetylsalicylic acid (NSAIDs/ASA) (41%, n=12), corticosteroids (66%, n=19; mean daily prednisone dose: 57.2mg +/- 13.9), colchicine 0.5 to 1mg/day (41%; n=12). There was a significant difference in SLEDAI-2K values at pericarditis onset between those treated with NSAIDs/ASA (7.5, [range: 0-16]) and those not (12, [range: 4-30]), (p<0.05). Only 41% (n=5) of colchicine prescriptions lasted at least 3 months; they were associated with a lower SLEDAI-2K at pericarditis onset compared to pericarditis not or insufficiently treated with colchicine (respectively, 7[range: 4-9] and 11[range: 4-30], p=0.04). Immunosuppressive drugs were prescribed in 17% (n=5) of the patients, always due to extra-pericardial involvements.

Recurrences were frequent (55%, 16 patients out of 29) and multiple (1 to 6, average 3 ± 1.26). Short and long-term relapse-free survival tended to be better in patients exposed to at least 3 months of colchicine (100% vs 75% at 1 year, p=0.09) (Figure 1). There was no statistical difference (p=0.25) in terms of short-term relapse-free survival in patients treated with NDAIDs/ASA compared to those who were not. Corticosteroid prescription and previous antimalarial treatment were not associated with a poorer or better outcome during the year following remission (p=0.78). No patient has progressed to constriction.

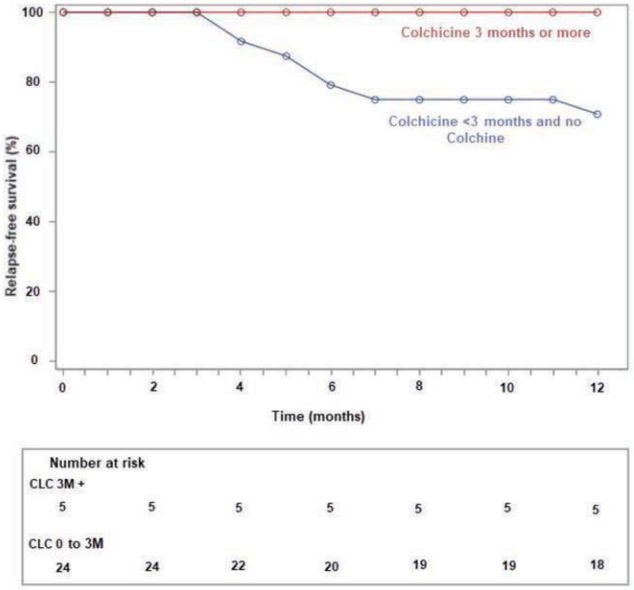

Figure 1. Relapse-free survival at 12 months according to colchicine prescription

Conclusion: Our conclusions are limited due to the small number of patients and lack of multivariate analysis.

Further studies are necessary to confirm the potential benefit of colchicine to prevent incessant pericarditis or relapses in this population.

AB0522 EARLY DAMAGE AS MEASURED BY THE DAMAGE INDEX FOR ANTIPHOSPHOLIPID SYNDROME (DIAPS) IS NOT A PREDICTOR OF MORTALITY IN THROMBOTIC ANTIPHOSPHOLIPID SYNDROME

P. Gaspar[1,2], F. Farinha[3], Z. Sayar[4], M. Efthymiou[5], H. Cohen[4,5], D. Isenberg[6]. *[1]Hospital de Santa Maria, Internal Medicine Department II, Lisboa, Portugal; [2]Instituto de Medicina Molecular (IMM), Cellular Immunology Lab, Lisboa, Portugal; [3]University College London, Centre for Rheumatology, London, United Kingdom; [4]University College London Hospitals NHS Foundation Trust, Department of Haematology, London, United Kingdom; [5]University College London, Haemostasis Research Unit, London, United Kingdom; [6]University College London Hospitals Nhs Foundation Trust, Department of Rheumatology, London, United Kingdom*

Background: Antiphospholipid syndrome (APS) patients experience damage accrual (1) but correlation with mortality is rarely reported. In systemic lupus erythematosus (SLE), early damage accrued in the first year of disease is a predictor of mortality (2).

Objectives: To determine whether damage accrued within the first year after APS onset as measured by the Damage Index for APS (DIAPS) predicts mortality.

Methods: Single-centre retrospective analysis of thrombotic APS patients (2006 Sydney criteria). The disease onset was determined as the time the first thrombotic event related to APS was diagnosed. Annual DIAPS assessments were determined for each patient. Early damage was considered to be a score ≥1 at the initial assessment (six months). DIAPS is shown as median (interquartile range [IQR]). Survival was analysed by the Kaplan-Meier method. Cox regression analysis was performed to investigate predictors of mortality.

Results: A total of 197 patients (71.1% female; 65.9% primary APS; 72.4% Caucasian) with a median age at APS onset of 40 years (IQR 51 - 28) were followed for up to 43 years (median 10 years). Cumulative damage developed

in 143 (73.6%) patients with a median DIAPS of 1 (IQR 2 - 0) at the last visit. Early damage was present in 69 (35.0%) patients. Patients with early damage had similar sex distribution (p=0.733), age at disease onset (p=0.526) and median time of follow-up (p=0.181) comparing to those without early damage. Secondary APS (SAPS) (odds ratio [OR] 1.89, 95% CI 1.03 - 3.48, p=0.041) and having a first arterial event (OR 7.24, 95% CI 3.74 - 14.03, p<0.001) were associated with early damage. Twenty-three patients (11.7%) died. SAPS (p=0.009), male sex (p=0.008) and age at onset ≥40years (p=0.001) were risk factors for death (Table 1). Early damage was not associated with death (hazard ratio [HR] 1.65, 95% CI 0.73 - 3.78, p=0.231; Figure 1: survival curve) even after adjusting individually for APS category (secondary, p=0.446), sex (male, p=0.374), age at onset ≥40years (p=0.115) and type of event (arterial, p=0.555).

Table 1. Predictors of mortality.

	Crude analysis		Adjusted analysis†	
	HR (95% CI)	*p-value*	HR (95% CI)	*p-value*
Male sex	3.14 (1.35 – 7.33)	**0.008**	1.46 (0.63 – 3.36)	0.374
Age at APS onset ≥ 40 years	5.34 (1.9 – 14.53)	**0.001**	1.95 (0.85 – 4.50)	0.115
Caucasian	0.95 (0.35 – 2.57)	0.918	1.61 (0.70 – 3.70)	0.257
Secondary APS	3.07 (1.32 – 7.12)	**0.009**	1.38 (0.59 – 3.20)	0.446
First event (arterial)	1.85 (0.79 – 4.27)	0.151	1.32 (0.53 – 3.32)	0.555
Early damage	1.65 (0.73 – 3.78,	0.231	-	-

† In this column, we present the *Early Damage* hazard ratio and 95% confidence intervals for death adjusted for the variable in each row. Statistically significant values are presented in bold. APS, antiphospholipid syndrome; CI, confidence interval; DIAPS, Damage Index for Antiphospholipid Syndrome; HR, hazard ratio.

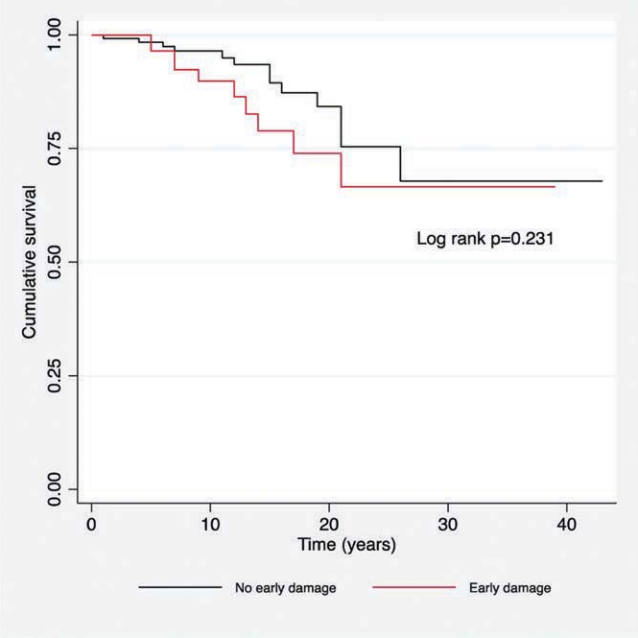

Figure 1. Survival probability in patients with and without early damage.

Conclusion: Unlike SLE, early damage accrual accessed by DIAPS is not a predictor of mortality regardless of the nature of the thrombotic event, gender, APS category and age at APS onset.

AB0523 THE ENTEROTYPES OF THE GUT MICROBIOTA IN CHINESE POPULATION WITH AUTOIMMUNE DISEASE

M. J. Chang[1,2,3], S. X. Zhang[2,3,4], J. Qiao[2,3,4], C. Wang[1,2,3], H. R. Chen[1], T. Huang[5], Q. Yu[1,6], P. F. He[6]. *[1]Shanxi Medical University, School of Management Shanxi Medical University, Tai Yuan, China; [2]Shanxi Medical University, Key Laboratory of Cellular Physiology, Tai Yuan, China; [3]Shanxi Medical University, Academy of Microbial Ecology, Tai Yuan, China; [4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Tai Yuan, China; [5]Shanxi Medical University, School of Basic Medical Sciences, Tai Yuan, China; [6]Shanxi Medical University, Medical Data Sciences, Tai Yuan, China*

Background: An increasing number of autoimmune disorders (AD) have been associated with microbial dysbiosis[1, 2]. However, this dysbiosis is difficult to characterize for individual patients owing to the high heterogeneity of the gut microbiota. Thus, researchers must find an accurate method of characterizing the AD gut microbiota that is meaningful to clinical diagnosis.

Objectives: The aim of this study was to investigate the enterotype characters of intestinal flora in AD and their associations with peripheral lymphocyte subpopulations and cytokines.

Methods: A total of 339 AD patients and 339 age- and sex- matched healthy controls (HCs) were enrolled in this study. Mathematical modeling using Dirichlet multinomial mixtures (DMM) was applied to describe the variability in the microbiome data and cluster samples into enterotypes. The peripheral lymphocyte subsets were detected by flow cytometry and the cytokines were assessed by ELISA. Differential abundance analysis was carried out the STAMP software. R (version 4.1.0) was used for comparative statistics, and spearman's correlation analysis was used to assess the correlations between the relative abundances of bacterial genera and clinical variables.

Results: Laplace approximation of DMM suggested gut microbiota of AD patients and HCs both can be divided into two distinct enterotypes (Figure 1 A-B), and AD E1 and HC E1 were primarily dominated by Prevotella while AD E2 and HC E2 by Bacteroides. Interestingly, the Prevotella-enriched enterotype (AD E1 and HC E1) had a higher alpha diversity than The Bacteroides-enriched enterotype (AD E2 and HC E2). Patients with AD always had a lower richness and diversity compared with those of HCs in each enterotype (p< 0.001), suggesting gut microbiome was markedly less diverse in composition in AD. Bray curtis distance-based beta-diversity were also different (P<0.001, ANOSIM.R =0.23, Figure 1 C-H). Significant differences in gut microbiota composition at the genus level between AD patients and HCs were found using the STAMP software in each enterotype. Compared with HCs, 37 species in AD E1 patients and 40 species in AD E2 patients of flora were discovered to be distinctly different. In the co-upregulated flora of both enterotypes, Lactobacillus was inversely associated with a variety of lymphocytes such as T, CD4+T, NK, Th2, Th17, Treg cells(P<0.05), and positive correlation with IL-10 and IFN-γ(P<0.05,Figure 1 I). However, in the co-downregulated floras Coprococcus had a positive correlation with B, NK and Treg cells, and anaerostipes had a negativate corrleation with IL-2 and IL-4(P<0.05,Figure 1 J).

Conclusion: There were both two enterotypes in patients and HCs with autoimmune disease, E2 exhibited a loss of Prevotella but a growth of Bacteroides, while E1 presented the opposite results, which were closely correlated with peripheral lymphocyte subsets and cytokines.

AB0524 RELATIONSHIP BETWEEN SERUM URIC ACID, CARDIOVASCULAR RISK AND INFLAMMATORY STATUS IN PRIMARY SJÖGREN'S SYNDROME

A. Alunno[1], F. Carubbi[1], F. M. Mariani[1], M. Rossi[1], J. Santilli[1], C. Ferri[1]. *[1]Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*

Background: An unhealthy diet, with or without impaired renal urate excretion, is the most frequent cause of hyperuricemia. Despite its pivotal role in the pathogenesis of gout, the clinical relevance of serum uric acid (SUA) levels goes well beyond the simple association with gout and/or nephrolithiasis. Several studies pointed to hyperuricemia as cardiovascular (CV) risk factor in the general population therefore, the 2018 guidelines of the European Society of Cardiology and the European Society of Hypertension included the assessment of uricemia among the screening tests to be performed in hypertensive patients. Furthermore, in view of the association between hyperuricemia and mortality (both CV and all-cause) and CV events, it is conceivable that cardiovascular damage begins with much lower levels of uricemia. In this context, the first results of the URRAH (Uric Acid Right for Heart Health) study identified a uricemia threshold value of 4.7 mg/dL for all-cause mortality and 5.6 mg/dL for CV mortality[1].
Objectives: Since patients with primary Sjögren's syndrome (pSS) have a higher risk of CV events compared to the general population, we aimed to explore how uricemia correlates with other CV risk factors and previous CV events in patients with pSS and without gout.
Methods: A cross sectional study was conducted recruiting consecutive patients with pSS without history of gout. SUA was measured upon recruitment alongside the assessment of disease activity (EULAR Sjögren's syndrome disease activity index, ESSDAI and ClinESSDAI), patient reported symptoms (EULAR Sjögren's syndrome patient reported symptoms, ESSPRI), CV risk factors including hypertension and diabetes among others, and previous CV events. Dietary habits were also explored with various food frequency questionnaires.
Results: One hundred and three patients with pSS were enrolled. SUA levels ranged between 2.9 and 6.8 mg/dl and, according to the cut-off values of the URRAH study, 16 (16%) patients had SUA levels >4.7 mg/dL while 5 (5%) had SUA levels >5.6 mg/dL. Patients with SUA levels >4.7 mg/dL were more likely males (20% vs 3%) with a higher number of CV risk factors compared to patients with SUA levels <4.7mg/dL. No differences were observed regarding dietary habits across groups. Disease activity assessed with both ESSDAI and ClinESSDAI was significantly higher in patients with SUA levels >4.7 mg/dL compared to patients with SUA levels <4.7 (9.3 vs 6.3 p= 0.04 and 9.0 vs 6.0 p=0.03). Conversely, patient reported symptoms (total ESSPRI and individual VAS scales for total dryness, xerostomia, xerophtalmia, pain and fatigue) did not differ across groups. Logistic regression analysis confirmed the association of SUA values >4.7 mg/dL and a higher number of CV risk factors (OR 2.8; 95% CI=1.2-6.5; p=0.016).
Conclusion: Accumulating evidence highlights the emerging role of hyperuricemia as an independent CV risk factor, but no data are available in pSS patients. This is the first study demonstrating that SUA levels >4.7 mg/dL correlate with both a higher number of CV risk factors and a higher disease activity in pSS patients. Large interventional studies are needed to clarify the possible benefits of urate-lowering treatments in pSS patients.

AB0525 MODELS OF SYSTEMIC LUPUS ERYTHEMATOSUS ACTIVITY (A RESTROSPECTIVE-PROSPECTIVE STUDY)

A. Shumilova[1], E. Travkina[1], M. Cherkasova[2], T. Reshetnyak[2,3], A. Lila[2,3]on behalf of The study was performed at the V.A.Nasonova Research Institute of Rheumatology within the framework of the fundamental topic FURS-2022-003.. *[1]V.A.Nasonova Research Institute of Rheumatology, 4th Rheumatological Department, Moscow, Russian Federation; [2]V.A.Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [3]Russian Medical Academy of Continuing Professional Education, Department of Rheumatology, Moscow, Russian Federation*

Background: Systemic lupus erythematosus (SLE) is a heterogeneous chronic autoimmune rheumatic disease with a wide range of clinical manifestations, characterized by impaired activation of cellular and humoral links of immunity, uncontrolled hyperproduction of autoantibodies of a wide spectrum to nuclear antigens and the formation of immune complexes that cause immuno-inflammatory damage to tissues and organs. This disease is characterized by periods of exacerbation and remission, over time, the activity of SLE may change, mainly in response to therapy. Despite this, patients can be classified according to the current or currently prevailing activity model.
Objectives: To study the activity patterns of patients with SLE.
Methods: The retrospective-prospective study was conducted from 2019 to 2021 based on the study of the history of the disease and annual visits of patients with an assessment of the activity of SLE by SLE Disease Activity Index-2000 (SLEDAI-2K). Depending on the level of SLEDAI-2k flare index, the models of SLE activity, the number of exacerbations during the observation period and the period of the disease, as well as the predominance of organs and systems involved in the process were analyzed. The study included 183 patients with SLE (163 women and 20 men). The average age was 37.5±12.8 y.o. The duration of the disease was Me=9.9 [2.0; 16.0] years.
Results: The clinical and immunological manifestations of SLE were evaluated in the study. The average number of exacerbations of SLE during the period of the disease was 2.9±1.9. The average number of exacerbations during the observation period was 1.1±0.78. The most frequent exacerbation was manifested by a lesion of the musculoskeletal system – 29,5% (54 patients), the skin-mucous system – 21,8% (40 patients) and lupus-nephritis – 21,8% (40 patients). The predominant activity model was relapsing-remitting disease (RRD) – 43,16% (79

patients), then chronic active disease (CAD) - 38,15% (70 patients), and minimal disease activity (MDA) – 7,1% (12 patients). Clinical quiescent disease (CQD) had 21 patients (11,47%). Models of SLE activity and involvement of systems and organs are presented in Table 1.

Table 1. ***Models of SLE activity and involvement of systems and organs in patients with SLE.***

Models of SLE activity / Damage to systems and organs	RRD	CAD	MDA	CQD
Skin-mucosal system	47,5% (19 patients)	37,5% (15 patients)	-	6% (15 patients)
Musculoskeletal system	31,5% (17 patients)	42,6% (23 patients)	11,1% (6 patients)	14,8% (8 patients)
Lupus- nephritis	52,5% (21 patients)	37,5% (15 patients)	-	10% (4 patients)
Polyserosities	42,8% (3 patients)	57,2% (4 patients)	-	-
Nervous system	37,5% (3 patients)	50% (4 patients)	-	12,5% (1 patient)
Hematological disorders	50% (10 patients)	40% (8 patients)	5% (1 patient)	5% (1 patient)
Immunological disorders	42,8% (6 patients)	7,1% (1 patient)	42,8% (6 patients)	7,1% (1 patient)

23 patients with involvement of the skin-mucosal system had 1 exacerbation of SLE in 3 years of the study. 23 patients with involvement of the musculoskeletal system had 1 exacerbation and 19 patients had 2 exacerbation of the disease in observation period. Exacerbation of lupus nephritis 1 time during the follow-up period was noted in 26 patients, 2 times - in 8 patients.

Conclusion: The most frequent model of SLE activity is RRD, which characterizes periods of exacerbation and remission. The most frequent clinical manifestations of exacerbation of SLE are lesions of the skin-mucous and musculoskeletal systems, as well as lupus nephritis.

AB0526 ASSESSMENT OF HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS USING SF-36 SCALE

M. Ardhaoui[1], M. Brahem[1], S. Arfa[2], B. Ben Rejeb[2], M. Hassayoun[1], R. Sarraj[1], H. Hachfi[1], O. Berriche[2], Y. Mohamed[1]. *[1]Taher Sfar Hospital, Rheumatology, Mahdia,Tunisia; [2]Taher Sfar University Hospital, Internal Medicine, Mahdia,Tunisia*

Background: Systemic Lupus Erythematosus (SLE) has diverse effects on patients' health-related quality-of-life (HRQoL), affecting both physical and mental domains of well-being. The Medical Outcomes Survey 36-item Short Form (SF-36) is one of the most common generic instruments used to measure HRQoL in SLE.

Objectives: Our objective in this study is to assess the aspects of HRQoL in patients with SLE and to explore the associations between HRQoL and disease-related parameters.

Methods: A cross-sectional study was conducted in patients followed in the departments of Internal Medicine and Rheumatology in Mahdia, Tunisia, who met either the 1997 ACR or the 2012 SLICC criteria for SLE. We evaluated for each patient, the global score and the eight domains of SF-36 (physical functioning (PF), role physical (RP), bodily pain (BP) and general health (GH) gathered into the Physical Component Summary (PCS); vitality (VT), social functioning (SF), role emotional (RE) and mental health (MH)) gathered into Mental component Summary (MCS), scored from 0 (worst) to 100 (best). The disease activity was evaluated by the SLE Disease Activity Index (SLEDAI).

Results: Forty SLE patients were enrolled. 90% of patients were female. The mean age was 47.75±17.59 years. The mean disease duration was 2.3±2.9 years. The mean SLEDAI was 5.78±4.94. The most commonly found manifestations of SLE were; cutaneous, musculoskeletal and neuro-psychiatric in 85%, 82.5% and 40% of cases, respectively. The anti-nuclear antibodies were positive in 100% of cases. Serum levels of complement C3 and C4 were low in 20% and 32.5% of cases, respectively. A biological inflammatory syndrome was found in 37.5% of cases and anemia in 42.5% of cases. Anti-malarial were prescribed for 85% of patients, Glucocortoids were prescribed for 62.5% of patients. The SF-36 global score was 60.5 ± 20.5 ranging from 18.5 to 93.1. Eighteen patients (45 %) had impaired HRQoL (SF-36 < 66.7). The physical domains were more affected than the mental ones with mean scores of PCS and MCS of 59.59 and 61.6, respectively. The means of different domains (PF, RP, BP, GH, VT, SF, RE and MH) were respectively 67.87±28.3; 52.5±50; 62.5±29; 55.49±25.6; 56±21.5; 64±25.7; 67.5 ±47.4 and 58.6±18.6. The most severely impacted domains were RP and GH. Increased age was correlated with reduced PF, BP and PCS (p=0.02, p=0.02, p=0.05 respectively). Longer disease duration was associated with reduced GH (p=0.004). The analysis of organ-specific damage revealed that musculoskeletal involvement was significantly associated with lower scores of PF, RP, BP and PCS (p=0.05, p=0.009, p=0.01 and p<0.001, respectively), While neurological involvement was associated with lower scores of SF, VT and MCS (p=0.01, p=0.05 and p=0.04, respectively). The SF-36 global score and its domains had no significant correlations with the SLEDAI, the biological abnormalities or the received treatments.

Conclusion: Impairment in the quality of life can be significant when suffering from SLE, affecting physical health more than mental health according to our study. HRQoL should be included in routine clinical care in SLE patients.

AB0527 DIFFUSE ALVEOLAR HEMORRHAGE IN LATIN AMERICAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A CASE-CONTROL STUDY

D. C. Quintero-González[1], M. Muñoz-Urbano[1], J. Sanchez-Bautista[2], Y. Santamaria-Alza[1], A. Ramírez[2], C. Muñoz[1,3], A. L. Vanegas-García[1,3], G. Vásquez[1], L. A. González[1]. *[1]Universidad de Antioquia, Rheumatology, Medellín, Colombia; [2]Universidad de Antioquia, Internal Medicine, Medellín, Colombia; [3]Hospital San Vicente Fundación, Rheumatology, Medellín, Colombia*

Background: Diffuse alveolar hemorrhage (DAH) is an uncommon and life-threatening complication of systemic lupus erythematosus (SLE) with a high mortality rate (estimated average 50%). The presence of respiratory symptoms (dyspnea, cough, hemoptysis), a new drop in hemoglobin levels, and diffuse infiltrates on chest imaging should raise suspicion of this complication.

Objectives: We aimed to describe DAH-SLE patients and compare them with non-DAH SLE patients.

Methods: We conducted a single-center, case-control study that enrolled hospitalized patients between 2012 and 2020 in Colombia. Twenty-three DAH-SLE patients (cases) were matched by age and sex with 23 non-DAH-SLE patients (controls). Descriptive, comparative, and logistic regression analyses were performed.

Results: In seven (30.4%) patients, DAH was the initial manifestation of SLE; 69.5% of DAH-SLE patients were females with a mean age of 35 years. Lupus nephritis was present in 65% of cases, mean hemoglobin decrease was 2.22 g/l [standard deviation (SD) 0.92 g/L], and 78% had hemosiderophages in bronchoalveolar lavage. All patients received intravenous (IV) pulses of methylprednisolone followed by high-dose steroids, 87.0% IV cyclophosphamide pulses, 60.8% plasmapheresis, 21.7% IV immunoglobulin, and 8.7% rituximab. Comparisons between DAH and non-DAH groups are shown in Table 1. Bivariate logistic regression analysis showed that male sex (OR 9.625 CI95% 1.07 - 86.17; p=0.043), higher SLEDAI-2K score (OR 1. 28 CI95% 1.10 - 1.48; p=0.001), and higher C-reactive protein (CRP) levels (OR 1.09 CI95% 1.01 - 1.18; p=0.016) were independently associated with the occurrence of DAH, whereas prior use of corticosteroids (OR 0.029 CI95% 0.003 - 0.25; p=0.001) and antimalarials (OR 0.121 CI95% 0.03 - 0.45; p=0.002), higher hemoglobin levels (OR 0.457 CI95% 0.29 - 0.71; p=0.001), higher C3 (OR 0.94 CI95% 0.91 - 0.97; p<0.0001) and higher C4 levels (OR 0.87 CI95% 0.80 - 0.95; p=0.002) were negatively associated with DAH occurrence (Graph).

Table 1. Demographic, clinical, serological, and therapeutic characteristics in DAH-SLE patients and non-DAH-SLE patients

Variable	Non-DHA SLE (n = 23)	DHA SLE (n = 23)
Female	95.6%	69.5%
Age (years)	27.9 (SD 12.8)	34.82 (SD 17.3)
Hospital stay (days)*	20.7 (SD 29.1)	34.39 (24.4)
SLEDAI-2K*	6.17 (SD 5.9)	21.77 (12.5)
Creatinine (mg/dL)*	2.5 (SD 3.7)	4.23 (SD 5.2)
Leucocyte (cell/mm3)	8907 (5668)	9408 (5477)
Neutrophil (cell/mm3)	7112 (5595)	8063 (5456)
Lymphocyte (cell/mm3)	1236 (759)	952 (425)
Hemoglobin (g/L)	10.5 (2.6)	6.9 (1.5)
Ureic nitrogen (mg/dL)*	33.79 (SD 28.87)	45.73 (SD 25.64)
ESR (mm/Hour)	51.5 (35.72)	64.65 (47.50)
CPR (mg/dL)*	5.21 (SD 8.16)	12.42 (9.63)
Ferritina (ng/mL)	509 (526)	891 (856)
Lactate dehydrogenase (U/L)*	314 (SD 114)	503 (SD 357)
C3 (mg/dL)*	84.8 (SD 23.07)	44.84 (SD 27.91)
C4 (mg/dL)*	20.5 (10.3)	9.5 (8.2)
Anti-dsDNA	42.8%	71.4%
Anti-Ro	38.8%	38.8%
Anti-La	11.1%	10.5%
Anti-RNP	44.4%	47.3%
Anti- Sm	38.8%	35%
IgG ACL	0	9%
IgM ACL	10.5%	13.6%
Lupus anticoagulant	33.3%	33.33%
Mucocutaneous involvement	78.2%	69.5%
Articular involvement	73.9%	60.8%
Hematological involvement	86.9%	69.5%
Renal involvement	91.3%	86.9%
Serosal involvement	34.7%	26.1%
Prior glucocorticoid*	95.6%	39.1%
Prior antimalarial*	69.5%	21.7%
Dead	4.3%	21.7%

***P value** < **0.05**

Conclusion: In about one-third of patients diagnosed with DAH, this life-threatening complication was the initial presentation of SLE. Male sex, higher SLEDAI-2K scores, and higher CRP levels were associated with DAH occurrence, whereas higher hemoglobin levels, elevated complement levels, prior use of glucocorticoids, and antimalarial treatment were negatively associated with the occurrence of DAH.

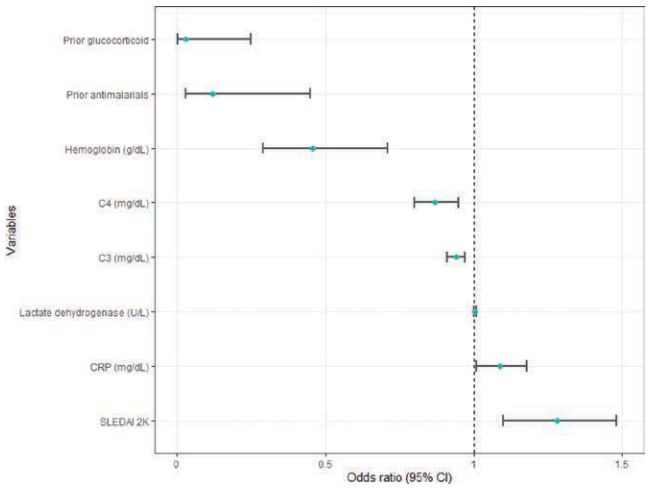

Figure 1. Forest plot of factors associated with DHA-SLE patients. **The Forest plot graph does not include the male sex variable due to its wide confidence intervals.

AB0528 CORRELATION BETWEEN ALBUMIN TO GLOBULIN RATIO AND DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Liu[1,2], Y. Huang[1], Z. Huang[1,2], Z. Huang[1], Q. Huang[1], T. Li[1,2,3]. *[1]Guangdong Second Provincial General Hospital, Department of Rheumatology and Immunology, Guangzhou, China; [2]Southern Medical University,The Second School of Clinical Medicine, Guangzhou, China; [3]Zhaoqing Central People's Hospital, Department of Rheumatology and Immunology, Zhaoqing, China*

Background: Neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) have been reported as useful inflammatory biomarkers associated with the disease activity of systemic lupus erythematosus (SLE). Recently, the albumin to globulin ratio (AGR) has emerged as a potential indicator to predict the prognosis of some cancers. However, whether AGR can predict the disease activity of SLE has been rarely investigated.
Objectives: This study was to explore the relation between AGR and SLE Disease Activity Index 2000 (SLEDAI-2K) in patients with SLE.
Methods: This retrospective study enrolled 101 SLE patients and 75 age- and gender-matched healthy individuals. According to the SLEDAI-2K score, SLE patients were classified into Group 1 with a score of 9 or lower (patients with mild disease activity, N = 60) and Group 2 with a score > 9 (patients with moderate to severe disease activity, N = 41). Albumin, globulin, NLR, PLR, monocyte to lymphocyte ratio (MLR), AGR, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), complement 3 (C3), complement 4 (C4), SLEDAI-2K and other clinical data were collected. Receiver operation characteristic (ROC) curves were conducted to discriminate SLE patients from healthy controls and SLE patients with different disease activity. Correlations between the inflammatory markers and SLEDAI-2K were checked. The prognostic value of AGR in the SLE disease activity was tested by logistical regression analyses.
Results: Albumin and AGR in SLE patients were lower compared to those of the healthy controls (P < 0.05), while NLR, PLR, MLR, globulin and CRP were higher (P < 0.05). Patients in Group 2 had lower levels of albumin, AGR, C3 and C4 than those in Group 1 (P < 0.05), NLR and PLR were higher (P < 0.05), while MLR (P = 0.198), globulin (P = 0.704), CRP (P = 0.224) and ESR (P = 0.135) displayed no significant differences. The ROC curves for differentiating SLE patients from healthy individuals showed that the area under curve (AUC) of AGR (0.812, 95%CI: 0.750 - 0.874) and albumin (0.840, 95%CI: 0.782 - 0.898) were higher than NLR (0.786, 95%CI: 0.719 - 0.853), PLR (0.708, 95%CI: 0.629 - 0.786), MLR (0.776, 95%CI: 0.708 - 0.845) and globulin (0.630, 95%CI: 0.548 - 0.713). Similarly, the ROC curves for predicting the disease activity of SLE patients displayed that the AUC of AGR (0.779, 95%CI: 0.689 - 0.870) and albumin (0.827, 95%CI: 0.746 - 0.909) were also higher than NLR (0.644, 95%CI: 0.534 - 0.753), PLR (0.672, 95%CI: 0.565 - 0.780), MLR (0.583, 95%CI: 0.466 - 0.701), globulin (0.521, 95%CI: 0.403 - 0.639), CRP (0.567, 95%CI: 0.452 - 0.683), ESR (0.589, 95%CI: 0.475 - 0.703), C3 (0.709, 95%CI: 0.603 - 0.815) and C4 (0.655, 95%CI: 0.542 - 0.768). AGR was negatively correlated with SLEDAI-2K (r = -0.543, P < 0.001) in SLE patients. Logistical regression analyses showed that AGR (OR = 13.047, 95%CI: 3.407 - 49.966, P < 0.001) was an inverse predictor for SLE disease activity, yielding a highest hazard than other inflammatory parameters.
Conclusion: AGR was significantly decreased in SLE patients compared with healthy subjects and negatively associated with the disease activity of SLE. AGR might be a potential indicator for evaluating inflammation in patients with SLE.

AB0529 PULMONARY HYPERTENSION (PAH) IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IS NOT DEFINED BY AUTO-ANTIBODY AND CLINICAL VARIABLES.

R. Baisya[1], M. G S R[2], P. K. Devarasetti[1], A. Aggarwal[3], V. Shobha[4], L. Rajasekhar[1]on behalf of INSPIRE. *[1]Nizam's Institute of Medical Sciences, Clinical Immunology & Rheumatology, Hyderabad,Telangana, India; [2]Indian Statistical Institute, Statistical Quality Control and Operational Research Division,, Hyderabad, India; [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India; [4]St John's Medical College Hospital, Clinical Immunology and Rheumatology, Bangalore, India*

Background: PAH is a well-recognized but infrequent manifestation of SLE. Often insidious in onset, PAH may have progressed for a while, before symptoms manifest. Prediction of clinical risk of PAH may have clinical benefit during the follow-up of a patient with SLE.
Objectives: The aim of the study was to develop a prediction algorithm for PAH in patients with SLE using clinical and auto-antibody variables.
Methods: The study included patients from the INSPIRE cohort which is, a national multi-center study enrolling patients with disease duration of less than three years. Lupus patients with symptomatic PAH confirmed by a transthoracic

2D ECHO right ventricular systolic pressure of more than 40 mm Hg were enrolled as cases. Controls were age, sex and date of enrolment matched patients from the same cohort without any clinical evidence of PAH. We excluded patients with underlying known heart disease and critical illness. The clinical variables and antibody data was retrieved from records. Outcome of death if any was noted. Using supervised learning, a logistic regression model was built for the prediction of SLE-PAH. The final Prediction model included one clinical variable (RP), sixteen autoantibodies (Sm-RNP, Smith, SS-A, Ro-52, SS-B, SCL-70, PM-SCL, Centromere, Jo1, PCNA, Nucleosome, dsDNA, histone, Ribosomal P and AMA, anticardiolipin antibody) and complement level. To ensure accuracy of the model, a confusion matrix using python was performed. The proportion of right predictions (ρ) is a measure of accuracy of the model. If the model is good, ρ must be close to 1.

Results: A total of 69 patients with symptomatic PAH, confirmed by 2D echo-cardiography were enrolled as cases. Raynaud phenomenon (RP), Interstitial lung disease (ILD) and ischemic stroke were significantly higher in cases than control (p= 0.026,0.001, 0.05 respectively). There was no difference in the prevalence of individual auto-antibodies between the groups except high prevalence of anti-cardiolipin antibody in cases (39% vs 23% p= 0.048). Mortality rate was higher in cases (17% vs 0.06%, p=0.003) during a follow up of 3 years with all the deaths occurring within one year of PAH diagnosis. Ten repetitions of the confusion matrix analysis using Python for this prediction model (both derivation and validation) yielded the following ρ scores 0.60, 0.47, 0.57, 0.63, 0.50, 0.60, 0.57, 0.43, 0.50, 0.57. which exhibited wide variability.

Conclusion: A prediction model using RP and commonly assayed autoantibodies failed to be informative for PAH in Indian lupus patients.

AB0530 CARDIOVASCULAR RISK STATUS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: WHICH ALGORITHMS IS THE BEST?

T. Panafidina[1], T. Popkova[1], L. Kondrateva[1], Y. Gorbunova[1], E. Nasonov[2]. *[1]V.A.Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation; [2]V.A.Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation*

Background: Systemic lupus erythematosus (SLE) has been strongly linked to accelerated atherosclerosis and increased cardiovascular morbidity and mortality. Rheumatological guidelines recommend evaluating the cardiovascular (CV) risk status in SLE patients, for an early identification of patients at high risk to preventive strategies.

Objectives: The aim of our study to compare three algorithms for CV risk estimation, namely Framingham, ACC/AHA (American College of Cardiology/American Heart Association) and QRISK3, in a cohort of patients with SLE.

Methods: This cross-sectional study included 279pts (84% females, median aged 37[28-45]years (median [interquartile range 25%-75%])) with SLE according to SLICC/ACR 2012 criteria, attending a routine visit at our Clinic between February 2018 and February 2020. Traditional risk factors (TRF), ongoing therapies, comorbidities and SLE-specific evaluation were assessed. In those without previous myocardial infarction or stroke (n=254, 83% females, aged 36[27-44]years), Framingham, ACC/AHA and QRISK3 algorithms were then used to estimate the individual risk of developing a CV disease over the next 10 years. In accordance with the NICE (National Institute for Health and Care Excellence) guidelines high-risk was considered for Framingham scores ≥10%, for ACC/AHA - ≥7,5% and for QRISK3 scores - ≥10%.

Results: Patients eligible for CV risk estimation were 254 of 279 enrolled. The median disease duration was 10[4-17]years, SLEDAI 2K-4[2-10], SLICC/DI–1[0-2]score. Framingham index reported (at the age 20-79years, n=238) a median risk score of 1[1-5]%, according to this algorithm 54/238 patients (23%) were classified as high-risk. ACC/AHA index (at the age 40-79years, n=99) showed a median risk score of 2[1-8]%, with 30/99 (30%) at high-risk. QRISK3 revealed (at the age 25-84years, n=211) a median risk score of 7,5[3,5-14,4]%, making it possible to classify 85/211 (40%) at high CV risk. To the same algorithm, the median relative risk (the ratio of the absolute risk of SLE patients to the estimated risk score in an age-, sex- and ethnicity-matched healthy ideal population) was 9,2[4,1-20,3]. «QRISK3 healthy heart age» showed a median of 64[56-71]years. The use of the QRISK3 scale revealed a greater number of SLE patients with CV high-risk compared to the Framingham: 40% vs 23% of patients, p<0,001.

Conclusion: QRISK3 classifies a greater number of SLE patients at high-risk of developing CV diseases over the next 10 years in comparison with classic algorithms as Framingham and ACC/AHA. According to QRISK3 score the absolute CV risk of SLE patients is 9 times higher than the CV risk of healthy individuals. The use of QRISK3 as a tool in the evaluation of SLE patients could lead to the early detection in a considerable part of high-risk CV diseases development individuals who would have otherwise been underestimated by the application of Framingham and ACC/AHA algorithms.

AB0531 GLUCOCORTICOID-ASSOCIATED MORBIDITY IN SLE USING THE GLUCOCORTICOID TOXICITY INDEX

E. Ermolaeva[1], E. Aseeva[1], N. Nikishina[1], T. Popkova[1], A. Lila[1]. *[1]Federal State Research Institution (FSRI) named after V.A. Nasonova, Systemic Lupus Erythematosus, Moscow, Russian Federation*

Background: Systemic glucocorticoid (GC) therapy remains a necessity for a significant subset of patients with SLE. Chronic corticosteroid use is associated with the accrual of irreversible organ damage over time, with the highest risk being among those exposed to a mean prednisone dose of ≥20 mg/day. That is why, CG toxicity assessment should be an important part of routine clinical care as well.

Objectives: The aim of this study is to describe for the first time individual patient GC toxicity in SLE patients using the Glucocorticoid Toxicity Index (GTI)

Methods: A total of 37 patients SLE (30 (81%) women and 7 (19%) men) were enrolled in this study. The mean age was 36± 11,9 years and the median disease duration was 36 [12; 128] months. At the first visit, all patients were assessed for SLE activity by the SLEDAI 2K index, irreversible organ damage by SLICC Damage Index (DAI), GTI *, and current treatment.

Results: The mean disease activity index SLEDAI 2K was 11,3±6,2, DAI SLICC ≥1 was in 20 (54%), 17 (46 %) patients had not any irreversible organ damage DAI SLICC = 0. During the period of illness the maximum GC dose was 33,7 mg ± 19,9 mg, the median of cumulative dose of GC administered intravenously was 1563 mg [293; 6478] mg, median duration of GC treatment was 22 months [8; 112]. 30 (81%) of patients had GTI with median 33 [19; 48] points. 2 (5%) patients had zero GTI, but there were severe organs' injuries from the GTI Specific List (1 patient had cataract and 1 patient had cataract and avascular necrosis). 5 (14%) patients had zero GTI with no severe organs' injuries from the TGI Specific List. In 3 out of 5 patients, the duration of GC treatment did not exceed 6 months, in 2 out of 5 patients, the maximum dose of GC during the period of the disease did not exceed 5 mg/day. In 1 out of 5 patients, the duration of GC treatment was 13 months, and the maximum dose of GC was 15 mg during the period of treatment. The most frequent changes occurred in 5 of 9 main domains: an increase in body mass index was detected in 10 (27%) patients, an increase in blood pressure was detected in 15 (41%) patients, hyperlipidemia was detected in 9 (24%) patients, a decrease bone mineral density was detected in 6 (16%) patients and the development of infectious complications in 5 (14%) patients; The less frequent changes occurred in 5 of 9 main domains: 3 (8%) patients had impaired glucose tolerance, 2 (5%) patients had steroid myopathy; neuropsychiatric intoxication was detected in 2 (5%) patients. Severe organs' injuries were identified, included in a Special list and not scored in points: cataracts were detected in 7 (19%) patients, avascular necrosis was detected in 3 (8%) patients, osteoporotic fractures - in 2 (5%) patients. GTI correlated with disease duration (r = 0.33); the maximum dose of GC per os (r = 0.43); duration of GC therapy (r = 0.37); DAI SLICC (r-0.39), p<0.05 in all cases.

Conclusion: GTI was detected in a significant number of patients with SLE (81%). ITG correlates with the duration of the disease, the maximum dose of GC during the period of illness, the duration of GC therapy, and the SLICC DAI. GTI should be used to evaluate the safety of GC therapy in patients with SLE who receive GC therapy for more than 6 months, together with the SLICC DAI.

**The GTI includes Composite Index and Specific List. Composite Index, consists of 9 domains and 31 elements, each of which is assigned a certain number of points. It contains information on the most common complications of GC therapy: BMI, glucose tolerance, BP, lipids, myopathy, bone mineral density, skin lesions, neuropsychiatric lesions, infections.*

Severe organ damages, which is less common but contributes significantly to GC toxicity, are included in a special list. The specific list includes 11 domains

(9 of which are also used in the Composite index) and 23 elements (avascular necrosis, osteoporotic fractures, cataracts, etc.).

AB0532 LACTATE DEHYDROGENASE AS A PREDICTOR OF FATIGUE IN PRIMARY SJOGREN'S SYNDROME:A POOLED ANALYSIS

L. Rajagopala[1], S. Jude Tan[1], W. F. Ng[1], J. Tarn[1]. [1]*Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, UK, Department of Rheumatology,Freeman Hospital,Newcastle upon Tyne NHS Trust,United Kingdom, Newcastle upon Tyne, United Kingdom*

Background: Fatigue is one of the most disabling symptoms in primary Sjogren's syndrome (pSS) and it significantly impacts patient's quality of life[1]. However, the cause of this symptom remains unclear.
Lactate dehydrogenase (LDH), is an enzyme of the anaerobic respiratory pathway. High lactate levels are a marker of inflammation and create a pro-inflammatory microenvironment[2]. LDH levels can be raised in myositis, haemolysis and lymphoma. For this reason, serum LDH is routinely monitored in patients with pSS. However given its role in metabolic pathways, we hypothesize that serum levels of LDH may also be a biomarker of fatigue in pSS.
Objectives: 1. To investigate the bivariate relationship between LDH and fatigue severity, hypothesizing a positive correlation between them.
2. To incorporate factors such as depression, anxiety, serum creatinine and haemoglobin levels as covariates, as these factors may also contribute to fatigue
Methods: We used routinely collected clinical and laboratory data from 512 pSS patients from the Newcastle Sjogren's syndrome cohort. The participants consented for their linked anonymised data to be used in pSS-related research. Severity of fatigue was measured using fatigue subscale of EULAR Sjogren's Syndrome Reported Patient Index (ESSPRI)– a Likert scale of 0-10. Fatigue severity was also categorised into 4 categories: 0-2 being minimal, 3-5 mild, 6-7 moderate and 8-10 severe. Hospital Anxiety and Depression Score was used to measure patients' anxiety and depression levels. Blood parameters including haemoglobin, full blood count, ESR, CRP, serum creatinine, alanine aminotransferase (ALT), alkaline phosphatase (ALP) and LDH were checked during each visit. Dryness was measured using ESSPRI dryness subscale.Statistical analysis of the relationship between the continuous blood parameters and categorical fatigue groups was performed using Kruskal-Wallis for categorical fatigue groups and linear regression for continuous fatigue measures.
Results: The majority of the patients were female (87%) and Caucasian. Baseline measurements of pain, anxiety, depression, abnormal fatigue, mental fatigue and overall ESSPRI score increased with increasing fatigue severity. This is seen most prominently in serum LDH levels. LDH levels increased with increasing fatigue scores. We identified significant differences in baseline LDH levels across the four fatigue groups ($p = 0.002$). Within groups comparisons showed significant differences between mild and minimal, severe and minimal and moderate and minimal fatigue groups only (p-values: 0.026, 0.019 and 0.032 respectively). A baseline linear regression model for fatigue using LDH, CPK, age and gender was performed and showed LDH has a significant relationship with fatigue p=0.007.Findings were also determined using ANOVA where significant difference ($p= 0.0023$) of LDH between fatigue groups were identified using Kruskal-Walis test. A supplementary Tukey-Kramer test was carried out to determine if LDH was significant between two-groups of fatigue severity score, where significant difference was seen between three different sets of fatigue categories: mild-minimal, severe-minimal and moderate-minimal. The test ensured that a relationship between the enzyme and fatigue was present especially between the groups of fatigue severity stated above.The actual-by-predicted and leverage plot further supporting our findings by showing the unique effect of LDH in the models.
Conclusion: The study concludes that a relationship between enzyme lactate dehydrogenase and fatigue exist; however, further study will be required to examine its role as a predictor of fatigue severity in pSS. The complex interconnection between inflammation, disease activity, psychological factors and LDH will have to be further investigated to advance the current understanding of chronic fatigue in Sjogrens syndrome.

AB0533 THE ASSESSMENT OF CLINICAL CHARACTERISTICS OF MALE SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. Canbaş[1], S. Colak[1], E. Tekgoz[1], M. Çınar[1], S. Yilmaz[1]. [1]*University of Health Sciences Turkey, Gulhane Faculty of Medicine, Gulhane Education And Research Hospital, Division of Rheumatology, Ankara, Turkey*

Background: Systemic lupus erythematosus (SLE) is a multisystemic chronic autoimmune disease that is nine times more frequent among females. Due to a female dominancy, the data regarding male patients is limited.
Objectives: This study aimed to evaluate the clinical characteristics of male patients with SLE.
Methods: This retrospective study included male SLE patients who followed up in a tertiary rheumatology outpatient clinic between October 2016 and December 2021. Those who met the Systemic Lupus International Collaborating Clinics (SLICC) criteria were included. The data of the patients and SLE Disease Activity Index-2000 (SLEDAI-2K) values were obtained from files.
Results: There were 40 male SLE patients with a mean age of 42.7 ± 17.3 years. The median age of diagnosis was 30 years, and the median disease duration was 63.5 months (ranges between 5-444). The mean value of the SLICC score was 4.7 ± 0.8. The most frequent initial clinical manifestations were thrombocytopenia and photosensitivity, which were seen in 8 (9.6%) patients each (Table 1). Six (15%) patients had secondary antiphospholipid antibody syndrome. Thirty-five (87.5%) patients achieved remission, but 14 (35%) patients had at least one relapse in the follow-up period. The most frequent manifestation after relapse was nephritis in 9 (22.5%) patients that had no renal involvement at the time of diagnosis. The median SLEDAI score was 2 (ranges between 0-12). The most commonly preferred drug for the treatment was hydroxychloroquine and corticosteroids (92.5% for each). Nineteen (47.5%) patients received pulse steroids. Besides, the most frequently prescribed immunosuppressive drug was mycophenolate mofetil (37.5%). The rates of azathioprine, cyclophosphamide, methotrexate, cyclosporine A, rituximab, intravenous immunoglobulin, and leflunomide usage were 30%, 27.5%, 17.5%, 10%, 7.5%, 7.5%, 5%, respectively. Antinuclear antibody (ANA) was positive in 35 (87.5%) patients, and anti-dsDNA was positive in 9 (22.5%). The median level of anti-dsDNA titers was 40 IU/ml (ranges between 23-200). Other autoantibody positivity rates were; 12 (30%) for anti-Sm, 6 (15%) for anti-histon, 4 (10%) for anti-RNP and 4 (10%) for anti-nucleosome. Thirteen (32.5%) patients had low C3 levels, and 11 (27.5%) patients had low C4 levels. The hospitalisation rate was 55%, and no death was seen during follow-up.

Table 1. Clinical characteristics of the patients (n=40)

Characteristics	Patients	
Clinical manifestations, n(%)	Initial	Relapse
Thrombocytopenia	8 (20)	None
Photosensitivity	8 (20)	None
Anemia	7 (17.5)	None
Malar rash	6 (15)	2 (15)
Nephritis	6 (15)	9 (22.5)
Arthiritis/synovitis	5 (12.5)	6 (15)
Subacute lesions	4 (10)	2 (5)
Leukopenia/lymphopenia	4 (10)	None
Thrombosis	3 (7.5)	4 (10)
Neurological involvement	3 (7.5)	None
Serositis	2 (5)	2 (5)
Pulmonery involvement	2 (5)	None
Discoid lupus erythematosus	1 (2.5)	1 (2.5)
Myositis	1 (2.5)	None

Conclusion: Since SLE is more prevalent among females, it may occur in male patients with mild or life-threatening manifestations. In the current study, the seropositivity was less than in the literature, which may indicate male patients should be cautiously evaluated. Although renal involvement is not an initial manifestation, it may develop during the follow-up.

AB0534 PROSPECTIVE STUDY OF 24 MONTHS OF EVOLUTION OF A COHORT OF PATIENTS WITH RHUPUS

I. Martínez Cordellat[1], C. Pávez Perales[1], S. Leal Rodriguez[1], A. V. Huaylla Quispe[1], C. Riesco Barcena[1], L. Mas Sanchez[1], P. Muñoz Martinez[1], I. Cánovas Olmos[1], M. De la Rubia Navarro[1], J. J. Fragío Gil[1], L. Gonzalez Puig[1], E. Grau García[1], J. Ivorra Cortés[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], E. Vicens Bernabeu[1], J. E. Oller Rodríguez[1], F. Ortiz-Sanjuán[1], J. A. Román Ivorra[1]. [1]*La Fe University and Polytechnic Hospital, Rheumatology, València, Spain*

Background: Rhupus syndrome (RhS) is a rare combination of rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Different studies describe cases of RhS with more frequent initial clinical manifestations in the form of erosive arthritis and the presence of rheumatoid factor (RF) and/or anti-CCP, with later manifestations of SLE appearing.
RhS has a low prevalence and it is useful to know the clinical characteristics of the patients and their evolution over time, since their treatment and clinical management differ from those who present RA or SLE in isolation.
Objectives: Our objective was to study the clinical, analytical and therapeutic evolution of our cohort of patients with Rhupus.

Methods: Prospective study of a cohort of patients with Rhupus during 2020-2021 with systematic review of electronic records for the analysis of clinical, analytical and therapeutic parameters throughout follow-up.
Results: Nine patients with RhS (88.9% women) who met SLICC 2012 criteria for SLE and ACR 2010 for RA were included. The mean age was 62.7 (45-86) years.
During follow-up, the death of one case due to metastatic pulmonary neoplasia was verified, as well as the incorporation of a new patient in the study population.
In 4 cases, RA was the first diagnosis, with a mean evolution of 6.25 years until the diagnosis of SLE. On the contrary, in 5 cases SLE was the first diagnosis with a mean evolution of 7.2 years until the diagnosis of RA. Photosensitivity and arthritis were the predominant clinical manifestations. One patient presented rheumatoid nodules in both elbows and 2 patients presented symptoms of serositis in the form of pleuro/pericarditis. No cases of renal or neurological involvement were recorded.
Clinically, the patients have remained stable, presenting joint manifestations as the predominant clinic.
Regarding the serological evolution, 8 patients presented positive RF at the beginning of the study, 3 of them becoming negative during follow-up. Likewise, the presence of ACPA was positive in 6 patients, maintaining this percentage at the present time.
On the other hand, the ANA were positive at the beginning in all the patients, with ANA becoming negative in 5 of them.
Antiphospholipidic antibodies were positive in 2 patients, however none of them developed antiphospholipidic syndrome..
4 patients were treated with biological drugs/JAK inhibitors (1 abatacept, 1 rituximab, 1 baricitinib and 1 tofacitinib) with a favorable response.
Conclusion: The analysis of our cohort continues to show that, unlike other series, 44.4%% of RhS cases begin with seropositive polyarticular arthritis. 55.6% of these start with manifestations compatible with SLE, in the form of hematological, cutaneous and serological alterations, and these show a more prolonged progression to develop polyarticular involvement. Therefore, a diagnosis of RhS continues to be reached earlier in patients who present with symptoms of RA.
37.5% of patients had a negative RF, maintaining ACPA + in all of them. ANA were negative in 55%. Neither of the 2 patients with anti PL Ab developed APS.
Clinically, joint manifestations in the form of arthralgia of small joints were the predominant clinic.
In general, the evolution has been favourable. Four patients were refractory to treatment with cDMARDs, requiring the use of biological drugs/JAK inhibitors with good response.

AB0535 LEPTIN LEVELS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS, CONNECTION WITH COURSE OF THE DISEASE AND ATHEROSCLEROTIC VASCULAR LESIONS

O. Shkilna[1], S. Shevchuk[1]. [1]*National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine Chair №2, Vinnytsia, Ukraine*

Background: Atherosclerosis and its complications remain the leading causes of death in patients with systemic lupus erythematosus (SLE). Along with the known pathological factors that significantly accelerate the development of cardiovascular events in patients with SLE (hyperinsulinemia, hypertension, atherogenic dyslipidemia, disease activity, etc.), in recent years the role of dysadipokinemia has been intensively studied. In patients with SLE serum leptin increases, but how its concentration changes under the conditions of the inflammatory process and how it is associated with other factors that aggravate the course, have not been studied enough. Its role in the formation of atherosclerotic vascular lesions in patients with SLE is also unknown.
Objectives: The aim of the study was to assess leptin levels in patients with SLE and to analyze its relationship with the course of the disease, lipid spectrum and atherosclerotic vascular lesions.
Methods: We examined 45 patients with SLE (31 women and 4 men), mean age - 46.23 ± 1.36 years). The average duration of the disease was 9.97 ± 0.82 years. SLE was verified on the basis of ACR / EULAR criteria (2019) and formulated according to the classification recommended by the Association of Rheumatologists of Ukraine (2020). The control group included 20 healthy individuals of the appropriate age and sex.
The content of leptin in the serum was determined by enzyme-linked immunoassay according to the instructions of the manufacturer. The SLEDAI index was used to assess activity. Assessment of endothelial function was determined by the Celermajer method.
Results: The level of leptin in the serum in apparently healthy individuals and patients with SLE differed significantly. In particular, the average hormone content in patients with SLE was 39.4 ± 3.4 ng / ml, while in the control group - 24.4 ± 3.8 ng / ml, ie it was higher by 38.1% (P <0.01). The patient's age and disease duration were weakly related to leptin levels (r = 0.25, r = 0.34, respectively).
It was found out that in patients with SLE serum leptin levels were directly proportional to the disease activity. In particular, a close associative relationship was established between the activity of the disease determined by the SLEDAI index and ESR (r = 0.81, r = 0.42, respectively). The study found a close association between serum leptin concentrations and blood lipid spectrum in patients with SLE. In particular, it was the highest with LDL(low density lipoprotein) (r = 0.54), and probable with total cholesterol and triglycerides (r = 0.32, r = 0.28, respectively). In patients with SLE with a high (≥42.2 ng / ml) leptin level, the endothelium-dependent vasodilation brachial artery (EDV BA) was 52.3% higher and the CCA IMT (common carotid artery intima-media thickness) was 32% higher than in patients with relatively normal leptin levels. In addition, the proportion of patients with a decrease in EDV BA and a thickening of CCA IMT among patients with high leptin levels was 12–25% higher than among patients with relatively normal levels of the enzyme under study. The presence of atherosclerotic plaques, their area and the severity of atherosclerotic lesions of the carotid arteries also determined the tendency to increase in proportion to the increase in serum leptin levels. Thus, hyperleptinemia in patients with SLE is associated with deterioration of vascular function of the carotid artery and the severity of atherosclerotic vascular lesions.
Conclusion: Significantly higher levels of serum leptin were found in patients with SLE, which were associated with inflammatory activity and dyslipidemia, as well as with structural and functional reorganization of blood vessels, which should be considered as an important risk factor for vascular lesions.

AB0536 RELATIONSHIP OF EXERTIONAL ACTIVITY AND MENTAL WELLBEING IN SYSTEMIC LUPUS ERYTHEMATOSUS

S. Beider[1], T. Witte[1], D. Ernst[1]. [1]*Medical School Hanover, Department of Rheumatology and Immunology, Hanover, Germany*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with a variety of clinical manifestations [1] and has a profound effect on physical health [2]. Anxiety and depression are common symptoms of SLE which can have a significant impact on the quality of life [3].
Objectives: To study whether or not the physical state of health relates to the extent of anxiety and depression in SLE patients.
Methods: The Physical Component Summary Score (PCS) was determined using the 36-Item Short Form Survey (SF-36) in a cohort of 146 SLE patients consecutively visiting our outpatient clinic. Two groups were compared: one group with low PCS<50 % (LPCS) and the comparison group with high PCS ≥50 % (HPCS). Patients with SLE who visited our Rheumatology clinic between March 2019 and December 2020 as part of a monocentric cross-sectional study completed additional standardized questionnaires: Hospital Anxiety and Depression Scale (HADS), Beck's Depression Inventory (BDI II), Multidimensional Assessment of Fatigue (MAF), Functional questionnaire Hanover (FFbH) and the international questionnaire on physical activity in short form (IPAQ-SF). The data was analyzed with SPSS 27 (IBM, Armonk, NY, USA). The tests include bivariate and partial correlations. Significance tests were performed using non-parametric tests.
Results: In total, 146 patients participated in the study. 14.4 % (n = 21) were male and the mean age was 48.6 ± 12.2 years. The mean state of physical health according to SF36 was 54.9 % ± 25.6 % in the examined cohort.
There were 62 (42.5 %) patients with LPCS, of average age 50.4 ± 10.3 years and 84 (57.5 %) with HPCS, of average age 47.2 ± 13.3 years. The majority of patients in both groups were female (55/7, 88.7 % and 70/14, 83.3 %).
A SLEDAI score > 2 was confirmed in 33.9 % (n = 21) of the patients with LPCS and in 25 % (n = 21) of patients with HPCS, the mean SLEDAI score did not significantly differ between LPCS and HPCS patients (2.4 versus 1.9, p = 0.261). Among patients with LPCS, 54.8 % (n = 34) presented low physical activity and 64.5 % reported functional impairment (FFbH < 80). More than half of LPCS-patients (53.2 %, n = 33) showed a low Mental Health summary score (MCS < 50 %) and over a third of them had moderate to severe depression (BDI II > 19, 38.7 %, n = 24) and indicated pathological anxiety (HADS > 10, 37.1 %, n = 23).
Compared to the LPCS group, a smaller number of patients with HPCS had low physical activity (36.9 %, n = 31, p = 0.031) and the difference in mean weekly MET between the two groups was 2730 counts (p = 0.003). There was no impairment of functional capacity in patients with HPCS (FFbH mean Score 90.9 %, p < 0.001). In contrast to the LPCS group, only 17.9 % (n = 15) of the patients with HPCS showed MCS < 50 % (p < 0.001). Completely free of depressive symptoms were 65.5 % (n = 55) of the patients with HPCS and only 4 patients (4.8 %) reported moderate to severe depression (p < 0.001).
Patients with LPCS reported fatigue (GFI > 20) more often than patients with HPCS (98.4 % versus 54.8, p < 0.001).
Conclusion: SLE patients with low physical health conditions have highly significant mental health impairment, particularly anxiety and depression. Physical functioning and limitations due to physical health should be considered and physical activity needs to be improved. Measurement of the PCS should be a routine tool in the overall assessment of the health conditions of SLE patients.

AB0537 DRY EYE SYMPTOMS STRONGLY CORRELATE WITH OCULAR AND EXTRAOCULAR PAIN IN PRIMARY SJÖGREN'S SYNDROME. INTERIM REPORT OF A PILOT CROSS-SECTIONAL MONOCENTRIC STUDY.

L. Moroni[1,2], G. Ferrari[3,4], F. Bonelli[4], V. Batani[1,5], M. Bellone[1,2], M. Matucci-Cerinic[1,6], L. Dagna[1,2]. *[1]IRCCS Ospedale San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; [2]Vita-Salute San Raffaele University, -, Milan, Italy; [3]IRCCS Ospedale San Raffaele, Cornea and Ocular Surface Unit, Milan, Italy; [4]IRCCS Ospedale San Raffaele, Eye Repair Lab, Milan, Italy; [5]University of Verona, Department of Medicine, Verona, Italy; [6]University of Florence, Department of Clinical and Experimental Medicine, Florence, Italy*

Background: Ocular involvement in primary Sjögren's Syndrome (pSS) has been traditionally assessed by Schirmer's test, Tear Break Up Time (TBUT) and Ocular Staining Score (OSS)[1]. The role of Ocular Surface Disease Index (OSDI), Visual Function Questionnaire-25 (VFQ-25) and Numerical Rating Scale (NRS) in measuring ocular pain and discomfort in pSS have not been yet investigated in detail.
Objectives: To explore the prevalence of ocular pain in patients with pSS, and to investigate the potential correlations between dry eye, ocular pain, extraocular patient-reported outcomes and disease activity.
Methods: In this ongoing cross-sectional study, OSDI, VFQ-25 and NRS for ocular pain were administered to 19 consecutive patients with a definite diagnosis of pSS at our outpatient clinic. All patients signed an informed consent for the study. Pearson coefficients were obtained to assess correlation among EULAR Sjögren's Syndrome (SS) disease activity index (ESSDAI), EULAR SS Patient Reported Index (ESSPRI), erythrocyte sedimentation rate (ESR), TBUT, OSDI, VFQ-25 and NRS.
Results: In the study, 19 consecutive patients have been enrolled so far. The sample demographics and disease-related features are representative of a typical pSS population (10% male sex, median age at diagnosis of 49 [IQR 24], median ESSDAI = 1 [IQR 6] being biological, haematological and glandular involvement the most represented). Prevalence of ocular pain of any grade (NRS>0) was 11/19 (58%); 6 patients (33%) reported severe ocular pain (NRS≥5). The correlation analysis was significantly strong for patient-reported dryness (ESSPRId), ocular surface-associated symptoms (OSDI), and stability of the tear film (TBUT) with NRS for ocular pain. Moreover, ocular pain also correlated with generalised pain (ESSPRIp) and fatigue (ESSPRIf), while a significant correlation was outlined for OSDI (but not TBUT) with ESSDAI and ESR. Detailed results are summarised in Table 1.

Table 1. Pearson r coefficients calculated for self-reported ocular pain (NRS), patient-reported outcomes (ESSPRI, OSDI, VFQ-25), physician-assessed dryness (TBUT), disease activity (ESSDAI) and erythrocyte sedimentation rate. *p<0.05 **p<0.01

	NRS	TBUT	ESSDAI	ESSPRId	ESSPRIp	ESSPRIf	OSDI	VFQ-25	ESR
NRS		-0.95**	+0.25	+0.73*	+0.69*	+0.59*	+0.68*	-0.54	+0.19
TBUT	-0.95**		+0.40	-0.56	-0.58	-0.64	-0.57	+0.24	-0.67
ESSDAI	+0.25	+0.40		+0.14	+0.43	+0.12	+0.77**	-0.33	+0.55*
ESSPRId	+0.73*	-0.56	+0.14		+0.73**	+0.36	+0.61*	-0.60*	+0.11
ESSPRIp	+0.69*	-0.58	+0.43	+0.73**		+0.53*	+0.51	-0.63*	+0.32
ESSPRIf	+0.59*	-0.64	+0.12	+0.36	+0.53*		+0.09	-0.31	+0.73
OSDI	+0.68*	-0.57	+0.77**	+0.61*	+0.51	+0.09		-0.60*	+0.56*
VFQ-25	-0.54	+0.24	-0.33	-0.60*	-0.63*	-0.31	-0.60*		+0.05
ESR	+0.19	-0.67	+0.55*	+0.11	+0.32	+0.73	+0.56*	+0.05	

Acronyms: NRS - Numerical Rating Scale (for ocular pain); TBUT - Tear Break Up Time; ESSDAI - EULAR Sjögren's Syndrome (SS) disease activity index; ESSPRI - EULAR Sjögren's Syndrome Patient Reported Index (d= dryness; p=pain; f=fatigue); OSDI - Ocular Surface Disease Index; VFQ-25 - Visual Function Questionnaire-25; ESR: erythrocyte sedimentation rate.

Conclusion: Ocular pain may represent an additional criterion for pSS patient stratification. The unexpected association between ocular pain and extra-ocular symptoms is a novel datum which may suggest that nociceptive mediators could be involved in the genesis of symptoms in pSS[2]. Indeed, OSDI seemed to perform better than TBUT in assessing the sufferance of the ocular surface thus mirroring a systemic inflammatory activity.

AB0538 INCREASED BURDEN OF MENTAL DISORDERS DESPITE IMPROVEMENT IN DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A PROSPECTIVE STUDY

M. Nikoloudaki[1], A. Repa[1], S. Pitsigavdaki[1], A. Molla Ismail Sali[1], P. Sidiropoulos[1], C. Lionis[2], G. Bertsias[1]. *[1]University of Crete Medical School, Rheumatology, Clinical Immunology, Heraklion, Greece; [2]University of Crete Medical School, Social and Family Medicine, Heraklion, Greece*

Background: Mental disorders such as anxiety and depression are highly prevalent in SLE patients,[1] yet their association with the underlying disease activity remains elusive and has been mostly evaluated at cross-sectional level.[2] This is further complicated by the often-increased rates of treatment non-adherence,[3] an important determinant of heightened lupus activity, among patients with depression.[4]
Objectives: To examine the relationship between longitudinal changes in anxiety (ICD-10-CM F41.9), depression (ICD-10-CM F32.x) and disease activity levels in adult SLE patients. Second, to test the association between the aforementioned mental disorders with treatment adherence and sociodemographic factors.
Methods: A prospective 6-month observational study of outpatients aged 18-65 years who fulfilled the EULAR/ACR 2019 classification criteria and had active disease ascertained by a SLEDAI-2K ≥3 and PGA (physician global assessment; scale 0–3) >1. Patients were enrolled by consecutive sampling technique during May-September 2021. Excluding criteria were overlap rheumatic diseases, active neuropsychiatric lupus, ongoing pregnancy or post-partum period, history of dementia or malignancy. Sociodemographic factors (age, disease duration, education level, working status) and comorbidities were collected. Anxiety and depression levels (assessed with the Hospital Anxiety and Depression Scale [HADS-A/D subscales]), disease activity (SLEDAI-2K, PGA), use of medications, and treatment adherence (Morisky Medication Adherence Scale-4 items scale) were monitored during the observation period.
Results: Forty SLE patients (39 females) with an average [standard deviation] age 50.5 (10.3) years and disease duration 10.3 (7.0) years, were enrolled. Baseline SLEDAI-2K was 6.0 (2.0) driven predominantly from the musculoskeletal and mucocutaneous domains. The prevalence of anxiety (HADS-A >11) and depression (HADS-D >8) were 42.5% and 45.0%, respectively. During follow-up, disease activity was significantly reduced (average [SD] reduction in SLEDAI-2K: 1.90 [2.80], p<0.001), however, anxiety and depression levels remained unchanged (average [SD] change in HADS-A -0.05 [3.76] and HADS-D 0.53 [3.25], respectively, p>0.300 for both). Accordingly, Spearman's non-parametric test showed that longitudinal changes in SLEDAI-2K were not significantly correlated with the corresponding changes in the HADS-A (*rho* = 0.13, p=0.417) or HADS-D (*rho* = -0.05, p=0.781) scores. Treatment non-adherence was found in 19 patients (47.5%) but did not correlate with anxiety and depression (p>0.500 for both). Notably, mental disorders were not significantly associated with comorbidities (including fibromyalgia) but unemployment status predicted the presence of anxiety (odds ratio 7.73, p-value 0.018).
Conclusion: Anxiety and depression are frequent comorbidities in active SLE and do not correlate with short-term disease improvement, thus underscoring the need for adjunct treatment. Physician awareness in the detection of treatment adherence is necessary. Larger studies in early disease and with longer follow-up will be required to further explore the possible interaction between of mental disorder and lupus disease course.

AB0539 **DEPRESSION, SELF-ESTEEM AND QUALITY OF LIFE IN SJÖGREN'S SYNDROME**

T. Ramia[1], S. Daada[1], I. Chaabene[1], R. Klii[1], S. Hammami[1], K. Ines[1], M. Kechida[1]. *[1]Fattouma Bourguiba University hospital, Internal Medicine Departement, Monastir,Tunisia*

Background: Sjögren's syndrome (SS) is a connective tissue disease characterized by a triad of fatigue, pain and dryness. SS is a chronic condition with important repercussions on functioning and a source of significant suffering. Therefore, the assessment of depressive symptoms, self-esteem and quality of life (QOL) is important in the clinical and research context.
Objectives: We aimed to describe the clinical picture, depression, QOL and self-esteem of patients followed for SS and to study their association with disease activity.
Methods: This is a descriptive and analytical cross-sectional study including 42 patients with SS diagnosed based on the criteria of the American European Consensus Group of 2002 (AECG). Depression was evaluated by the Beck 13 scale, QOL by the SF-36 and self- esteem by the Rosenberg scale. Disease activity was assessed by EULAR Sjörgen Syndrome Disease Activity Index (ESSDAI).
Results: The average age was 54.5 ±15.67 years and the sex ratio was 0.2. Assessment of disease activity of these patients showed an average activity score of 8.23 ±6.39 with low activity in 16 patients (38.1%), moderate activity in 18 patients (42.9%) and severe activity in 8 patients (19%). The QOL measured by SF-36 was impaired in all areas with averages ranging from 39.76 for physical limit to 66.28 for emotional limit. Depression score evaluated by the Beck scale was 8.42 ±7.05on average with 59.5% of the patients having depression. The self-esteem score evaluated by Rosenberg scale was 32.8 ± 5.7on average. Self-esteem was rated as low to very low in 30.95% of patients.
Disease activity score was correlated to Beck's depression score (r= 0.545; p= 0.001); and Rosenberg's self-esteem score (r= -0.51; p= 0.001). Likewise, we found a correlation between the SF-36 score and Beck's depression score; the SF-36 score and Rosenberg's self-esteem score (p< 0.05).
Conclusion: As QOL, self esteem and depression were correlated to disease activity, taking into account these aspects in SS can improve the overall management of the disease.

AB0540 **INTERRELATION OF HYPERURICEMIA AND BURDEN OF COMORBIDITIES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

E. Kornilova[1], V. Mazurov[1,2], A. Fonturenko[1,2], R. Bashkinov[1,2], O. Inamova[1,2], I. Gaydukova[1,2]. *[1]North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E.Eichwald, St Peterburg, Russian Federation; [2]Clinical Rheumatological Hospital #25, Department of Rheumatology, St Petersburg, Russian Federation*

Background: Comorbidities play an important role in the course and prognosis of systemic lupus erythematosus (SLE) [1]. Hyperuricemia (HP) could cause an increased burden of comorbidities in SLE patients (pts).
Objectives: To evaluate the interrelation between HP and comorbidities in pts with SLE.
Methods: We performed retrospective analysis of the data from 191 SLE pts that were collected in electronic Saint-Petersburg rheumatological register in a period from 01 Jan 2009 until 31 Dec 2020. In analysis were involved data of 85 SLE patients with hyperuricemia (serum uric acid level >360 μmol/l in 3 reports) (group 1) and of 106 SLE pts with normal uric acid level in 3 laboratory reports (≤360μmol/l) – group 2. Pts with rheumatological diseases other then SLE, with gout, active infections, oncological diseases, with glomerular filtration rate <30 ml/min*1.73 m2 and other secondary reasons of HP were excluded. The clinical and laboratory data, presence of comorbidities, Charlson Comorbidity Index, SELENA-SLEDAI were analyzed. SPSS2020 was used to Statistics. Local ethics committee approved the study.
Results: SLE pts with and without HP were matched in age, sex and disease activity characteristics, Table 1(p≥0.05). Uric acids' level did not correlate with activity of SLE (SELENA-SLEDAI), Spearmen' r=0.06, p≥0.05. Hypertension, obesity, hypercholesterolemia, diabetes mellitus, lower renal function were more common in SLE patients with HP than in SLE patients without HP, Table 1. Charlson comorbidity index was higher in SLE pts of than in SLE pts without HP (p<0.05).

Table 1. Clinical characteristics and occurrence of comorbidities in SLE pts.

Patients and Disease' characteristics	Group 1 (n=85)	Group 2 (n=106)	P-value
Age, years, mean ± SD	47.05±13.51	44.84±12.11	≥0.05
Female, n (%)	69 (81.18)	95(89.62)	≥0.05
SELENA-SLEDAI, mean ± SD	7.33±5.03	6.15±3.92	≥0.05
SLE duration, years, mean ± SD	4.73±5.01	0.97±2.15	<0.05
Serum uric acid, μmol/l, mean ± SD	434.6±63.16	238.38±59.36	<0.05
Hypertension, n (%)	52(61.18)	30(28.3)	<0.05
Obesity, n (%)	15(17.65)	5(4.72)	<0.05
Hypercholesterolemia, n (%)	54(63.53)	34(32.08)	<0.05
Diabetes mellitus, n (%)	14(16.47)	3(2.83)	<0.05
Glomerular filtration rate, ml/min*1.73 m^2, mean ± SD	80.29±28.35	95.81±23.38	<0.05

SD - standard deviation

Conclusion: Elevated serum uric acid levels in SLE patients are associated with a higher incidence of hypertension, hypercholesterolemia, obesity, diabetes mellitus, decreased glomerular filtration rate, with a higher Charlson comorbidity index, but not with disease activity.

AB0541 **NEUROPSYCHIATRIC MANIFESTATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS: PREVALENCE, MANAGEMENT AND ASSOCIATED FACTORS**

M. Ardhaoui[1], M. Brahem[1], S. Arfa[2], R. Grassa[1], B. Ben Rejeb[2], H. Hachfi[1], O. Berriche[2], Y. Mohamed[1]. *[1]Taher Sfar Hospital, Rheumatology, Mahdia, Tunisia; [2]Taher Sfar Hospital, Internal Medicine, Mahdia,Tunisia*

Background: Neuropsychiatric involvement is one of the major causes of morbidity and mortality in systemic lupus erythematosus (SLE). Its prevalence varies in the literature because of its clinical polymorphism.
Objectives: The aim of our study is to evaluate the clinical, biological, immunological and therapeutic characteristics of neuropsychiatric complications and to analyze the associated factors.
Methods: This is a retrospective descriptive study including patients followed for SLE (ACR 1997/ SLICC 2012) during the period between 2010 and 2021 at the Rheumatology and Internal Medicine departments in Mahdia, Tunisia.
Results: Our study included 82 SLE patients among whom 29 had neuropsychiatric manifestations (NPM) with a frequency of 35.4%. They were 28 women and 1 man. Their mean age was 52.41 ± 18.11 years [21 - 85]. The mean disease duration was 2.4 ± 3 years [15 days-15 years]. The mean

SLEDAI was 9.3 ± 7.85 [0-32]. NPM were inaugural of SLE in 14 cases (17%). Central neurological manifestations consisted of cerebral vasculitis (n=11), epiletic seizures (n=1), ischemic stroke (n=1), aseptic meningitis (n=1) and transverse myelitis (n=1). Peripheral neurological manifestations of mono/polyneuropathy were found in 6 cases. Cranial nerves involvement was described in 2 cases (Optic neuropathy and vestibular nerve damage). Psychiatric manifestations were present in 7 cases (25%): Depression in 4 cases and psychosis in 3 cases. The most frequent associated clinical manifestations were: musculoskeletal (100%), dermatological (89.7%), hematological (72.5%) and cardiovascular (24.1%). Biological findings included: leucopenia (31%), lymphopenia (44.8%), anemia (44.8%) and biological inflammatory syndrome (41.4%). The mean sedimentation rate (ESR) was 53.75 ±34 mm [2-130]. The mean C-reactive Protein was 13.6 ±27.8 mg/dL [0-130]. Anti-nuclear antibodies and anti-DNA were positive in 100% and 41.4% of cases, respectively. Anti-Sm antibodies were positive in 13.5%, anti-SSA in 24.1% and anti-SSB in 13.8% of cases. Antiphospholipid was positive in 8 patients. C3 and C4 consumption was found in 20.7% and 27.6% of cases, respectively. Brain magnetic resonance imaging showed T2 white matter hyperintensities, particularly in the periventricular area, in 8 cases and ischemic brain lesions in 2 cases. The treatment of NPM required: Glucocorticoids (75.9%), Azathioprine (AZT) (24.1%), Cyclophosphamide (13.7%), Mycophenolate Mofetil (3.4%), anticoagulants and antiplatelet agents (40%). The evolution was favorable for our patients except for one patient who developed AZT-induced hepatotoxicity. Statistical analysis showed that NPM were significantly correlated with older age (p=0.003), hematological involvement (p=0.02), lymphopenia (p=0.004), ESR (p=0.01), anti-Sm antibodies (p=0.03) and SLEDAI score (p=0.008).

Conclusion: NPM during SLE are a serious complication of the disease. Our study shows the frequency and variety of neuropsychiatric presentations during SLE. They must be systematically sought, especially if the disease is active, with older patients and anti-Sm antibodies positivity.

AB0542 ANTIPHOSPHOLIPID ANTIBODY CARRIERS WITH THROMBOCYTOPENIA COULD BE AN INDEPENDENT PHENOTYPE OF PRIMARY ANTIPHOSPHOLIPID SYNDROME

Y. Shi[1], J. Zhao[1], X. Zeng[1]. [1]*Chinese Academy of Medical Sciences, Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China*

Background: Among patients with immune thrombocytopenic (ITP), 10-20% of them were found with positive antiphospholipid antibodies (aPLs) but without typical clinical manifestations of antiphospholipid syndrome (APS), especially thrombotic events[1].

Objectives: To compare the clinical characteristics and prognosis between aPLs carriers and patients with APS.

Methods: This is a single center prospective cohort study consecutively enrolling thrombocytopenic patients with continuous positive aPLs. Patients developing thrombotic events are classified as the APS group. The exclusion criteria are other underlying connective tissue diseases such as lupus and other causes that might manifest as thrombocytopenia, such as virus infection, hypersplenism, etc.

Results: This cohort included 47 thrombocytopenic patients with continuous positive aPLs and 55 with diagnosed primary APS. The proportion of thrombotic high risk demographic characteristics including smoking, hypertension, and higher level of homocysteine are higher in the APS group (p = 0.03, 0.04, 0.03, respectively). The prevalence of nephropathy was significantly higher in patients with diagnosed APS [0 vs 7 (12.7%), p =0.01]. Laboratory results and antibody profiles are presented in Table 1. The platelet count of aPLs carriers at admission was lower than APS patients [26×10^9/L (9×10^9/L, 46×10^9/L) vs 64×10^9/L (24×10^9/L, 89×10^9/L), p = 0.0002]. The proportion of positive anti-β2-glycoprotein I, anticardiolipin and lupus anticoagulant separately was similar, but triple aPLs positivity is more common in primary APS patients with thrombocytopenia [24 (51.1%) vs 40 (72.7%), p = 0.04]. There is no significant differences over the complement levels between the two groups [p = 0.2 for low complement 3 (C3), p = 0.8 for low C4]. Regarding the treatment response, the complete response (CR) rate is similar between aPLs carriers and primary APS patients with thrombocytopenia (p = 0.2). Nonetheless, the proportion of response, no response and relapse differed significantly between the two groups [13 (27.7%) vs 4 (7.3%), p < 0.0001; 5 (10.6%) vs 8 (14.5%), p < 0.0001; 5 (10.6%) vs 8 (14.5%), p < 0.0001, respectively]. In Kaplan-Meier analysis (Figure 1), primary APS patients had significantly more thrombotic events than aPLs carriers (p = 0.0006). aPLs carriers with thrombocytopenia share similar clinical manifestations with primary APS patients but hardly develop thrombotic events.

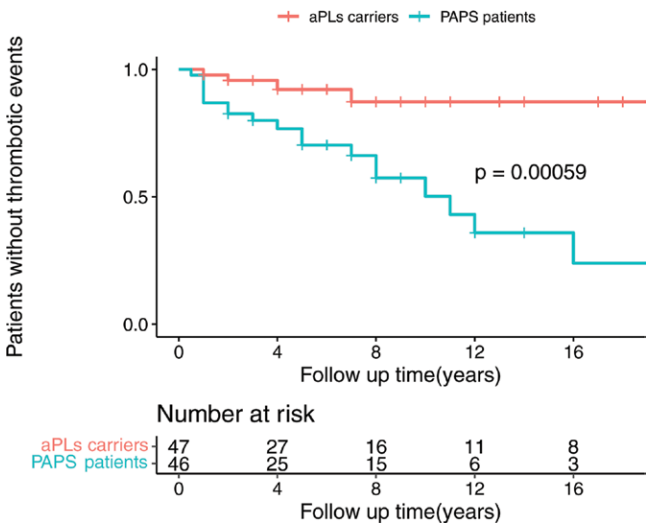

Figure 1. Kaplan-Meier analysis of thrombotic events. aPLs: antiphospholipid antibodies; PAPS: primary antiphospholipid syndrome.

Table 1. Baseline characteristics of laboratory results and antibody profiles.

Characteristics	aPLs carriers (n=47)	Primary APS with thrombocytopenia (n=55)	p-value
Laboratory results, median (Q1, Q3)			
Platelet count ($\times10^9$/L)	26 (9,46)	64 (24, 89)	0.0002*
hsCRP (mg/L)	1.39 (0.475, 2.845)	1.08(0.41, 2.565)	0.8
ESR (mm/h)	5.5 (2.75, 10.75)	7.5 (5, 14.25)	0.06
LDH (U/L)	221 (176, 252)	228 (184.8, 282)	0.3
Low C3, n (%)	3 (6.4)	9 (16.4)	0.2
Low C4, n (%)	5 (10.6)	8 (14.5)	0.8
Antibody profiles, n (%)			
Positive aCL	45 (95.7)	33 (69.1)	0.3
Positive Anti-β2GP I	38 (80.9)	48 (87.3)	0.5
Positive LA	35 (74.5)	50 (90.9)	0.05
Triple positivity	24 (51.1)	40 (72.7)	0.04*
Positive Coombs,	6 (12.8)	10 (18.2)	0.4

*p < 0.05, statistically significant. aPLs: antiphospholipid antibodies; APS: antisphopholipid syndrome; Q1/3: quantile 1/3; hsCRP: hypersensitive C-reactive protein; ESR: erythrocyte sedimentation rate; LDH: lactate dehydrogenase; C3/4: complement 3/4; aCL: anticardiolipin; GP: glycoprotein; LA: lupus anticoagulant.

Conclusion: In the absence of other high risk factor for thrombosis, Thrombocytopenia could be an independent and long-lasting clinical phenotype for aPLs carriers.

AB0543 HIGHER LEFT VENTRICULAR MASS INDEX IN PATIENTS WITH LUPUS NEPHRITIS

N. Guajardo-Jauregui[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], A. Cárdenas[1], A. N. Garza-Cisneros[1], A. Garcia-Heredia[2], M. A. Balderas-Palacios[1], A. B. Rodriguez-Romero[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico;* [2]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*

Background: Systemic lupus erythematosus (SLE) patients have a worse cardiovascular prognosis than the general population. It is estimated that approximately 40% of SLE patients develop lupus nephritis (LN) throughout the evolution of the disease (1). Patients with LN had 8 times more risk of myocardial infarction and 4 times more risk of cardiovascular mortality than SLE patients without LN (2).

Objectives: To compare the echocardiographic parameters between SLE patients with and without LN.

Methods: This was a cross-sectional study nested of a SLE cohort. We recruited patients with SLE diagnosis, according to the 2019 EULAR/ACR

classification criteria, aged ≥ 18 years. Patients with a previous cardiovascular event, another connective tissue disease or pregnancy were excluded. A transthoracic echocardiogram was performed by two certified echocardiographers blinded to clinical information. Patients with LN were included and matched to patients without LN by age and gender. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with Chi-square test or Fisher's exact test for qualitative variables, and Student's T test or Mann-Whitney's U test for quantitative variables. A p-value < 0.05 was considered statistically significant.

Results: A total of 48 SLE patients, 24 with LN and 24 without LN were included. Mean age of patients with LN was 36.9 ± 10.4 years, compared to 36.5 ± 9.3 years in patients without LN, p = 0.873. There were no significant differences in demographic characteristics between groups (Figure 1). When evaluating echocardiographic parameters we found a significant difference in the left ventricular mass index, higher in LN patients (66.9 g/m^2 vs 54.8 g/m^2, p = 0.035) (Table 1).

Figure 1. Comparison of demographic characteristics between SLE patients with and without LN.

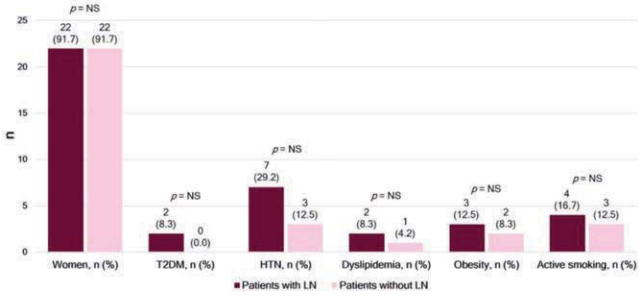

Table 1. Comparison of echocardiographic findings of SLE patients with and without LN.

Variables	Patients with LN (n=24)	Patients without LN (n=24)	p-value
LV mass index, g/m^2, mean ± SD	66.9 ± 21.8	54.8 ± 16.1	**0.035**
RWT, mean ± SD	0.37 ± 0.08	0.34 ± 0.10	NS
LV geometry abnormality, n (%)	7 (29.2)	4 (16.7)	NS
LAESVI, ml/m^2, mean ± SD	29.72 ± 10.80	26.04 ± 8.76	NS
LVEF, %, mean ± SD	58.16 ± 7.42	58.04 ± 7.04	NS
LVESV, ml, median (IQR)	39.0 (26.0-54.5)	32.5 (23.7-39.7)	NS
LVEDV, ml, mean ± SD	92.10 ± 25.09	81.57 ± 27.80	NS

SLE, systemic lupus erythematosus; LN, lupus nephritis; NS, not significant; LV, left ventricular; RWT, relative wall thickness; LAESVI, left atrial end-systolic volume index; LVEF, left ventricular ejection fraction; LVESV, left ventricular end-systolic volume; LVEDV, left ventricular end-diastolic volume.

Conclusion: SLE patients with LN had higher left ventricular mass index than SLE patients without LN. An increased left ventricular mass could lead to the development of ventricular hypertrophy, which is associated to a higher risk of cardiovascular mortality. A transthoracic echocardiogram should be considered as part of the cardiovascular evaluation of SLE patients, especially those with LN.

LEFT VENTRICULAR GEOMETRY ABNORMALITIES ASSOCIATED WITH DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

N. Guajardo-Jauregui[1], J. R. Azpiri-López[2], I. J. Colunga-Pedraza[1], D. Á. Galarza-Delgado[1], A. Cárdenas[1], A. N. Garza-Cisneros[1], A. Garcia-Heredia[2], M. A. Balderas-Palacios[1], A. B. Rodriguez-Romero[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico; [2]Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Cardiology, Monterrey, Mexico*

Background: Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disease. Patients with SLE have higher risk of developing a cardiovascular event than the general population (1), with multiple factors contributing to this increased risk, including systemic inflammation (2).

Objectives: To compare the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and other disease characteristics of SLE patients with and without left ventricular (LV) geometry abnormalities.

Methods: This was a cross-sectional study nested of a SLE cohort. We recruited patients with SLE diagnosis, according to the 2019 EULAR/ACR classification criteria, aged ≥ 18 years. Patients with a previous cardiovascular event, another connective tissue disease or pregnancy were excluded. A transthoracic echocardiogram was performed by two certified echocardiographers blinded to clinical information. Disease activity was assessed with SLEDAI. SLE patients with LV geometry abnormalities were included in this study and matched by age and gender to SLE patients with normal LV geometry by a certified rheumatologist blinded to clinical information. Comparisons were done with Chi-square test or Fisher's exact test for qualitative variables, and Student's T test or Mann-Whitney's U test for quantitative variables. A p-value < 0.05 was considered statistically significant.

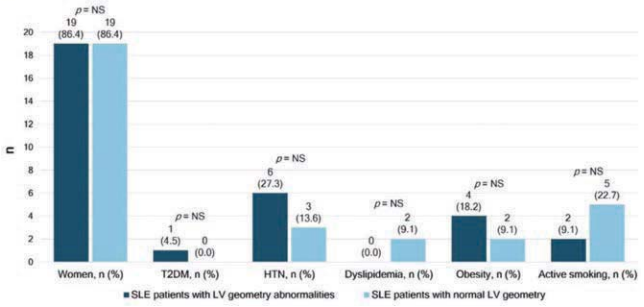
Results: A total of 44 SLE patients were included, 22 patients with LV geometry abnormalities and 22 patients with normal LV geometry. Mean age of SLE patients with LV geometry abnormalities was 35.1 ± 12.2 years, compared to 35.4 ± 9.4 years of SLE patients with normal LV geometry, p = 0.923. The rest of demographic characteristics are shown in Figure 1. When evaluating disease characteristics, the SLEDAI score was significantly higher in SLE patients with LV geometry abnormalities (26.45 vs 17.33, p = 0.016) (Table 1).

Table 1. Comparison of disease characteristics of SLE patients with and without LV geometry abnormalities.

Variables	Patients with LV geometry abnormalities (n=22)	Patients with normal LV geometry (n=22)	p-value
Disease duration, months, median (IQR)	60.0 (12.7-150)	72.0 (43.0-117.7)	NS
SLEDAI, median (IQR)	10.5 (4.0-15.0)	6.0 (2.0-9.0)	**0.016**
CRP, mg/dl, median (IQR)	0.52 (0.33-1.29)	0.60 (0.41-0.85)	NS
ESR, mm/h, median (IQR)	26.0 (13.2-34.2)	29.0 (8.7-58.5)	NS
ANA titers, median (IQR)	640 (160-3200)	480 (160-5120)	NS
Anti-dsDNA, median (IQR)	0 (0-160)	0 (0-200)	NS
C3, mean ± SD	94.6 ± 31.4	100.5 ± 46.1	NS
C4, median (IQR)	13.6 (9.8-14.9)	12.8 (6.4-19.8)	NS
Anti-Ro, median (IQR)	4.5 (2.0-190.5)	3.5 (2.0-82.2)	NS
Anti-La, median (IQR)	2.0 (2.0-4.0)	2.0 (2.0-3.0)	NS
Hydroxychloroquine, n (%)	20 (90.9)	18 (81.8)	NS
Glucocorticoids, n (%)	19 (86.4)	17 (77.3)	NS

SLE, systemic lupus erythematosus; LV, left ventricular; NS, not significant; SLEDAI, Systemic Lupus Erythematosus Disease Activity Index; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; ANA, antinuclear antibodies; anti-dsDNA, anti-double stranded DNA.

Figure 1. Comparison of demographic characteristics of SLE patients with and without LV geometry abnormalities.



Conclusion: SLE patients with LV geometry abnormalities had higher SLEDAI score than patients with normal LV geometry. A transthoracic echocardiogram may be useful detect early cardiovascular abnormalities in SLE patients with high disease activity, and therefore should be considered as part of the cardiovascular evaluation of these patients.

AB0545

THYMUS VARIANTS ON IMAGING IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME AND POLYMYOSITIS/DERMATOMYOSITIS PATIENTS

O. Murata[1,2], K. Suzuki[2], T. Takeuchi[2]. [1]*Iwate Medical University School of Medicine, Division of Allergy and Rheumatology, Department of Internal Medicine, Morioka, Japan;* [2]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: The thymus, a primary lymphoid organ, plays a crucial role in immune system homeostasis [1,2]. Although several studies of an association between radiographic thymus variants and serological features in systemic autoimmune diseases such as systemic scleroderma, have been reported [3-6], information in patients with other systemic autoimmune disease, especially in primary Sjögren's syndrome (pSS) or polymyositis/dermatomyositis (PM/DM) patients, is quite limited.
Objectives: We investigated the association between radiographic thymus variants and clinical and immunological features in patients with pSS and PM/DM, and clarified its significance.
Methods: Patients with pSS and PM/DM were randomly selected from all patients who had visited our department and underwent chest CT scan between April 2009 and March 2019. Patients with thymoma or thymic cyst and those aged less than 30 years were excluded. Thymic enlargement and thymus attenuation score in axial images of CT scans were quantitatively interpreted. We defined thymic enlargement as a thickness of more than 13mm and graded the score by a four-point scale (score 0-3) according to previous studies [7, 8]. Association with radiographic thymus variants and clinical and immunological features was statistically analyzed.
Results: 72 pSS and 47 PM/DM patients were enrolled. 90% and 63.8% were women and mean age was 62.7 ± 12.2 and 56.2 ± 13.7 years in pSS and PM/DM patients, respectively. Thymic enlargement was found in 16 (22.2%) and 14 (29.8%) patients with pSS and PM/DM, respectively. Thymus attenuation (score ≥ 2) was found in 11 (15.3%) and 9 (19.1%) patients with pSS and PM/DM, respectively. These findings were more frequent than in non-connective tissue diseases patients (9.1% and 9.1%, respectively). In pSS patients, radiographic thymus variants, both thymic enlargement and the thymus attenuation score, were significantly positively associated with body weight ($P < 0.0073$ and 0.037, respectively). Although there was no significant difference between immunological features such as titres of serum RF, the ratio of RF-positivity, SS-A antibody-positivity or SS-B antibody-positivity, and radiographic thymus variants, titres of serum RF tended to be positively associated with thymic enlargement ($P = 0.057$). In PM/DM patients, thymic enlargement was significantly positively associated with titres of serum RF ($P = 0.046$), and the thymus attenuation score was significantly positively associated with titres of serum IgG ($P = 0.042$) and significantly negatively associated with age ($P = 0.033$). There was no significant difference between the ratio of myositis specific antibody-positivity and radiographic thymus variants.
Conclusion: Radiographic thymus variants were frequently observed in pSS and PM/DM patients, and particularly, in case of PM/DM, may reflect an abnormal immune response involved in the pathogenesis.

DETERMINANTS OF VASCULITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

S. Saud Sunny[1], N. Islam[1], A. T. M. Asaduzzaman[2]. [1]*BSMMU, Rheumatology, Dhaka, Bangladesh;* [2]*BSMMU, Dermatology, Dhaka, Bangladesh*

Background: Among the manifestations of SLE, vasculitic presentation is common. This study was aimed to identify the predictors of vasculitis in SLE patients.
Objectives: To identify the determinants of vasculitis in SLE patients.
Methods: The study was conducted in the Department of Rheumatology, BSMMU, Dhaka from December 2019 to January 2021. A total 168 consecutive confirmed cases of SLE patients were enrolled. The patients were evaluated for the features of vasculitic rashes, digital gangrene, mesenteric vasculitis, mononeuritis multiplex. The cutaneous vasculitis was confirmed by a dermatologist. Study subjects were grouped into vasculitic and no vasculitic groups. The disease activity and damage were assessed using SLEDAI and SLICC/ACR DI. The rate of vasculitis was expressed in percentage. The multivariate logistic regression analysis was done to determine the independent predictors of vasculitis in SLE. P value <0.05 was considered significant.
Results: Rate of lupus vasculitis was 14.3%. The features shown significant difference between vasculitic and no vasculitic groups were: ACLE (79.2% vs. 18.8%, p<0.001), oral ulcer (70.8% vs. 13.2%, p<0.001), alopecia (83.3% vs. 27.1%, p<0.001), Raynaud's phenomenon (20.8% vs. 5.6%, p=0.011), fever (54.2% vs. 25.0%, p=0.002), arthritis (70.8% vs. 29.9%, p<0.001), pregnancy loss (68.8% vs. 32.7%, p=0.003), lupus nephritis (25.0% vs. 45.1%, p=0.032), seizure (8.3% vs. 0.7%, p=0.027), pleurisy (8.3% vs. 0.7%, p=0.027), leucopenia (8.3% vs. 1.4%, p=0.049), anti ds-DNA positivity (87.5% vs. 62.5%, p=0.008), hypocomplementemia (87.5% vs. 59%, p=0.003), higher mean SLEDAI (p<0.001) and SLICC/ACR damage index score (p<0.001). Though not significant the rate of antiphospholipid antibody positivity was high (69.2% vs. 42.9%, p=0.052) in vasculitis group. In multivariate logistic regression analysis, higher SLEDAI score (OR = 1.296, 95% CI =1.114-1.508) was positively and lupus nephritis (OR= 0.055, 95% CI =0.007-0.413) was negatively associated with lupus vasculitis.
Conclusion: In SLE, vasculitic presentation is common. Higher the SLEDAI score greater the chance of lupus vasculitis.

PLACENTAL ANGIOGENESIS MARKERS IN THE SCREENING FOR ADVERSE PREGNANCY OUTCOMES IN SLE AND APS

J. S. Brigger[1], A. Zbinden[1], L. Raio[2], F. Förger[1]. [1]*University Hospital and University of Bern, Department of Rheumatology and Immunology, Bern, Switzerland;* [2]*University Hospital and University of Bern, Department of Obstetrics and Gynecology, Bern, Switzerland*

Background: Pregnancies in patients with systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) are at risk for adverse pregnancy outcomes such as preeclampsia or placental insufficiency and prematurity. In these high-risk pregnancies, maternal serum concentration of

the anti-angiogenic factor soluble Fms-like tyrosine kinase-1 (sFlt-1) and the pro-angiogenic factor placental growth factor (PlGF) can predict fetal growth restriction and preeclampsia (1-3).

Objectives: To evaluate the sFlt-1/PlGF ratio in routine assessment of singleton high-risk pregnancies in patients with SLE and APS.

Methods: Patients with SLE and APS that followed in our outpatient clinic were retrospectively analysed for their pregnancy course and outcomes. In these high-risk pregnancies, the sFlt-1/PlGF ratio was measured in the context of screening for preeclampsia and a ratio below 38 was applied to exclude preeclampsia. We compared the sFIT-1/PlGF ratio between patients with and without adverse pregnancy outcome. Adverse pregnancy outcome (APO) was defined as preeclampsia, preterm delivery and small for gestational age newborns.

Results: We analysed sFlt-1/PlGF ratios of 13 singleton pregnancies in 12 patients with SLE and/or APS (4 SLE, 6 SLE with APS or aPL, 2 obstetric APS). Low-dose aspirin was used in all but one pregnancy with de-novo obstetric APS. Low-molecular weight heparin was given in seven pregnancies. Adverse pregnancy outcome occurred in five pregnancies thereof two with preeclampsia. The median sFlt-1/PlGF ratio measured between gestational week 22 and 37 was higher in patients with APO (median 173, range 4 -1904) than in patients without APO (median 7.5, range 1-50) (P=0.03). The sFlt-1/PlGF ratio > 38 was found in 6 pregnancies including two with preeclampsia. Highest sFlt-1/PlGF ratios were found in a case with severe intrauterine growth restriction without signs of preeclampsia (sFlt-1/PlGF=1940) and in a case with early preeclampsia < week 34 (sFlt-1/PlGF=1187). In pregnancies with a sFlt-1/PlGF ratio < 38 there were no signs of preeclampsia or intrauterine growth restriction.

Conclusion: The detection of a dysbalanced sFlt-1/PlGF ratio is clinically useful as it differentiates between pregnancies with adverse outcome and those without. More data are needed to further evaluate the predictive potential of these placental biomarkers in the first trimester and their usefulness for treatment adjustments in order to improve pregnancy outcome.

A COMPARATIVE STUDY BETWEEN THE NEUROPSYCHIATRIC INVOLVEMENTS IN ADULT-ONSET AND CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

G. K. Yardımcı[1], S. Sener[2], G. Ayan[1], A. Taghiyeva[3], N. P. Acar Ozen[4], E. D. Batu[2], L. Kılıç[5], H. İ. Öncel[6], A. Tuncer[4], R. Göçmen[7], K. Karlı Oğuz[7], Y. Bilginer[2], U. Kalyoncu[1], S. Özen[2], Ş. A. Bilgen[1]. *[1]Hacettepe University Faculty of Medicine, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University Faculty of Medicine, Department of Pediatric Rheumatology, Ankara, Turkey; [3]Hacettepe University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey; [4]Hacettepe University Faculty of Medicine, Department of Neurology, Ankara, Turkey; [5]Faculty of Medicine; Hacettepe University, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey; [6]Hacettepe University Faculty of Medicine, Department of Pediatric Neurology, Ankara, Turkey; [7]Hacettepe University Faculty of Medicine, Department of Radiology, Ankara, Turkey*

Background: Neuropsychiatric(NP) manifestations in systemic lupus erythematosus(SLE) encompass a wide spectrum of neurologic and psychiatric features.The nervous system is frequently affected by adult-onset and childhood-onset SLE patients,but disease course and clinical features may differ between both groups.

Objectives: The aim of this study is to evaluate and compare NP manifestations in adult-onset and childhood-onset SLE patients.

Methods: The study included a retrospective analysis of medical records of adult-onset SLE patients and childhood-onset SLE patients following at Hacettepe University from Jan 2015 to Jan 2021.NP events were identified using the ACR established case definitions seen in SLE.Additionally, posterior reversible encephalopathy syndrome, cerebral venous thrombosis, small fiber neuropathy and pseudotumor cerebri were evaluated as having NPSLE in this study.NP were also divided into three categories:neurologic syndromes of the central nervous system, neurologic syndromes of the peripheral nervous system,and diffuse neuropsychological syndromes.

Results: 1062 adult-onset and 161 childhood-onset SLE patients were followed-up median 150 (84-227) months.At least one neuropsychiatric event occurred in 101 (9.51%) adult-onset and 29 (18.01%) childhood-onset SLE patients (p=0.002). NP events were present before or around the time of SLE diagnosis 64.6% of the adult-onset patients and 72.4% of the childhood-onset patients.One-third of the patients in both groups were diagnosed with NPSLE during the follow-up.At the time of NPSLE diagnosis, 60.4% of adult-onset and 86.2% of childhood-onset patients had additional involvement other than neurologic manifestations and overall disease activity(SLEDAI-2k)was higher in childhood-onset patients (17vs.14p=0.036). Almost all patients in the pediatric group and half of the adult patients were given pulse corticosteroids.Cyclophosphamide was the most preferred regimen and was given to 36.6% of the adult patients and 75.9% of the pediatric patients.Rituximab (11.9% and 27.6%) and mycophenolate mofetil (13.9% and 3.4%) were other induction treatments. The adult-onset and childhood-onset NPSLE patients were followed-up median 105(54-165) and 80(40-132) months, respectively.On the last follow-up visit, disease damage scores (SLICC) were similar in both groups,with a median score of 2.

Conclusion: The nervous system was more commonly involved in childhood-onset patients, and disease presentations vary significantly between adult-onset and childhood-onset NPSLE patients.Disease activity appeared to be more severe in children at diagnosis, but permanent organ damage was similar in both groups on follow-up.

Table 1. Demographics, clinical features of adult-onset and childhood-onset NPSLE patients

	Adult-onset NPSLE (n=101)	Childhood-onset NPSLE (n=29)	P value
Cerebrovascular disease	63 (62.4)	8 (27.6)	0.001
Arterial cerebrovascular events	44 (43.6)	5 (17.2)	0.007

OBESITY AND TOBACCO SMOKING ARE INDEPENDENTLY ASSOCIATED WITH POOR PATIENT-REPORTED OUTCOMES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS FROM A SWEDISH TERTIARY REFERRAL CENTRE

A. Gomez[1], I. Parodis[1,2], C. Sjowall[3]. [1]*Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockhlm, Sweden;* [2]*Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden;* [3]*Linköping University, Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection, Linköping, Sweden*

Background: Patients with systemic lupus erythematosus (SLE) experience impaired health-related quality of life (HRQoL), pain, fatigue and functional disability. The effect of pharmacotherapy on these aspects has been inconclusive in literature. In light of this, investigation of the impact of lifestyle facets is needed to support complementary non-pharmacological interventions such as weight control strategies and tobacco smoking cessation.
Objectives: To evaluate associations of obesity and tobacco smoking with SLE patients' HRQoL, pain, fatigue and functional disability.
Methods: Patients from the Linköping University Hospital with an SLE diagnosis according to the 1982 American College of Rheumatology (ACR) and/or the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria (n=325) were included in the present cross-sectional analysis of data captured at visits between January 2008 and September 2021. Among consecutive visits, the first visit with complete demographic, clinical and patient-reported data was selected for the present analysis.
Body mass index (BMI) categories were based on the World Health Organization classification: underweight (BMI <18.5 kg/m^2), normal weight (18.5≤ BMI <25 kg/m^2), pre-obesity (25≤ BMI <30 kg/m^2) and obesity (BMI ≥30 kg/m^2). Smoking status was self-reported and categorised into never, prior and current smoking.
HRQoL was self-reported using the 3-level EuroQoL 5-Dimension (EQ-5D-3L) index scores. Visual analogue scales (VAS; 0–100) were used to self-report fatigue, pain and well-being within the preceding 7 days. Functional disability was evaluated using the Swedish version of the Health Assessment Questionnaires Disability Index (HAQ-DI). Disease activity was evaluated using the clinical (c) SLEDAI-2K (serology excluded).
Comparisons of continuous data between different BMI and smoking categories were performed using the Mann-Whitney U test and Kruskal-Wallis test. Multivariable linear regression analysis was employed to assess independence and priority of contributors to HRQoL and functional impairment.
Results: Compared with normal weight, obese individuals reported lower EQ-5D-3L index score [0.73 (0.36–0.80) versus 0.78 (0.68–0.85); P=0.014], as well as higher VAS fatigue [50.0 (27.0–72.5) versus 32.0 (6.5–59.5); P=0.008], VAS pain [40.0 (11.0–67.0) versus 20.5 (5.3–46.5); P=0.011] and HAQ scores [0.63 (0.13–1.13) versus 0.13 (0.0–0.63); P<0.001]. Similarly, ongoing smokers reported higher VAS fatigue [56.0 (28.0–78.0) versus 32.0 (8.0–58.0); P=0.001], VAS pain [45.0 (18.0–62.0) versus 18.0 (5.0–39.8); P=0.001] and HAQ scores [0.63 (0.13–1.13) versus 0.13 (0.0–0.63); P=0.001] compared with individuals who were never exposed to regular tobacco smoking. There were no differences across groups regarding cSLEDAI-2K scores.
In multivariable linear regression models, obesity and current tobacco smoking were independently associated with lower EQ-5D-3L index scores (β=-0.12; P=0.021 and β=-0.11; P=0.029, respectively), and higher VAS fatigue (β=12.8; P=0.007 and β=17.5; P<0.001), VAS pain (β=12.1; P=0.004 and β=15.5; P<0.001), VAS well-being (β=9.6; P=0.028 and β=9.8; P=0.035) and HAQ scores (β=0.30; P=0.001 and β=0.27; P=0.007), but not with cSLEDAI-2K (β=-0.73; P=0.189 and β=0.34; P=0.572).
Conclusion: In a Swedish SLE population, obesity and ongoing tobacco smoking were independently associated with worse outcomes - compared with normal weight and individuals who never smoked, respectively - regarding HRQoL, fatigue, pain and functional disability but were not associated with clinical disease activity.

AB0550

CLINICAL AND PROGNOSTIC SIGNIFICANCE OF ANTINUCLEAR ANTIBODIES IN PRIMARY ANTIPHOSPHOLIPID SYNDROME: FRENCH MULTICENTER RETROSPECTIVE STUDY

L. Ricard[1], L. Charlotte[1], M. Papo[2], A. Mekinian[1]. [1]*Saint Antoine, Internal Medicine, Paris, France;* [2]*Pitie, Internal Medicine, Paris, France*

Background: The antiphospholipid syndrome (APS) is defined by the development of vascular thrombosis, or pregnancy morbidity in the presence of persistent antiphospholipid antibodies (APL). Antinuclear antibodies (ANA) can be detected in primary APS patients without any clinical systemic autoimmune disease. The presence of ANA antibodies could confer a specific phenotype in primary APS.
Objectives: To evaluate the characteristics of APS patients with antinuclear antibodies without other autoimmune disease (ANA-positive APS patients) in comparison with primary APS without ANA (ANA-negative APS) or secondary APS patients with associated systemic lupus erythematosus (SLE-APS).
Methods: Clinical and biologic data from 195 APS were retrospectively collected. ANA test was considered to be positive when titers were superior or egal to the 1/80 dilution. ANA-positive APS patients did not fulfilled SLE ACR/EULAR classification criteria.
Results: 40 patients (21%) with ANA-positive APS were included, 77 patients (39%) with primary APS without ANA autoantibodies (ANA-negative APS) and 78 patients (40%) with SLE-associated APS (SLE-APS). Patients with ANA-positive APS presented arterial thrombosis in 20 cases (51%) and venous thrombosis in f 14 cases (41%), adverse obstetrical in 19 cases (51%), non-criteria APS features were noted in 19 cases (51%). ANA-positive APS patients had more non criteria manifestations than ANA-negative APS (48% versus 25%; p=0.01). ANA-positive APS patients had more triple APL positivity and more thrombosis recurrences in comparison with ANA-negative APS patients, respectively (59% versus 18%; p<0.001) and (63% versus 36%; p<0.01). ANA-positive APS and SLE-APS patients had similar clinical manifestations and recurrences. Despite a limited follow-up (28 months (11-50)) none of the ANA-positive APS patients develop SLE. Antiplatelet and anticoagulant therapies were similar for the three groups. SLE-APS patients received more immunomodulatory therapies.
Conclusion: ANA positivity in patients with APS enables to individualize a subset of patients with a more severe phenotype. Whereas the ANA positivity does not seem to be associated with the risk to develop SLE, prospective studies with a longer follow-up are necessary, in particular to evaluate the effect of additional therapies in this subset of APS.

CUTANEOUS LUPUS AREA AND SEVERITY INDEX(CLASI) CORRELATES WITH SELF-IMAGE SCORE BUT NOT QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. H. Malepati[1], D. Maikap[2], P. Padhan[2], R. Misra[2], S. Cr[1], S. Ahmed[2]. [1]*Kalinga Institute of Medical Sciences, Dermatology, Bhubaneshwar, India;* [2]*Kalinga Institute of Medical Sciences, Clinical Immunology and Rheumatology, Bhubaneshwar, India*

Background: Systemic lupus erythematosus (SLE) has multi-system involvement including skin. We explored how skin involvement influenced with the quality of life of patients with SLE.
Objectives: To correlate the domains of SLE QoL with skin involvement and total lupus disease activity.
Methods: A cross-sectional survey of patients with SLE was carried out to assess Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) and SLE-QoL. Lupus disease activity and damage were quantified using Mex-SLEDAI (Mexican SLE Disease Activity Index) and SLICC (Systemic Lupus International Collaborating Clinics) Damage Index respectively. Data is expressed as median (IQR).

Table 1. Correlations between different domains of the SLE(Systemic Lupus Erythematosus) -QoL(Quality of Life) with CLASI (Cutaneous Lupus Area and Severity Index) and Mexican SLE-DAI(SLE Disease Activity Index).

SLE-QoL Domains	Physical functioning	Physical activity	Symptoms	Treatment	Mood	Selfimage	Total
CLASI Activity	.028 (p=0.87)	-.062 (p=0.73)	.242 (p=0.16)	.103 (p=0.56)	.113 (p=0.52)	.252 (p=0.15)	.102 (p=0.56)
CLASI Damage	.125 (p=0.47)	.010 (p=0.95)	.257 (p=0.13)	.239 (p=0.17)	.233 (p=0.18)	.446** (p=0.007)	.243 (p=0.16)
CLASI total	.047 (p=0.80)	-.062 (p=0.75)	.448* (p=0.013)	.331 (p=0.07)	.332 (p=0.07)	.315 (p=0.09	.281 (p=0.13)
Mexican SLEDAI SCORE	.001 (p=0.99)	.130 (p=0.47)	.390* (p=0.025)	.251 (p=0.16)	.115 (p=0.52)	.197 (p=0.27)	.200 (p=0.27)

Results: In the cohort of 35 patients with SLE, with an age of 26(IQR:17-32) years and including eight (22.8%) males, the CLASI score was 5.5(IQR:3-11.5) with an activity score of 3(1-5) and a chronicity score of 1(0-4). The disease duration was 4years (IQR: 2-3) while SLE-QoL was 73(62-86). Overall, most of the patients had active disease at inclusion with a mex-SLEDAI of 8(6.5-11.5). SLICC was 1(0-4).

The correlation matrix of different domains of the SLE-QoL with CLASI, and Mex-SLEDAI is presented in Table 1. Correlation with SLICC was not analysed since it was zero in the majority of participants. Multivariate analyses were not done since there was lack of association on univariate analysis.

Conclusion: In this cohort of patients with active SLE, the SLE-QoL did not correlate with either the overall disease activity score nor the skin specific score. Only the Self-image domain correlated with the skin score. This implies that in active disease, the skin involvement may have only a minor effect on the quality of life.

AB0552 ELEVATED KYNURENINE LEVELS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

H. Apaydın[1], C. Bİçer[2], E. F. Yurt[3], M. A. Serdar[4], I. Dogan[5], S. Erten[5]. *[1]Ministry of Health Ankara City Hospital, Department of Rheumatology, Ankara, Turkey; [2]Ankara Yıldırım Beyazıt University, Ankara City Hospital, Biochemistry, Ankara, Turkey; [3]Ankara City Hospital, Biochemistry, Ankara, Turkey; [4]Acıbadem University, Biochemistry, İstanbul, Turkey; [5]Ankara Yıldırım Beyazıt University, Ankara City Hospital, Rheumatology, Ankara, Turkey*

Background: Sjögren's syndrome (SS) is a chronic autoimmune systemic inflammatory disease of unknown origin that predominantly affects the exocrine glands (mainly salivary and lacrimal glands). Primary Sjögren's syndrome (pSS) is a disease whose etiology is not yet fully understood, as in most autoimmune diseases, where genetic, epigenetic and environmental factors are hypothesized to play to the pathogenesis of the disease. Metabolism of tryptophan (Trp) via the kynurenine (Kyn) pathway has been proposed to act a substantial role in inflammatory processes.

Objectives: In the present study, we investigated levels of Trp and its metabolites in the Kyn pathway in patients with pSS and in healthy controls. Also, the relationship between Trp metabolites and laboratory parameters, disease activity was evaluated in patients with pSS.

Methods: The study included 34 pSS patients and 42 healthy individuals, and serum Trp and Kyn concentrations were measured by liquid chromatography with tandem mass spectrometry (LC-MS/MS). Trp degradation was predicted using the ratio of Kyn and Trp concentrations (Kyn/Trp). The EULAR Sjögren's syndrome disease activity index (ESSDAI) and the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) were used to evaluate pSS activity.

Results: In our study, the mean serum Trp concentration was found to be considerably lower in the pSS group compared to the control group (p= 0.001). The levels of Kyn (p= 0.019) and Kyn/Trp ratio (p <0.001) were significantly higher in the pSS group compared to the control group (Table 1). Trp concentration was negatively correlated with physician global assessment (r=-0.568, p<0.001), positively correlated with albumin (r=0.384, p=0.025) and hemoglobin (p=0.396, r=0.020). The Kyn/Trp ratio was negatively correlated with CRP (r=-0.369, p=0.032). There was no correlation between the Trp pathway and disease activity parameters ESSDAI and ESRPI.

Table 1. Comparison of the kynurenine pathway results of patients with Sjögren's syndrome and the controls

	Sjögren's syndrome (n=34) median (IQR)	Control(n=42) median (IQR)	p
Kynurenine (ng/ml)	485 (378-601)	386 (356-496)	**0.019**
Tryptophan (ng/ml)	10660 (9160- 12282)	12258 (11442-14711)	**0.001**
Kynurenine/tryptophan ratio (%)	4 (3-6)	3 (3-4)	**<0.001**

*Mann-Whitney U test

Conclusion: In conclusion, we found that kynurenine pathway metabolism was altered in patients with pSS. This suggests that tryptophan metabolism may be closely linked to the disease pathogenesis of pSS.

AB0553 KIDNEY BIOPSY IN FIRST RENAL FLARE OF SLE – WHAT DOES IT TELL US?

L. Karlsson[1], A. Zickert[1,2], E. Svenungsson[1,2], I. Gunnarsson[1,2]. *[1]Karolinska Institutet, Department of Medicine, Division of Rheumatology, Solna, Sweden; [2]Karolinska University Hospital, Rheumatology, Solna, Sweden*

Background: Lupus Nephritis (LN) is an immune-complex mediated glomerulonephritis affecting up tp 60% of all SLE patients during the disease course. A kidney biopsy is indicated in SLE patients presenting with signs of renal involvement, such as persistent proteinuria, and is generally recommended to evaluate the inflammatory findings but also to rule out other etiologies of renal involvement and to guide the need of immunosuppressive therapy.

Objectives: To investigate the histopathologic findings in first-time renal biopsies from a large cohort of SLE patients. We especially evaluated the type and occurrence of histopathological findings other than LN as these may lead to a risk of inadequate therapeutic interventions.

Methods: Patients from the Karolinska SLE cohort who had a first-time onset of renal involvement from 1995 to 2021 and subsequent renal biopsy were included in the study. All patients fulfilled the American College of Rheumatology (ACR) and/or Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) disease classification criteria (1, 2) for SLE and were biopsied on clinical indication, i.e., proteinuria > 0.5 g/day or active SLE in combination with a rise in plasma creatinine, decrease in glomerular function or new onset proteinuria with concurrent active urine sediment.

Results: In total, 141 patients with first time presentation of renal involvement who had been subject to renal biopsy were included. Of these 107 patients (75.9 %) were female. The median age at the time of biopsy was 34.5 years (range 15.5 - 86.4). For more patient baseline characteristics, see Table 1. One-hundred twenty-five patients (88.7 %) had findings consistent with LN according to ISN/RPS classification system. Twenty-five patients (18.4 %) had class I - II, 43 (30.5 %) class III ± V, 31 (22.0 %) class IV ± V and 26 (18.4 %) class V. Sixteen patients (11.3 %) did not have histological changes in accordance with LN. Of these, 3 had hypertensive nephrosclerosis, 2 had antiphospholipid associated nephropathy, 1 had IgA nephropathy, 1 had tubulointerstitial nephritis and 7 had evidence of systemic vasculitis. Of these, 5 were later found to be ANCA-positive and were re-diagnosed with concomitant ANCA-associated vasculitis. Two patients did not

show any classifiable histological changes. Of the 16 non-LN patients, 6 had proteinuria > 0.5 g/day, 2 had new-onset low-grade proteinuria and concurrent active urine sediment, 2 had new-onset low-grade proteinuria with concurrent increasing SLE disease activity, and 5 patients had isolated persistent low-grade proteinuria. In one case data was missing.

Table 1. Baseline characteristics, 141 patients

Age at SLE diagnosis (years); M (IQR)	**32.2 (22.0 – 44.9)**
SLE duration at biopsy (years); M (IQR)	0.6 (0.2 – 5.3)
Systolic blood pressure (mm Hg); Mean (SD)	127.5 (20.8)
Ethnicity	
Caucasian; n (%)	119 (84.4)
Asian; n (%)	9 (6.4)
African; n (%)	7 (5.0)
Hispanic; n (%)	6 (4.3)
Prednisone equivalent dose (mg/day); M (IQR)	10.0 (0–20.0)
Diagnosis according to ISN/RPS	
Class I-II	25 (17.7)
Class III ± V	43 (30.5)
Class IV ± V	31 (22.0)
Class V ± II	26 (18.4)
TMA/antiphospholipid syndrome	2 (1.4)
Vasculitis	7 (5.0)
Hypertensive nephrosclerosis	3 (2.1)
IgA nephropathy	1 (0.7)
Tubulointerstitial nephritis	1 (0.7)
Nonspecific changes	2 (1.4)

Conclusion: We demonstrate that renal histopathology confirmed other causes than LN in a significant proportion (11.3 %) of SLE patients with signs of renal involvement. Since these patients may need other therapeutic interventions than patients with classic LN, we can conclude that the renal biopsy is important in order to guide the choice of therapeutics.

AB0554 CLINICAL CHARACTERISTICS AND BURDEN AMONG PATIENTS WITH SLE STRATIFIED BY SLEDAI DERIVED SEVERITY: RESULTS FROM A REAL-WORLD STUDY IN THE US

A. Vadhariya[1], J. Birt[1], J. Wu[1], K. Griffing[1], F. Bailey[2], J. Hetherington[2], E. Rottier[2], S. Barlow[2], K. Costenbader[3]. *[1]Eli Lilly & Co,, Indianapolis, United States of America; [2]Adelphi Real World,, Bollington, United Kingdom; [3]Brigham and Women's Hospital, Division of Rheumatology, Inflammation and Immunity, Boston, United States of America*

Background: Data are limited concerning the distribution of Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) scores among patients with SLE in clinical practice and the characteristics of patients with specific SLEDAI scores.

Objectives: To investigate SLE patient demographics, clinical status, treatment patterns, and patient reported outcomes (PROs), overall and stratified by SLEDAI score.

Methods: Data were drawn from the Adelphi Real World Lupus IV (2021) Disease Specific Programme™, a point-in-time survey of 79 US rheumatologists and patients with SLE. Rheumatologists completed questionnaires regarding patient demographics, clinical status, and treatment. The same patients were invited to complete questionnaires containing the EuroQoL 5-Dimensions (EQ-5D), Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACIT-Fatigue) and Work Productivity & Activity Impairment questionnaire (WPAI) Patient-Reported Outcomes (PRO) tools.

Physicians completed 24 questions based on the SLEDAI-2K questionnaire regarding their patients' current clinical manifestations, from which a SLEDAI score was derived[1]. Patients were grouped based on their score: SLEDAI=0 (none), SLEDAI=1-6 (mild), SLEDAI=7-12 (moderate), and SLEDAI>12 (severe)[2]. Data from patients without rheumatologist-perceived renal organ involvement and ≥ 1 year of SLE duration were included for analysis using bivariate tests.

Results: A total of 273 patients were included in this analysis. Mean [SD] patient age was 47.0[14.2] years, 83.9% were female, 57.1% were White/Caucasian, and 24.9% were African American.

Conclusion: A disconnect between point-in-time SLEDAI and physician-perceived severity exists. Patients with SLE, irrespective of SLEDAI, had high prevalence of joint symptoms, but higher SLEDAI impacted quality of life.

AB0555 SYMPTOMATIC NON-SEROSITIC LUNG INVOLVEMENT IN A MONOCENTRIC COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): A REAL-LIFE EXPERIENCE

D. Schilirò[1], E. Elefante[1], C. Stagnaro[1], V. Signorini[1], D. Zucchi[1], F. Trentin[1], G. La Rocca[1], L. Carli[1], F. Ferro[1], C. Tani[1], M. Mosca[1]. *[1]University of Pisa, Rheumatology Unit, Pisa, Italy*

Background: A growing interest has been addressed to the study of lung involvement in systemic autoimmune diseases. Non-serositic pulmonary manifestations have also been described in SLE. However, little is known about their exact prevalence, clinical features and outcomes.

Objectives: To describe the prevalence, clinical and immunological characteristics of symptomatic non-serositic lung involvement in a monocentric cohort of SLE patients.

Methods: This observational, retrospective study included patients with SLE, regularly followed at the Rheumatology Unit of Pisa, that presented a clinically relevant non-serositic pulmonary involvement during their disease history. Patients with lung manifestations related to other causes (e.g. infections,

Mean [SD] WPAI overall (0= no impact to 100= completely impacted)		26.8 [21.2]	25.2 [15.8]	19.5 [23.6]	35.7 [20.2]	31.9 [26.7]	0.131

49% of SLE patients were categorized as SLEDAI 7-12 or >12 (moderate or severe). Among the SLEDAI 7-12 (moderate) patients, 75.7% were subjectively categorized by their physician as having mild SLE. Of the SLEDAI >12 patients (severe), 73.4% were categorized as having mild SLE. Joints symptoms and flaring in the last 12 months were not significantly different across SLEDAI groups. Patients with greater SLEDAI reported lower EQ5D and greater FACIT-Fatigue scores. There was no statistical difference in WPAI between the SLEDAI groups.

emphysema, Chronic Obstructive Lung Disease, bronchial asthma etc.) were excluded. The following data were collected from clinical charts: demographics, smoke exposure, comorbidities, respiratory symptoms, disease duration and disease activity (SELENA-SLEDAI) at the onset of lung involvement, immunological profile, treatment, CT and spirometry parameters.

Results: Over 450 SLE patients in regular follow-up, we found 11 female patients with a history of clinically relevant non-serositic lung involvement: 7 interstitial lung disease (ILD), 2 acute lupic pneumonitis (ALP), 1 diffuse alveolar hemorrhage (DAH) and 1 shrinking lung syndrome. 45.4% of patients had a history of smoke exposure and had stopped smoking on average 9 years before the onset of lung manifestations. For the 2 patients with ALP, this was the first manifestation of SLE. Among the other 9 patients, lung involvement was diagnosed after a mean disease duration of 14 ± 15 years. At the diagnosis of pulmonary involvement, 10/11 patients presented respiratory symptoms and an overall active disease, with a median SLEDAI of 9 (IQR 6-13). Clinical characteristics are summarized in Table 1. All patients were hospitalized and 2 of them (1 ALP and 1 DAH) were admitted in intensive care unit.

Table 1. Clinical characteristics at the diagnosis of lung involvement

Systemic	Active skin manifestations	36%
	Arthritis	36%
	Fever	36%
	Leukopenia	36%
	Hypocomplementemia	91%
	Anti-dsDNA positivity	36%
Respiratory	Dyspnea	54%
	Exertional dyspnea	18%
	Cough	45%
	Acute respiratory failure	27%

As for the immunologic profile, SSA/Ro60 were positive in 72% of patients and SSA/Ro52, SSB, U1-RNP in 36%; 36% had Sjogren Syndrome (SS) in overlap.

Spirometry was available for 6/11 patients: a restrictive pattern and a moderate/severe reduction of diffusing capacity of the lung for carbon monoxide was found in 5 patients.

In the ILD subgroup, the most prevalent CT pattern was the Non-specific interstitial pneumonia (NSIP) (5/7). 2 patients presented a Bronchiolitis obliterans/organizing pneumonia (BOOP) pattern.

Lung involvement was the driving manifestation in the treatment choice for 6/11 patients: 1 DAH, 2 ALP, 1 Shrinking lung and 2 ILD. All received pulse steroids and in 3 cases (2 ILD and 1 DAH) cyclophosphamide was added for the induction treatment; the patient with Shrinking lung had an overlap SS and was treated with Rituximab.

At last visit (mean follow-up of 8 ± 8.7 years since lung disease onset), 7/11 patients presented no respiratory symptoms and a complete resolution of CT alterations. 3/11 presented a residual exertional dyspnea and mild spirometry alterations. No patients developed respiratory insufficiency; only 1 patient died for cardiovascular complications.

Conclusion: In our large cohort of SLE patients, non-serositic lung involvement seems to be overall rare; the most frequent type of lung manifestation is ILD which appears to be associated with anti-SSA/SSB and anti-U1RNP positivity. The low prevalence of lung involvement (2.4%) in our cohort could be due to the presence of patients with a subclinical involvement. Further studies are needed to assess the real prevalence of subclinical lung manifestations in SLE and to identify the clinical phenotype of patients more prone to develop pulmonary disease.

AB0556 CHARACTERISTICS OF PATIENTS DIAGNOSED WITH UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE

C. Siegel[1], B. Stamm[2], J. Vega[2], E. Sevim[3,4], M. Lockshin[2,5], L. Sammaritano[2,5], M. Barbhaiya[2,5]. *[1]Hospital for Special Surgery, Medicine, New York, United States of America; [2]Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, United States of America; [3]Montefiore Medical Center, Medicine, Bronx, United States of America; [4]Albert Einstein College of Medicine, Medicine, Bronx, United States of America; [5]Weill Cornell Medicine, Medicine, New York, United States of America*

Background: Patients with undifferentiated connective tissue disease (UCTD) struggle with physical symptoms as well as diagnostic uncertainty.[1] UCTD diagnosis requires exclusion of other connective tissue diseases (CTD). Prior studies use variable definitions of UCTD that do not account for updated classification criteria thus limiting generalizability.

Objectives: We identified characteristics associated with rheumatologist-diagnosed UCTD, applied strict exclusion criteria, and compared UCTD patients to those with criteria-defined CTD.

Methods: We recruited patients ≥18 years old seen between 2018-2022 who had rheumatologist-diagnosed UCTD with positive ANA and ≥1 sign/symptom of a CTD. We reviewed medical records to identify those who fulfilled ACR/EULAR-endorsed classification criteria for SLE, RA, SSc, Primary Sjögren's, Idiopathic Inflammatory Myopathy, and 2006 Revised Sapporo Criteria for APS. We compared sociodemographic, clinical, serologic, and treatment variables between UCTD and CTD using chi-square, Fisher's exact, and t-tests.

Results: Of 89 patients with rheumatologist-diagnosed UCTD (mean age 49.0 ± 13.7 years, 97.8% female, 66.3% White), 59 (66.3%) had UCTD and 30 (33.7%) had criteria-defined CTD (27 SLE, 3 SLE and RA, 1 RA, and 1 APS).

Patients in both groups had similar non-criteria manifestations, most commonly arthralgia (89.8% UCTD vs. 83.3% CTD, p=0.50) and fatigue (55.9% UCTD vs. 73.3% CTD, p=0.17). Compared to patients with CTD, those with UCTD were less likely to have nonerosive arthritis (27.1% vs. 56.7%, p=0.01) (Table 1).

Table 1. Characteristics of Patients with UCTD or Criteria-Defined CTD

1. Do not fulfill ACR/EULAR classification criteria for SLE, RA, SSc, PSS, IIM, APS
2. Diagnosed with UCTD and fulfill ≥1 set of listed CTD classification criteria.
3. Defined per listed classification criteria.
4. Criteria with n≤5: fever, proteinuria/cellular casts, pulmonary hypertension, interstitial lung disease, dysphagia/esophageal dysmotility

Patients with UCTD were less likely than those with CTD to have any hematologic manifestation (lymphopenia, leukopenia, thrombocytopenia, or hemolytic anemia) (p=0.02), anti-dsDNA or anti-Smith antibodies (p<0.01), or hypocomplementemia (p<0.01). The frequency of RA, Sjogren's, and APS-related serologies did not differ between groups (Table 1**).** Compared to those with CTD, UCTD patients were less likely to have ever received systemic corticosteroids (71.2% vs. 96.7%, p<0.01); ever use of any disease-modifying antirheumatic drug (DMARD) was similar (35.6% vs. 46.7%, p=0.36).

Conclusion: Among patients diagnosed with UCTD, 66.3% met a stringent definition. Compared to those with criteria-defined CTD, UCTD patients had lower frequency of arthritis, hematologic abnormalities, SLE-specific antibodies, and hypocomplementemia. While use of DMARDs did not differ, UCTD patients were less likely to use systemic corticosteroids. Rheumatologists diagnose UCTD even when criteria are met for other CTDs. Our findings suggest UCTD is nonetheless a distinct clinical entity; more rigorous characterization will enable generalizable prognostic and therapy trials.

AB0557 THE SPECTRUM OF PEDIATRIC LUPUS: DATA FROM THE KENYA PEDIATRIC RHEUMATOLOGY (KAPRI) REGISTRY

A. Migowa[1], J. Orwa[1], R. Odhiambo[1]. *[1]Aga Khan University Hospital-Westlands, Pediatrics and Child Healh, Nairobi, Kenya*

Background: Childhood-onset systemic lupus erythematosus (cSLE) is a prototype autoimmune condition characterized by systemic organ involvement, high morbidity and mortality (1-5). A pediatric rheumatology registry is critical in defining the spectrum of pediatric lupus within the region The **Kenya Pediatric Rheumatology**

Table 1. Clinico-epidemiological features of paediatric Lupus patients

Patient	Gender	Age	End Organ Involvement	Autoantibody profile	Treatment	Current Clinical Status
1	Female	14 years	Arthritis	ANA +ve Antiphospholipid antibody +ve (B2 glycoprotein IgA)	Declined treatment of Hydroxychloroquine and Methotrexate to seek 2nd opinion	Lost to follow up
2.	Female	14 years 9 months	Skin	ANA +ve Anti ds DNA +ve	Hydroxychloroquine	Lost to follow up
3.	Female	11years	Arthritis Interstitial Lung Disease	ANA+ve >1:640 (fine granular) Anti Rib +ve Anti P protein +ve Anti SSA +ve	Mycophenolate Mofetil Hydroxychloroquine Prednisone 1 dose of Rituximab	Stable with minimally active disease
4.	Female	15 years 2 months	Lupus Gangrene	ANA +1:640 (Homogenpous) Anti Sm +ve Anti RNP +ve Anti ds DNA +ve Anti nucleosome+ve Anti ribosome +ve	Cyclophosphamide Mycophenolate Mofetil Aspirin	Lost to follow up
5.	Female	8 years 7 months	Neurolupus Lupus Gangrene	ANA +VE 1:640(speckled) Anti Sm +ve Anti RNP +ve Anti Ribosome +ve	Cyclophosphamide (6 courses) Rituximab (2 courses) Mycophenolate Mofetil Prednisone Hydroxychloroquine	Minimally Active Disease
6.	Female	6 years 11 months	Arthritis Skin rash Class IV Lupus Nephritis	ANA+VE (1:320 homogenous) Anti ds DNA +ve Anti nucleosome +ve	Mycophenolate Mofetil Hydroxychloroquine Prednisone	Minimally Active Disease
7.	Female	14 years 6 months	Class II Lupus Nephritis	ANA VE 1:320 (Homogenous)	Mycophenolate Mofetil Hydroxychloroquine	Remission

Registry (KAPRI) registry offers a unique opportunity to pioneer and spearhead a systematic and organized format in collecting pertinent clinical information that will offer information on current clinical scenarios and offer a platform to conduct other research projects to improve pediatric lupus healthcare in sub-Sahara Africa.

Objectives: Our objective was to determine the clinic-epidemiological profile of paediatric lupus patients by describing their baseline patient characteristics and clinical features at the Aga Khan University Medical College East Africa who were enrolled into the KAPRI registry from inception in March 2019 to December 2021.

Methods: All patient records were selected from the KAPRI registry database using the ICD 10 code M32 that denotes Systemic Lupus Erythematosus (SLE) Age, gender, laboratory, clinical features at diagnosis, treatment options offered at time of diagnosis were extracted from the database.

Results: Among the 207 patients enrolled thus far in the registry, 7 had a diagnosis of cSLE (3.4%). The commonest symptom among the patients were joint pain, fever and rash. Other clinical features and outcomes are highlighted in the Table 1.

Conclusion: Over a 2 year period, 57% of our cSLE patients (4 of 7) achieved remission while 43% (3of 7) were lost to follow up. Further studies are required to elucidate predictors of good clinical response and reasons for loss to follow up among our cSLE patients.

AB0558 PREVALENCE OF LATENT TUBERCULOSIS INFECTION AND ITS ASSOCIATIONS WITH CLINICAL AND SEROLOGICAL PARAMETERS IN SYSTEMIC LUPUS ERYTHEMATOSUS

G. Ms[1], P. B. Narasimhan[2], C. Kavadichanda[2], A. Gopal[2], D. Bairwa[2], M. M. Thabah[2], S. Sarkar[3], V. Negi[2]. *[1]JIPMER, Clinical Immunology, Pondicherry, India; [2]JIPMER, Clinical Immunology, Pondicherry, India; [3]JIPMER, Preventive and Social Medicine, Pondicherry, India*

Background: Systemic Lupus Erythematosus (SLE) and Tuberculosis are complicatedly related and studies have shown increased risk of TB in SLE. Studies of Latent TB and SLE are inadequate. This study intended to assess the prevalence of latent TB and its association with disease parameters in SLE.

Objectives: To assess the prevalence of latent TB in patients with SLE. To investigate the demographics and clinical characteristics in patients with SLE and concomitant latent TB compared to those without.

Methods: This is a single center cross sectional study. 124 adult patients with SLE without past h/o TB were recruited. SLE demography, disease activity indices, autoantibody profile and steroid use were noted. Presence of Latent TB infection was assessed in all patients based on the IFN-g release assay (TB-IGRA). Based on the results of IGRA, SLE cases were divided into 2 groups-IGRA positive and IGRA negative. The collected parameters were compared between the 2 groups.

Results: Among 124 patients, 19 had latent TB resulting in a point prevalence of 15.4 %. The average disease duration was 4.3 years in IGRA positive and 4.6 in IGRA negative group(p>0.05). Among antibody profile, though no statistical significance among the groups, proportion of antibodies like anti Ku, Ro 60, Ro 52 and La were numerically higher in the IGRA positive group (21.1%, 42.1%, 42.1% and 21.1% respectively) when compared to the IGRA negative group (11.5%, 28.8%, 28.1% and 7.7% respectively). Likewise, anti nucleosome, histone, U1RNP, PCNA, aCLA IgG and IgM, beta 2 GPI IgG and LAC were numerically higher in IGRA negative group (42.3%, 40.4%, 43.3%, 8.7%, 23%, 18.3%, 28.8%, 14.4%) when compared to IGRA positive group (31.6%, 21.1%, 31.6%, 0, 15.8%, 5.3%, 15.8%, 5.3%). Mean clinical SLEDAI was 2.37 ±5.1 in IGRA positive and 3.5 ±5.77 in IGRA negative group. Among clinical features, 1 person in IGRA positive and none in the IGRA negative group had current gastrointestinal involvement. Comparison of other organ manifestations yielded no statistically significant difference in the 2 groups at this point. Serology revealed greater proportion of C4 in IGRA negative as compared to the positive group(p<0.042).

Conclusion: Prevalence of latent TB in SLE cases was 15.4%. Although comparison of demographic, clinical and autoantibody profile did not yield any statistically significant differences, the early turnover from this pilot study mandates further evaluation with larger sample size.

Table 1. Comparison of clinical and laboratory parameters between IGRA positive and IGRA negative SLE cases

	IGRA POSITIVE(n=19)	IGRA NEGATIVE(n=105)	p VALUE

AB0559 PATIENTS WITH EARLY-ONSET SJÖGREN'S SYNDROME

R. Caetano Ataides[1], O. H. Bentivoglio de Menezes Pereira[1], V. Barbosa[1]. *[1]Hospital das Clínicas da Universidade Federal de Goiás, Ambulatório de Reumatologia, Goiânia, Brazil*

Background: The primary Sjögrens Syndrome (pSS) is an autoimmune systemic disease characterized by chronic inflammation of exocrine glands,

especially lacrimal and salivary glands. The onset of pSS is usually between 50 and 60 years of age, but it may also occur in younger patients, in which case may be associated with a worse progression of the disease and a worse prognosis.
Objectives: To describe the clinical and immunological profile of patients with primary SS, aiming to investigate the clinical and laboratory characteristics of early-onset pSS patients (diagnosis before 35 years old)
Methods: The data of 58 medical records were analysed retrospectively. Based on the disease onset age, the patients were divided into two groups those with the onset age of 35 years old or younger and those with the onset age of older than 35 years old. Data normality was verified with the Shapiro-Wilk test. The comparison between patients' profiles with the late and early diagnosis was done with Pearson's Chi-squared test, Student's t-test, and Mann-Whitney test. P <0.05 was considered statistically significant.
Results: 55 patients were female (94,8%) and 3 were male (5,2%) and the average age on the last medical visit was 45,91±12,46 years old and the time between the diagnosis and the last appointment (follow up time) was 56,90±61,57 months. 14 patients had early-onset pSS and 44 had late-onset pSS. The mean diagnosis age in the early-onset group and the late-onset group. was 30,21±4,21 vs 50,91±9,73 years old (p<0.001) respectively and a mean follow-up time was of 41,40±50,27 vs 61,75±64,64 months respectively. There was no significant difference in demographic profile between the two studied groups, except for the age. There was no significant difference in cutaneous, joint, renal, and nervous system involvement. However there was a significantly higher frequency of xerophthalmia in the late-onset group (88.6% vs 64.3% p=0.036) and a significantly higher frequency of parotid enlargement in the early diagnosis group (42.9% vs 20.5% p=0.036) There was no significant difference in laboratory profiles between the two groups (anti-Ro, anti-La, ANA, rheumatoid factor, hypergammaglobulinemia and low complement).
Conclusion: The profile clinical of early-onset pSS patients may be different to those with later onset, with a higher prevalence of parotid enlargement. This group of patients needs to be monitored to determine the risk of a worse prognosis.

AB0560 CLINICAL, SEROLOGICAL AND IMAGING CHARACTERISTICS OF LATIN AMERICAN PATIENTS WITH LUPUS MYOCARDITIS: A CASE-CONTROL STUDY

D. C. Quintero-González[1], J. Sanchez-Bautista[2], C. Agudelo[1], A. L. Vanegas-García[1,3], C. Muñoz[1,3], Y. Santamaria-Alza[1], A. Cardona - Cardona[1], M. Muñoz[1], G. Vásquez[1], L. A. González[1]. *[1]Universidad de Antioquia, Rheumatology, Medellín, Colombia; [2]Universidad de Antioquia, Internal Medicine, Medellín, Colombia; [3]Hospital Universitario San Vicente Fundación, Rheumatology, Medellín, Colombia*

Background: Lupus myocarditis (LM) is an uncommon manifestation of systemic lupus erythematosus (SLE), with a prevalence of 9% that tends to be lower in recent studies; it can range from subclinical to life-threatening manifestations (1). The clinical and immunological characteristics of LM have not been established in Latin American patients.
Objectives: To determine the clinical, serological, and imaging characteristics of patients with LM.
Methods: We conducted a single-center, case-control study that enrolled hospitalized patients between 2012 and 2020 in Colombia. Fifteen LM patients (cases) were matched by age and sex with thirty non-LM patients (controls). Descriptive, comparative, and logistic regression analyses were performed.
Results: Patients with LM were mostly females (93.3%) with a mean age of 28.2 years. The major affected clinical domains associated was renal (80%). Myocardial involvement occurred after SLE diagnosis with a mean of 5.1 years. Dyspnea (73.3%) was the main clinical manifestation. Troponin was high in 92.3% and echocardiographic findings included decreased left ventricular ejection fraction (LVEF) in the 60% of cases (mean 40%), diastolic dysfunction (61.5%), left ventricular dilatation (53.3%) and global hypokinesia 35.7%. The most common valvulopathy was mild mitral regurgitation. Nine LM patients underwent cardiac magnetic resonance. In this modality, mean LVEF was 38%, increased regional intensity on T2-weighted images, increased myocardial potentiation ratio on T1, and non-ischemic enhancement (mainly epicardial) was presented on 85.7%, 60%, and 57.1%, respectively. All patients received glucocorticoids and cyclophosphamide. Comparisons of the demographic, clinical, serological between LM and non-LM groups are shown in Table 1.

Table 1. Demographic, clinical and serological characteristics.

Variable	LM (n=15)	Non-LM	P-value
Female	93.3%	100%	0.333
Age SLE	24.9 (SD 12)	28.3 (SD 13.9)	0.515
Clinical domains

Creatinine mg/dL	1.4 (SD 0.9)	1.9 (SD 2.5)	0.294
C3 mg/dL	57.4 (SD 22.4)	86.2 (SD 29.9)	0.002
C4 mg/dL	9.6 (SD 8.3)	16.4 (SD 9.3)	0.009
Anti-dsDNA	86.7%	52.4%	0.034
SLEDAI score	14.7 (SD 5.7)	6.8 (SD 7.6)	0.0003

SD: Standard deviation

Bivariate logistic regression showed that LM was independently associated with anti-dsDNA (OR 1.17, IC 1.04 – 1.31, p= 0.004), higher SLEDAI score (OR 1.17, IC 1.04 – 1.31, p=0,006), higher RCP (OR 1.21, IC 1.04 – 1.4, p=0.013), lower C3 (OR 0.96, IC 0.93 – 0.98, p:0,06) and lower C4 (OR 0.90 IC 0.82 – 0.99 P=0,036), highlighting its relationship with disease activity.
Conclusion: LM is a potentially severe manifestation and occurs in patients with higher disease activity, as was evidenced in the present study by low complement, anti-dsDNA and SLEDAI score. In the proper clinical context, noninvasive diagnostic tests should detect myocardial involvement in SLE.

AB0561 LONG-TERM PERSISTENCE OF ANTIPHOSPHOLIPID ANTIBODIES ANDASSESMENT RISK PROFILE IN WOMEN

I. Starodubtseva[1], N. Vereina[2], V. Chulkov[2], V. Chulkov[2], S. Sinitsin[2]. *[1]NN Burdenko Voronezh State Medical University, Internal Diseases, Voronezh, Russian Federation; [2]South-Ural State Medical University, Faculty Therapy, Chelyabinsk, Russian Federation*

Background: The evidence supporting the prognostic role of risk assessment in antiphospholipid antibodies (APA) positive patients has been obtained from several studies.
Objectives: to assess the association of the persistence of APA ≥ 12 weeks in women with an initial score on the aGAPSS scale, the presence of double and triple antibodies and a history of thrombosis or obstetric events.
Methods: A total of 117 women were included in the case-control study: 44 patients with persistence ≥ 1 antiphospholipid antibodies (APA) for 12 or more weeks (cases); 73 patients with transient circulation of APA less than 12 weeks (controls). An initial examination of women with a subsequent persistence of antiphospholipid antibodies ≥ 12 weeks compared with their transient circulation revealed.
Results: A higher incidence of arterial and venous thrombosis events, and a history of placenta-associated obstetric complications were observed in women with persistence of APA ≥ 12 weeks compared to transient circulation of APA, as well as a higher laboratory risk profile (double and triple positivity of APA. Overall, significantly higher aGAPSS were seen in women with persistence of APA ≥ 12 weeks compared to those with transient circulation of APA (7.37 ± 3.5 vs. 4.8 ± 0.6, p<0.05).
Conclusion: The aGAPSS scale is an additional tool available in clinical practice to clarify the risk profile in patients with APA-positivity in order to choose an adequate antithrombotic strategy. Future studies should evaluate the informativeness of the scale and determine cut-off points for predicting thrombosis and obstetric events.

AB0562 LIVER ENZYME ABNORMALITIES IN HOSPITALIZED LUPUS PATIENTS – A RETROSPECTIVE STUDY

V. Shobha[1], R. S. Kodali[1], B. Pinto[1], R. Aithala[1], S. Selvam[2]. *[1]St John's National Academy of Medical Sciences, Clinical Immunology and Rheumatology, Bangalore, India; [2]St. John's Research Institute, Division of Epidemiology and Biostatistics, Bangalore, India*

Background: Around 25% to 50% of lupus patients may present with alterations in the liver enzymes of variable severity including fulminant hepatic failure.[1]

Table 1. Aetiology and associations of liver enzyme abnormalities

Aetiologies for elevated transaminases						
				Macrophage activation syndrome	33/77(42.9%)	
				Lupus activity	16/77(20.8%)	
				Overlap Myositis	12/77(15.6%)	
				Autoimmune Hepatitis	6/77(7.8%)	
				Sepsis	5/77(6.5%)	
				Primary Biliary Cirrhosis	3/77(3.9%)	
				Drugs	2/77(2.6%)	
Comparison between patients with and without MAS				Comparison between patients with and without mortality among MAS patients		
	MAS (N=33)	No MAS (N=44)	P-value	Mortality (N= 9/33)	No Mortality (N=24/33)	P-value
AST	228(169,377.5)	(128,281)	**0.098 ***	265(232.5,545)	209(139.5,360)	**0.036***

ABBREVATIONS- AST- Aspartate aminotransferase; ALT- Alanine aminotransferase; ALP- Alkaline phosphatase, GGT- Gamma glutamyl transferase. Statistically significant *P-value = < 0.05.

Objectives: To study the prevalence, aetiology and the outcome in lupus patients hospitalized with liver enzyme abnormalities.

Methods: We analysed liver enzymes of all hospitalized lupus patients from June 2018–June 2021. Patients with abnormal liver enzymes(>2 times Upper Limit Normal)[2] were identified and categorized as per the standard definitions/criteria.[3,4] The outcomes and association of liver enzymes to mortality was analysed.

Results: Liver enzymes were available in 461/535 hospitalisations amongst 383 lupus patients of whom abnormalities were detected in 95/461 (20.6%). Among 77 patients with elevated transaminases, 33/77(42.9%) fulfilled criteria for macrophage activation syndrome (MAS) as per HLH criteria and parodie et.al[4]. Other aetiologies are represented in Table 1. Overall the mortality rate was 12/77(15.58%), highest being MAS 9/12(75%). Higher aspartate aminotransferase/alanine aminotransferase (AST/ALT) ratio was associated with adverse outcomes in patients with MAS.

Conclusion: MAS was the most frequent cause of elevated transaminases and was associated with mortality in subset with higher AST/ALT ratio.

AB0563 ALEXITHYMIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

R. Grekhov[1,2]. *[1]Zborovsky' Research Institute for Clinical and Experimental Rheumatology, Rehabilitation Dept, Volgograd, Russian Federation; [2]Volgograd State Medical University, Chair of General and Clinical Psychology, Volgograd, Russian Federation*

Background: The growth of psychosomatic disorders is the most important medical and social problem of modern healthcare. Particular attention of researchers is attracted by the alexithymic radical in the structure of the patient's premorbid personality, as one of the possible psychological risk factors for the development of psychosomatic disorders. Alexithymia is a psychological phenomenon that described as difficulty in definition one's own feelings, difficulty in distinguishing between feelings and bodily sensations, a decrease in the ability to symbolize, and a focus on external events rather than internal experiences.

Objectives: The aim of this work was to study the level of alexithymia in patients with systemic lupus erythematosus (SLE).

Methods: There were 87 patients under observation, the majority were women (82.8%), of 35.33 ± 1.77 years old in average. The average duration of the disease was 7.09 ± 0.89 years.

The Toronto Alexithymia Scale (TAS) [1] was used to measure alexithymia.

Results: It should be noted that in healthy people [1] the level of alexithymia is 59.3 ± 1.3 points. The mean value of alexithymia in SLE patients was 74.05 ± 2.62 points. The high and medium rates of alexithymia were established in 54 cases from 78 patients, and there were low levels in 24 cases indicating the absence of alexithymia. It was not possible to identify the dependence of alexithymia on gender and age. There was also no significant dependence of the level of alexithymia on the duration of the disease, the course and the activity of the pathological process. However, a significant direct correlation between the severity of alexithymia and depression and anxiety was revealed (see Table 1).

Table 1. Dependence of the level of alexithymia on some characteristics of SLE patients

	Disease course	Disease activity	Age of patients	Disease duration	Asthenia	Depression	Anxiety	Hypochondria
TAS	0.24	0.21	-0.09	0.44	0.33	0.51*	0.46*	0.35

* - p < 0.05

Our data indicate that patients with SLE have a high level of alexithymia. Indeed, patients suffering from this disease experience difficulties in understanding and verbalizing feelings, persistently strive to draw the doctor's attention to their physical sensations, without attaching importance to or denying trouble in the emotional sphere.

Conclusion: The results of the study indicate a certain role of the phenomenon of alexithymia in the pathogenesis of psychosomatic disorders in SLE, and the level of alexithymia does not depend on gender, age, and the main clinical characteristics of the disease, but correlates with general neuroticism. It is possible that the high level of alexithymia in SLE patients leads to an increase in depression and anxiety, and generates psychological distress.

Thus, the study of alexithymia, among other risk factors of a biological and psychosocial nature, is important for a better understanding of the role of psychological mechanisms in the pathogenesis of psychosomatic diseases, the organization of preventive measures aimed at correcting alexithymic features, carried out in individual and group forms of psychotherapy.

AB0564 PROGNOSTIC ROLE OF PRE-CONCEPTIONAL COMPLEMENT CONSUMPTION ON PREGNANCY OUTCOMES IN ANTI-PHOSPHOLIPID ANTIBODY SYNDROME, POLIABORTIVITY AND RECURRENT IMPLANTATION FAILURE

V. Canti[1,1], R. De Lorenzo[1], C. Gerbino[2], G. Adorno[2], F. Pasi[3], M. T. Castiglioni[3], P. Rovere-Querini[1]. *[1]San Raffaele Hospital, Internal Medicine, Milan, Italy; [2]San Raffaele University, San Raffaele University, Milan, Italy; [3]San Raffaele Hospital, Obstetrics and Gynecology, Milan, Italy*

Background: In anti-phospholipid antibody syndrome (APS), complement (C3/C4) activation favours the development of adverse pregnancy events. The prognostic role of complement in recurrent pregnancy loss (RPL) and recurrent implantation failure (RIF) has never been clinically studied. Additionally, the influence of hydroxychloroquine and heparin on complement modulation at the molecular level has already been accepted, while few clinical studies on these drugs have been published up to date.

Objectives: The aim of the study was to investigate whether C3/C4 levels represent a risk factor for pregnancy outcomes in a population of patients with APS, patients with RPL and patients with RIF. Moreover, the study investigated the

effects of therapies during pregnancy (low dose aspirin, low molecular weight heparin and hydroxychloroquine and their combinations).
Methods: We collected data of 136 patients (33 APS, 69 RPL, 34 RIF) prospectively followed from September 2018 to June 2021 in the "Recurrent pregnancy loss and Recurrent implantation failure clinic" of the "Centro Scienze della Natalità" department of San Raffaele Hospital, Milan, Italy. For all the patients, serum C3/C4 levels were determined at San Raffaele local laboratory.
Results: 30/136 (22%) patients had pre-conceptional complement consumption. Of these, 5/30 (17%) had anamnestic history of adverse pregnancy outcomes and 29/30 (97%) had at least one abortion in the past. 106/136 (78%) patients had normal pre-conceptional complement levels: 8/106 (7%) had anamnestic history of adverse pregnancy outcomes and 91/106 (86%) had at least one abortion in the past. In 64/136 pregnancies prospectively followed in our centre, 17/64 (26%) had pre-conceptional complement consumption. In patients with complement consumption, abortion (4/17, 24%) and adverse pregnancy outcomes (3/17, 18%) rates were homogeneous to the ones of patients with normal complement levels (16/47, 34% e 5/47, 11% respectively). Hypocomplementemia was associated with a significantly higher (p<0.05) probability of active treatment during pregnancy (both with low dose aspirin, low molecular weight heparin and hydroxychloroquine), which might explain the uniformity of gestational outcomes between the two groups. Thus, additional therapy with hydroxychloroquine provided in our clinic might have improved gestational outcomes in patients with hypocomplementemia.
Conclusion: Measurement of pre-conceptional complement level is an easy and cheap procedure that might be useful to identify those patients at a higher risk of adverse gestational outcomes. The presence of consumed pre-conceptional C3/C4 levels might represent an indication to strengthen therapy in those pregnant patients with history of pregnancy loss. Our study stresses the importance of a personalized diagnostic-therapeutic pathway in patients with RPL and RIF, independently of the presence of APS.
Further studies in larger cohorts with RPL and RIF will be needed to confirm our findings.

AB0565 PREVALENCE OF LIVER FIBROSIS ASSESSED BY TRANSIENT ELASTOGRAPHY IN PATIENTS WITH SJÖGREN'S SYNDROME

T. Androutsakos[1], T. Voulgaris[2], A. D. Bakasis[1], M. L. Koutsompina[1], L. Chatzis[1], O. Argyropoulou[1], V. Pezoulas[3], D. I. Fotiadis[3], A. Goules[1], G. Papatheodoridis[2], A. Tzioufas[1]. *[1]National and Kapodistrian University of Athens, School of Medicine, Department of Pathophysiology, Athens, Greece; [2]National and Kapodistrian University of Athens, School of Medicine, Department of Gastroenterology, Athens, Greece; [3]University of Ioannina, Unit of Medical Technology and Intelligent Information Systems, Ioannina, Greece*

Background: Liver is considered one of the most commonly involved extra-glandular organs in patients with Sjögren's syndrome (SS). Primary biliary cholangitis, hepatitis C virus infection, non-alcoholic fatty liver disease (NAFLD) and drug hepatotoxicity are the major contributors of liver disease among SS patients. Especially, NAFLD comprises a major health problem worldwide with a rapidly rising incidence and a prevalence of approximately 25% in the general population. In both NAFLD and SS, inflammatory and apoptotic pathways are implicated in pathogenesis, pathways that are also linked to fibrogenesis. No studies so far have investigated the net effect of SS in liver fibrosis.
Objectives: To assess whether SS is associated with advanced liver fibrosis (LF) in the absence of viral, alcohol-related, autoimmune hepatitis or primary cholangitis.
Methods: In this prospective study, consecutive SS patients from the rheumatology outpatient clinic of the Department of Pathophysiology, "Laiko" General Hospital, Athens, Greece between June 1st and December 31st, 2021, underwent transient elastography (TE) with measurement of liver stiffness and controlled attenuation parameter, assessing LF and liver steatosis (LS), respectively. For LF the following cut-offs were used: F0-1: 2-7 kPa, F2: 7-10 kPa, F3: 10-14 kPa, and F4: >14 kPa. F0-F1 stages were considered as clinically insignificant and F2-F4 as advanced. For LS the following cut-offs were used: S0-S1: 100-260 dB/m, S2: 260-290 dB/m, and S3: >290 dB/m. LS stage S0-S1 was classified as low and S2-S3 as high. Individuals who were evaluated in the hepatology outpatient clinic for possible NAFLD/LS based on ultrasonographic criteria (higher echogenicity than renal cortex and/or splenic parenchyma) served as a comparator group. In all participants, those with viral or alcoholic hepatitis, autoimmune liver diseases, transaminasemia or liver disease attributed to drug hepatotoxicity were excluded. Clinical, demographic and laboratory data were collected from all participants at the time of TE.
Results: Fifty-two patients with SS (49 females, 94.2%) with a median disease duration (range) of 8 (1-46) years and 198 comparators (104 females, 52.5%) were included in this study. The median age (range) of SS and comparators was 62.5 (30-81) and 55 (19-86) years, respectively. Comparators and SS patients had comparable prevalence regarding type 2 diabetes mellitus (T2DM), hyperlipidemia and body-mass index (BMI). Patients with SS had less frequently high LS (27% vs 62%, p<0.001) and advanced LF [2 (3.8%) vs 34 (17.2%), p=0.014], compared to comparator group. The 2 SS patients with advanced LF had also high LS. Univariable analysis in terms of T2DM, hyperlipidemia, BMI, age, gender, steatosis, and disease status (SS or comparators) between individuals with insignificant and advanced LF revealed age, liver steatosis, BMI, and disease status as the only statistically significant parameters; of these, only age was finally identified as independent risk factor in the multivariable logistic regression analysis (Table 1).

Table 1. Multivariable logistic regression analysis for risk factors associated with advanced liver fibrosis among patients with Sjögren's Syndrome and comparators.

Variables	Coefficient	Odds ratio	p-value	CI low	CI upper
Age	0.057	1.059	0.023	1.019	1.1
Body Mass Index	0.099	1.105	0.121	1.012	1.207
Presence of Sjögren's syndrome	-0.941	0.419	0.346	0.067	2.826
High Liver Steatosis	0.344	1.473	0.62	0.355	6.167

Conclusion: Sjögren's syndrome per se is not associated with advanced liver fibrosis.

AB0566 CLINICAL AND SEROLOGICAL ASSOCIATION BETWEEN SJÖGREN SYNDROME AND VASCULITIS

À. Valls-Villalba[1], J. Mestre[1], A. Nuñez-Conde[1], S. Bujan Rivas[1], R. Solans-Laqué[1]. *[1]Hospital Universitari Vall d'Hebron, Internal Medicine-Systemic Autoimmune Disease Department, Barcelona, Spain*

Background: Sjögren Syndrome (SS) is a systemic autoimmune systemic disease which mainly affects the exocrine glands, presenting mainly as persistent eye and mouth dryness as a result of a functional impairment of the lacrimal and saliva glands. Cutaneous vasculitis is one of the most characteristic extraglandular manifestations, especially in patients with anti-Ro antibodies. Although vasculitis may affect a wide range of organs and systems, the clinical characteristics and the diversity of vasculitis associated with SS have not been thoroughly studied.
Objectives: To describe the clinical and analytical characteristics of patients with SS and cutaneous, or systemic vasculitis, as well as their outcome.
Methods: Retrospective, descriptive study, of patients with primary SS and vasculitis attended at a Tertiary Hospital. Collected data were analysed using the SPSS statistical package. Quantitative data were expressed as a mean +/- 2SD and qualitative data as a proportion. A p-value 0.05 was considered significant.
Results: From a total of 395 patients with primary SS, 53 patients presented with both SS and vasculitis (51, 96.2%, women). The mean age at diagnosis was 56.12 (±2.17) years. Globally, 84.9% of patients met the 2002 classification criteria; 90.6% the 2012 criteria, and 83.0% the 2016 criteria. Thirty-two (60.4%) patients presented with cutaneous vasculitis (mainly purpura), and 7 (13.2%) with systemic vasculitis with renal, neurological and/or lung involvement. Extraglandular manifestations were frequent. Out of the 53 patients, twenty-five (47.2%) presented pulmonary involvement; 43(81.1%) articular involvement (19 [35.8%] arthritis); 21(39.6%) Raynaud phenomenon, and 15.1% peripheral neuropathy. Six (11.3%) patients developed a lymphoma. All patients presented positive ANA; 69.8% anti-Ro60, 52.8% anti-La, 75.5% RF; 62.3% polyclonal hypergammaglobulinemia; 33.9% cryoglobulins, 58.5% elevated beta2-microglobulin levels, and 12 (22.65%) hypocomplementemia (4 decreased C3, and 8 decreased C4). Biopsy specimens showed in 8 (15.9%) cases urticaria vasculitis; in 1 (1.9%) PAN; in 2 (3.8%) Cryoglobulinaemic vasculitis, in 5 (9.4%) ANCA associated vasculitis (4 PAM-MPO, and 1 GPA-PR3); and in 1 SNC vasculitis. 64.2% of patients received glucocorticoids and 37.7% hydroxychloroquine. 5 (9.4%) patients received Rituximab. Vasculitis were significantly more frequent in patients with anti-Ro60 (p=0.005, OR2.5 IC95% 1.33-4.74); anti-La (p=0.009, OR 2.39, IC95% 1.29-4.43); RF (p<0.000, OR 3.78, OR 3.72 IC95%1.90-7.26); C4 hypocomplementemia (p<0.00, OR 6.42, IC 95% 2.65-15.56); cryoglobulins (p=0.016, OR 2.29, IC95% 1.21-4.33); hypergammaglobulinemia (p=0.004, OR 2.53, IC95% 1.36-4.71), arthritis (p= 0.001, OR 3.26, IC95% 1.72-6.19), lung fibrosis (p=0.010, OR 2.92, IC95% 1.38-6.17) and lymphoma (p=0.011, OR 4.05, IC95% 1.5-10.94).
Conclusion: In our series, most patients with SS presented repetitive flares of cutaneous vasculitis as previously reported. Nonetheless, our patients showed a greater proportion of lung and articular manifestations as well as anti-La positivity.

Five patients presented with ANCA associated vasculitis, which represents and exceedingly rare and severe manifestation in this context.
Patients with SS may present a wide range of vasculitis, ranging from the most common leucocytoclastic vasculitis to the more severe systemic vasculitis, such as: AAV and cryoglobulinaemic vasculitis.
The association of SS with vasculitis is more common in patients with anti-Ro, anti-La and/or RF, hypocomplementemia, cryoglobulins and hypergammaglobulinemia.

AB0567 SHORT AND LONG-TERM RENAL OUTCOMES OF PATIENTS WITH PROLIFERATIVE LUPUS NEPHRITIS: DATA FROM A SINGLE INSTITUTE INCEPTION COHORT.

E. Kapsia[1], S. Marinaki[1], I. Michelakis[2], G. Liapis[3], P. Sfikakis[4], J. N. Boletis[1], M. Tektonidou[4]. *[1]Medical School National & Kapodistrian University of Athens, Laiko Hospital, Department of Nephrology and Renal Transplantation, Athens, Greece; [2]Medical School National & Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Athens, Greece; [3]Medical School National & Kapodistrian University of Athens, Laiko Hospital, Department of Pathology, Athens, Greece; [4]Medical School National & Kapodistrian University of Athens, Laiko Hospital, Rheumatology Unit, First Department of Propaedeutic Internal Medicine, Athens, Greece*

Background: Renal involvement in SLE is associated with high risk of morbidity with proliferative lupus nephritis (PLN) having the worst prognosis. Although advances in immunosuppressive treatment led to better renal survival rates, response to treatment and short- and long-term outcomes differ among cohorts.
Objectives: To evaluate short and long term renal outcomes in an inception cohort of patients with PLN. We also aimed to define clinical, laboratory, histological and treatment determinants of partial (PR) or complete response (CR), flare, and long-term renal and patient survival.
Methods: An inception cohort of 83 patients with biopsy-proven PLN (class III, IV, or III/IV+V)(diagnosed between 1992 and 2019) was retrospectively studied. Data collected included histologic characteristics at baseline, demographic, clinical, laboratory, and therapeutic parameters at baseline, 6-9-12-18-24-36-72 months after PLN diagnosis, time of renal flare and last follow-up visit.
Univariate logistic and Cox regression analyses were performed to estimate response to treatment, flare and long-term renal survival. Variables found to be significant in the univariate analyses were included in the multivariate models.
Results: Mean age of the patients was 43±12 years, 78% were women, 96% were Caucasians and median duration of SLE before PLN diagnosis was 12 months (IQR 60).Mean SLEDAI score at PLN diagnosis was 12.8±4 and mean proteinuria was 3.69±3.3g/d. At baseline, 73.5% (61/83) had eGFR>60ml/min/1.73m^2, 15.5% (13/83) eGFR 30-60 and 11% (9/83) eGFR<30. 32% (27/83) of patients had class III LN, 46% (38/83) IV, and 22% (18/83) III/IV+V. Median follow-up time was 107 months(IQR 94).
Induction immunosuppressive treatment consisted of cyclophosphamide (CYC) in 71% (59/83) of patients (12/59 in combination with rituximab (RTX)), mycophenolic acid (MPA) in 25% (21/83)(2/21 in combination with RTX) and RTX alone in 2 patients. 1 patient did not receive any immunosuppressive treatment due to ESRD. Patients treated with CYC had a higher baseline SLEDAI score, lower C3 and C4 levels, higher biopsy activity index and higher proteinuria levels than those treated with MPA. 76% (63/83) received MPA as maintenance treatment, 8% (7/83) azathioprine, 7% (6/83) CYC and 8% (7/83) did not receive any maintenance regimen (3/7 due to ESRD, 2/7 received RTX as induction and continued with steroids only, 1/7 due to non-compliance, 1/7 lost to follow-up after 6months). Median duration of treatment was 43.6 months (IQR 44.6).
66% of patients had response (CR or PR) at 6 months (43% CR, 23% PR), 73% at 9 months (46%CR, 27% PR), 77% at 12 months (61%CR, 16%PR) and 91% at the end of follow-up (80%CR, 11%PR)(Figure 1). Median time to complete remission was 9 months (IQR 14) and median time to partial remission was 4 months (IQR 7). In multivariate analysis, baseline eGFR>60ml/min correlated with shorter time to remission (HR 1.7, p=0.05). No clinical, laboratory or histological (PLN class, activity/chronicity index, number of crescents) parameters or any of induction immunosuppressives could predict time to remission.

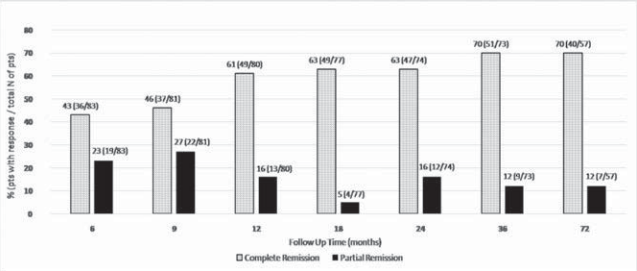

Figure 1.

38.5% of patients (32/83) had ≥1 renal flare in a median time of 40.5 months (IQR 44). In multivariate analysis, proteinuria >1g/d at 12 months correlated significantly with risk of flare (OR 3.65, p=0.039), while induction treatment with MPA was associated with lower risk of flare compared to CYC (OR 0.21, p=0.031) (in combination or not with RTX).
At a median follow-up time of 107 months, 2 patients died, 15.6% (13/83) developed chronic kidney disease (CKD) (<60ml/min/1.73m^2), and 9.6% (8/83) ESRD. In multivariate analysis, baseline eGFR<60ml/min (OR 14.0, p=0.02) and 12-month proteinuria >1g/d (OR 12.0, p=0.02) were the only predictors of CKD.
Conclusion: In our inception cohort of patients with PLN, 66% of patients achieved response at 6 months, 77% at 12 months and 91% at the end of follow-up. Proteinuria >1g/d at 12 months emerged as an important risk factor of renal flare and CKD, while MPA treatment was associated with lower risk of renal flare.

AB0568 CHRITHIDIA LUCILAE IMMUNOFLUORESCENCE PRESENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS ASSOCIATION WITH POSITIVE CHAGAS TESTS

E. Picco[1], B. Cañizares[2], R. Rojas Tessel[1], E. Buschiazzo[1], M. Aciar[1], N. Cucchiaro[1], L. N. Belbruno[1], M. B. Lecumberri[1], A. C. Ralle[1], V. Juarez[1], M. E. Crespo Espindola[1]. *[1]Hospital Sr del Milagro, Rheumatology, Salta, Argentina; [2]Hospital Sr del Milagro, Biochemistry, Salta, Argentina*

Background: Systemic lupus erythematosus (SLE) is characterized by the presence of auto-antibodies, including anti-double strained DNA (dsDNA), which are highly specific for the disease diagnosis and its follow up. Indirect immunofluorescence (IIF) using *chritidia luciliae* (CL) as the antigenic substratum, is the most widely used method to detect it, and its positivity is defined with the staining of the kinetoplast and/or the nucleus. CL is a flagellated parasite, included in *trypanosomatidae* family, which also includes *trypanosoma cruzi*, the cause of Chagas Disease (CD). Some studies suggest that membrane and flagellum fluorescence (considered 'atypical' staining) could be related with positive CD serology.
Objectives: Describe the prevalence of positive IIF-CL images and its association with positive CD test in SLE patients.
Methods: A cross sectional study was designed including consecutive outpatients with SLE diagnosis (SLICC criteria), in which anti-dsDNA antibodies was requested to monitor disease activity. At the same time, two serologic CD tests were performed, since they improve sensibility to detect the disease.
Anti-dsDNA by IIF were performed by an experienced laboratory biochemistry blinded to patients clinical data. Pregnant patients and those ≤ 18 years old were excluded from this analysis.
Standard descriptive analysis was performed, data was compared by exact fisher test or chi2, student's T test or Mann Whitney. A p value < 0.05 was considered as significative.
Results: Thirty five patients were included, 33 (94.3) female, median age 38 (IQR 31-48), with 20 (57.1) patients being from middle-low socioeconomic status (measured by Graffar score). Twenty-six (74.3) patients were receiving glucocorticoids, 28 (80) hydroxychloroquine, 5 (14.3) azathioprine, 12 (34.3) mofetil mycophenolate, 5 (14.3) cyclophosphamide and 4 (11.4) rituximab.
Twelve (34.4) had positive anti-dsDNA test, with atypical staining in membrane and flagellum 31 (88.9), only membrane 4 (11.4) and 9 (25.7) only basal body. One patient had previous chronic CD diganosis without specific treatment.
Five (14.3) CD serologies were positive, and 1 had undefined result. This group of patients had positive staining in membrane and flagellum of CL. No other atypical CL staining images were found. (Table 1)

Table 1. CL staining in CD positive v negative serology

Chritidia luciliae Structure	CD negative (n = 29)	CD positive (n = 5)	p value
Membrane and flagellum – n (%)	25 (86.2)	5 (100)	0.51
Only Membrane – n (%)	4 (13.8)	0	0.51
Basal body – n (%)	7 (24.1)	1 (20)*	0.66

* undefined result

Conclusion: Although we could not find a statistical association between atypical CL staining and positive CD serology, this could be due to the low number of patients included in the study since all the patients with positive CD serology had a positive staining in CL-IIF. A trained biochemistry operator is necessary to avoid false positive tests in regions with high prevalence of CD.

AB0569 FRECUENCY, TYPE AND DETERMINANTS OF COGNITIVE DEFICIT IN A COLOMBIAN COHORT OF PATIENTS WITH SLE

M. Rubio Rivera[1,2], Y. Medina[1,2], L. Duarte[1,2], O. Ayala[1], E. Ruiz[1], C. Rodíguez[1], C. Rodríguez[3]. *[1]Universidad Nacional de Colombia, Bogotá, Bogotá, Colombia; [2]Colombia National University Hospital, Bogotá, Bogotá, Colombia; [3]Hospital El Tunal, Bogotá, Bogotá, Colombia*

Background: Cognitive deficit is part of the neuropsychiatric syndromes associated with systemic lupus erythematosus (SLE) (1). SLE patiens have 2.8 times more risk to develop cognitive deficit (2) and the prevalence is unknown among this population, with variable data from 5% to 80% (3). ACR (American Collegue of Rheumathology) recomends a specific neuropsychological battery (4), but many of the published studies uses variables diagnostic tests. Cardiovascular comorbidities and the use of certain immunosuppressive are involved in the development of cognitive deficit and may be confusors at the time of diagnosis (5). Cognitive deficit affects the quality of life and predisposes to the development of dementia (6). In our setting, the frequency of cognitive deficit as a manifestation of neuropsychiatric SLE is unknown. Determining conditions of it are unknown as well.
Objectives: 1.To define the frequency and degree of cognitive deficit in a cohort of patients with SLE
2.To describe associated factors (including quality of life and depression).
Methods: This was a cross-sectional observational study with 94 patients with SLE. The presence of cognitive deficit was established through a screening test (MoCA test). The diagnosis was confirmed through a battery of specific neuropsychological tests that were performed to patients with abnormal MoCA test. Quality of life was assessed using the LupusCol questionnaire wich is a validated scale for for measuring quality of life in SLE Colombian population. To measure the presence of depression we use the Beck inventory, this scale is also validated in SLE population. An exploratory analysis of the variables was performed and differences were established. A multivariate analysis was performed to find the variables associated with the cognitive deficit.
Results: Of the 94 patients, 90 (95.7%) were women. Of the 94 patients, 43 (51.2%) presented some degree of depression. The median for the loss of quality of life was VIII 21.03% (IQ 10.2 - 40.3). 35 (37.2%) patients had abnormal screening test. Specific neuropsychological tests were applied to 31 (90%) and of those, 11 patients (12.2%) presented a cognitive deficit. An association between cognitive deficit with a greater deterioration in quality of life was found (OR 1.05, 95% CI 1.01,1.09).
Conclusion: The frequency of cognitive deficit is important. There is an association of cognitive deficit with worse scores in quality of life. In addition, it was found that half of the patients presented some degree of depression. The comprehensive assessment of patients with SLE should include the evaluation of cognitive deficit and depression, because of their impact in quality of life, among other clinical aspects.

AB0570 CLINICAL AND IMMUNOLOGICAL MANIFESTATIONS IN SLE PATIENTS IN A THIRD LEVEL HOSPITAL IN ROSARIO, ARGENTINA

D. Carbone[1], J. P. Ruffino[1], F. Martinez[1], S. Chulibert[1], M. C. Argento[1], B. Abdala[1], A. Gatica[1], F. Lucci[1], A. Ringer[1], L. Cichillitti[1], M. N. Cortese[1], M. Palatnik[1], J. C. Crema[1], M. Abdala[1]. *[1]Hospital Provincial del Centenario, Rheumatology, Rosario, Argentina*

Background: Systemic lupus erythematosus (SLE) is a chronic and complex inflammatory disease which predominantly affects young females during reproductive ages. Its prognosis is worse in males, young people, Afro-American and Latin patients. Clinical and immunological features had been described around the world but few reports had been done in Argentinian patients.
Objectives: The purpose of this study was to describe the clinical and immunological pattern in SLE patients, characteristics of lupus nephritis (LN), disease male's course of SLE, treatments and causes of hospitalization.
Methods: Retrospective study including patients (>18 years) followed in Rheumatology Department, which had unless two visits in the last year before data collection, its clinical reports were complete, and fulfilled SLICC or EULAR/ACR SLE criteria. We recorded data from the medical reports.
Results: Of the 70 patients, 63 were female (90%). The mean age at diagnosis was 27,86 ± 9,4 years. The most frequent manifestations were arthritis (75,7%), malar rash (65,7%), photosensitivity (31,4%), leukopenia (31,4%), alopecia (31,4%), Raynaud's phenomenon (24,3%) and nasal and oral ulcerations (21,4%). 94,3% of patients were positive for antinuclear antibodies, 45,7% had anti-Ro/SSa, 28,6% anti-RNP and 21% anti-Smith. 75% had low complement and 45,7% anti-DNA antibodies. LN occurred in the 50% of patients, and class IV was the most prevalent in this group. 66% of patients developed LN in the first year of SLE diagnosis. Autoantibodies in this manifestation were: anti-DNA 60%, anti-Ro/SSa 37%, 31% anti-RNP and 26% anti-Smith. The most common comorbidity was high blood pressure followed by hypothyroidism (34,3% and 25,7% respectively). All patients received hydroxychloroquine and 62,9% prednisone; half of the patients who were into prednisone treatment received 5mg or less. Other treatments were cyclophosphamide (42,9%), mycophenolate (28,6%) and methotrexate (15,7%). 60% of patients had been hospitalized because of SLE flares and 15,7% due to infections. 75% of flares were due to LN and 8% because of serositis. Is known that SLE in male patients is more aggressive and with poor prognosis. Although this study had only 7 men, 86% had LN, 29% had pericardial and pleural effusion and 29% thrombocytopenia, were we found several differences in female's SLE presentation.
Conclusion: This study shown similar results reported in other populations. We found that 50% of SLE patients developed LN, which is the most important cause of hospitalization. Although cutaneous and musculoskeletal manifestations were the most frequent, it's important to take into account the clinical and prognostic differences between male and female.

AB0571

DERIVATION AND INDEPENDENT VALIDATION OF THE LUPUS ARTHRITIS AND MUSCULOSKELETAL DISEASE ACTIVITY SCORE (LAMDA): A MORE SENSITIVE, SPECIFIC AND RESPONSIVE TOOL FOR LUPUS ARTHRITIS

K. Mahmoud[1], A. Zayat[1], M. Y. MD Yusof[1], L. S. Teh[2], S. Khan[2], C. S. Yee[3], D. D'cruz[4], N. Ng[4], D. Isenberg[5], C. Ciurtin[5], P. G. Conaghan[1], P. Emery[1], C. J. Edwards[6], E. Hensor[1], E. Vital[1]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [2]Royal Blackburn Hospital, Rheumatology, Blackburn, United Kingdom; [3]Doncaster & Bassetlaw Hospitals NHS Trust, Rheumatology, Doncaster, United Kingdom; [4]Guy's and St Thomas' NHS Foundation Trust, Louise Cootes Lupus Unit, London, United Kingdom; [5]University College London, Rayne Institute, London, United Kingdom; [6]University Hospital Southampton NHS Foundation Trust, Rheumatology, Southampton, United Kingdom*

Background: The MSK components of the BILAG and SLEDAI have limited sensitivity, specificity and responsiveness.
Objectives: To develop a better disease activity tool for MSK lupus.
Methods: "LAMDA" was derived using data from the multicentre USEFUL study (PMID:33792659); 133 patients with inflammatory MSK pain received intramuscular depomedrone then were assessed for 66/68 SJC/TJC, BILAG-2004, SLEDAI-2K, physician MSK-VAS, inflammatory markers, patient pain and disease-activity-VAS and MSK-ultrasound. Baseline variables were modelled against US using penalized (Lasso) regression. For validation we evaluated: (i) responsiveness at week 6 in USEFUL and (ii) association with quality of life and treatment decision in an independent study (n=100).
Results: LAMDA was a composite of SJC, patient-MSK-pain-VAS, physician-MSK-disease-activity-VAS and ESR ranging from 0 to 26.5. Response effect size was greater for the LAMDA (0.37) than the BILAG-MSK (0.31), SLEDAI-MSK (0.27) and total US score (0.33). With active US at baseline, LAMDA's effect size was 0.42.
In the validation study LAMDA score correlated with better physical function (R = -0.49, p<0.001), pain (R = -0.44, p=0.002) and Burden to Others (R = -0.38, p=0.009). LAMDA was higher when therapy was increased (mean (95% CI) difference 12.9 (5.8, 19.9), p<0.001).
Conclusion: LAMDA is a continuous disease activity instrument for MSK lupus that is sensitive to imaging-synovitis without swelling, more responsive than other instruments and correlates with quality of life and treatment decision. LAMDA may improve the ability of clinicians to monitor and treat MSK lupus, and determine the efficacy of therapies in clinical trials.

AB0572

USEFULNESS OF MINOR SALIVARY GLAND BIOPSY IN THE DIAGNOSIS OF PATIENTS WITH SUSPECTED PRIMARY SJÖGREN'S SYNDROME

N. de la Torre Rubio[1], J. Campos Esteban[1], M. Pavía Pascual[1], M. Machattou[1], P. Navarro Palomo[1], O. Rusinovich[1], C. Merino Argumánez[1], B. Garcia-Magallon[1], H. Godoy[1], C. Barbadillo Mateos[1], L. F. de Villa[1], J. Sanz[1], J. L. Andréu Sánchez[1], M. Fernandez Castro[1]. *[1]Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain*

Background: The classification system for Sjögren's syndrome (SS) proposed by the American-European Consensus Group (AECG) and the revised diagrams proposed by the American College of Rheumatology (ACR) include an altered minor salivary gland biopsy (MSGB) or positive antiRo, among other findings. Thus, an altered MSGB is a particularly important finding in patients with autoantibody-negative. A retrospective cohort study showed that a positive biopsy result led to a definitive diagnosis in 80% of patients[1].
Objectives: To assess the usefulness of MSGB in the diagnosis of SS in anti-SSA/SSB (Ro/La) negative patients.
Methods: Retrospective descriptive study in patients with suspected SS in which MSGB were collected according to standard clinical practice over a consecutive period (from September 2020 to May 2021) in the Rheumatology Department of a tertiary hospital.
Patients were grouped according to the reason for requesting the biopsy: 1) Dry eye/oral syndrome (DEOS), 2) DEOS + altered Saxon/Schirmer, 3) DEOS + positive antinuclear antibodies (ANA+), 4) DEOS + (ANA+) + other serological alterations (hypergammaglobulinaemia, rheumatoid factor (RF), hypocomplementemia), 5) DEOS + extraglandular manifestations (EG) + (ANA+) +/- other serological alterations. The following variables were collected: age, sex, dry eye/oral syndrome, Raynaud's phenomenon, EG manifestations (arthritis, autoimmune hepatitis, primary biliary cirrhosis, interstitial lung disease, pleuropericarditis, autoimmune chronic nephropathy suspected or tubulointerstitial nephritis and/or neurological manifestations), ANA, hypergammaglobulinaemia, RF, hypocomplementemia, Saxon and Schirmer tests and histological result of MSGB according to its Focus Score (FS); MSGB was considered altered when FS was ≥1. Descriptive analysis was performed (means and frequencies); Chi-square test was used to compare the reasons for requesting MSGB between patients with altered and unaltered results and to compare whether any of the groups (Groups 2-5) were more frequently associated with an altered MSGB compared to patients presenting only with dry syndrome (Group 1).
Results: Seventy-eight MSGB were collected. Mean age of patients was 55 years; 90% were women. ANA were present in 17% of patients with altered MSGB. DEOS was the suspected manifestation in 83% of patients, 13% had Raynaud's phenomenon and 47% had some EG manifestation. MSGB was compatible with a diagnosis of SS (according to 2002/2016 classification criteria) in 28% of anti-SSA/SSB negative patients. Patients with dry syndrome and positive ANA (Group 3) were significantly associated with MSGB altered (Table 1).

Table 1. Comparative table of patterns inidicated in the reasons for requesting a MSGB. *Not significant (NS).

Reason for request (%)	MSGB altered	MSGB unaltered	p	p vs dryness
DEOS (50)	19	46	0.65	
DEOS + Saxon/Schirmer (38)	15	34	0.47	NS
DEOS + ANA (30)	11	27	0.67	NS
DEOS + ANA + others (8)	6	4	0.41	0.05
DEOS + EG + ANA (14)	9	15	0.69	NS

Conclusion: MSGB was compatible with a diagnosis of SS in 28% of anti-SSA/SSB negative patients. The data suggest that patients presenting with objectified dryness with Saxon and/or Schirmer test, as well as those with extraglandular manifestations and ANA+ and/or other serological alterations, are more likely to have a compatible with SS result on MSGB. Studies with larger numbers of patients are needed.

AB0573

PERIPHERAL BLOOD B-CELLS SUBSETS IN PATIENTS WITH SJOGREN'S SYNDROME DEPENDING ON SOME IMMUNOLOGICAL PARAMETERS.

A. Torgashina[1], E. Sokol[1], B. Chalcev[1], J. Khvan[1], M. Kireeva[2], D. Tabakov[3], A. Aleksankin[3], S. Glukhova[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rare Rheumatic Disease and Sjogren`s Syndrome, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Educational-Methodical Department, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Immunology and Molecular Biology, Moscow, Russian Federation*

Objectives: To examine B-cell subsets in peripheral blood of Sjogren`s syndrome (SjS) patients (pts) and to analyze the association between B-cell subsets and different clinical and immunological parameters.
Methods: 67 active SjS pts (65F/2M); mean age 51±14,4 years; disease duration 60 (24-120) months were included. SjS was diagnosed based on the ACR-EULAR2016 criteria. Twenty healthy donors composed the control group. CD19+B cells, memory B-cells (CD19+CD27+), non-switched memory B-cells (CD19+IgD+CD27+), switched memory B-cells (CD19+IgD-CD27+), naïve (CD19+IgD+CD27-), double negative (CD19+IgD-CD27-), transitional (CD19+IgD+CD10+CD38+) B-cells, plasmablasts (CD19+CD38+++IgD-CD27+) were analyzed by multicolor flow cytometry using cytometer Navios (Beckman Coulter, USA).

The nonparametric Mann-Whitney test, the Pearson`s x2 criterion, Spearman rank correlation coefficient were used for statistical analysis. Data were shown as median (Me) with an interquartile range of 25 - 75 percentile. The differences were considered statistically significant when p<0.05. Statistica 10 for Windows (StatSoft Inc., USA) package was used for statistical data processing.

Results: The percentages/absolute numbers of plasmablasts, transitional B-cells, memory B-cells in SjS were significantly higher than in healthy donors, p<0.01 for all cases. At the same time percentages/absolute numbers of naïve cells in SjS were reduced compared to healthy donors (p=0.005, p=0.04). Shorter duration of SjS (less than 2 years) correlated with higher rates of naïve cells (p=0.02).

ESSDAI score was ≥5 in 33 pts and <5 in 34 pts. We didn`t find any correlation between B cells subsets and disease activity. The presence of lymphoma in pts (n=5) had no impact on B-cells subsets as well. Significant changes were in B-cells subsets were found depending on immunological parameters. Pts with an isolated increase of antinuclear antibodies (ANA) (ANA positive, RF/aRo/aLa negative) had no plasmablasts in peripheral blood, level of plasmablasts in other pts was 1.5 (1-4.5)x10^3/μL, p=0,004. ARo-positive pts had higher amount of plasmablasts and transitional B-cells than aRo-negative pts (2 (1-5) and 1 (0-1) x10^3/μL, p= 0.004). Higher level of plasmablasts and transitional B-cells also correlated with decrease in C3 and/or C4 (p≤0.03) and increase in IgG (p<0.025).

Conclusion: According to our data elevated level of plasmablasts and transitional B-cells had positive correlation with some immunological diagnostic markers and immunological activity parameters of SjS but didn`t associate with ESSDAI.

AB0574 PREDICTOR FACTORS IN EMPOWERMENT OF PATIENTS WITH PRIMARY SJOGREN SYNDROME IN THE FRAME OF VALUE BASED HEALTH CARE

G. Mumcu[1], K. Abacar[2], İ. Tatlı[3], F. Türe-Özdemir[3], O. C. Kitapçı[1], N. Şişman Kitapçı[1], M. Yay[4], Ü. Karaçaylı[5], F. Fortune[6], N. Inanc[2]. *[1]Marmara University, Faculty of Health Science,, Department of Health Management, Istanbul, Turkey; [2]Marmara University, School of Medicine, Division of Internal Medicine, Department of Rheumatology, Istanbul, Turkey; [3]Marmara University, Medical School, Division of Haematology-Imunology, Istanbul, Turkey; [4]Mimar Sinan Fine Art Faculty, Department of Statistics,, Istanbul, Turkey; [5]Gulhane Faculty of Dentistry, University of Health Sciences, Department of Oral and Maxillofacial Surgery,, Ankara, Turkey; [6]Queen Mary University of London, Barts and the London School of Medicine and Dentistry, Director of the Behçet's Centre of Excellence, London, United Kingdom*

Background: Patient empowerment is a key component in developing awareness of the disease in patient-centred care in the setting of chronic disease management.

Objectives: This study aimed to evaluate predictive factors in the empowerment of patients with Sjögren's Syndrome (pSS), while examining patients reported outcome measures (PROMs) in the setting of value-based health care.

Methods: In this cross-sectional study, 169 patients with pSS (F/M: 162/7; mean age: 52.94±12.20 years) were included. Data was collected from the clinical examination, major salivary gland ultrasonography (SGUS) and a structured questionnaire regarding utilisation of health services and PROMs regarding Oral Health Impact Profile-14 (OHIP-14), Hospital Anxiety and Depression Scale (HADS; HADS-Anxiety and HADS-Depression) and Self-reported General Health Status (100-m VAS; 0: very poor vs 10: very good). Both stimulated (S-SFRs) and unstimulated salivary flow rates (U-SFRs) of patients were measured as ml/min. Patients with hyposalivation were grouped as according to U-SFR (≤0.1 ml/min). Furthermore, Outcome Measures from Rheumatology ultrasonography (OMERACT US) scores (from 0: normal to 3 points: severe inhomogeneity) were collected to evaluate glandular involvement of patients. After initial statistical analyses was carried out, mediation analysis was performed to evaluate the associations.

Results: The rate of patients with hyposalivation was found as 45% and most (85.7%) had elevated SGUS scores (≥2 points). In addition, self-reported oral health problems were common in the study group (from 23.8% to 53.4%). Among this cohort, the patients suffered from Burning oral sensation (27 %) had poor scores in OHIP-14 (29.81±14.48 vs 20.22±12.43), HADS-Depression (10.07±4.49 vs 6.65±4.20) and Self-reported general health status (45.43±17.95 vs 55.56±22.43) compared to those without Burning oral sensation (p=0.006, p=0.019, p=0.018, respectively). Furthermore, significant correlations were observed between OHIP-14 score and HADS-A score (r: 0.4 p: 0.004) and HADS-D scores (r: 0.58 p=0.000). Utilising mediation analysis, the HADS-Depression score was directly mediated by the presence of Burning oral sensation (p=0.0005) and indirectly mediated by OHIP-14 score (p=0.0360). In this group, the interval from the last dental visit was mean: 19 months. Interestingly, 60% preferred to relate their oral discomfort during visits (3 times a year), to rheumatologists.

Conclusion: Better health outcomes could be achieved by reducing oral discomfort, increasing dental visits, improvement of oral health related quality of life and managing depression by a multidisciplinary team with dentists and psychiatrists in patient-centred care. Since these factors have a significant effect on patients' daily life, treatment plans are needed to provide patient empowerment by using suitable strategies in the frame of value-based health care.

AB0575 MESANGIAL C1Q DEPOSITION, BUT NOT C3 AND C1Q DEPOSITION IN OTHER RENAL COMPARTMENTS, IS A PREDICTOR OF RENAL OUTCOME IN LUPUS NEPHRITIS

T. Knežević[1], I. Padjen[2], V. Ivković[1], S. Bulimbašić[3], M. Ćorić[3], I. Jezic[2], Z. Biloglav[4], M. Laganović[5], B. Anic[2]. *[1]University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Division of Nephrology, Hypertension, Dialysis and Transplantation, National Referral Centre for Glomerular and Tubulointerstitial Diseases, Zagreb, Croatia, Zagreb, Croatia; [2]University Hospital Centre Zagreb, Division of Clinical Immunology and Rheumatology,, Zagreb, Croatia; [3]University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia, Department of Pathology and Cytology, University Hospital Centre Zagreb, Croatia, Zagreb, Croatia; [4]University of Zagreb, School of Medicine, Zagreb, Croatia, Department of Epidemiology, Zagreb, Croatia; [5]University Hospital Merkur, Division of Nephrology, Zagreb, Croatia*

Background: Complement activation is an important pathophysiological process in the pathogenesis and development of systemic lupus erythematosus and lupus nephritis (LN). However, the prognostic value of complement factors deposition in different kidney compartments has received little attention and, to the best of our knowledge, no study examined its association with renal outcomes in LN.

Objectives: To evaluate prognostic significance of C1q and C3 complement factors in renal tissue compartments.

Methods: We have conducted a retrospective cohort study and collected data on demographics, clinical and laboratory parameters and histopathology (light, immunofluorescent and electron microsopy) at the time of biopsy and after long-term follow-up. C1q and C3 expression graded in different kidney compartments (mesangium, glomerular basement membrane (GBM), tubular basement membrane (TBM) and blood vessel wall) and dichotomized into no or low (grades 0 and 1) and high expression (grades 2 and 3). Remission (defined as complete or partial remission) was defined as per EULAR 2019 guidelines.

Results: A total of 51 patients with biopsy-proven LN were followed up for 4.5±2.9 years (80% women, mean age at biopsy 38±14). A total of 29 (71%) achieved complete or partial remission. Complement expression in different kidney compartments was as follows: mesangium (C1q 54%, C3 59%), GBM (C1q 34%, C3 41%), TBM (C1q 5%, C3 5%) and blood vessel wall (C1q 0%, C3 5%). Patients with proliferative lupus had more frequently C1q and C3 deposition in the mesangium (69% vs. 14%, p<0.001 and 72% vs. 29%, p=0.005, respectively), while there were no differences between proliferative and non-proliferative LN in other renal compartments (all p>0.05). Subjects who achieved remission more frequently had C1q deposition in the mesangium (64% vs. 31%, p=0.045), but there was no association between remission and deposition of C1q or C3 in other renal compartments (all p>0.05). Interestingly, the association between C1q mesangial deposition and renal outcome was significant even after adjustment for age at biopsy, gender and lupus type (proliferative vs. non-proliferative) (OR 0.13 [0.02, 0.98], p=0.047).

Conclusion: C1q deposition in the mesangium might be an important prognostic factor in LN and more aggressive treatment of these patients may explain the better outcomes of these patients.

Vasculitis - large vessel vasculitis

AB0576 SERUM 25-HYDROXYVITAMIN D WAS CORRELATED WITH THE DISEASE ACTIVITY IN TAKAYASU'S ARTERITIS

H. Liao[1]. [1]*Beijing Anzhen Hospital, Rheumatology and Immunology, Beijing, China*

Background: 25-Hydroxyvitamin D [25(OH)D] deficiency has been linked to autoimmune disease. However, the relationship between 25(OH)D and Takayasu's arteritis (TAK) disease activity remains largely unknown[1]
Objectives: This study aimed to investigate the association between serum 25(OH)D and disease activity in TAK patients.
Methods: A total of 117 patients with TAK (TAK group) and 75 healthy people (control group) were enrolled in our study. Fifty-nine of the patients were re-evaluated after six months of therapy. The serum 25(OH)D levels were compared between the groups. The correlations between the 25(OH)D levels and TAK disease activity were analyzed.
Results: The serum 25(OH)D levels were markedly lower in the TAK patients than those in the healthy subjects [(12.16±4.9) μg/L vs (21.97±8.33) μg/L] (P<0.001). Serum 25(OH)D in all TAK patients was negatively correlated with IL-6 (r=-0.214, P=0.035). The serum 25(OH)D levels in the TAK patients were significantly higher after six months of therapy with glucocorticoid and immunosuppressive agents than those at baseline [(12.16±4.9) μg/L vs (18.01±7.32) μg/L] (P<0.001). Finally, we showed that elevated changes in the 25(OH)D levels before and after treatment were positively correlated with reduced changes in the NIH, ITAS2010 and ITAS-A scores (r=0.490, P<0.001; r=0.496, P<0.001; and r=0.306, P=0.018, respectively).
Conclusion: The serum 25(OH)D levels were significantly downregulated. The changes in 25(OH)D were positively correlated with changes in disease activity.

AB0577 CLINICAL MANIFESTATIONS AND VARIANTS OF THE COURSE OF TAKAYASU ARTERITIS IN A KYRGYZ COHORT

G. Koilubaeva[1], A. Bolotbekova[1]on behalf of researchers of the Department of Rheumatology of National Center of Cardiology and Internal Medicine. [1]*3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan*

Background: The lack of a unified clinical classification and standardized methods of diagnosis creates additional difficulties for timely verification of the diagnosis in real clinical practice. According to a number of studies, there are some differences in phenotypic manifestations among patients with Takayasu arteritis (TAK) of different ethnicity, which determined the objectives of this study.
Objectives: To study the features of the course of the TAK in the Kyrgyz cohort (KC) of patients.
Methods: The angiographic classification of R. Moriwaki et al. was used to determine the anatomical type of vascular bed lesion [1]. The TAK activity was evaluated according to BVAS index, developed by R. Luqmani et al. R. [2], Jefferson's classification was used to characterize the clinical stage of TAK [3]. K. Ishikawa's classification was used to detect the severity of complications and assess the forecast of the disease [6]. All patients underwent a standard laboratory tests, with the mandatory determination of highly sensitive CRP (hs-CRP) and interleukin 6 (IL6). Degree of peripheral vessels lesion was assessed according to data from Duplex Doppler ultrasound scanning of arteries in the color Doppler imaging mode.
Results: The study included 130 patients who were diagnosed with TAK, verified according to criteria of the American College of Rheumatology (ACR, 1990) [4,5] and who received treatment at the NCCIM from January 2014 to November 2021. The majority of patients were women (93.08%), of Kyrgyz nationality (90.77%), of young age - 32 years old [23; 41], with a disease duration of 6.5 years [3.0; 11.0], with the onset of the disease at the age of 23 [18; 31]. By anatomical type of vascular lesion, the patients were distributed as follows: type I was detected in 18 (13.85%), II (a and b) - in 24 (18.46%) patients, III - in 2 (1.54 %), IV - in 5 (3.85%) and V - in 81 (63.3%) patients, which indicated the prevalence of generalized and diffuse lesions of all parts of aorta. According to the BVAS index, most patients had a severe exacerbation - 74 cases (57%), mild exacerbation observed slightly less (42 cases or 32.3%), partial remission occurred in 13 cases (10%) and complete remission in only 1 case (0,77%). By clinical classification, the majority of patients (119 or 91.54%) had vascular stage; none of the patients had the criteria for the prevasculitis stage. In the overwhelming majority of patients (43.84%) nature of vascular lesion was represented by isolated stenosis while a combination of stenosis with occlusive changes was observed in almost 40% of patients.
Conclusion: In the KC of patients with TAK, the overwhelming majority of cases was among women (90.77%) of young age with the onset of the disease at 23 years. Generalized lesions of the arterial bed (63.3%) and severe exacerbation (57%) were mainly observed. The vascular stage predominated (in 91.54% of cases), with the prevalence of stenotic and occlusive changes (40%).

AB0578 C-REACTIVE PROTEIN TO ALBUMIN RATIO IN BEHÇET'S DISEASE

A. Ünal Engİnar[1]. [1]*Konya City Hospital, Rheumatology, Konya, Turkey*

Background: Behcet's Disease (BD) is a systemic variable vessel vasculitis that involves the skin, mucosa, joints, eyes, vascular, nervous and the gastrointestinal system.
Objectives: There is no specific laboratory test for the diagnosis and following of Behçet's disease (BD).This study aims to evaluate the relationship between C-reactive protein (CRP)/albumin ratio (CAR) and other hematological parameters in BD.
Methods: A total of 200 participants (100 BD patients and 100 healthy control) were recruited from the rheumatology outpatient clinic in this cross-sectional study. The laboratory data were obtained from the hospital database. Laboratory tests were conducted to measure complete blood count, erythrocyte sedimentation rate (ESR), CRP, albümin, CAR, neutrophil to lymphocyte ratio (NLR), and platelet to lymphocyte ratio (PLR). Laboratory findings of BD patients and healthy controls were compared and evaluated. BD Activity scores (BDCAF/Behcet's Disease Current Activity Form) were calculated. The inclusion criteria were fulfilling the international diagnostic criteria of BD, being over 18 years and accepting to participate in the study.
Results: In the BD group, there were 42 male and 58 female participants with a mean age of 42.49 ± 13.15 and in the healthy control group, 44 male and 56 female participants with a mean age of 44.90 ± 10.98. The age and gender distributions of the groups were as similar (P: 0.16 and P: 0.78, respectively). NLR, CRP, ESR and CAR values were significantly higher in patient group than in the healthy controls (respectively p:0.022, p: 0,013, p:0.001, p:0,011). BDCAF score varied between 0 and 4 with a mean of 1.55± 0.64. A statistically significant correlation was observed between BDCAF and CRP, ESR and CAR (p<0.0001).
Conclusion: In this study, a significant correlation was found between CAR and BDCAF, NLR, CRP, albumin and ESR. CAR can be useful in the diagnosis and following of BD patients. However, further studies are needed.

AB0579 EVALUATION OF PATIENTS WITH PEDIATRIC BEHÇET'S DISEASE: A TERTIARY CENTER EXPERIENCE

Z. Karali[1], Ş. Çekiç[1], I. Çakır[1], S. S. Kilic[1]. [1]*Bursa, Uludag University Faculty of Medicine, Division of Pediatric Immunology and Rheumatology, Bursa, Turkey*

Background: Behçet's disease (BD) is an systemic inflammatory vasculitis characterized by recurrent oral aphthae and genital ulcers. In the course of the disease, skin, eye, musculoskeletal, nervous system and gastrointestinal system involvements can be detected.
Objectives: To evaluate the clinical, laboratory and radiological findings of pediatric cases diagnosed with BD.
Methods: Fifty patients (0-20 years old) who were followed up with the diagnosis of BD at the Pediatric Rheumatology outpatient clinic of Uludag University Faculty of Medicine between January 2011 and July 2021 were included in our study. The patients were diagnosed according to the diagnostic criteria of the International BD Study Group.
Results: Twenty-four (48%) of the patients were male and 26 (52%) were female. The mean age at the diagnosis of patients was 9 ±4.55 years (10.75±4.55 years in boys, 12.35±3.65 years in girls). Twenty patients (36.3%) had a family history of Behçet's Disease. Oral aphthae were present in 96% (n=48) patients, while genital ulcers were in 32% (n=16) (Table 1). Of the nine patients with uveitis, 6 had panuveitis, 2 had anterior uveitis and 1 had posterior uveitis. . There was no difference in the distribution of symptoms according to the gender of the patients. HLA-B51 allel was found in 39 (78%) and ANA was positive in 14 patients (28%). Immunological tests showed that serum immunoglobulins were low in 11 (32.3%) of 34 patients. Low IgG levels were detected in 6 patients, low IgM levels were in 3, and low IgA levels were in 2. Thrombus was presented in three cases (thrombus in the right ventricle in one case, in the intracranial transverse sigmoid sinus and left jugular vein in two cases). The most commonly used drug for aphthae was colchicine (n=45, 82%). The use of biological agents according to patient manifestations is shown in Table 2. In the follow-up, clinical findings improved in 35 patients (70%) Complete improvement was detected only with biological agents in 8 patients with uveitis. One patient was operated due to the development of complicated cataracts secondary to uveitis. Three patients were diagnosed with Covid-19, one of them was followed without treatment, while two of them were treated with favipiravir at home. Three patients with Covid-19 infection were using only colchicine treatment.

Table 1.

Findings at the time of diagnosis	n	%
Uveitis	9	18
Skin findings	18	36
Gastrointestinal tract involvement	19	38
Central nervous system involvement	6	12
Vascular involvement	3	6
Arthritis	17	34

Table 2.

Findings Biological Agents	Uveitis (n)	Arthritis (n)	Venous thrombus (n)	Central nervous system involvement (n)
Azathioprine	2	2	3	1
Methotrexate	2	2	-	-
Adalimumab	3	1	-	-
Infliximab	3	1	-	-

Conclusion: Behçet's disease is rare in childhood. Although it is not common, life-threatening complications can be observed. To reduce morbidity and complications, physicians should be aware of manifestations and rare clinical pictures of the BD.

AB0580 BEHÇET'S DISEASE IN OSLO NORWAY IN PERIOD 1999 – 2021

J. L. Lorentsen[1], K. Lerang[1], T. Garen[1], Ø. Palm[1]. [1]*Rikshospitalet, Rheumatology, Oslo, Norway*

Background: Bechet's disease (BD) is a multisystemic, inflammatory disease, characterized by variety of clinical manifestations, including mucocutaneous, ocular, vascular, neurological (CNS) and gastrointestinal (GI) involvements. The disease can be seen at any age and occurs across gender, ethnic groups, and geographical areas. However, there are only a few studies from northern Europe.
Objectives: To study the demographics and clinical feature of patients with Bechet's disease (BD) in Oslo Norway.
Methods: In this retrospective study we reviewed hospital records from Oslo University Hospital (OUS), a referral hospital for systemic inflammatory vasculitis in Norway. All patients living in Oslo with ICD-10 code M35.2 were identified, and their BD-related data recorded. Those fulfilling either the International Study Group criteria (ISG) or International Criteria for Bechet's disease (ICBD) were included. Patients were defined as non-Norwegian when none of the parents was of Norwegian ancestry. The differences between groups were compared by Chi-square test using the Statistical Package for the Social Sciences (SPSS).
Results: We identified a total of 58 patients fulfilling the inclusion criteria (Table 1). Among them, 30 (52%) were females and 25 (43%) of Norwegian ancestry. Mean age at onset was 26 years, and at diagnosis 32 years.

Table 1. Demographics of Behcet`s patients in Oslo Norway

Counts (%)	Norwegian ancestry	Non-Norwegian ancestry	All (%)
All (%)	25 (43)	33 (57)	58 (100)
Male (%)	8 (29)	20 (71)	28 (48)
Female (%)	17 (57)	13 (43)	30 (52)
ISG Criteria (%)	20 (47)	23 (53)	43 (100)
ICBD Criteria (%)	25 (43)	33 (57)	58 (100)
Age at diagnosis mean (SD) years	33 (11.85)	32 (9.36)	32 (10.41)
Age at onset mean (SD) years	24 (9.34)	27 (9.52)	26 (9.42)

The most prevalent clinical manifestations were oral ulcers (n=58, 100%), genital ulcers (n=49, 84%) and skin lesions (n=40, 69%). Ophthalmic complications (n=21, 36%), arthritis (n=20, 34%), vascular involvement (n=7, 12%), CNS (n=3, 5%) and gastrointestinal (GI) complications (n= 4, 7%) were also present. There was no significant difference of clinical features between patients with Norwegian ancestry and those with non-Norwegian ancestry (data not shown).

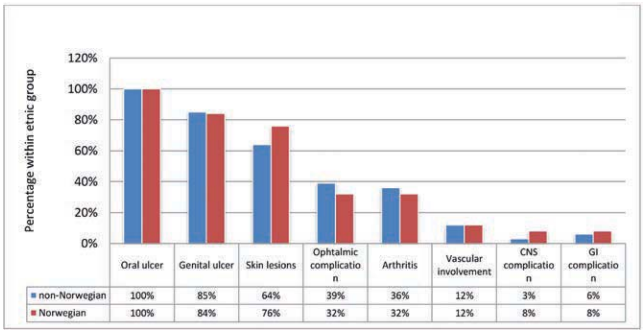

Figure 1.

Conclusion: BD was most prevalent among patients of non-Norwegian ancestry. We found a wide spectrum of clinical manifestations occurring during the disease course. Mucocutaneous lesions were most frequent, but potential serious manifestations were also present. These manifestations were similarly distributed between patients with Norwegian and non-Norwegian ancestry (Figure 1).

AB0581 TRACHEAL STENOSIS; AN IMPORTANT INVOLVEMENT IN GRANULOMATOSIS WITH POLYANGIITIS

O. Ozdemir Isik[1], F. Tuncer[1], O. Sadioglu Cagdas[1], A. Yazici[1], A. Cefle[1]. [1]*Kocaeli University, Faculty of Medicine, Rheumatology, Kocaeli, Turkey*

Background: Granulomatosis with polyangiitis (GPA) is a granulomatous systemic vasculitis of unknown etiology that can affect many organs. Approximately 90% of patients with GPA have upper respiratory tract involvement, including the nasal cavity, sinuses, ear and trachea. Subglottic stenosis (SGS) may develop in some patients due to tracheal involvement.
Objectives: It is aimed to evaluate the general characteristics, treatments and disease prognosis of our GPA cases with tracheal stenosis as it is a significant cause of morbidity and mortality.

Methods: The data of 48 patients diagnosed with GPA between 2000-2021 were analyzed retrospectively and the data of 6 patients with tracheal stenosis (TS) were evaluated.
Results: TS was present in 13% of the patients. All patients with TS were female. The mean age of the patients with TS was 46.5±6.5 years, the mean age of disease onset was 35.5 ±13.4 years, and the mean disease duration was 10.8±10.2 years. Constitutional symptoms were in 17% of patients, and 17% had mastoiditis, sinusitis, otitis, bloody nasal discharge and renal involvement. None of the patients had hearing loss, skin, eye and neurological involvement. 83% of patients had limited disease. While all patients had SGS, one patient also had glottic and bronchial stenosis. The most common symptoms in patients were hoarseness and shortness of breath. All patients received systemic treatment according to their organ involvement, local treatment (dilatation, steroid injection) was also applied to two patients. All patients had anti-neutrophil cytoplasmic antibody (ANCA) positivity. When patients with and without tracheal stenosis were compared, there was a difference in terms of gender, lung and kidney involvement, presence of anemia, increased erythrocyte sedimentation rate, pANCA, cANCA and PR3-ANCA positivity, and myalgia. In addition, our patients with tracheal stenosis had a younger age of onset and a longer delay in diagnosis.
Conclusion: The incidence of SGS in large series has been reported as 8-23% of GPA patients.[1,2] Although the number of cases in our study was small, this rate was 13%. Symptoms range from cough and shortness of breath to progressively life-threatening severe stridor. Early diagnosis and treatment are important. For this reason, TS is strongly emphasized.

AB0582 TAKAYASU ARTERITIS PRESENTS AT AN OLDER AGE IN EUROPEAN POPULATION

F. Coath[1], G. Ducker[1], T. Eccleston[1], S. Fordham[1], C. Mukhtyar[1] on behalf of Mukhtyar Vasculitis group. [1]*Norfolk & Norwich University Hospital, Rheumatology, Norwich, United Kingdom*

Background: The definition of Takayasu arteritis includes the age of onset of disease as being <50 years. It has been reported most frequently in young females from Asian populations.
Objectives: We investigated whether the epidemiological features are the same in Norfolk, UK, where the population is predominantly of Northern European ancestry.
Methods: In our centre, cases are classified using validated international criteria. The electronic records of our vasculitis clinic were reviewed to identify all individuals with a new diagnosis of large vessel vasculitis between 2011-2020 who met a modified ACR 1990 criteria for Takayasu arteritis. The original criteria include decreased brachial artery pulse, bruit over subclavian arteries or aorta, and arteriogram abnormality. The respective modifications of these three criteria were to accept decreased radial pulse as well as the brachial pulse, bruit over the axillary artery as well as the subclavian artery, and abnormality of positron emission tomography and/or ultrasonography instead of arteriograms.
Results: 15 individuals met the modified ACR 1990 criteria for Takayasu arteritis. 2 of them also met the criteria for GCA and were excluded. 13 individuals were classified as having Takayasu arteritis. 11 were female. The mean (standard deviation) age at diagnosis was 66.9 (8.9) years. None of individuals were <40 years old. On presentation - 9 had upper limb claudication, 7 had pulse discrepancy, 3 had a blood pressure difference >10 mm Hg systolic, 7 had an audible bruit over either subclavian or axillary artery. The diagnosis was confirmed on positron emission tomography in 8. Ultrasonography of extracranial arteries was abnormal in 7. The mean (standard deviation) ESR was 53.2 (33.6) and CRP was 37.5 (32.8).
Conclusion: Takayasu arteritis can present at an older age in Norfolk, UK, where the population predominantly has Northern European ancestry. This has implications for treatment, identification of immunogenetic factors and disease classification.

Background: In most countries polymyalgia rheumatica (PMR) is diagnosed and managed by both general practitioners (GP) and rheumatologists. However, the referral pattern from GP's to specialist around the world has not been described. The initial prednisolone dose recommended by EULAR/ACR is between 12.5 and 25 mg[1], but little is known about whether these guidelines are followed everywhere by GP's in clinical practice[2].
Objectives: This study aims to describe the refererral pattern and treatment strategy for PMR in general practice in several countries worldwide.
Methods: An English language questionnaire was drafted by a working group of rheumatologists and GP's from 6 different countries. The questionnaire contained questions on: 1: Respondent, 2: Referral pattern and 3: Prednisolone. Questionnaires were distributed to GP's via members of the International PMR/GCA study group. Answers were collected via an online survey tool (Redcap), from 3rd of November 2021 to 27th of January 2022. Countries with more than 15 responders to the questionnaire were included in the analysis.
Results: Data from 11 countries were analysed. Referral patterns differed widely among countries (Table 1). Almost all patients initially seen by rheumatologists were returned to GP's for treatment. In all countries a proportion of the GP's prescribed higher initial prednisolone doses than recommended, with a large variation between countries (Table 1).

Table 1. Characteristics of responders, referral pattern, and treatment strategy

	Austria	Canada	Colombia	Denmark	Italy	Nether-lands	New Zealand	Romania	Russia	Switzer-land	United Kingdom

Patients returned to GP for treatment (%)	100 (50-100)	50 (2-100)	8 (0-50)	85 (40-100)	50 (0-100)	50 (10-90)	100 (90-100)	80 (50-98)	1 (1-1)	80 (10-100)	100 (100-100)
Patients referred during treatment (%)	50 (25-90)	50 (10-100)	100 (50-100)	20 (10-33)	50 (15-80)	15 (10-30)	20 (10-25)	30 (10-80)	1(1-1)	20 (10-30)	10 (10-20)
Prednisolone											
Initial dose (mg)	38 (25-50)	20 (20-50)	20 (10-30)	25 (15-40)	25 (25-25)	15 (15-15)	20 (15-40)	15 (12-20)	15 (15-15)	50 (25-50)	15 (15-20)
Initial dose > 25 mg, n (%)	12 (47)	4 (25)	7 (40)	14 (26)	9 (25)	1 (5)	6 (38)	7 (20)	3 (8)	22 (83)	3 (9)
Duration of treatment (months)	9 (6-12)	6 (2-9)	6 (4-24)	12 (8-18)	5 (3-12)	11 (6-12)	12 (10-18)	2 (2-5)	6 (6-6)	12 (12-14)	15 (12-24)

Data are presented as weighted median (interquartile range) unless otherwise stated. GP: general practitioner, PMR: polymyalgia rheumatica, GCA: great cell arteritis.

Conclusion: Although many patients were referred to the hospital for initial PMR diagnosis or during the disease course, a large proportion of patients received treatment in general practice worldwide. GPs frequently use a higher starting dose of prednisolone and shorter treatment duration than recommended by EULAR/ACR.

Background: Polymyalgia rheumatica (PMR) is diagnosed and treated by both general practitioners (GP) and rheumatologists. How rheumatologists around the world manage the referral process of patients with PMR from GP's has not been described. EULAR/ACR guidelines recommend initial prednisolone doses between 12.5 and 25 mg, but it is unknown if guidelines are followed in daily clinical practice[1]. In addition, the understanding of challenges for recruitment to clinical trials in PMR is currently limited.

Objectives: This study aims to describe the management of referrals, treatment strategy, and recruitment to clinical trials in PMR among rheumatologists worldwide.

Methods: An English language questionnaire was drafted by a working group of rheumatologists and GP's from 6 different countries. Questions concerned: 1: respondent, 2: referrals, 3: prednisolone, and 4: barriers to research. Questionnaires were distributed to rheumatologists via members of the International PMR/GCA study group. Answers were collected via an online survey tool (Redcap), from 2nd of November 2021 to 27th of January 2022. Countries were grouped by income and geographical region based on the World bank classifications. Data were weighted by number of inhabitants in a country, based on the United Nations age specific population count, divided by number of respondents in a country. Countries with more than 20 respondents were included.

Table 1. Characteristics of reponders, referrals, and treatment.

		Geographical region							Income	
		The world	Europe and Central Asia	North America	Latin America	East Asia and Pacific	South Asia	Middle East and Africa	High- income countries	Low- and middle-income countries
Responders	Responders (n), Completed questionnaire (total)	875 (1000)	294 (304)	78 (81)	136 (152)	53 (53)	53 (72)	261 (338)	446 (458)	429 (542)
	Experience as rheumatologist (years)	11 (6-20)	12 (6-20)	7 (4-20)	11 (6-23)	21 (10-30)	7 (4-10)	9 (5-18)	11 (5-22)	8 (5-12)
Referrals	GP's can discuss patients prior to referral, %	64	79	79	57	58	60	67	74	61
	Referred patients seen (%)	100 (90-100)	100 (90-100)	100 (100-100)	100 (100-100)	100 (95-100)	100 (100-100)	100 (60-100)	100 (100-100)	100 (90-100)
	Evaluation > 2 weeks after referral, %	26	49	80	60	21	6	18	58	15
Prednisolone	Started prior to rheumatological evaluation (%)	50 (20-50)	60 (30-80)	70 (50-80)	50 (10-50)	30 (20-50)	50 (20-80)	20 (0-50)	50 (30-80)	50 (10-70)
	Initial dose (mg)	20 (15-40)	20 (15-20)	20 (15-20)	20 (20-40)	15 (15-15)	20 (15-40)	20 (15-40)	15 (15-20)	20 (15-40)
	Initial dose > 25 mg, %	32	9	6	41	0	41	43	6	42
	Duration of treatment (months)	12 (6-12)	12 (12-18)	12 (10-18)	6 (3-12)	18 (12-18)	12 (6-12)	6 (3-12)	12 (12-18)	9 (6-12)

Data presented as weighted median (interquartile range) unless otherwise stated. GP: general practitioner

Results: Results from 27 countries were analysed including 1000 responders in total (Figure 1). There was large variation in time from referral to first assessment, initial dose of prednisolone was high, duration of treatment was relatively short, and a large proportion of patients with newly diagnosed PMR received prednisolone prior to rheumatological evaluation (Table 1). Concerning the 15% of respondents who performed research in PMR, 52% had participated in clinical trials and 56% of the responders experienced difficulties with recruitment.

Conclusion: This is the first description of current practice in managing referrals and treatment of PMR by rheumatologists worldwide. In general, median treatment duration was according to EULAR/ACR guidelines, but initial dose of prednisolone was often higher than recommended in many parts of the world. PMR patients were often seen more than two weeks after referral, and treatment had started prior to first rheumatological evaluation.

AB0585 NEURO-BEHÇET'S DISEASE: A TUNISIAN EXPERIENCE

A. Baya Chatti[1], S. Skhiri[1], A. Guiga[1], W. Ben Yahia[1], A. Atig[1], N. Ghannouchi[1].
[1]*Hospital Farhat Hached, Internal Medecine, Sousse, Tunisia*

Background: Behçet's disease (BD) is a systemic inflammatory vasculitis with a wide range of manifestations including neurological involvement. Though neuro-Behçet's disease (NBD) is relatively uncommon, it encompasses some of the most serious manifestations of BD. Its diagnosis can be challenging, as there is no specific diagnostic test.

Objectives: Our study aimed to describe epidemiological, clinical and paraclinical characteristics of BD, and compare them between patients with and without NBD.

Methods: We conducted a retrospective study, including all patients meeting the revised international study group criteria for BD, over an 18-year period. We divided patients into 2 groups, based on the presence or absence of neurological involvement, retained according to the international consensus recommendation criteria for NBD. Epidemiological, clinical and paraclinical features were then analysed and compared between the two groups.

Results: We obtained a cohort of 77 patients with a gender ratio (M/F) of 1.85 and a mean age at diagnosis of 34.4 years [20-60]. Mucocutaneous involvement inaugurated BD in 81.8% of cases, followed by joint involvement (19.5%), vascular involvement (17.9%), neurological involvement (10.7%) and ocular involvement (2.6%). Mucocutaneous involvement was dominated by oral aphtosis (100%) and genital aphtosis (79.2%) with a mean frequency of episodes per year of 8.3 ± 6.2 and 6.9 ± 5.1 respectively, followed by pseudo-folliculitis (66.2%), erythema nodosum (19.5%), and positive pathergic test (13%). Joint involvement (62.3%) was mainly peripheral (arthralgia in 98% and arthritis in 25%), affecting large joints (85.1%) and bilateral in 78.8% of cases (asymmetric in 48.6%). Axial involvement and sacroiliitis were observed in 14.6% and 10.4% of cases, respectively. Only one patient had a popliteal cyst. Vascular manifestations (36.4%) were venous thrombosis (92.9%), arterial thrombosis (12.9%) and arterial aneurysms (6.5%). Ocular manifestations (35%) were uveitis and vasculitis in 77.8% of patients respectively, with predominance of bilateral lesions (70.4%). Other manifestations were cardiac involvement (5.2%), intestinal involvement (3.4%) and fever (23.4%). One patient developed membranous glomerulonephritis without any other underlying aetiology. Biological inflammatory syndrome was found in 42.9% of patients. Twenty-eight patients developed NBD with 34 outbreaks during follow up. The mean delay from onset of BD was 6.3 years [0-26]. Parenchymal NBD was more frequent (73.5%). Non-parenchymal syndromes (38.2%) were acute meningitis (17.6%), cerebral venous thrombosis (11.8%), pseudotumour cerebri (5.9%) and isolated intracranial hypertension (2.9%). One patient developed peripheral neurological involvement. Headache

(59%) and motor deficits (32.4%) were the most common signs. Neurological examination most frequently revealed a pyramidal syndrome (32.3%). Severe forms (modified Rankin scale ≥2) dominated clinical presentations (64.7%). CSF study revealed abnormalities in 10 (35.7%) cases: Increased protein with pleocytosis in 6 cases with lymphocytic predominance (n=3), mixed formula (n=2) and PNN predominance (n=1), decreased glucose levels and increased pressure in 3 cases respectively, and one case of albuminocytological dissociation. The predilection sites of NBD lesions on MRI were brainstem and basal ganglia (35.5%, respectively), periventricular white matter (26.5%), subcortical WM (23.5%), internal capsule (20.6%), centrum semiovale and cerebral cortex (11.8%, respectively) and cerebellum (3%). Comparison between the two groups revealed, in patients with NBD, an older mean age at diagnosis (37.7±11.97 vs 32.3 ±7.14, p=0.023) and a lower frequency of ocular involvement (21.4% in G1 vs 42.9% in G2, p=0.05). We found no statistically significant differences when comparing gender ratio and other clinical and biological features.

Conclusion: Ocular lesions were more frequent in patients without NBD. Large-scale studies are needed in order to determine markers associated to neurological involvement.

AB0586 OCULAR ISCHEMIC SYNDROME CAUSING ACUTE BINOCULAR VISION LOSS IN THREE PATIENTS WITH TAKAYASU ARTERITIS TYPE V: A THERAPEUTIC QUANDARY

A. Krishnan[1], U. Dhakad[2], P. Dogga[2], J. Dixit[1], A. Pm[1]. *[1]King George's Medical University, Clinical Immunology and Rheumatology, Lucknow, India; [2]King George's Medical University, Department of Clinical Immunology and Rheumatology, Lucknow, India*

Background: Ocular Ischemic syndrome (OIS) is a rare manifestation in Takayasu Arteritis (TA) which can cause irreversible retinal ischemia and neovascular changes. Ocular Ischemic syndrome denotes hypoperfusion of both anterior and posterior segments of eye and orbital structures as a result of common/internal carotid artery occlusion[1,2]. Although described as a chronic phenomenon, we report three young female patients, diagnosed Takayasu Arteritis Type V (Angiographic Classification) who presented to us with acute binocular loss of vision which were managed with individually tailored approaches to restore vision.

Objectives: 1.To elaborate on three patients diagnosed Takayasu Arteritis type V presenting with acute onset binocular vision loss and discuss critical aspects of management in OIS.

Methods: Case series of three patients of TA satisfying 1990 ACR classification criteria.

Results: 18-year-old female presented with acute onset painless loss of vision in both eyes and severe vertigo. She appreciated hand motion on visual acuity testing. She was started on Methotrexate (MTX)and Prednisolone (PSL). In view of acute vertebrobasilar and carotid insufficiency, she underwent bilateral carotid and vertebral angioplasty. She tested 20/80 on visual acuity in both eyes and ambulated without support by two weeks after procedure.

15-year-old female presented with episodic vertigo, amaurosis fugax and claudication of both upper and lower limbs. She was kept on MTX and tapering doses of PSL and when dose of PSL reached less than 0.25mg/kg, she developed acute binocular vision loss with absent pupillary reflexes. Visual acuity testing revealed perception of hand motion in both eyes which improved to 20/40 within 2 weeks after increasing steroid dose to 0.5mg/kg and tocilizumab.

14-year-old female presented with acute binocular painless vision loss with previous history of limb claudication. Examination revealed no light perception on visual acuity testing in both eyes with absent pupillary reflexes. She was started on tapering doses of PSL and MTX. Also, she underwent a bilateral carotid and vertebral artery angioplasty. By first week, she could identify hand motion in both eyes and is continued on inpatient care.

Conclusion: We suggest that combining vascular surgical and pharmacological intervention in acute vision loss in TA may restore vision, even in active disease. Prompt follow-up and wider sample size is needed to draw insights into ocular involvement in TA.

AB0587 THE RISK OF PATIENTS WITH POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS TO DEVELOP DIABETES AND OSTEOPOROSIS ON FOLLOW UP

M. Bahl[1,2], M. Stöcker[2,3], S. Tsiami[1,2], X. Baraliakos[1,2], J. Braun[1,2], U. Kiltz[1,2]. *[1]Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany; [2]Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany; [3]Augusta-Kranken-Anstalt gGmbH, Pneumology, Bochum, Germany*

Background: Patients with polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are commonly treated with glucocorticoids (GC) in different dosages. Therefore, the most common comorbidities that may develop are osteoporosis (OPO) and diabetes mellitus (DM).

Objectives: To study the development of these comorbidities in the management of PMR and GCA in a real-life setting.

Methods: In a retrospective study design, longitudinal data of patients with a clinical diagnosis of PMR and GCA treated in a tertiary center were studied. Patients and disease characteristics were documented according to clinical routine in patients in whom ≥ 2 documented visits ≥ 3 months apart had been documented.

Results: A total of 550 patients (382 PMR, 168 GCA) was analysed (Table 1). The time period of follow up (FU) ranged between 3 months and 13.6 years (mean 1.4 (0.3) years). The majority of patients received a diagnosis of PMR or

Table 1. Characteristics of patients of TA with acute binocular vision loss

Age	Duration(years)	Absent peripheral pulse	Hypertension	CRP levels	CT aortogram involvement	TA type	Fundus angiogram findings	Fundus examination
18	1	Both brachial and radial	No	High	Both proximal subclavian arteries, common carotid, Infrarenal aorta, coeliac and superior mesenteric arteries	V	capillary non perfusion areas	Normal
15	2	Both brachial, radial, right popliteal and Dorsalis pedis.	Yes	High	Both subclavian arteries, common carotid, renal and iliac arteries with >50% narrowing of abdominal aorta	V	capillary non perfusion areas	Grade II Hypertensive retinopathy
14	4	Left Brachial and radial	Yes	Normal	Both subclavian, renal, iliac arteries and > 70% diffuse stenosis of bilateral carotids	V	increased foveal avascular zone, capillary non perfusion areas	Cotton wool spots, venous engorgements

GCA in our center while 29.5% of patients came for a second opinion. Their mean age was around 70 years, and most patients were female (Table 1). Eight GCA patients were already blind (4.8%) at first presentation, and 77 and 80 patients had a diagnosis of DM (15.5%) and OPO (16.0), respectively, already at baseline. During FU 56 PMR (16.0%) and 7 GCA patients (4.2%) were diagnosed with another autoimmune disease, mainly with rheumatoid arthritis (n=50 (69.4%)). The mean dose of GC differed substantially between groups (Table 1). On FU, 9 (2.4%) and 5 (3.0%) of PMR and GCA patients developed DM and 17 (4.5%) and 14 (8.4%) OPO, respectively. Thus, about 20% and 25% of patients with PMR or GCA finally had DM and OPO, respectively. Almost all patients received vitamin D and antiresorptive agents.

Table 1. Patients and disease characteristics

	PMR patients (n=382)	GCA patients (n=168)	Significance
Age (years)	68,2 (9.3)	71.1 (8,6)	0.9
BMI (kg/m^2)	27.0 (4.9)	26.0 (5,3)	0.44
Female sex, n (%)	216 (56.6)	121 (72,0)	<0.001
Time to rheumatologist (months)	2.1 (9,7)	1.4 (5,4)	0,33
CRP at baseline (mg/dl)	3,8 (4,6)	4,5 (5,5)	0,07
Prednisolone at baseline (mg/d)	25.1 (20,2)	52.0 (69,7)	<0.001
Comorbidities at baseline			
-Number of comorbidities (mean)	1.45 (1.12)	1.51 (1.12)	0.26
-Diabetes, n (%)	61 (16.0)	24 (14.3)	0.36
-Osteoporosis, n (%)	64 (16.8)	30 (17.9)	0.7
-Ischemic heart disease, n (%)	38 (9.9)	19 (11.4)	0.46
Organ manifestation and comorbidities at FU			
-Blindness n (%)	6 (1.6)	8 (4.8)	0.048
-Aneurysm n (%)	1 (0.3)	9 (5.4)	<0.001
-Diabetes, n (%)	70 (18.4)	29 (17.3)	0.89
-Osteoporosis, n (%)	81 (21.4)	44 (26.3)	0.003
-Vascular stenosis	4,6	10,1	0,048

values given as mean (SD)

Conclusion: In this large real-life cohort, patients with PMR and GCA aged around 70 years were seen by rheumatologists about 1-2 months after their first symptom but 8 GCA patients were already blind at first visit. DM and OPO were frequent comorbidities in both, PMR and GCA patients, already at baseline and during follow-up more patients developed these comorbidities despite prophylactic and therapeutic medication. OPO and DM should be a routine concern in the care of PMR and GCA patients - already when glucocorticoids are started.

AB0588 GIANT CELL ARTERITIS: DO DIFFERENT PHENOTYPES OF PRESENTATION MEAN DIFFERENT CLINICAL ENTITIES?

N. Italiano[1], F. Di Cianni[1], E. Elefante[1], F. Ferro[1], P. A. Erba[2], R. Talarico[1], M. Mosca[1]. *[1]University of Pisa, Rheumatology Unit, Pisa, Italy; [2]University of Pisa, Department of Translational Research and New Technologies in Medicine and Surgery, Section of Nuclear Medicine, Pisa, Italy*

Background: Giant cell arteritis (GCA) represents the most common primary vasculitis of the elderly, affecting large and medium-sized arterial vessels. GCA often also involves the aorta and its major branches and may lead to aortic aneurysm/dissection as well as large artery stenoses; it seems that unrecognized extra-cranial involvement may be even more common.
Objectives: The primary aim of this study was to explore the different clinical entities in a large cohort of patients with GCA; a secondary aim was to evaluate long-term outcome of GCA patients with at least 5 years of follow-up.
Methods: A cohort of 278 GCA patients (54 males and 224 females, mean ± SD age 75 ± 6 years) were retrospectively studied. Clinical symptoms at disease onset and during the follow-up, time delay until diagnosis, as well as laboratory findings at the time of diagnosis and therapeutic approach were retrospective evaluated. In order to characterize the different clinical phenotypes, overall clinical symptoms were grouped for macro-area (cranial versus systemic). Moreover, long-term outcomes in patients with a minimum follow-up of 3 years were evaluated. A disease flare was defined as the presence of any further clinical manifestation compatible with the clinical spectrum of GCA and an increase of ESR ≥ 30 mm/hour, not otherwise justifiable, that required higher doses or new introduction of glucocorticoids (GC) therapy and/or the introduction of steroid sparing treatments (e.g. tocilizumab, methotrexate).
Results: The most frequent clinical manifestations presented at the onset included: constitutional symptoms 69%, new onset headache and/or scalp pain 64%, jaw claudicatio 32%, vision loss 30%, abnormal temporal artery on examination 19%, neuropsychiatric symptoms 17%, cough not otherwise justifiable 7%, cerebrovascular accidents 6% and hearing loss 3%. Irreversible (mono- or bilateral) blindness was reported in 7% of patients, mainly due to a latency period between onset and treatment of ≥ 3 months. Temporal artery biopsy was performed in 171 patients, resulting positive in 72%. Globally, about 38% of subjects (was characterized by a clinical profile compatible with extra-cranial GCA. In all cases, extra-cranial involvement was confirmed by (18)F-fluorodeoxyglucose (FDG) positron emission tomography (PET). Moreover, patients who presented symptoms compatible with large-vessel involvement were characterized by a more relapsing course compared with patients with cranial involvement GCA profile (both in terms of dose of corticosteroids and use of steroid-sparing agents).
Conclusion: According to the literature data, different phenotypes of GCA exist and they may probably represent different clinical entities, also in terms of prognosis and therapeutic approach. This is particularly crucial in order to plan a tailored therapy and prevent disease damage in the short and long-term follow-up.

AB0589 TOCILIZUMAB FOR GIANT CELL ARTERITIS: BASELINE AND TWELVE MONTH AUDIT DATA FROM THE UK BRISTOL AND BATH MULTIDISCIPLINARY MEETING.

C. N. R. Jayatilleke[1], A. Anilkumar[1], S. Janagan[1], R. W. Marshall[1], S. Skeoch[2], C. Guly[3], F. E. Sin[4], K. Austin[2], L. Al-Sweedan[5], A. Bourn[5], L. Clarke[4], H. Gunawardena[4], B. Boyce[6], S. Knights[5], J. D. Pauling[2], E. Reilly[1], T. D. Reynolds[1], S. Villar[4], J. C. Robson[1,7]. *[1]University Hospitals Bristol and Weston NHS Foundation Trust, Rheumatology, Bristol, United Kingdom; [2]Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom; [3]Bristol Eye Hospital, University Hospitals Bristol and Weston NHS Foundation Trust, Ophthalmology, Bristol, United Kingdom; [4]North Bristol NHS Trust, Rheumatology, Bristol, United Kingdom; [5]Yeovil District Hospital NHS Trust, Rheumatology, Yeovil, United Kingdom; [6]Hereford County Hospital, Wye Valley NHS Trust, Rheumatology, Hereford, United Kingdom; [7]University of the West of England (UWE Bristol), Faculty of Health and Applied Sciences, Bristol, United Kingdom*

Background: Giant Cell Arteritis (GCA) is a systemic vasculitis involving large and medium-sized blood vessels. Treatment is with high dose glucocorticoids. Steroid-sparing agents and Tocilizumab (TCZ) are used for refractory or relapsing cases. NHS England requires all GCA patients to be discussed in a regional multidisciplinary team meeting (MDT) prior to commencing TCZ. TCZ has only been permitted for a maximum of one year; this time limitation was extended during the Covid-19 pandemic (1). The monthly virtual Bristol and Bath regional MDT started in November 2018.
Objectives: We aimed to review: 1) Baseline data on all patients referred to the Bristol and Bath TCZ for GCA MDT, including demographics, clinical presentation and previous steroid-sparing agents used and 2) 12 month follow up data including number of completions, adverse effects, and flares on treatment.
Methods: The TCZ MDT referral proforma, adapted from the NHS England Blueteq approval form, was reviewed for all patients referred. 12 month follow up data was obtained from clinic letters.
Results: *Baseline data*
Thirty-eight cases were referred between November 2018 and September 2021. Of these, 31 were approved for TCZ usage; 100% fulfilled the criteria for either refractory (n=11) or relapsing (n=20) disease. Mean age was 74 years and 74.2% were female. Average disease duration was 161.5 days for the refractory and 827.3 days for the relapsing group.
77.4% had cranial GCA, 48.4% had large vessel involvement, 45.2% had visual symptoms and 25.8% had ischaemic visual loss. The positive investigations were PET-CT (48.4%), temporal artery ultrasound (41.9%) and temporal artery biopsy (32.3%).
64.5% had trialled a steroid-sparing agent at time of referral (61.3 % methotrexate, 9.7% azathioprine, 6.5% leflunomide), 35.5% had received intravenous methylprednisolone and 58% were receiving greater than 40mg prednisolone at the time of referral.
Glucocorticoid adverse effects of osteoporosis, weight gain, cataracts and hypertension were each seen in 19.4%; whilst diabetes, neuropsychiatric symptoms and sleep disturbance were each reported in 16.1%.
Those with ocular involvement tended to be referred earlier than those without (478.2 days vs 648.1 days), were referred on higher doses of glucocorticoids (71.4% vs 47.1% on ≥ 40mg) and had less steroid-sparing agents prior to referral.
Follow up data
In December 2021, a follow-up audit revealed 14/31 patients had completed at least 12 months of tocilizumab; 5 of these had had an extension under Covid-19 exceptional guidance (mean duration of 5.2 months). Of the remaining 17: 3 patients had stopped early (1 death, 1 moved away, 1 due to adverse effects of headache and gastro-intestinal side effects), 4 had not started tocilizumab and 10 had not completed 12 months of treatment at that point.
Adverse events in the 14 patients at 12 months included: liver abnormalities (2/14; 14.3%), neutropenia (2/14; 14.3%), thrombocytopaenia (1/14; 7.1%), soft tissue

infections (3/14; 21.4%), urinary tract infection (1/14; 7.1%) and lipid derangement (4/14 28.6%). One case of GCA relapse occurred on TCZ (mild headache and raised inflammatory markers settled on small increase in prednisolone). After 12 months, mean prednisolone dose was 3mg (range 0-15mg).

Conclusion: All patients approved for Tocilizumab in the GCA MDT fulfilled NHS England criteria for either relapsing or refractory disease. The majority of cases had cranial disease, but almost half had either ocular or large vessel involvement, reflecting a severe spectrum of disease. Cases showed a high burden of glucocorticoid toxicity. Follow up data suggests that TCZ was effective in allowing glucocorticoid weaning and disease control, but with some adverse effects. Future work to follow up patients after stopping Tocilizumab would be informative, as the twelve month limitation on treatment is likely to be re-instated.

AB0590 GREATER STEROID-SPARING EFFECT OF TOCILIZUMAB THAN METHOTREXATE: A REAL-LIFE MONOCENTRIC EXPERIENCE

E. Treppo[1], M. Isola[2], M. De Martino[2], G. Del Frate[1], M. Binutti[1], S. De Vita[1], L. Quartuccio3. *[1]Rheumatology Division, Department of Medicine, University of Udine, Udine, Italy; [2]Institute of Statistics, Department of Medicine, University of Udine, Udine, Italy; [1]Rheumatology Division, Department of Medicine, University of Udine, Udine, Italy*

Background: Glucocorticoids (GCs) are still the mainstay of treatment of Giant Cell Arteritis (GCA), while Tocilizumab (TCZ) has been licensed as the first biologic treatment for GCA. Although GCs are highly effective in GCA, it is well documented the high burden of toxicity of GCs as well as the disease relapse during GC tapering. Therefore, patients with GCA may benefit from GC-sparing treatments[1].

Objectives: The aim is to compare the efficacy as steroid-sparing agents of Tocilizumab (TCZ) or Methotrexate (MTX) in GCA.

Methods: A single-center retrospective study included 39 patients with newly diagnosed GCA confirmed by temporal artery biopsy, temporal artery ultrasound, or TC-PET. Patients were collected from December 2010 to December 2020. The inclusion criterion was the initiation of treatment with MTX or TCZ as GC-sparing agent within the first year of disease, whereas the exclusion criterion was previous treatment with other immunosuppressive agents.

Results: 11 patients received TCZ (162mg/week), while 28 patients MTX (up to 20mg/week) as a GC-sparing agent. Baseline characteristics were reported in Table 1.

Table 1. Baseline characteristics of 39 newly diagnosed GCA patients.

Median (IQR) or n (%)	TCZ (n=11)	MTX (n=28)	All (n=39)	P value
Age, years	66 (57-77)	72 (66-76)	71 (65-76)	0.125

TAB positive	6 (54.5)	13 (46.4)	19 (48.7)	1.000
Halo sign positive	5 (45.5)	6 (21.4)	11 (28.2)	0.234
TC-PET positive	6 (54.5)	12 (42.9)	18 (46.2)	0.676
Comorbidities*	5 (45.5)	15 (53.6)	20 (51.3)	0.648

*Presence of at least one among diabetes mellitus, hypertension, ischaemic heart disease, obesity, or osteoporosis.

The follow-up time between groups was 20 (IQR 18.5-24.5) months *vs* 36 (IQR 24-60.5) months, respectively. At the last medical examination, all patients were in sustained remission, 6/11 (54.5%) and 17/28 (60.7%) had discontinued GCs. The prednisone equivalent dosage of 5 mg/day was achieved at 5 (IQR 2.75-5.5) and 7 (IQR 5-10) months (p-value 0.078), respectively, while discontinuation of GCs was achieved at 7.5 (IQR 6.25-11) and 19 (IQR 14-24) months (**p-value 0.015**), respectively. No differences were observed as concerns GC-related adverse events at 1 year after the onset of GCA (1 event in 11 patients [9.1%] vs 3 events in 28 patients [10.7%]). In details, GC-related adverse events were development of diabetes (2/4), hypertension (1/4), or osteoporosis (1/4). Two patients in the first group (18.2%) and 9 in the second one (32.1%) experienced at least one relapse (median time to relapse was 6.5 [IQR 5.75-7.25] and 18 [IQR 12-24] months). Relapses required the association of MTX with TCZ (1/11 [9.1%]) or start of TCZ (1/11 [9.1%] in the former group, while they required an increase in steroid dosage (7/11 [63.6%]), switch from MTX to TCZ (1/11 [9.1%]), or reinstatement of MTX therapy after its discontinuation (1/11 [9.1%]) in the latter.

Overall, both drugs were well tolerated. 1/11 (9.1%) and 5/28 (17.9%) had discontinued TCZ and MTX, respectively, due to mild and reversible drug-related adverse events (4/6 general malaise or discomfort, 1/6 gastrointestinal symptoms, or 1/6 abnormal liver function tests). No serious infections were observed.

Conclusion: TCZ showed a faster steroid-sparing effect than MTX. Both immunosuppressants are safe, effective and allow the discontinuation of GCs.

AB0591 ANALYSIS OF THE CLINICAL DIFFERENCES BETWEEN THE SUBTYPES OF GIANT CELL ARTERITIS.

M. D. C. Uyaguari Morocho[1], E. Fernández-Fernández[1], A. Ginon[2], I. Monjo[1], E. de Miguel[1]. *[1]La Paz University Hospital, Rheumatology, Madrid, Spain; [2]Autónoma University of Madrid, Medical Student, Madrid, Spain*

Background: Giant cell arteritis GCA is the most frequent vasculitis over the age of 50. Nowadays, it is known that there are several subtypes of GCA depending on the vessels that are involved: cranial, extracranial and mixed. However, the clinical manifestations that differentiate these three subtypes have not been extensively examined until now. In the future, it is likely that the differential characteristics in the expression of the disease will be relevant in the prognosis and the follow up of these patients.

Objectives: The objective of the study is to investigate the clinical differences associated with these different patterns of GCA involvement.

Methods: This is a retrospective study of new consecutive patients diagnosed with GCA in our hospital for three years. All patients underwent color Doppler ultrasound of both cranial (superficial temporal arteries in the common superficial temporal artery and their frontal and parietal branches) and extracranial arteries (axillary, subclavian and carotid arteries) were explored. The ultrasound diagnosis was made according to the OMERACT definitions of the halo sign and a cut-off the intima media thickness of ≥0.34 mm for the branches of the temporal arteries ≥0.42 in the common superficial temporal artery and ≥ 1 mm for the axillary, subclavian, and carotid arteries was established. The clinical records of the patients were reviewed and their demographic, clinical and laboratory data were compared between the different patterns of ultrasound involvement of GCA. A $p < 0.05$ was established as the limit of statistical significance. The EULAR recommendations of 2019[1] were used to establish the definitions of remission and relapse. The statistical analysis was performed using SPSS version 25.

Results: A total of 74 patients were included, 44(58.7%) women with a mean age of 78.6±8.6 years. Regarding the GCA subtypes, 18 (24.3%) patients had exclusive involvement of cranial giant cell arteritis CGCA, 12 (16.2%) patients had isolated involvement of extracranial giant cell arteritis LVGCA and 44 (59.5%) patients had mixed forms with cranial and extracranial MGCA. The characteristics of the population and of the GCA subtypes are shown in Table 1.

The analysis of the results showed that patients with LVGCA are younger, have less ischemic symptoms and have lower ESR than patients with CGCA $p<0.05$. Cranial involvement was associated with more ischemic symtoms than GCA with large vessel involvement, even in the mixed forms in which the cranial vessels are involved $p<0.05$. Additionally, we observed a trend towards a higher percentage of present greater constitutional syndrome in the LVGCA group. The main limitation of the study is its low sample size when analyzing the subgroups, which does not allow confirming some of the trends observed in Table 1.

Conclusion: There are significant clinical phenotypic differences in the presentation of the different subtypes of vascular involvement in GCA.

Table 1. Clinical characteristics and GCA subtypes.

Clinical characteristics	Total GCA = 74	CGCA = 18	LVGCA = 12	MGCA = 44	CGCA vs. MGCA p	CGCA vs LVGCA p	LVGCA vs MGCA P

Background: Patients with giant cell arteritis (GCA) have heterogeneity in terms of not only symptoms and findings but also extent of arterial involvement. In era of personalized medicine, therapy of patients is based on these diverse parameters.
Objectives: This study is aimed to identify subphenotypes of GCA, treatments have been used and outcomes in a prospective database of Eastern Mediterranean Vasculitis Centre.
Methods: Among 2454 patients recorded into Hacettepe University Vasculitis Research Centre database since October 2014; 181 of them were Takayasu's arteritis and 89 of them GCA. 17 GCA patients were excluded due to missing data. Patients were grouped as Cranial GCA, Cranial GCA+ PMR, Cranial and LV GCA + PMR, Cranial and LV GCA, and LV GCA.
Demographic and clinical findings, histopathological and imaging data as well as outcome was collated for each subphenotype.
Results: Of 72 patients enrolled into further analysis, a female predominance (72.2%) was observed with mean age at diagnosis of 68.3(±8.2) years. Seventy-four percent of patients had cranial GCA (Figure 1) and leading subphenotype of all patients was only cranial GCA. Usage of temporal artery biopsy (TAB), temporal artery and axillary artery ultrasonography, and imaging modalities were different according to phenotypes of GCA.

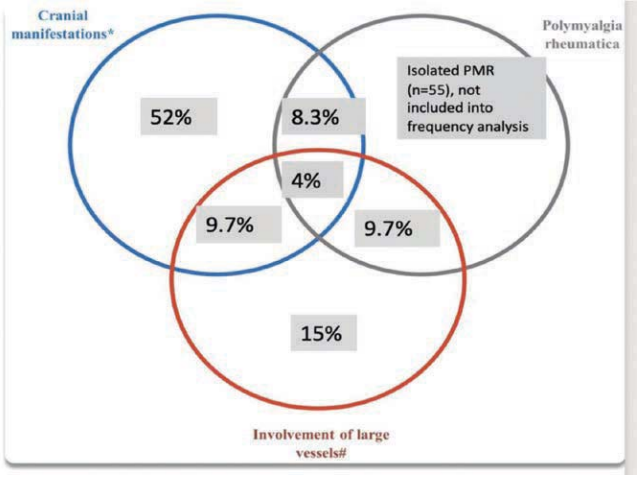

Figure 1. Distribution of GCA subphenotypes

Of the 38 patients having TAB, 20(42.9%) were consisted with GCA. The main histopathological finding were inflammation rich in lymphohistiocytic cells in the temporal artery (44.7%) and fragmentation and loss of integrity of the internal elastic lamina (36.8%).
All of the patients have been used corticosteroids with a median starting dose of 16 mg/day(8-64) had used pulse therapy. Any of conventional DMARDS (AZA, MTX, LEF, CYC) have been used in 60 of patients. In all cases, Tocilizumab was recommended after resistant/intolerant to conventional DMARDs (n=6).
Follow-up data was based on 64 patients. During a median 5,8 (±4.0) years follow-up, 6 (9.3%) patients deceased. Thirteen (20.3%) had one and more relapses, 8(61.5%) from isolated GCA group and 4(30.7%) from Only LV GCA group.
Conclusion: GCA is less frequent than TAK in our centre. Female predominance and a seventh decade of disease onset was observed in our cohort. Heterogeneity of disease was observed in or cohort along with different frequently used diagnostic confirmatory modality among subphenotypes. Relapse rate was 20 percent during a 6-year follow up with a 83% additional DMARD usage.

Background: Temporal arteritis is the most common systemic vasculitis in patients aged >50 years, the most serious complications of which is visual loss. The arterial biopsy is the diagnostic gold standard; alongside the classic finding of transmural infiltrate and giant cells, other abnormalities have been described, of which it is not yet known whether they identify specific clinical subsets. PET is not yet used for diagnosis, but it can be suggestive in patients with high clinical suspect; it may be useful for assessing the extention of the disease in already diagnosed patients and for ruling out alternative diagnoses as infections and neoplasms. More recently, PET has been used to assess disease metabolic activity

Objectives: The aim of our study is to evaluate, in patients with histologically confirmed temporal arteritis, correlations between pathological subsets, metabolic activity and different clinical behavior.

Methods: We have recovered the medical records of patients with the diagnosis of temporal arteritis made in our Rheumatology service from January 2007 until now. We selected those satisfying the ACR 1990 criteria and, finally, those with a positive biopsy. We analyzed age at onset of symptoms, diagnostic delay, presence of PMR, fever, constitutional symptoms, headache, temporal artery induration, visual loss; we analyzed CRP, ESR, plasmatic Hb, PLT count, hypocomplementemia, ANA, aCL, ANCA. The referring pathologist, who didn't know the history of patients, re-examined all the biopsies performed, focusing on: transmural, periadventitial, limited to small vessels or vasa vasorum infiltrate, presence of giant cells, macrophages, eosinophils, neutrophils, lymphocytes, plasmacells, stenosis, thrombosis, fibrinoid necrosis. The nuclear doctor retrieved the PET images by re-assigning each patient the relative PET VAS score. Descriptive analysis was performed: absolute and percentage frequencies were calculated for categorical variables and mean, standard deviation, range and percentiles for quantitative variables. The relationship between variables was tested by the chi-square test and the Mann-Whitney rank test. All analyzes were performed with the STATA software 14.2.

Results: We analyzed 46 patients (F 32, M 14), average age at onset of symptoms of 75.5 yrs and average diagnostic delay of 3.2 months. Headache was reported by 37 patients, fever and asthenia by 26 and 24 respectively, jaw claudication and PMR by 18 and 7. 11 patients had visual loss while 4 and 2 respectively reported amaurosis and diplopia. Temporal artery induration was described in 24 patients. Tests of systemic inflammation were abnormal (mean CRP 85 mg/L, ESR 72.7 mm /1h); the finding of hypocomplementemia (1/26 patients), ANA, aCL and ANCA positivity (2/31, 1/27 and 1/25) was negligible. Histological analysis showed the prevalence of transmural infiltrate (100% of patients), giant cells (87%) and lymphocytes/macrophages (85% both); small vessel vasculitis (59%) and the presence of plasma cells (53%), neutrophils (48%) and eosinophils (22%) were less represented. Periadventitial infiltrate was described in 29% of patients, with negligibility of vasculitis limited to the adventitia and of the vasa vasorum (2 and 0/46). Intimal hyperplasia and necrosis (22 and 14/46) prevailed over calcifications, stenosis and thrombosis (7-5-1/46). PET was available in 14 patients including 6 positive (43%), with a median PET VAS score of 7 (range 6-21); 8/13 patients had not taken steroids prior to PET.

Conclusion: In our retrospective study we observed, in addition to transmural infiltrate and giant cells, the presence of lymphocytes, macrophages and small vessel vasculitis. No correlation was observed between clinical findings, biological and metabolic activity, apart from the increased presence of giant cells in PET positive patients. Visual loss is slightly more common in PET negative patients. This may be due to severity of the cases which needed early steroid treatment.

AB0594 ULTRASOUND INTIMA MEDIA THICKNESS CUT-OFF VALUES FOR CRANIAL AND EXTRACRANIAL ARTERIES IN PATIENTS WITH GIANT CELL ARTERITIS

K. López Gloria[1], P. Rodríguez-Merlos[1], B. Serrano-Benavente[1], J. C. Nieto González[1], C. Gonzalez[1], I. Monteagudo Sáez[1], T. González[1], I. Castrejon[1], J. M. Alvaro-Gracia[1], J. Molina Collada[1]. [1]*Hospital Universitario Gregorio Marañón, Rheumatology, Madrid, Spain*

Background: Ultrasound (US) is a valid imaging tool to detect signs of giant cell arteritis (GCA). Although the halo sign has always been considered the most useful finding for GCA diagnosis, modern high frequency transducers are able to precisely measure the intima-media thickness (IMT) of cranial and extracranial arteries. However, data on optimal cut-off values for IMT to differentiate patients and controls in clinical practice are limited.

Objectives: To determine the optimal cut-off value for IMT of cranial and extracranial arteries in patients with suspected GCA.

Methods: This is a retrospective observational study of patients referred to our US fast-track clinic with suspected GCA. All patients underwent bilateral US examination of the cranial and extracranial (carotid, subclavian and axillary) arteries within 24 hours per protocol. The exam was performed using an Esaote-MyLab8 with a 12-18 MHz frequency transducer for cranial arteries and an 8-14 frequency transducer for extracranial arteries. The IMT was measured in gray scale mode and the presence of a non-compressible halo sign was checked in all arteries. The gold standard for GCA diagnosis was clinical confirmation by the referring rheumatologist after 6 months follow-up. Mean IMT values of each artery were compared between patients with and without GCA by independent samples T-test. Receiver operating characteristics analysis was performed and the Youden index was used to determine the optimal cut-off value for IMT of each artery.

Results: Of the 157 patients with suspected GCA (67.5% female, mean age 73.7 years) referred to the fast-track clinic, 47 (29.9%) had GCA clinical confirmation after 6 months. 41 (87.2%) patients with GCA had positive US findings (61.7% had cranial involvement, 44.7% extracranial involvement and 19.1% a mixed pattern of cranial and extracranial arteries). The following IMT cut-off values showed the highest diagnostic accuracy: 0.44mm for the common superficial temporal artery; 0.34 mm for the frontal branch; 0.36 mm for the parietal branch; 1.1 mm for the carotid artery: 1 mm for the subclavian and axillary arteries. The area under the ROC curve of the IMT for a clinical diagnosis of GCA was 0.984 (95% CI 0.959 - 1) for common superficial temporal artery, 0.989 (95% CI 0.976 -1) for frontal branch, 0.991 (95% CI 0.980 - 1) for parietal branch, 0.977 (95% CI 0.961 – 0.993) for carotid, 0.99 (95% CI 0.979 - 1) for subclavian and 0.996 (95% CI 0.991 -1) for axillary arteries (Table 1).

Table 1. Optimal IMT cut-off values for cranial and extracranial arteries

Artery	Side	Patients without GCA	Patients with GCA	Cut-off (mm)	AUC (CI 95%)	Sensitivity (%)	Specificity (%)
Common superficial	Right	0.33 (0.06)	0.68 (0.28)	0.43	0.997 (0.988 -1)	100	97.1
temporal artery mm, mean (SD)	Left	0.35 (0.11)	0.57 (0.21)	0.45	0.966 (0.905 -1)	100	92.3
	Both	0.34 (0.08)	0.63 (0.25)	0.44	0.984 (0.959 -1)	94.7	95.1
Frontal branch mm, mean (SD)	Right	0.26 (0.05)	0.4 (0.18)	0.34	0.994 (0.983 -1)	100	97.1
	Left	0.27 (0.05)	0.4 (0.18)	0.34	0.985 (0.962 -1)	100	96.1
	Both	0.26 (0.05)	0.4 (0.18)	0.34	0.989 (0.976 -1)	100	96.6
Parietal branch mm, mean (SD)	Right	0.27 (0.05)	0.43 (0.18)	0.36	0.994 (0.981 -1)	100	98.9
	Left	0.27 (0.05)	0.41 (0.16)	0.36	0.987 (0.967 -1)	100	97.6
	Both	0.27 (0.05)	0.42 (0.17)	0.36	0.991 (0.980 -1)	100	98.3
Carotid mm, mean (SD)	Right	0.8 (0.17)	0.88 (0.29)	1	0.974 (0.949 – 0.999)	100	92.6
	Left	0.82 (0.15)	1 (0.42)	1.2	0.982 (0.961 - 1)	90.9	96.2
	Both	0.81 (0.16)	0.96 (0.36)	1.1	0.977 (0.961 – 0.993)	90	94
Subclavian mm, mean (SD)	Right	0.74 (0.18)	0.99 (0.44)	1	0.987 (0.97 - 1)	100	93.4
	Left	0.67 (0.17)	0.9 (0.35)	1.1	0.991 (0.975 - 1)	100	98.3
	Both	0.7 (0.18)	0.94 (0.4)	1	0.99 (0.979 - 1)	100	96
Axillary mm, mean (SD)	Right	0.69 (0.16)	0.99 (0.5)	1	0.992 (0.982 - 1)	100	96
	Left	0.67 (0.17)	0.99(0.49)	1	0.998 (0.995 -1)	100	98.3
	Both	0.68 (0.17)	0.99 (0.49)	1	0.996 (0.991 -1)	100	97.1

Conclusion: Different IMT cut-off values for each artery are necessary to establish a correct US diagnosis of GCA. These proposed IMT cut-off values may help to improve the diagnostic accuracy of US in clinical practice.

AB0595 INFANTILE TAKAYASU: CLINICAL FEATURES AND LONG TERM OUTCOME

A. Miller Barmak[1,2], F. Sztajnbok[3], S. Özen[4], Z. Balik[4], A. Borzutzky[5], L. Fogel[6], O. Goldzweig[7], Y. Butbul[1,8,9]. *[1]Rambam Medical Center, Pediatrics B, Haifa, Israel; [2]Rambam Medical Center, Rheumatology Unit, Haifa, Israel; [3]Federal University of Rio de Janeiro, Pediatric Rheumatology Unit, Rio de Janeiro, Brazil; [4]Hacettepe University, Pediatric Rheumatology, Ankara, Turkey; [5]Pontifical Catholic University of Chile, Department of Pediatric Infectious Diseases and Immunology,, Santiago, Chile; [6]Washington university in St. Louis, Pediatrics, St. Louis, United States of America; [7]Kaplan Medical Center, Pediatric Rheumatology Unit, Rehovot, Israel; [8]Rambam Medical Center, Pediatric Rheumatology Unit, Haifa, Israel; [9]Technion - Israel Institute of Technolog, The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel*

Background: Takayasu arteritis (TA) is a large vessel vasculitis rarely reported in children, and its incidence is extremely low in infants. Most articles on pediatric TA have not focused on infants. We present the largest case series of infantile TA aiming to characterize demographic and clinical data and compare it with existing data on older children.
Objectives: Characterize demographic and clinical data reagrding TA and compare it with existing data on older children
Methods: We conducted an international multi-center retrospective cohort study. Epidemiological and clinical data were collected from patient charts by doctors from six centers.
Results: Twelve patients (50% female) meeting the ACR criteria of TA were included. Median age of symptom onset was 11 months, with a diagnostic delay of 4 months and median time of follow up of 7.5 years. The most common symptoms at presentation were hypertension, BP difference between upper and lower limbs, and fever. The arteries most commonly involved at diagnosis were the abdominal aorta, renal artery, and superior mesenteric artery. Different medications used included steroids, conventional and biological DMARDS, and other immunosuppressive therapies. Half of the patients received biologic agents of which infliximab had the highest complete remission rate (40%). Other medications resulting in complete remission were cyclophosphamide (40%) and methothrexate (38%). Invasive procedures were needed in 58% of patients. The most common complications were cardiac (50%), strokes (42%) and serious infections (33%). None of the patients died.
Conclusion: This study presents the largest series of infantile TA. Compared to reported series on older children, infants with TA were more likely to receive biologic agents, develop complications and require invasive interventions.

AB0596 AORTIC MANIFESTATIONS IN GIANT CELL ARTERITIS: SINGLE CENTRE 10-YEAR EXPERIENCE

F. Coath[1], A. Sharma[2], R. Ershad[2], J. Mo[3], J. Davies[2], B. Dasgupta[1]. *[1]Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom; [2]Southend University Hospital, Mid and South Essex NHS Foundation Trust, Cardiology, Southend-on-Sea, United Kingdom; [3]Southend University Hospital, Mid and South Essex NHS Foundation Trust, Radiology, Southend-on-Sea, United Kingdom*

Background: Disease stratification in GCA is an urgent need, with patients categorised into cranial and large-vessel GCA (LV-GCA) subgroups. LV-GCA may have worse outcomes with regards relapsing disease, poor response to glucocorticoids (GC) and aortic involvement.
Objectives: We report a single centre experience using clinical, imaging and treatment outcomes from a specialist clinic.
Methods: 134 patients with LV-GCA were identified over a 10-year period at Southend University Hospital (2012-2022). Medical records were reviewed retrospectively for baseline demographics, clinical presentation, inflammatory markers, imaging (vascular ultrasound, PET-CT, echocardiography), vascular damage and treatment.
Results: There was a female predominance (female n=91). Age at presentation ranged from 46 to 86 years (median 70 years). Co-morbidities implicated in aortic disease included hypertension (n=60), hypercholestrolaemia (n=29), diabetes (n=14), aortic valvular disease (n=5) and atherosclerotic disease including coronary and carotid artery disease (n=19). Constitutional disturbance was most frequently observed presentation (70%, n=94), and the only feature for 11 patients. This was followed by cranial symptoms (62%, n=83), polymyalgia (53%, n=71), ischaemic symptoms i.e., visual disturbance or tongue/jaw claudication (24%, n=32) and cardiovascular presentations (7%, n=9). The latter included limb claudication, stroke, and aortic aneurysm. Although LV-GCA refers to extra-cranial disease, 12 patients (9%) had isolated cranial and/or ischaemic symptoms at initial presentation.
Inflammatory markers were typically elevated at presentation, C-reactive protein ranged from 1-425mg/L and ESR 1-130mm. Vascular ultrasound was used at diagnosis in 93 patients, with positive temporal artery findings in 50% (n=38) and positive axillary findings in 75% (n=57). PET-CT data was available for 125 patients, of which 113 were positive for LV-GCA. Thoracic aorta FDG-uptake was seen in 77%, with 7 ascending and 1 abdominal aortic aneurysm observed. Transthoracic echocardiogram was available for 46% (n=62). Four (6.5%) patients had a dilated aortic root when indexed to height as per British Society of Echocardiography (BSE) guidelines[1] (SOV (mm/m) > 21.8mm in males and > 20.7mm in females). Values for our patients were 22.6 and 21.2 mm/m for the female patients and 29.2 and 25.2 mm/m for the male patients. Furthermore, 32 patients showed some extent of diastolic dysfunction as per BSE criteria (52%).
All patients received GC as part of their treatment, 60% (n=82) needing one or more DMARDs and 17% (n=23) Tocilizumab for relapsing disease. DMARDs used included Leflunomide (n=63), Methotrexate (n=18), Mycophenolate mofetil (n=3) and Azathioprine (n=1). One patient received cyclophosphamide.
Conclusion: By combined imaging modalities, 11 patients (8%) had evidence of ascending aortic damage. Grade 1 diastolic dysfunction can be age related, so this may be association rather than causation[2,3]. Over half of patients had not undergone echocardiogram evaluation, so there may be a hidden burden of disease. Many patients required GC-sparing therapy, showing GC alone are often not enough to halt disease progression, and vascular damage was relatively reduced compared to historical reports. The authors feel GCA services should include standardised protocols for early DMARDs, continuing thorough assessment for LV-GCA and vascular damage, including echocardiography, progressing to cross-sectional imaging if indicated.

AB0597 FDG-PET/CT IN THE DIAGNOSE AND FOLLOW UP OF TAKAYASU VASCULITIS

B. Gudbrandsson[1], Ø. Palm[2], Ø. Molberg[2], H. Giltvedt[3], M. Revheim[4]. *[1]Oslo University Hospital, Rheumatology, Oslo, Norway; [2]Rikshospitalet, Rheumatology, Oslo, Norway; [3]Oslo University Hospital, Division of Radiology and Nuclear Medicine, Oslo, Norway; [4]Rikshospitalet, Division of Radiology and Nuclear Medicine, Oslo, Norway*

Background: Takayasu vasculitis (TAK) is a chronic disease, where clinic and serological markers as CRP/ESR may fail to predict development of new vascular lesions in the disease course (1). Similarly, ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) studies show conflicting results on the association between vessel uptake of FDG and clinical and laboratory finding. A study on new FDG-PET activity scoring system, PETVAS was newly published but has not been validated in other cohorts (2). To date there are limited data on FDG-PET/CT finding at time of diagnoses before treatment induction and 18-FDG uptake and development of new stenosis during follow up.
Objectives: The goal of this study was to see; 1) FDG-PET/CT uptake in newly diagnosed patients before any treatment start 2) FDG-PET/CT uptake and development of new vascular lesions during follow up magnetic resonance angiography (MRA) 3) assess PETVAS score before and after treatment induction.
Methods: All patients in a population-based TAK cohort with FDG-PET/CT at the time of diagnoses before treatment induction were identified. Disease activity was assessed with the NIH activity score (1). Patients had to have clinical, laboratory and MR-angiography prior to/or right after FDG-PET/CT and a minimum of one follow up MRA. The clinical report from the FDG-PET/CT and MRA were reviewed and arteries/aorta regions with reported pathological uptake and stenosis/aneurysm were registrated. Images were reviewed and uptakes in 16 arteries/aorta regions of interest (supraaortic arteries, aorta, iliaca and femoral arteries) scored from 0-3, where 0 represent no uptake, 1 less then liver, 2 same as liver and 3 higher than liver and finally summarized these to PETVAS score.

Results: Twenty-three patients fulfilled the study's inclusion criteria. Twenty-one of the patients were females (91%) and twenty-two were European Caucasian. The mean age was 39.3 (SD 14) at the time of diagnose (Table 1). Five patients were in clinical and laboratory remission at diagnose (NIH=0). Correspondently, none of them had sign of active FDG vessel uptake at PET-CT. They had a median 7 in PETVAS (range 0-13). The remaining 17 patients had clinical active disease (NIH>1) at diagnoses. All 17 patients had uptake on PET/CT in at least one artery/aorta region. The mean PETVAS score at diagnosis was 21.5 (SD 8). At last imaging the patients had developed median 2 new lesions. All the arteries that developed new lesion had active uptake on the original PET/CT. Fourteen patients had FDG PET/CT after treatment start. The PETVAS score decreased from 22.4 (SD 8.7) to 10.7 (SD 6.8) after treatment start (p<0.001).

Table 1.

Patient	Age at pet 1	NIH 0-4	Crp	PETVAS1	PETVAS 2	Treatment at PET2

15	63	4	106	35	16	predn 10 mg, mtx 20
16	22	4	120	20		
17	27	4	263	21		

Conclusion: All patients with clinical active disease at diagnoses had pathological FDG uptake. Only arteries with increased FDG uptake in the vascular wall subsequently developed new lesion. The study also showed that the PETVAS score fell significantly after treatment induction.

ASSOCIATION OF PROLONGED DISEASE DURATION AND TG/HDL-C RATIO IN ACCELERATING ATHEROSCLEROSIS IN PATIENTS WITH TAKAYASU'S ARTERITIS

J. Du[1], L. Pan[2]. *[1]Beijing An Zhen Hospital, Affiliated of Capital University of Medical Sciences, Rheumatology and Immumology, Beijing, China; [2]Beijing An Zhen Hospital, Affiliated of Capital University of Medical Sciences, Rheumatology and Immumology, Beijing, China*

Background: Takayasu's arteritis (TA) is an autoimmune vasculitis that frequently occur in young women.Multiple previous studies have demonstrated that accelerated atherosclerotic changes were commonly found in TA patients[1-4]. More specifically, data indicated that as much as 27% of all TA patients developed carotid artery plaque, while which was only 2% in the age- and sex-matched healthy individuals[1]. In addition, up to 20% of TA patients developed stroke and/or transient ischemic attack(TIA), which both have been known to be associated with atherosclerotic lesions[1-3]. Inflammation of the vascular wall may promotes atherosclerosis (As) in TA,which accelerates the development of As.Higher triglyceride (TG)/HDL-C ratio was found to be associated with presence of endothelial dysfunction and As[5].

Objectives: This study aimed to identify the risk factors associated with the development of atherosclerosis in TA.

Methods: This retrospective study enrolled a total of 101 TA patients. All patients were divided into two groups according to the absence or presence of atherosclerosis(43 vs 58). Baseline demographic features and clinical characteristics were compared between two groups. A logistic model was applied to determine the risk factors associated with the development of atherosclerosis.

Results: Our data suggested that the disease duration of patients in the atherosclerosis group was significantly longer than that of patients in the non-atherosclerosis group [96(18.00,180.00) vs 48.00(12.00,111.00) months] (p=0.015). In addition, the average age of patients with atherosclerosis was significantly older compared to patients without atherosclerosis [44.00 (38.00 , 48.00) vs 28.50 (24.00 , 37.00) years] (p<0.001). Logistic regression analysis showed that the risk of developing atherosclerosis increased by 9.2% per 1 year increase in thedisease duration(p=0.005, OR 1.092,95%CI:1.027-1.162).Patients with TG/HDL-C ratio more than 0.8875 were associated with a 5.861fold increase of risk developing atherosclerosis(p<0.001, 95%CI:2.299-14.939).

Conclusion: Our study indicated that prolonged disease duration and elevated TG/HDL-C ratio are associated with the development of atherosclerosis in TA patients.

AB0599

THE VALUE OF ULTRASOUND IN GCA FOLLOW-UP: RESULTS FROM A SCOTTISH SINGLE CENTRE.

A. Melville[1], A. Ciechomska[2]. *[1]University of Glasgow, Institute of Infection, Immunity & Inflammation, Glasgow, United Kingdom; [2]University Hospital Wishaw, Rheumatology Department, Wishaw, United Kingdom*

Background: Ultrasound (USS) is important diagnostically in GCA, but its value during follow-up is unclear[1]. In our centre, ad hoc follow-up USS has been performed routinely.

Objectives: To describe how USS appearances i) changed over time (at defined timepoints), ii) correlated with clinical relapse (at any time), iii) were affected by tocilizumab.

Methods: Patients diagnosed with GCA in NHS Lanarkshire, November 2018 - October 2021, were included. Treatment was in accordance with international guidelines[2]. Follow-up visit data included clinical status (remission, stable, relapse), treatment, and (when USS performed) temporal artery (TA) and axillary artery (LV) intima media thickening (IMT) (TA+ = IMT ≥0.5MM; LV+ = IMT >1mm). Follow-up USS were compared to baseline, pre-relapse or pre-tocilizumab.

Results: 55 patients were diagnosed with GCA; mean (SD) age 73.1 (8.0) years; 31 female (56.4%). Mean (SD) follow-up was 63.8 (40.6) weeks. All patients had baseline USS [48 positive (TA+ or LV+)], 7 negative; 36 (65.5%) had ≥1 follow-up USS. 7 patients had USS at 6-12 weeks; all were clinically stable; all had positive baseline USS; at 6-12 weeks, 3/7 remained TA+, 1/7 remained LV+ (TA-LV+). 25 patients had USS at 16-36 weeks; 9/25 were in remission, 11/25 stable, 5/25 relapsing. Of remission patients, 7/9 had positive baseline USS; at 16-36 weeks, 2/7 remained TA+. Of stable patients, all had positive baseline USS; at 16-36 weeks, 4/11 remained TA+, 3/11 remained LV+. Of relapsing patients, 5/5 had positive baseline USS; at 16-36 weeks, 2/5 remained TA+, 1/5 LV remained LV+.

Table 1. Follow-up and corresponding baseline ultrasound results, at defined timepoints, grouped by clinical status.

			Baseline ultrasound				Follow-up ultrasound			
Time	Clinical status	N[a]	TA+ LV-	LV+ TA-	TA+ LV+	TA- LV-	TA+ LV-	LV+ TA-	TA+ LV+	TA- LV-
6-12 week	All stable	7	6	0	1	0	3	1	0	3
16-36 week	All	25	17	0	6	2	6	4	0	15
	Remission	9	6	0	1	2	2	0	0	7
	Stable	11	7	0	4	0	4	3	0	4
	Relapse	5	4	0	1	0	2	1	0	2
42-62 week	All	15	11	1	2	1	3	5	1	6
	Remission	8	6	0	1	1	3	0	0	5
	Stable	3	2	0	1	0	0	1	1	1
	Relapse	4	3	1	0	0	0	4	0	0

a.Number of patients scanned.

15 patients had USS at 42-62 weeks; 8/15 were in remission, 3/15 stable, 4/15 relapsing. Of remission patients, 7/8 had positive baseline USS; at 42-62 weeks, 3/7 remained TA+. Of stable patients, 3/3 had positive baseline USS; at 42-62 weeks, 1/3 was TA-LV+, 1/3 remained TA+LV+. Of relapsing patients, 4/4 had positive baseline USS (3/4 TA+, 1/4 LV+); at 42-62 weeks, all were TA-LV+. The Table 1 below provides additional detail for each timepoint. 11 patients in total had clinical relapse (any time) and contemporaneous USS; mean (SD) time to relapse was 36.6 (18.3) weeks; median (IQR) prednisolone dose 7mg (4,9). At relapse, 2/11 were TA+LV+, 6/11 LV+, 3/11 TA-LV-. Comparing relapse USS to most recent USS pre-relapse, 4/11 were newly LV+, while other positive findings were seen previously. 11 patients treated with tocilizumab had ≥1 USS post-initiation [at mean (SD) 27.1 (16.7) weeks]. 5/11 were LV+ pre-tocilizumab, 6/11 TA+. At follow-up, all were in remission or stable; 4/5 remained LV+, 4/6 remained TA+.

Conclusion: While many patients had rapid normalisation of USS changes with treatment, others remained abnormal despite stable disease or remission, including at approx. 12 months follow-up. Ad hoc follow-up scans therefore appear unreliable in isolation, but the value of systematic longitudinal scanning warrants further study. Emergence of LV positivity was seen in several cases of relapse and may characterise an evolution in disease phenotype. Positive USS findings largely persisted at approx. 6 months despite disease control on tocilizumab.

AB0600

ANALYSIS OF RISK FACTORS AND PROGNOSIS IN PATIENTS OF TAKAYASU'S ARTERITIS WITH CORONARY ARTERY LESIONS

J. Du[1], L. Pan[1]. [1]*Beijing An Zhen Hospital, Affiliated of Capital University of Medical Sciences, Rheumatology and Immunology, Beijing, China*

Background: Takayasu's arteritis (TA) can involve coronary artery lesions. The pathogenesis is complex and lacks the best treatment strategy.The coronary artery lesions were typical seen in the ostia of the left and right coronary arteries which were major risk factors for sudden death and ischemia heart failure[1-2].Coronary artery lesions is an important predictor of poor prognosis in TA patients.The incidences of coronary artery lesions were more common in type V TA patients [3-4].The prevalence of metabolic syndrome and its related characteristics (including dyslipidemia, diabetes and hyperinsulinemia) in TA patients are higher compared with healthy people[5].Thus , under the action of vascular inflammation and traditional risk factors, coronary artery stenosis or even occlusion occurs earlier, which can lead to MACE events.

Objectives: The aim of our study is to investigate the risk factors and prognosis of coronary artery lesions in TA patients.

Methods: This retrospective study enrolled a total of 120 TA patients.All patients were divided into two groups according to the absence or presence of coronary artery lesions in TA patients (61 vs 59). A logistic model was applied to determine the risk factors associated with the incidence of coronary artery lesions in TA patients.According to the before and after imaging comparison of TA with coronary artery lesions, the influencing factors of improving TA with coronary artery lesions were analyzed.

Results: The incidence of coronary artery lesions in TA patients increased by 1.618 times for each additional year (p=0.034, OR1.618,95%CI: 1.036-2.529). History of hyperlipidemia indicated 10.124 fold higher risk of coronary artery lesions in TA patients(p=0.003, OR10.124,95%CI: 2.159-47.483).In the follow-up of TA with coronary artery lesions, 27 patients had coronary CTA results before and after comparison. It was found that 11 patients had remission of coronary artery lesions and 16 patients had no remission of coronary artery lesions. The age in the group with improved coronary imaging was significantly younger than that in the group without improved coronary imaging[(39.00±9.81 vs (47.44±10.06) years,p=0.041)].TNF-α and interleukin-6 were significantly higher in the group with improved coronary imaging than in the group without improved coronary imaging[(26.40(10.08 , 165.90) vs 7.80(6.73 , 21.70)pg/dl,p=0.047;12.50(5.83 , 19.30) vs3.71(2.80 , 4.40)pg/dl,p<0.001].Numano type V (75.00% vs 27.27%, p = 0.022) and vascular calcification (56.25% vs 9.09%, p= 0.018) were significantly higher than those in the group without improved coronary imaging, while numano type IIb in the group with improved coronary imaging was significantly higher than that in the group without improved coronary imaging(45.45% vs 6.25% , p=0.027).

Conclusion: Hyperlipidemia and age are the risk factors of coronary artery lesions in Takayasu arteritis.Numano type V and vascular calcification are not conducive to the improvement of TA with coronary artery lesions.All patients with TA of numano type IIb should be screened for coronary artery. Early control of inflammation is more conducive to the imaging improvement of arteritis coronary lesions.

FACTORS ASSOCIATED WITH THROMBOSIS IN BEHÇET SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

G. Guzelant Ozkose[1], B. Yurttas[1], M. C. Ar[2], S. N. Esatoglu[1], V. Hamuryudan[1], H. Yazici[1], G. Hatemi[1]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey;* [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Hematology, Istanbul, Turkey*

Background: Behçet syndrome (BS) is a unique vasculitis that can affect arteries and veins of all sizes. Thrombosis is an important component of vascular involvement in BS. Although several studies were conducted to highlight the mechanism of thromboinflammation in BS, it is still not fully understood.
Objectives: We performed a systematic review and meta-analysis of studies investigating thrombotic, fibrinolytic, and endothelial factors in BS.
Methods: We searched PubMed and EMBASE with the keyword "Behcet*" in four languages (English, German, French and Turkish) from their inception up to April 2020. Titles and/or abstracts of all studies were screened independently by two reviewers (GGO and BY) and conflicts were solved by a third reviewer (GH). Studies comparing BS patients with and without thrombosis and studies comparing BS patients with thrombosis and patients with thrombosis due to other causes were analyzed separately. The pooled odds ratios (OR) with 95%CI were calculated for binary outcomes and standardized mean differences (MD) were calculated for continuous outcomes using RevMan 5.3. We categorized the factors into 4 groups based on acting mechanism 1- those that decrease anticoagulant activity 2- those that increase procoagulant activity 3- those that decrease the activity of fibrinolytic system 4- pathogenetic/endothelial factors.
Results: Of 15548 articles, 15157 were excluded due to duplication and inappropriate study design after reviewing titles and abstracts. Full text review of the remaining 391 articles yielded 103 papers meeting our predetermined inclusion criteria. Factors significantly associated with BS thrombosis compared to BS without thrombosis were high frequency of factor V Leiden mutation (15 studies, OR 2.55, 95%CI 1.66-3.93), high homocysteine level (14 studies, MD: 4.27, 95%CI 2.31-6.22), high protein C level (5 studies, SMD: 0.80, 95%CI 0.15-1.45) and high alpha1-antitrypsin level (1 study, MD: 3.00, 95%CI 0.15-5.85) in Group 1; high factor 8 level (4 studies, MD: 17.17, 95%CI 7.79-6.55), high thrombin level (1 study, MD: 35.90, 95%CI 12.40-59.40), high neutrophil/lymphocyte ratio (2 studies, MD: 1.37, 95%CI 0.24-2.50) and high platelet/neutrophil complex level (1 study, MD: 10.50, 95%CI 0.76-20.24) in Group 2; high TAFI activity (1 study, MD: 28, 95%CI 4.12-51.88) in Group 3; high VEGF level (2 studies, SMD: 1.63, 95%CI 0.21-3.05), high CEC concentration (2 studies, SMD: 1.00, 95%CI 0.22-1.77), high MCP-1 level (1 study, MD: 74.16, 95%CI 61.29-87.03), high anti-C1q level (1 study, MD: 9.11, 95%CI 0.51-17.71), high platelet microaggregate formation (1 study, MD: 75.00, 95%CI 7.62-142.38), high frequency of P-selectin glycoprotein ligand 1 gen polymorphism (heterozygous (AB+AC+BC)) (1 study, OR: 1.88, 95%CI 1.07-3.31), high ADMA level (1 study, MD: 0.16, 95%CI 0.08-0.24), high sICAM-1 level (1 study, MD: 59.30, 95%CI 3.35-115.25) and low brachial artery flow-mediated (endotelium-dependant) dilatation (1 study, MD: -3.22, 95%CI -5.18--1.26) in Group 4.
Factors that were associated with BS thrombosis compared to thrombosis due to other causes including JAK-2 mutation, circulating endothelial cells, activated protein C resistance, tPA, and PAI were assessed in 1 study each. Among these, tPA levels (MD: -6.00, 95%CI -10.99--1.01), APCR (OR: 0.09, 95%CI 0.01-0.73) and JAK-2 mutations (OR: 0.01, 95%CI 0.00-0.06) were significantly less in patients with BS thrombosis compared to patients with thrombosis due to other causes.
Conclusion: Several factors were identified that may potentially be associated with thrombosis in BS. However, the cut-offs used for defining the normal level for these factors, time of blood collection (during acute or chronic stage of thrombosis, use of anticoagulants) and the type of thrombosis (arterial, venous, or cerebral sinus) were not uniform across the studies. Studies investigating these factors together, in a large number of patients, and together with appropriate controls are needed to confirm these results.

TEMPORAL ARTERY BIOPSY POSITIVITY RATES VARY MORE BETWEEN SIMILAR HOSPITALS THAN BY LENGTH, WITH PARTICULAR VARIATION BETWEEN GEOGRAPHIC REGIONS

C. McMaster[1,2,3], V. Yang[1], R. Malik[4,5,6], E. Norman[7], C. Fraser[4,8], B. Sutu[9], A. Sammel[4,7,10], D. Liew[1,2,11]. [1]*Austin Health, Rheumatology, Heidelberg, Australia;* [2]*Austin Health, Clinical Pharmacology and Therapeutics, Heidelberg, Australia;* [3]*University of Melbourne, The Centre for Digital Transformation of Health, Parkville, Australia;* [4]*Sydney Eye Hospital, Sydney Eye Hospital, Sydney, Australia;* [5]*UNSW Sydney, Port Macquarie Clinical School, Sydney, Australia;* [6]*University of Newcastle, Medicine and Public Health, Callaghan, Australia;* [7]*Prince Of Wales Hospital, Rheumatology, Randwick, Australia;* [8]*Save Sight Institute, Save Sight Institute, Sydney, Australia;* [9]*The Royal Melbourne Hospital, Rheumatology, Parkville, Australia;* [10]*UNSW Sydney, Prince of Wales Clinical School, Sydney, Australia;* [11]*University of Melbourne, Medicine, Parkville, Australia*

Background: Clinical practice surrounding giant cell arteritis (GCA) diagnosis, including the use of temporal artery biopsy (TAB) where appropriate, needs to be consistently accurate to minimise both GCA-related end-organ damage and unnecessary glucocorticosteroid toxicity in all patients. Despite this imperative, the delivery of such clinical care, which can be measured by diagnostic investigation performance characteristics such as TAB positivity rates, varies substantially between different hospitals as it is traditionally reliant on unstructured clinical intuition. While clinical care practices plausibly might be more consistent between neighbouring hospitals given they frequently exchange medical staff and use common teaching sources, these factors are less likely to be applicable when comparing hospitals in different geographical regions within a country, even though educational standards, online information resources, and access to clinical care should be consistent. It therefore stands to reason that variation of diagnostic practice might be greater between geographically distant hospitals.
Objectives: To compare clinical practice surrounding GCA diagnosis, using TAB positivity rates, between similar hospitals in the same city and a geographically distant city in a different region, to understand the contribution of geographic separation to variance in practice.
Methods: TAB histopathological reports were reviewed at three tertiary referral hospital centres: two with neighbouring catchments in the same city, and one in a different city in a neighbouring geographical region in the same country. All three had similar resourcing and catchment demographics during the study period, and none used formal clinical risk stratification scores for GCA pre-test probability. Characteristics including age, sex, biopsy laterality, biopsy length, and hospital were captured, in addition to key histopathological features. Multivariable logistic regression with site-varying intercept was performed, using cubic splines for biopsy length to account for the non-linearity observed.
Results: TAB reports from 708 patients were captured between the three hospitals in two geographical regions. All three sites had a median age of 74 years, had 67-69% of patients being female, and reported median biopsy length between 1.7-2.0cm (Table 1). Despite these similarities, they reported positivity rates varying widely (16% and 24% in Region 1, 29% in Region 2). Apart from age, hospital site was the strongest contributing factor to TAB positivity, with length having little effect outside the very extreme high end and 90% of patients had a biopsy length <4.8cm (Figure 1). For these patients, hospital site differentiated TAB positivity across all biopsy lengths, with Region 2 reporting the highest TAB positivity odds ratio of 2.39 (95%CI: 1.37-4.19).

Table 1.

Characteristic	Site1Region1 N = 218	Site2Region1 N = 361	Site1Region2 N = 129
Bilateral laterality (%)	66 (30%)	105 (29%)	1 (0.8%)
Biopsy length (cm, median (IQR))	2.0 (1.4, 3.0)	1.7 (1.2, 3.5)	1.7 (1.4, 2.2)
Female sex (%)	149 (68%)	249 (69%)	86 (67%)
Age (y, median (IQR))	74 (65, 81)	74 (65, 80)	74 (68, 81)
TAB positivity (%)	34 (16%)	88 (24%)	38 (29%)

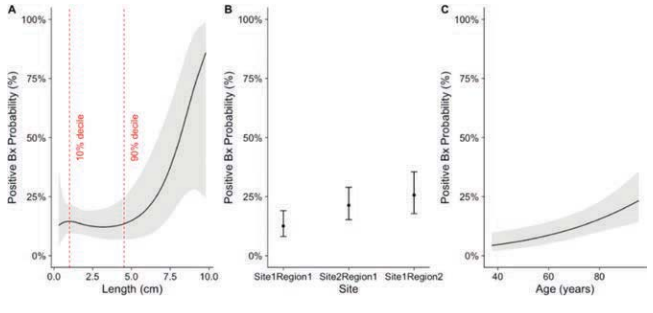

Figure 1. Marginal probabilities of positive TAB obtained from the multivariable logistic regression model (A) across biopsy lengths, with 80% of observed lengths falling between the two vertical red lines (10% and 90% deciles); (B) across hospital sites; (C) across patient age.

Conclusion: Hospital site contributes more greatly to variation in GCA diagnosis clinical practice than demographics or other clinical features do, with particular variation between geographic regions. As part of clinical care standards, using

a replicable pre-test GCA probability score[1] to select patients is likely to be as important to diagnosis as the diagnostic tool characteristics themselves.

AB0603 INCREASED INCIDENCE OF RAYNAUD'S PHENOMENON IN GIANT CELL ARTERITIS, POSSIBLY ASSOCIATED WITH LARGE VESSEL GIANT CELL ARTERITIS.

B. Slijkhuis[1], M. Sandovici[2], A. Eman Abdulle[2], K. van der Geest[2], E. Brouwer[2], D. J. Mulder[1]. *[1]University Medical Center Groningen, Internal Medicine, Groningen, Netherlands; [2]University Medical Center Groningen, Rheumatology, Groningen, Netherlands*

Background: Large Vessel Giant Cell Arteritis (LV GCA) can cause significant narrowing of the subclavian and axillary arteries, either by inflammation or remodelling, which reduces blood pressure in the arms. Also, Raynaud's phenomenon (RP) has been observed in GCA patients.

Objectives: This study aims to investigate the presence of Raynaud's phenomenon in patients with GCA.

Methods: Patients diagnosed with GCA were given a validated questionnaire (CSQ)[1] on symptoms fitting RP, divided into the different phases of RP (white, blue/purple, and red discoloration provoked by cold exposure) as not every patient exhibits all phases. In total, 30 GCA patients were enrolled in this study. Furthermore, imaging data (PET-CT, MRI, ultrasound (US), or temporal artery biopsy (TAB) of all GCA patients were evaluated.

Results: 30 GCA patients were included, with a mean age of 68,6 (±6,5) years, when diagnosed. 76,7% were female. Of the 30 GCA patients, 12 (40%) reported monophasic discoloration. Of these 12 GCA patients, 2 (6,7%) patients reported bi- or triphasic discoloration. Of the 12 GCA patients with at least monophasic discoloration, 6 patients reported a new onset RP (< 1 year of diagnosis). Imaging data of these 6 patients showed severe Large Vessel GCA (with subclavian and axillary involvement) in all of these patients, without displaying cranial GCA. Of these 6 patients, 1 was examined with US alone, 3 with PET-CT, and 2 had both US and a PET-CT. 3 patients reported that the RP complaints, disappeared during treatment of the GCA, 3 still had complaints. Interestingly all these 3 patients had stenosis of either the subclavian, the axillary artery, or both.

Conclusion: We found an increased prevalence of monophasic Raynaud's phenomenon in GCA patients that is 3,7 times higher, when compared to a local background population[2]. When looking at new onset RP in GCA, all patients were found positive for Large Vessel GCA, without cranial symptoms. The data of this study warrants a closer look at LV involvement in patients presenting with Raynaud's phenomenon and GCA or PMR like symptoms.

AB0604 INFLUENCE OF THE LOCATION AND SEVERITY OF VASCULAR INVOLVEMENT ON THE BASAL PHENOTYPIC EXPRESSION AND ON THE EVOLUTION OF GIANT CELL ARTERITIS

A. Ginon[1], M. D. C. Uyaguari Morocho[2], E. Fernández-Fernández[2], I. Monjo[2], E. de Miguel[2]. *[1]University Autonoma Madrid. Medicine Faculty, Rheumatology, Madrid, Spain; [2]Hospital Universitario La Paz, Rheumatology, Madrid, Spain*

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in adults. There is increasing evidence about clinical subtypes of the disease depending on the cranial or extracranial vessels involvement. However, how this type of affectation influences the phenotypic expression of the disease and whether there are differences between them in terms of the thickness of the vessels wall, are still aspects that remain to be clarified.

Objectives: To evaluate the association between the subtypes of GCA and the basal phenotypic expression and severity of the artery walls affectation in the disease.

Methods: This is a retrospective study of new consecutive patients diagnosed with GCA in our hospital from July 2018 to December 2020. The patients underwent Color Doppler ultrasound at the time of diagnosis of cranial arteries (superficial temporal arteries in the common superficial temporal artery and their frontal and parietal branches) and extra-cranial arteries (axillary, subclavian, and carotid arteries). The ultrasound diagnosis was made according to the OMERACT definitions of the halo sign and cut-off the intima media thickness was established as ≥0.34 mm for the branches of the temporal arteries, ≥0.42 in the common superficial temporal artery and ≥1 mm for the axillary, subclavian, and carotid arteries. The "halo score" (HScore) was calculated according to the criteria published by Van der Geest KSM et al. [1] In addition, the clinical records of the patients were reviewed and their demographic, clinical and laboratory data were compared between the different sonographic subtypes of GCA. A $p < 0.05$ limit of statistical significance was established. The Statistical analysis was performed using SPSS version 25.

Results: A total of 74 patients were included, of which 44 (58.7%) were women with a mean age of 78.6 ± 8.6 years. Analyzing the GCA subtypes: 18 (24.3%) had exclusively cranial involvement (CGCA), 12 (16.2%) patients had GCA of extra-cranial large vessels (LVGCA) and 44 (59.5%) patients had mixed forms cranial and extra-cranial (MGCA). The characteristics of the population and of each of the GCA subtypes, as well as thickening of the wall of the arteries are described in Table 1.

Table 1. Clinical characteristics of the study population.

Clinical characteristics	Total GCA = 74	CGCA = 18	LVGCA = 12	MGCA = 44	CGCA vs MGCA p	CGCA vs LVGCA p	LVGCA vs MGCA p

GCA: giant cell arteritis; CGCA: Cranial giant cell arteritis; LVGCA: Large vessel giant cell arteritis; MGCA: Mixed giant cell arteritis; SD: standard deviation; p: value p

Conclusion: The constitutional syndrome was always present in LVGCA but it is also very common in subtypes with cranial involvement. The ischemic syndrome occurs preferentially in groups with cranial vessel involvement, but not exclusively. The thickening of the arterial wall of the cranial arteries shows no difference between CGCA and MGCA; and the same occurs in the large vessels between the LVGCA and the MGCA. Serious adverse effects due to ischemia showed a similar risk regardless of whether it was CGCA or MGCA.

AB0605 **GIANT CELL ARTERITIS. PREVALENCE OF EXTRACRANIAL LARGE VESSEL VASCULITIS DIAGNOSED WITH 18-FDG POSITRON EMISSION TOMOGRAPHY.**

V. Aldasoro[1], M. J. Garcia Velloso[2], J. Á. Richter Echevarria[2]. [1]*Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain;* [2]*Clínica Universidad de Navarra, Nuclear Medicine, Pamplona, Spain*

Background: The prevalence of extracranial involvement in giant cell arteritis (GCA) is unknown although there are series that has published prevalences of 20-65% depending on the technique used (1).
Objectives: To asses the prevalence of extracranial large vessel vasculitis (LVV) in GCA diagnosed by positron emisión tomography (PET) and to describe clinical and radiological features.
Methods: Prospective and descriptive study of newly diagnosed GCA patients who underwent PET between july 2020 and october 2021. 1990 ACR criteria (2) and/or physician criteria was used to classified patients as having GCA. Clinical and radiological features were described. All patients should not be taken any other inmunosupresant drug but glucocorticoids (GCs).
Results: Fourteen consecutive patients were diagnosed as GCA. Eight patients were female with a median age of 64.4 years. All patients but one underwent temporal artery biopsy (TAB) with a positive result in 54%. PET was positive in 85.7% patients. The median dose of GCs when PET was done was 31.4 (0-45) mg/day and the median delay in PET performance was 8 days (0-22). The 2 patients with negative PET had positive TAB. Proximal thoratic aorta involvement was observed in all patients with positive PET. Late PET images were taken in 6 patients with a median dose of GCs of 43,3 mg/day and median delay of 11,3 days with positive result in all of them (Table 1).

Table 1. PET late images

PET LATE IMAGES	N=6
-SEX (female) %	66
-AGE (years)	60.1
-BAT (positive) %	40
-PET RESULT (positive) %	100
-GCs DOSE (mg)	43.3 (40-45)
-DAYS OF DELAY	11.3 (3-22)

Conclusion: Despite the high dose of GCs and the delay in PET performance, in our serie PET has diagnosed LVV in 85,7% of GCA patients. PET within 3 days after start GCs, has been usefull to diagnosed extracranial involvement in GCA (3). In our series the prevalence of extracranial involvement diagnosed by PET in GCA has been higher than others published until now (2). Further patients are needed to confirm these data.

AB0606 **HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH RITUXIMAB-INDUCED REMISSION OF ANCA-ASSOCIATED VASCULITIS: REGISTRY-BASED COHORT STUDIES**

V. Babak[1], M. Suprun[1], T. Beketova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Department of Systemic Sclerosis, Moscow, Russian Federation*

Background: Survival rate in ANCA-associated vasculitis (AAV) has significantly improved due to anti-B cell therapy with rituximab (RTX). The main issue now appears to be the management of comorbidities and the improvement of quality of life.
Objectives: Based on a prospective analysis of the single centre registry of AAV patients (pts) treated with RTX, to study the impact of sustained remission on health-related quality of life using Short-Form 36 (SF-36).
Methods: Health-related quality of life was assessed in 70 AAV pts: 35 (50%) with granulomatosis with polyangiitis (GPA), 24 (34.3%) - microscopic polyangiitis (MPA) and 11 (15,7%) - eosinophilic granulomatosis with polyangiitis (EGPA). The mean age was 49,7 ± 15,7 years, 53% women. The median total dose of RTX was 4.3± 2,5 g. As a rule, a reduced dose of RTX 500 mg was used for repeated courses. Mean duration of RTX therapy 46.8 ± 29.4 months. Remission of AAV was defined as a Birmingham Vasculitis Activity Score = 0 regardless of prednisone treatment or dosage. All pts were in remission.
Results: In 70 patients the average indicators of physical functioning: MPA 62.5 (47.5, 78.8), GPA 75 (55, 92.5), EGPA 60 (45, 77.5); social functioning: MPA 25 (0, 56.3), GPA 50 (25, 100), EGPA 50 (12.5, 62.5), physical health component: MPA 41.6 (31.5, 44.8), GPA 43.7 (36.7, 52.5), EGPA 38.7 (33.8, 45). There were no significant differences between men and women within the GPA, MPA, and EGPA groups. There were also no differences between different age groups. When comparing the EGPA group with GPA or MPA, no significant differences were found. At the same time, in patients with MPA, the indicators of physical functioning (p=0.015, w= 3.92) and the physical component of health (p=0.012, w 4.026) were significantly lower than in patients with GPA.
Conclusion: RTX maintenance allows to achieve a good quality of life in AAV pts. SF-36 summary measures were significantly higher in GPA pts compared with MPA. Further research is required to analyze the effect of AAV phenotype and complications on health-related quality of life.

AB0607 **VASCULAR INVOLVEMENT IN BEHÇET'S DISEASE**

I. Chaabene[1], S. Tahri[1], M. Kechida[1], S. Daada[1], S. Hammami[1], R. Klii[1], I. Khochtali[1]. [1]*Fattouma Bourguiba University Hospital, Internal Medicine and Endocrinology department, MONASTIR, Tunisia*

Background: Behçet's disease (BD) is a multisystemic inflammatory vasculitis, which can affect all types and sizes of blood vessels. It diagnosis is based on a multitude of classification criteria, which include vascular complications associated to this vasculitis.
Objectives: In this study, we reported the main characteristics of vascular involvement in patients with BD.
Methods: In total, 243 patients with BD were, retrospectively, collected in the Internal Medicine Department over 18 years.
Results: Vascular involvement was present in 72 patients (29.6%), whose 57 men and 15 women. The mean age was 32.9 years (range: 5-56 years). It revealed the disease in 26.3% of cases. Venous involvement was predominant, found in 68% of patients. Venous thrombosis interested: the upper limbs (51%), the lower limbs (38.7%), the pulmonary veins (18.3%), the inferior vena cava (12.2%) and the cerebral veins in 1 patient. Superficial venous thrombosis was present in 20.8% of cases. Arterial involvement was present in 11.1% of patients. It included pulmonary artery aneurysms in 8 cases and occlusion of the central retinal artery in one patient. The other associated systemic manifestations were: skin and mucous membrane disorders (100%), joint involvement (34.7%), ocular (29.2%), neurological (27.8%) and cardiac involvement in 7 patients. Treatment was based on long term curative anticoagulation (70%), corticosteroid therapy (50%) and immunosuppressive treatment in 21% of cases. Embolization was performed in two patients with good results.
Conclusion: Our study illustrates the frequency and the polymorphism of vascular involvement in BD.

AB0608 **TIME OF DIAGNOSIS AND INITIATION OF TREATMENT OF GIANT CELL ARTERITIS (GCA) ACCORDING TO CLINICAL PHENOTYPE AND REFERRAL ORIGIN**

M. López I Gómez[1], P. Moya[2], I. Castellví[3], H. Corominas[3]. [1]*Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain;* [2]*Hospital de la Santa Creu i Pau, Rheumatology Service Systemic Autoimmune Diseases Unit Functional Unit of Aortic Pathology, Barcelona, Spain;* [3]*Hospital de la Santa Creu i Pau, Rheumatology Service Systemic Autoimmune Diseases Unit, Barcelona, Spain*

Background: Giant cell arteritis (GCA) presents two phenotypic patterns: cranial and extracranial. Cranial manifestations are relatively easier to recognize and to diagnose, however since the extracranial are more insidious and less known, it may lead to a delay in diagnosis and in treatment. The main treatment are glucocorticoids (GC) at high doses followed by a descending pattern. The time between the begin of the symptoms and the start of the treatment with GC it's of vital importance in the prognosis of the disease.
Objectives: The present AUDIT describes our cohort's clinical features, the time from symptom onset to rheumatology visit and diagnosis of GCA, as well as the differences in time according to the service originating the referral.
Methods: Audit retrospective, descriptive study of patients diagnosed with GCA by the CGA 1990 criteria. All patients diagnosed with GCA from 2011 to 2021, in a single hospital center and referred to the Rheumatology Service were included. Patients were classified as: cranial phenotype, extracranial or mixed. Demographic and clinical variables and complementary examinations were collected. As well as the time from the first symptom until the patients are referred and diagnosed.
Results: Seventy patients were included in the study. Fifty-one patients (72.9%) were female, their clinical features are shown in Table 1. Twelve of them (17,39%) had a cranial phenotype, sixteen (23,18%) an extracranial phenotype and forty-one (60,42%) a mixed one. Extracranial phenotype patients showed to be younger at the time of the diagnoses than the other groups. Cranial phenotype patients had a lower increase of the acute phase reactants than the other phenotypes (without finding statistically significant differences). In Table 2 are shown the other demographic, clinical and analytic data.

Table 1. Disease Characteristics of the Patients at Baseline according to their phenotype

PHENOTYPE	CRANIAL	EXTRACRANIAL	MIXED	TOTAL
	N=12	N=17	N=41	N=70
Age	75.543 ± 7.48	73.543 ± 8.1	76.356 ±7.46	75.56 ±7.46
Smoker	8.3% (n=1)	11.8% (n=3)	14.6% (n=6)	12.9% (n=9)
Headache	91.7% (n=11)	0%	90.2% (n=37)	68.6% (n= 48)
Ocular involvement	58.3% (n=7)	0%	34.1% (n=14)	30% (n=21)
Fever of unknow origin	0%	29.4% (n=5)	34.1% (n=14)	27.1% (n=19)
Polymyalgia rheumatica	0%	41.2% (n=7)	53.7% (n=22)	41.4% (n=29)
Constitutional syndrome	0%	23.5% (n=4)	36.6% (n=15)	27.1% (n=19)
Cutaneous hyperalgesia	25% (n=3)	0%	31.7% (n=13)	22.9% (n=16)
Anaemia	0%	41.2% (n=7)	46.3% (n=19)	37% (n=26)
C reactive protein	51.33 ± 40.16	77.83 ± 75.30	85.55 ± 81.67	77.58 ± 74.57
Erythrocyte sedimentation rate	60.64 ± 33.13	76.20 ± 36.35	77.93 ± 35	74.65 ± 35.07

Patient referral were made from: Emergency room/ Internal Medicine hospitalization (30%, 21 patients), Primary Care (21.4%, 15 patients), Internal Medicine outpatient clinic (15.7%, 11 patients), Neurology (18.6%, 13 patients) and other specialties outpatient clinic (cardiology, vascular surgery, ophthalmology, hematology and gastroenterology). The median of the time from the first symptom until the patients are diagnosed are 12,9, 13,97 and 7,91 weeks in the cranial, extracranial and mixed respectively. The median of time from the first symptom until the patient referral to rheumatology are 9.34, 12.74 and 5.87 weeks in the cranial, extracranial and mixed respectively. The median of time from patient referral to rheumatology to be assessed are 3.73, 5.59 and 3.43 weeks in the cranial, extracranial and mixed respectively. 75.7% of the patients received treatment with glucocorticoids before being referral to rheumatology.
Conclusion: In our cohort, most of the patients with CGA had a mixed phenotype. The patient referral to rheumatology is made mainly from the emergency room, internal medicine hospitalization and primary care. Patients with mixed phenotype are diagnosed faster than the ones with an exclusively extracranial phenotype. The time between the first symptom and the referral to rheumatology is still long.

AB0609 GAPS IN THE DIAGNOSIS OF TAKAYASU ARTERITIS: A ROMANIAN COHORT

A. Predoiu[1,2], C. Pamfil[1,2], I. Felea[1], L. Muntean[1,2], L. Damian[1], M. M. Tamas[1,2], I. Filipescu[1,2], S. P. Simon[1,2], S. Rednic[1,2]. [1]*Emergency County Hospital, Rheumatology Clinic, Cluj-Napoca, Romania;* [2]*Iuliu Hatieganu University of Medicine and Pharmacy, Dept. of Rheumatology, Cluj-Napoca, Romania*

Background: The diagnosis of Takayasu arteritis still represents a big challenge, even though the disease was first described more than 100 years ago. Proof of that is the continuing effort to develop criteria with high specificity and sensitivity.[1]
Objectives: The aim of the study was to describe the clinical and paraclinical aspects of the disease at the time of diagnosis. Additionally, we wanted to evaluate the damage score in view of the diagnosis delay.
Methods: We retrospectively studied the clinical chart of 17 consecutive patients admitted to the Rheumatology Clinic of Emergency County Hospital from Cluj-Napoca, Romania between 2003 and 2021.
Results: There was just one man in the cohort (0.05%). The average age at the time of diagnosis was 37.5 years old. The average delay in the diagnosis was 33 months, while the biggest delay was of 240 months. The diagnosis was made by rheumatologists in 58% of the cases, while 29% by cardiologists and 11.7% by internal medicine specialists. The most frequent symptoms were limb claudication (64.7%), fatigue (52.9%) and headache (52.9%). Vascular bruits were found in most of the patients at the time of diagnosis (70.5%), as well as blood pressure and pulse difference between arms (52.9%). Unobtainable blood pressure was seen in 5 patients (29.4%). There was a discrepancy in 3 patients (17.6%) between inflammatory markers and inflammation in the vessels' walls, as confirmed by imaging techniques (angioMRI or angioCT). Most of the patients were classified as type V arteritis (35%), followed by type IV (18%), type I (17%), type IIA, respectively type IIB (12% each) and type III (6%). Stenosis of the involved arteries occurred 4.3 times more than aneurysm formation. Eight patients required vascular interventions at the time of diagnosis – four were treated by balloon angioplasty and six by stent placing. The average TADS (Takayasu Arteritis Damage Score) was 1.5 and it was not associated with delay in diagnosis (p>0.05).
Conclusion: Takayasu arteritis is a disease with heterogenous and nonspecific symptoms. For those reasons the delay in diagnosis is usually long, the treatment is started late and damage appears early in the course of the disease. This is reflected by the high amounts of vascular procedures needed at the time of diagnosis. We need better diagnostic criteria and specific monitoring scores.

Vasculitis - small vessel vasculitis

AB0610 DEVELOPMENT OF MALIGNANCY IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

M. Bektaş[1], B. Ince[1], S. Zaralı[2], U. A. Gulseren[2], E. Ük[2], B. F. Agargun[2], D. Y. Guzey[3], Y. Yalçınkaya[1], B. Artim-Esen[1], A. Gül[1], M. Inanc[1]. [1]*Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey;* [2]*Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey;* [3]*Istanbul Faculty of Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey*

Background: Patients (pts) with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) reported to have an increased risk of malignancy compared to general population [1]. However, studies on risk factors for the development of malignancy in AAV pts are limited.
Objectives: We aimed to evaluate the frequency, clinical features and associated factors of malignancy in pts with AAV.
Methods: In this study, we retrospectively evaluated 287 pts with AAV. Thirty-three pts with EGPA and 14 pts with missing data were excluded. ANCA test was analysed based on immunofluorescence and/or Elisa results and divided into two serological groups; c-ANCA/PR3$^+$ (positive) and p-ANCA/MPO$^+$.
Results: Data of 240 pts (54.6 % female) were analysed. Mean age of diagnosis was 55.6±14 (range; 17-88) years and median disease duration was 67.5 (range; 3-255) months. Of those pts, 175 (73 %) had GPA and 65 (27 %) had MPA. ANCA results were available in 230 pts; 123 were c-ANCA/PR3$^+$ (53.5 %), 85 were p-ANCA/MPO$^+$ (37 %) and 22 were ANCA negative (ANCA$^-$) (9.5 %). Kidney (75.8 %) and lower respiratory tract (74.4 %) were the most common organs involved but they did not differ according to presence of malignancy (9.4 % vs 5.1 %; p=0.4 and 9.4 % vs 5 % p=0.4 respectively.) Twenty-two malignancies were observed in 20 pts (8.3 %; eleven c-ANCA/PR3$^+$, three p-ANCA/MPO$^+$ and two ANCA negative pts). Lung and thyroid papillary cancer in three; bladder, prostate, breast and kidney in two; adrenal gland, oral squamous cavity and sarcoma of retroperitoneum in one patient, hematological (three myelodysplastic syndrome, one chronic lymphocytic leukemia and one lymphoma) in five pts. Six pts (30 %) had prior and/or concomitant AAV diagnosis. Development of malignancy did not differ according to age, gender, diagnosis, seropositivity (ANCA$^+$ vs ANCA$^-$) and ANCA subgroups (Table 1). There was no association between malignancy and cumulative dose of cyclophosphamide (CYC) or history of smoking (p=0.96 and p=0.2, respectively). In univariate analysis, malignancy was associated with presence of cardiovascular disease (CVD) (p=0.003 OR 11.7) and mortality (p=0.04 OR 4.6), higher BVAS score at baseline (p=0.049) and higher VDI score (p=0.02). Significant association was observed between malignancy with CVD (95 % CI 2.2-83 OR 13.4 p=0.005) and mortality (p=0.044 95 % CI 1.03-8.5 OR:2.95) in multivariate analysis.

OR: Odds ratio *(n, %) ǂ mean± Std dev. ᴷmedian; IQR

In survival analysis, mortality rate was higher in pts had malignancy compared to those without (Figure 1, p=0.035).

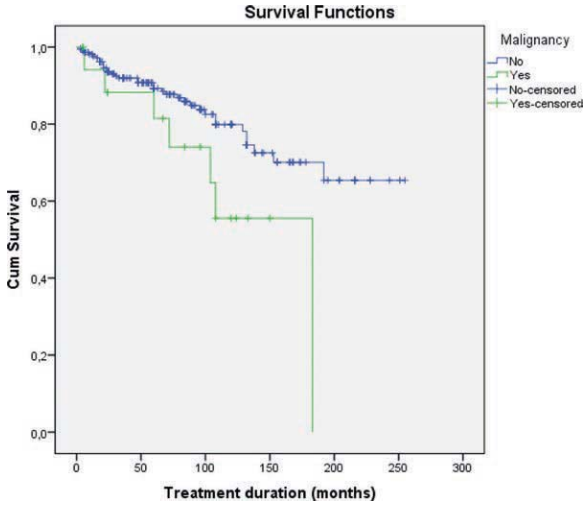

Figure 1. Survival analysis of mortality according to presence of malignancy in pts with AAV. Log-Rank: p=0.035

Conclusion: Significant proportion of pts with AAV developed malignancy in our cohort. Development of malignancy was associated with CVD, higher baseline BVAS and VDI scores. Our study also revealed lower survival rate in patients who developed malignancy. Further studies are needed to clarify risk factors for malignancy in patients with AAV.

NEUTROPHIL EXTRACELLULAR TRAPS AND INTERSTITIAL LUNG DISEASE IN ANCA-ASSOCIATED VASCULITIS: A SCOPING REVIEW

E. Conticini[1], M. D'alessandro[2], L. Bergantini[2], P. Falsetti[1], P. Cameli[2], E. Bargagli[2], L. Cantarini[1], B. Frediani[1]on behalf of Siena Vasculitis Study Group. *[1]University of Siena, Rheumatology Unit, Siena, Italy; [2]University of Siena, Respiratory Diseases and Lung Transplantation Unit, Siena, Italy*

Background: Deregulated neutrophil extracellular traps (NET) formation is implicated in various diseases, including ANCA-associated vasculitis and pulmonary fibrosis (PF). Lung involvement is frequent in AAV, and interstitial lung diseases (ILD) are strongly related to MPO-ANCA positivity and mainly reported in microscopic polyangiitis. The association between AAV and ILD is a strong indicator of poor prognosis and limited survival. Neutrophils, ANCA and NET interplay in PF development in AAV.

Objectives: This study aimed to review the literature concerning the implications of NET in lung fibrogenesis focused specifically on AAV associated with ILD, and the potential of NET as a theranostic marker.

Methods: Through scoping review methodology, we used a descriptive thematic analysis to understand the pathogenic role of NETs in patients with AAV and pulmonary fibrosis and their further role as a theranostic marker of this disease.

Results: Quality assessment of articles was evaluated through SANRA methodology (Table 1). The implications of NET in the pathogenesis of AAV and ILD (Figure 1), as well as an association between these two diseases, have been identified, but the underlying pathophysiological mechanisms are still unknown. Pharmacological or genetic inhibition of NET release reduces disease severity in multiple inflammatory disease models, indicating that NETs are potential therapeutic targets. In this regard, despite the lack of clinical data, we may hypothesize that an optimal management of AAV-ILD patients would require not only B-cells targeted therapy, but also NETs inhibition.

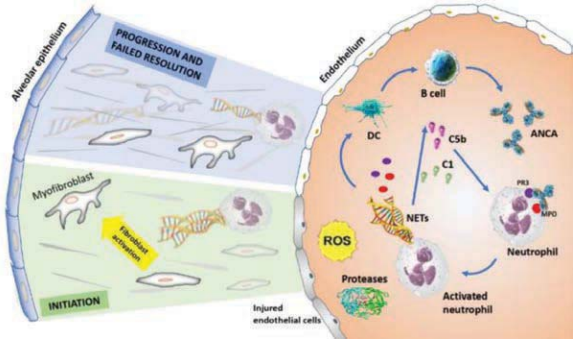

Figure 1. The role of NET in interstitial lung disease associated with ANCA-associated vasculitis

Conclusion: Preliminary findings seem to display a lack of efficacy of traditional immunosuppressants, such as Rituximab, in this subset of patients, while to date no patients suffering from a definite ILD was enrolled in clinical trials. Further insights would be provided by their employment, as a combination treatment, in the common clinical practice. Although we can imagine that inhibition of NETs in patients with AAV-ILD could reduce severity and mortality, we still lack a scientific basis that could improve our understanding of the disease from a molecular point of view.

CHRONIC PANCREATITIS DUE TO SYSTEMIC AUTOIMMUNE AND BACTERIAL SEPTIC VASCULITIS IN RHEUMATOID ARTHRITIS – A HYPOTHETIC PATHWAY OF CHRONIC PANCREATITIS IN POST-COVID 19 CONDITION

Á. Apáthy[1], M. Bély[2]. [1]*St. Margaret Clinic, Department of Rheumatology, Budapest, Hungary;* [2]*Hospital of the Order of the Brothers of Saint John of God in Budapest, Department of Pathology, Budapest, Hungary*

Background: The etiology of pancreatitis is heterogeneous; it may be due to chronic excessive alcohol use, gallstones, medications, infections, autoimmune diseases, metabolic disorders, trauma, congenital malformations etc.
Objectives: The **aim** of this study has been to describe a hypothetic pathway of chronic pancreatitis in post-Covid 19 condition, based on the role of autoimmune and bacterial septic vasculitis in the pathogenesis of chronic pancreatitis (**ChrP**) in rheumatoid arthritis (**RA**).
Methods: At the National Institute of Rheumatology **9475** patients died between 1969 and 1992; among them **161** with **RA** and all of them were autopsied.
RA was confirmed clinically according to the criteria of the **ACR**.
Tissue samples of pancreas were available for histologic evaluation in **111** patients. Pancreatitis and vasculitis were determined and characterized histologically [1,2]. The possible role of autoimmune vasculitis and bacterial septic vasculitis in the pathogenesis of **ChrP** was analyzed by Pearson's chi-squared (χ^2) test.
Results: ChrP – characterized by diffuse and/or focal fibrosis and atrophy – was present in **10** (**9.01**%) of 111 patients. Systemic vasculitis complicated **RA** in **28** (25.23%) of 111 patients. **Twenty-five** (89.3 %) of 28 systemic vasculitis proved to be of autoimmune origin. Autoimmune vasculitis involved the pancreatic blood vessels (**pAV**) in **8** (32.0 %) of these 25 patients. Non-specific (n=37), fibrinoid necrotic (n=14), and granulomatous type (n=5) of **pAV** were detected side by side in the same histologic section, involving pancreatic arteries of different sizes. The veins and venules were not involved. **pAV** was not associated with chronic pancreatitis. The relationship between **pAV** and **ChrP** was inverse with a negative colliquation coefficient (c=-1.0, χ^2=0. 0801, p <0.7772 – NS). **Three** (10.7 %) of 28 systemic vasculitis cases proved to be of septic (bacterial) origin. Pancreatic blood vessels (**pSV**) were involved in **2** (66.7 %) of these 3 patients. Granulomatous vasculitis was not seen with **pSV**, and the veins and venules were also spared. Non-specific (n=9), fibrinoid necrotic (n=2) vasculitis involving different size of pancreatic arteries were associated with chronic pancreatitis. The relationship between **pAV** and **ChrP** was significant (c=0.92308, χ^2=6.3201, p <0.012).
Conclusion: Chronic pancreatitis is characterized clinically by abdominal pain and diarrhea, which are common in post-Covid 19 condition [2]. The strong and significant correlation between **pSV** and **ChrP** indicates that subclinical or manifest bacterial septic processes may play a role in the pathogenesis of **ChrP**. Hypothetically a similar pathway is plausible in post-Covid 19 chronic pancreatitis due to viral infection and vasculitis, analogous to bacterial septic vasculitis. Systemic vasculitis of autoimmune origin involving blood vessels of the pancreas may cause a special multifocal relapsing lipo-necrotic pancreatitis [1,2], and according to our results, do not influence the prevalence of **ChrP**. The autoimmune origin of pancreatic vasculitis may be excluded histologically by the presence of granulomatous vasculitis of the most frequently involved arterioles and small arteries.

VASCULAR EVENTS AND ASSOCIATED FACTORS IN ANCA-ASSOCIATED VASCULITIS: ANALYSIS OF 237 PATIENTS WITH LONG-TERM FOLLOW-UP

M. Bektaş[1], B. Ince[1], S. Zaralı[2], U. A. Gulseren[2], E. Ük[2], Y. Yalçınkaya[1], B. Artim-Esen[1], A. Gül[1], M. Inanc[1]. [1]*Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey;* [2]*Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*

Background: Patients with ANCA-associated vasculitis (AAV) reported to have an increased risk of vascular events (VE) compared to general population [1]. However, studies on risk factors for the development of VE in AAV patients (pts) are limited.
Objectives: In our study we aimed to evaluate the frequency, risk factors and mortality risk of VE pts with AAV.
Methods: In this study we retrospectively evaluated 287 pts with AAV. Patients with EGPA (n=33) were not included and 17 pts were excluded due to missing data. Arterial vascular events (a-VE) were recorded as myocardial infarction, unstable angina pectoris, peripheral artery disease, need for revascularization and cerebrovascular accident. Deep venous thrombosis and pulmonary embolism were recorded as venous thrombotic events (VTE). History of a-VE and/or VTE were grouped as all VE. ANCA test results were analyzed based on IFA and/or Elisa results and divided into two serological groups; c-ANCA/PR3$^+$ (positive) and p-ANCA/MPO$^+$.
Results: Data of 237 pts (46 % male) was analyzed. Mean age at diagnosis was 55.6±14 (range; 17-88) years and median disease duration was 77 (range; 3-255) months. Of those pts, 173 (73 %) had GPA and 64 (27 %) had MPA. ANCA results were available in 230 pts; 122 were c-ANCA/PR3$^+$ (53.5 %), 85 were p-ANCA/MPO$^+$ (37 %) and 22 were ANCA negative (ANCA$^-$) (9.5 %). The most common organ involvements were kidneys (75.8 %) and lower respiratory tract (74.4 %). Overall, 22 % (n=52) of the pts developed VE, 17 % (n=40) a-VE, 9 % (n=21) VTE and 3.8 % (n=9) both a-VE and VTE. In univariate analysis; development of VE was significantly higher in males, pts with c-ANCA/PR3 and pts with higher baseline CRP levels, GFR<50 mL/min, history of smoking, severe infection, higher VDI score. Development of a-VE was higher in pts with males, advanced age, pts with c-ANCA/PR3, history of smoking, higher VDI score, GFR<50 mL/min. Additionally, mortality was increased in pts with VE and a-VE. In multivariate analysis; while VE were associated with smoking [95 % CI:1.7-21; OR:6], c-ANCA/PR3 positivity [95 % CI: 1.15-92; OR:10.3] and higher VDI score [95 % CI:1.007-2.4; OR:1.5]; a-VE were associated with advanced age [95 % CI:1.002-1.08; OR:1.04], higher VDI score [95 % CI:1.3-2; OR:1.6] and c-ANCA/PR3$^+$ [95 % CI:1.06-8.6; OR:3]. Development of VTE was associated with higher VDI score (p<0.001) in univariate and multivariate analysis [95 % CI: 1.2-1.8; OR:1.5]. In survival analysis, mortality rate was significantly higher in pts who had a history of VE (Log-Rank: p=0.04).
Conclusion: Our observational data of more than 5 years of follow-up revealed that, one in five pts with AAV developed VE after diagnosis. The risk of VE was significantly higher in c-ANCA/PR3$^+$ pts, smokers and pts with high VDI scores. Older age increased the risk of a-VE. Mortality was increased in AAV pts with VE after diagnosis. Additional studies needed to delineate the mechanism of VE in AAV and precautions should be undertaken to avoid morbidity and mortality.

LATE-ONSET NEUTROPENIA AFTER RITUXIMAB TREATMENT IN PATIENTS WITH ANCA-ASSOCIATED SYSTEMIC VASCULITIS: A RETROSPECTIVE ANALYSIS OF A REGISTER-BASED PATIENT COHORT

I. Popov[1], V. Babak[1], T. Beketova[1,2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of systemic sclerosis, Moscow, Russian Federation; [2]Central Clinical Hospital of the General Management Department of the President of Russian Federation, Rheumatology, moscow, Russian Federation*

Background: Anti-B-cell therapy with rituximab (RTX) plays an important role in the induction and maintenance therapy of ANCA- associated vasculitis (AAV). Late-onset neutropenia (LON) has been reported following RTX therapy.
Objectives: Based on a retrospective analysis of the register of AAV patients (pts) treated with RTX, to study the incidence and outcomes of LON.
Methods: 140 AAV pts (median age 52 (20-83) years, 57% women) were treated with RTX between 2009 to 2021: 63 with granulomatosis with polyangiitis (GPA), 45 microscopic polyangiitis (MPA), 24 eosinophilic granulomatosis with polyangiitis (EGPA), and 8 unclassified AAV. The median total dose of RTX was 3.5 (0.5-45) g. As a rule, single 500-mg infusions were used with an interval of 4-6 months for retreatment courses. The duration of follow-up exceeded 6 months after the first dose of RTX. Regular pts monitoring every 3 months included estimation absolute neutrophil count (ANC). LON was defined as unexplained neutropenia occurring 3 weeks after the last RTX infusion.
Results: LON I-IV grade was noted in 16 (11.4%) AAV pts: 6 GPA, 4 MPA, 4 EGPA, and 2 unclassified AAV. In 7 out of 16 cases (43.7%) LON developed after the first course of RTX. Neutropenia grade I was observed in 3 pts (ANC 1.68-2.0x10^9/l, 2-15.5 months after the last RTX infusion), grade II - in 4 patients (1.1-1.5x10^9/l, 3-9 months after RTX). Neutropenia grade I-II resolved independently, without adverse reactions. LON grade IV was noted in 9 pts (0.06-0.3x10^9/l, 1.1-11 months after RTX), 3 of them received leukopoiesis-stimulating drugs with normalization of ANC. In one EGPA pt febrile LON grade IV developed twice (in 2017, 11 months after RTX; in 2019, 4 months after RTX and complicated by uterine bleeding). Fatal outcome occurred in 5 out of 16 cases (31.2%): 1 MPA, 3 GPA, and 1 EGPA. In 3 fatal cases LON was complicated by pneumonia (in 2 with septic shock), in one with acute myocardial infarction and another one with progression of chronic renal failure. According to our registry, the total mortality among 140 AAV pts receiving RTX was 11.4%, while 5 of 16 fatal cases (31.2%) had LON grade IV. Three of the 5 death were noted in 2013-2014, which attributed to the use of cyclophosphamide >2 gm before RTX, as well as insufficient awareness of the risk of LON, which contributed to the delay in control of a full blood count, untimely diagnosis of LON and late treatment. At the beginning, the original drug Mabthera was used, while after 2014 biosimilar Acellbia was mainly used. The disadvantages of this study: the lack of information about the ANC in 4 cases with COVID-19 and fatal outcome.
Conclusion: LON after RTX therapy can develop in 11.4% of AAV pts, which exceeds the data for rheumatoid arthritis (1,3-3%) [1,2]. Our register data are lower than the rate of LON in AAV, presented by D. Tesfa et al. (23%) [1], which could be affected by the use of low-dose RTX for retreatment courses. LON accounts for a significant part in the structure of deaths of AAV pts (31.2%). It needs to careful monitoring of ANC in pts receiving RTX and awareness of both pts and physicians about the risk of LON.

AB0615

CLINICAL IMPACT OF CERULOPLASMIN LEVELS AT ANCA-ASSOCIATED VASCULITIS DIAGNOSIS

L. Camboulive[1], F. Grandhomme[1], N. M. Silva[1], H. de Boysson[1], A. Dumont[1], A. Nguyen[1], D. Mariotte[1], K. Khoy[1], T. Lobbedez[1], A. Aouba[1], S. Deshayes[1]. *[1]University Of Caen Normandie Hospital Center, Basse Normandie, Caen, France*

Background: Myeloperoxidase (MPO) plays a major role in loss of immunological tolerance leading to tissue destruction in ANCA-associated vasculitis (AAV). Ceruloplasmin is a protein with antiproteinase and antioxidant properties that inhibits MPO activity. Whether serum level of ceruloplasmin at AAV diagnosis has an impact is unknown.
Objectives: The objective of this study was to evaluate the prognostic impact of serum level of ceruloplasmin at diagnosis in patients with granulomatosis with polyangiitis or microscopic polyangiitis.
Methods: We conducted a retrospective unicentric study at Caen University Hospital, involving consecutive adult patients with granulomatosis with polyangiitis or microscopic polyangiitis between 2010 and 2021 who had available serum at diagnosis. Data was collected using the health records.
Ceruloplasmin was measured by standardized nephelometry (normal values: 0.15 – 0.50 g/L). Patients in each subgroup (whole cohort, microscopic polyangiitis and anti-MPO patients) were divided into two groups based on the median serum level of ceruloplasmin.
We estimated survival using the Kaplan-Meier survival curve, and between-group differences were evaluated by the log-rank test. The study was approved by the local ethics committee of Caen University Hospital (n° 1947).
Results: Ninety-two patients were included, 46 (50%) granulomatosis with polyangiitis (41 anti-proteinase 3 and 5 anti-MPO) and 46 (50%) microscopic polyangiitis (45 anti-MPO and 1 anti-proteinase 3). The median level of ceruloplasmin was 0.44 g/L. No significant differences in the clinical presentation were observed between patients in the two groups (p>0.05). We observed 9 (19.6%) deaths in the low ceruloplasmin group and 5 (10.9%) in the high ceruloplasmin group (p=0.39). Vasculitis relapse occurred in 10/46 patients (22%) and 11/46 patients (24%) (p=1), renal failure leading to dialysis and/or renal transplant in 6/46 patients (13%) and 8/46 patients (17%) (p=0.77), respectively. No significant difference in survival was found (p=0.07). The same analyses were performed

between the low and the high ceruloplasmin group with the microscopic polyangiitis subgroup (n=46), and no significant differences were found (p>0.05). However, within the anti-MPO subgroup (n=50), the survival was worse in the low ceruloplasmin group (p=0.03).

Conclusion: In anti-MPO AAV patients, serum level of ceruloplasmin at diagnosis seems to be associated with a significant impact on survival.

MYELOPEROXIDASE (MPO) POSITIVE EXTRACELLULAR VESICLES (EVS) EXPRESSING COMPLEMENT SPLIT PRODUCTS IN ANTI - NEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA) -ASSOCIATED VASCULITIS (AAV)

A. Juto[1,2], N. Mahmoud Hourani Soutari[3], A. Taxiarchis[3], V. Malmström[1], A. Bruchfeld[4,5,6], A. Antovic[1,2], I. Gunnarsson[1,2]. *[1]Karolinska Institutet, Department of Medicine, Division of Rheumatology, Solna, Stockholm, Sweden; [2]Karolinska University Hospital, Rheumatology, Stockholm, Sweden; [3]Karolinska Institutet, Department of Molecular Medicine and Surgery, Solna, Stockholm, Sweden; [4]Linköping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden; [5]Karolinska Institutet, CLINTEC, Stockholm, Sweden; [6]Karolinska University Hospital, Department of Renal Medicine, Stockholm, Sweden*

Background: Complement activation has a critical role for the development of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). We have previously shown increased expression of complement split products C3a and C5a on myeloperoxidase (MPO) positive EVs (MPO^+EVs) in plasma from AAV patients with kidney involvement compared to the patients with non-renal disease and the EV-levels correlated with disease activity (1).

Objectives: To investigate the expression of a larger set of complement components on circulating MPO^+EVs in relation to disease activity and kidney involvement in patients with AAV.

Methods: Eighty-nine patients with AAV and 23 healthy controls were included. The concentration of MPO^+EVs expressing complement split products C3a, C4d, C5a, terminal complement complex-TCC (C5b-9) or complement factor B (CFB) were analyzed from citrate plasma by flow cytometry. The assessment of vasculitis disease activity was performed using the Birmingham Vasculitis Activity Score (BVAS).

Results: In the AAV group, there were 47 males (52.8%), the median age was 56 years and 33 (37.1%) patients were anti-MPO-positive and 54 (60.7%) were anti-PR3-positive. Two patients were positive for both antibodies. Median disease duration for patients with active AAV (BVAS>0; n=81) was 4 days and for patients in remission (BVAS 0; n=8) 1259 days. 64% had kidney involvement (n=52). Highly active AAV (BVAS ≥12) was noted in 62 patients, of whom 49 patients had kidney involvement. Active disease (0<BVAS<12) was seen in 19 patients. AAV patients had significantly higher levels of MPO^+, MPO^+C3a^+, MPO^+C4d^+ and MPO^+TCC^+ EVs compared to healthy controls (all p<0.001). Patients in remission had higher levels of MPO^+, MPO^+C4d^+ and MPO^+TCC^+ EVs compared to healthy controls (all p≤0.001). There was a significant difference in levels of MPO^+(p=0.02), MPO^+C3a^+(p<0.001), MPO^+C4d^+(p<0.001) and MPO^+TCC^+ EVs (p<0.001) in patients with kidney involvement compared with patients without (n=29) (Figure 1). For patients with BVAS>0 there was a weak correlation between MPO^+, MPO^+C3a^+, MPO^+C4d^+, MPO^+TCC^+ EVs and BVAS. Kidney biopsies from 34 patients were classified according to histopathological class (2): crescentic (n=6), focal (n=18), mixed (n=6), sclerotic (n=4). The level of MPO^+C4d^+EVs was higher in the sclerotic type compared to focal (p=0.04, 95% CI [2.4–103.7]) and mixed (p=0.04, 95% CI [1.4–119.1]).

Conclusion: Levels of EVs expressing complement split products were generally increased in AAV patients and patients with kidney involvement had higher levels of total MPO^+EVs exposing C3a, C4d or TCC compared with patients without suggesting a role in kidney AAV pathogenesis. Patients with sclerotic kidney histotype had higher levels of MPO^+C4d EVs compared with focal and mixed subgroups pointing to that activation of the classical complement pathway may be of importance in severe forms of kidney AAV.

HIGH PREVALENCE OF OSTEOPOROSIS AND FRAGILITY FRACTURES IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS: A CROSS-SECTIONAL STUDY

P. Delvino[1], S. Monti[1], G. P. Grieco[2], E. Bozzalla Cassione[1], G. Franchi[1], L. Bogliolo[1], C. Montecucco[1]. *[1]IRCCS Policlinico San Matteo Foundation, University of Pavia, Rheumatology, Pavia, Italy; [2]University of Pavia, School of Medicine and Surgery, Pavia, Italy*

Background: The advent of effective immunosuppressive treatments significantly improved the prognosis of ANCA-associated vasculitides (AAV), which have become chronic relapsing diseases. Patients with inflammatory rheumatic disorders are particularly prone to reduced bone mineral density (BMD) and fragility fractures (FF), due to chronic glucocorticoid therapy, immunosuppressant-induced hypogonadism, systemic inflammation, functional disability and comorbidities. At present, there is paucity of data concerning the risk of osteoporosis and FF in AAV.

Objectives: To describe the occurrence of osteoporosis and major FF in a cross-sectional cohort of patients with AAV.

Methods: Patients diagnosed with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA), according to ACR criteria and/or Chapel Hill definitions and regularly followed-up in our vasculitis center were included. BMD was measured by dual-energy X-ray absorptiometry (DEXA) of the proximal femur and lumbar spine, between March 2016 and September 2021. Osteoporosis was defined by a T-score below –2.5 SD, whereas osteopenia was defined by a T-score between -1 and -2.5 SD, according to the World Health Organization criteria. Vertebral fractures were assessed by X-ray of the dorso-lumbar spine. Data on previous osteoporotic hip fractures were collected.

Results: Sixty-two consecutive patients were included (59.7% female, mean age at time of DEXA 61.8±10.5 years, disease duration 97.0±76.1 months). Sixteen (25.8%), 8 (12.9%) and 38 patients (61.3%) were affected by GPA, MPA and EGPA, respectively. BMD findings indicating osteoporosis and osteopenia, at either the lumbar spine and/or the proximal femur, were observed in 15 (24.2%) and 39 patients (62.9%), respectively, whilst only 8 patients (12.9%) had normal BMD values at both sites. Fifteen patients (24.2%) reported 51 major FF (50 vertebral fractures, 1 hip fracture) during follow-up, with multiple major FF being recorded in 10 patients (16.1%). Osteoporosis, at least at one site, was frequent not only in post-menopausal women (19.4%), but also in 6 males (24%), 3 pre-menopausal women (50%) and 3 patients under 50 years of age (37.5%), respectively (Figure 1). Similarly, major FF occurred in 4 males (16.7%), 1 pre-menopausal female (16.7%) and 1 patient under 50 years of age (12.5%), respectively (Figure 1). Patients with osteoporosis presented a lower body mass index (BMI) (23.1±4.1 vs 25.9±4.4, P=0.03) and a higher prevalence of major FF (53.3% vs 14.9%, P=0.003) compared to patients without osteoporosis. Compared to patients without major FF, those affected by major FF were older (68.8±1.8 vs 59.4±9.3 years, P=0.003), had a higher disease duration (146.9±78.8 vs 81.8±68.9 months, P=0.003) and presented with lower proximal femur BMD values (0.657±0.122 vs 0.761±0.127 g/cm^2, P=0.007) and proximal femur T-score (-2.0±0.9 vs -1.4±0.8 SD). Notably, 7 out 15 patients with FF (46.7%) did not exhibit BMD findings of osteoporosis. Other variables, including sex, disease subtype, ANCA status, chronic kidney disease or treatment with cyclophosphamide were not related to bone loss or FF.

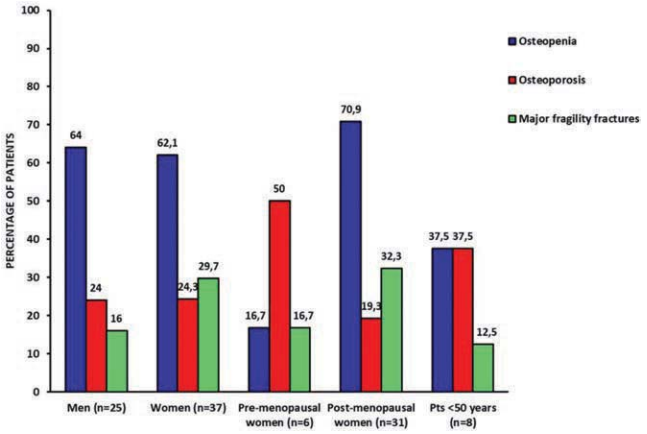

Figure 1. Proportion of patients with osteopenia, osteoporosis and major fragility fractures stratified according to sex, menopausal status and age.

Conclusion: Patients with AAV are particularly susceptible to BMD loss and fractures, with osteoporosis and major FF being reported in about a quarter of patients. Short-term and long-term monitoring for reduced BMD and FF is warranted in all patients with AAV, including male patients, premenopausal females and those under 50 years of age.

AB0618 TOLERABILITY AND SAFETY OF 23-VALENT POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH SYSTEMIC VASCULITIS, PRELIMINARY RESULTS

G. Tarasova[1], O. Egorova[1], T. Reshetnyak[1,2], B. Belov[3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [2]Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Comorbid Infections and Vaccinal Prevention, Moscow, Russian Federation*

Background: Systemic vasculitis (VS) is a severe autoimmune disease requiring active immunosuppressive therapy. The probability of infectious complications in these patients is very high. Immunization with the 23-valent polysaccharide pneumococcal vaccine (PPV-23) is required to reduce the risk of severe respiratory infections in this group of patients.

Objectives: The aim of the study was to study the tolerability and safety of PPV-23 in patients with SV.

Methods: At this stage, the study included 13 patients with WS: 10 with vasculitis associated with antineutrophil cytoplasmic antibodies (ANCA) (AAV), (5 with granulomatosis with polyangitis (GPA), 4 with eosinophilic granulomatosis with polyangiitis (EGPA), 2 - with microscopic polyangiitis (MPA)), 1 - with polyarteritis nodosa, 1 - with Takayasu's arteritis (AT); of which 10 women, 3 men, aged 22 to 76 years. 9 (69%) patients were older than 50 years. Remission of the disease was observed in 1 patient (EGPA), in 3 - low disease activity, in 9 - active vasculitis (all 9 with AAV, BVAS from 4 to 13). All patients received glucocorticoids (GC): 2 - 55-60 mg/day, 9 - 10-20 mg/day, 2-2.5-5 mg/day; 5 -bDMARD: 4 - rituximab (RTM), 1 - TNF inhibitors; 11 - cytostatics (CS): 4 - mycophenolate mofetil (MM), 3 - azathioprine (AZ), 2 - cyclophosphamide (CPh), 2 - methotrexate (MTX). Two patients were on induction therapy (GC 55-60 mg + CPh) with a plan to switch to RTM. Only 1 patient with EGPA received HA as monotherapy. The 23-valent polysaccharide pneumococcal vaccine was administered subcutaneously in 0.5 ml (1 dose). The follow-up period was 1-6 months. During the visits, standard clinical and laboratory tests and the determination of antibodies to S.pneumoniae were carried out.

Results: Vaccination tolerance was good in all patients. One (7,7%) patient with EGPA (in remission) had a mild local reaction (pain at the injection site) within 1 day. Another 1 (7,7%) patient with severe concomitant pathology (EGPA + multiple sclerosis) had a general reaction in the form of a transient increase in weakness in the lower extremities for up to 5 days (this symptom was a manifestation of polyneuropathy, persisted earlier, and to a greater extent was associated with multiple sclerosis than with EGPA). Vaccinal reactions were completely reversible and did not require additional prescriptions. During the follow-up period, no deterioration in the course of SV was recorded in any case, and no new autoimmune phenomena, both laboratory and clinical, were noted in any of them. 7 (53,8%) patients (all 5 with GPA, 2 with EGPA) had ENT lesions (destructive rhinosinusitis (5), sinusitis (2)) with frequent exacerbations. 1 patient with GPA reported a significant improvement in the condition of the ENT organs (no exacerbations of rhinosinusitis, disappearance of nasal discharge for 5 months). In the remaining 6 patients, the condition also remained stable, no progression of sinusitis was noted during the observation period (1-4 months). No infections of the lower respiratory tract were registered during the observation period.

Conclusion: 1. All patients had a high risk of infectious complications: combined immunosuppressive therapy (92% of patients), age over 50 years (69% of patients), severe lesion of ENT organs (53,8% of patients). 2. The tolerance of PPV-23 vaccination was good. 3. There was no deterioration in the course of SV.

AB0619 RATIONALE AND DESIGN OF THE 52-WEEK, RANDOMIZED, PHASE 3, HEAD-TO-HEAD MANDARA STUDY TO EVALUATE THE EFFICACY AND SAFETY OF BENRALIZUMAB, A HUMANIZED, ANTI-INTERLEUKIN–5 RECEPTOR A MONOCLONAL ANTIBODY IN REFRACTORY OR RELAPSING EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

M. Wechsler[1], P. A. Merkel[2], S. Necander[3], L. Börjesson Sjö[3], E. A. Duncan[4], N. Makulova[5], G. D'angelo[6], R. A. Chen[7], V. H. Shih[8], R. Katial[8], U. J. Martin[8]. *[1]National Jewish Health, Division of Pulmonary, Critical care, and Sleep Medicine, Denver, United States of America; [2]University of Pennsylvania, Division of Rheumatology, Philadelphia, United States of America; [3]AstraZeneca, Late-stage development, Respiratory & Immunology, Gothenburg, Sweden; [4]AstraZeneca, Late-stage development, Respiratory & Immunology, Durham, United States of America; [5]AstraZeneca, Late-stage development, Respiratory & Immunology, Gaithersburg, United States of America; [6]AstraZeneca, Data Science & AI, Gaithersburg, United States of America; [7]AstraZeneca, Early Respiratory & Immunology, Cambridge, United Kingdom; [8]AstraZeneca, BioPharmaceuticals Medical, Gaithersburg, United States of America*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA, formerly Churg-Strauss syndrome) is a rare, potentially organ- and life-threatening disease characterized by systemic eosinophilia, airway disease, and multi-system small-vessel vasculitis. Management of EGPA generally focuses on reducing active inflammation using corticosteroids and immunosuppressants, both of which are associated with serious adverse effects and incomplete disease control. High blood eosinophil (bEOS) levels are a central component of the pathophysiology of EGPA, and studies have shown that bEOS-reducing therapies, such as mepolizumab, are effective in some patients with EGPA. Benralizumab is a humanized, afucosylated, anti-interleukin-5 receptor α monoclonal antibody that induces direct, rapid, and near complete depletion of eosinophils through antibody-dependent cell-mediated cytotoxicity. Eosinophil depletion by benralizumab is effective in eosinophilic asthma, corticosteroid-dependent asthma, and has shown promise in a small phase 2 trial in hypereosinophilic syndrome, which has overlapping organ systems involvement and similar clinical features to EGPA. Collectively, the evidence from these indications supports examination of the efficacy of benralizumab as an eosinophil-depleting therapy in patients with EGPA.

Objectives: The phase 3, head-to-head MANDARA (NCT04157348) study will evaluate the efficacy and safety of benralizumab versus mepolizumab in adults with relapsing or refractory EGPA.

Methods: This randomized (1:1), multicentre, double-blind (DB), active-controlled study is enrolling adults with a diagnosis of EGPA, defined as a history of asthma and eosinophilia together with ≥2 additional clinical features, a history of relapsing or refractory disease, and maintained on a stable prednisolone/prednisone dose ≥7.5 mg/day for ≥4 weeks prior to baseline. Patients will receive either benralizumab 30 mg or mepolizumab 300 mg every 4 weeks over the 52-week DB study period. Patients who complete the DB treatment period will be eligible to continue into an optional open-label extension, during which all patients will receive benralizumab (Figure 1). The primary endpoint is the proportion of patients who achieve EGPA remission, defined as a Birmingham Vasculitis Activity Score (BVAS)=0 and prednisolone dose of ≤4 mg/day, at both Week 36 and 48 of the DB period, and it will assess non-inferiority (NI) between benralizumab and mepolizumab. Secondary endpoints include duration of remission, time to first EGPA relapse, annualized relapse rate, average daily prednisolone dose between Weeks 48 to 52, and the proportion of patients who achieve and maintain remission from Week 24 through the end of the DB period. Other endpoints include safety, symptoms, health-related quality of life, healthcare utilization due to EGPA, and tolerability. The trial also includes a non-interventional patient interview sub-study, which will collect data related to patients' EGPA personal experience and perceived impact on study treatment, and a mechanistic sub-study, which will explore the pharmacodynamic response and mechanism of action of benralizumab compared to mepolizumab.

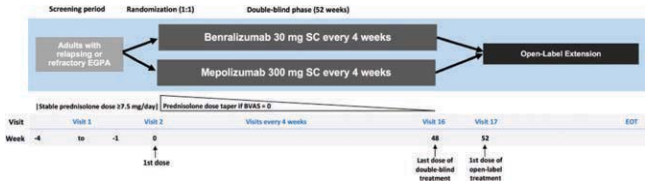

Figure 1. MANDARA Study Design

Results: The study aims to enrol 140 patients which will provide ~90% power to demonstrate NI with a NI margin of -25% at the 2.5% one-sided significance level, assuming each treatment group has a remission rate of 32%. Screening started in Oct 2019 and the trial is ongoing.

Conclusion: MANDARA is one of few multicentre randomized trials conducted to date in EGPA. Results from this phase 3, head-to-head study will characterize the efficacy and safety of benralizumab compared with mepolizumab in adults with relapsing or refractory EGPA. The trial's active comparator design will also provide critical evidence of efficacy and safety in a disease with considerable unmet needs.

AB0620 DO PATIENTS WITH ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA)-ASSOCIATED VASCULITIS (AAV) NEED ANTICOAGULANTS?

G. Tarasova[1], O. Egorova[1], A. Kolomeychuk[1], T. Reshetnyak[1,2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [2]Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Department of Rheumatology, Moscow, Russian Federation*

Background: Patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) have a two- to threefold greater risk of developing `thrombotic events. The expediency of thrombosis prevention in AAV continues to be discussed. The issue of prescribing anticoagulants (AC) is being discussed

Objectives: Retrospectively to analyze the parameters of routine blood clotting indicators in patients with AAV depending on receiving AC.

Methods: The study included 45 patients with AAV (15 -with granulomatosis with polyangiitis (GPA), 15 - microscopic polyangiitis (MPA), and 15 - eosinophilic granulomatosis with polyangiitis (EGPA), aged 23 to 73 years. Duration of the disease was in 6 patients had <12 months, in 20 - 1-5 years, in 13 - 5-10 years, in 6 - >10 years. High AAV activity were registered in 22 patients (BVAS > 5)), 21 - low activity (BVAS < 5) points), 2 - remission (BVAS 0-1 points). The VDI damage index in 5 patients was 0, in 30 – from 1 to 3, in 10 – > 3 points. Glucocorticoids (GC) received 44: 78% of patients at a dose of 5-20 mg /day, 16% - >20-40 mg / day, 4% - >40-60 mg /day. AC 23 (51%) of 45 patients took AC. Blood clotting parameters were measured in 40 patients, including activated partial thromboplastin time (APTT), thrombin time (TT), soluble fibrin monomer complexes (SFMC), the number of platelets, 22 of them received AC.

Results: Thrombosis in the past history was registered in 8 (18%) patients, 7 of them continued taking AC. 16 patients received AC without thrombosis for prevention ones. Patients with GPA received AK more often than patients with MPA and EGPA (73%, 40%, 40%, respectively).

AC were prescribed in 51% of patients. AC were prescribed to 51% of patients receiving GC at a dose of up to 20 mg/day and 44% of patients with a dose of GC above 20 mg/day. The appointment of anticoagulants was associated with the duration of the disease. With a disease duration of up to 1 year, AK was prescribed in 33% of cases, with a duration of > 10 years - in 67% of cases. 59% of patients received AC with BVAS>5, 38% of patients - with BVAS<5. The following AC were prescribed to patients: direct oral AC (DOAC) in 16 (69.6%), unfractionated heparin (UH) - 1, low molecular weight heparins (LMWH) -6. LMWH (46%) and DOAC (54%) were prescribed with the same frequency to patients with BVAS>5, while DOAC (87.5%) prevailed in patients with BVAS<5. Hemorrhagic complications during the follow-up period were not registered in any case. Prolongation of APTT, TT was not significantly noted against the background of AC. I. There was a shortening of APTT in 14 (35%) of 40 patients, TT - in 1 (2.5%). An increase in the level of fibrinogen was recorded in 11 (27.5%) patients and in all 40 patients there was an increase in SFMC, which was an indicator of thrombotic readiness. Increased fibrinogen levels were associated with AAV activity (3 out of 11 had a history of thrombosis).

Conclusion: 1. Our retrospective analysis revealed that 51% of 45 patients with AAV received AC, they were more often prescribed with active AAV and more often with GPA. Our retrospective analysis showed that 51% of 45 patients with AAV received AC, more often with active AAV and more often with GPA.

2. DOAC was prescribed more often (in 70% of cases) compared to others.

3. The appointment of AC was associated with the duration of the disease.

4. The dose of GC did not affect the decision to prescribe AC.

5. Hemorrhagic complications during AC therapy were not observed in any case.

AB0621 CHARACTERISTICS OF ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY ASSOCIATED VASCULITIS WITH SEVERE PERIPHERAL NEUROPATHY.

S. Ishigaki[1], M. Akiyama[1], Y. Kaneko[1]. *[1]Keio University School of Medecine, Division of Rheumatology Department of Internal Medicine, Tokyo, Japan*

Background: Peripheral neuropathy is one of major manifestations of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and has a significant impingement on patients' quality of life.[1,2]

Objectives: The aim of this study was to clarify clinical features of AAV patients with peripheral neuropathy and identify risk factors for severe motor neuropathy.

Methods: All consecutive patients with active, treatment-naïve AAV who were admitted to our hospital between April, 2012 and October, 2021 were reviewed. Patients were divided into two groups according to the presence or absence of peripheral neuropathy, and their baseline clinical characteristics were compared.

Results: A total of 76 patients (microscopic polyangiitis, MPA, n=37, granulomatosis with poly angiitis, GPA, n=24, eosinophilic GPA, EGPA, n=15) were included in the study. Among them, 28 patients (36.8%) had peripheral neuropathy including 12 with MPA, 4 with GPA, and 12 with EGPA. The clinical characteristics of all patients with peripheral neuropathy were younger age (66.0 years versus 74.5 years, $p<0.05$) and showed higher white blood cell counts (11500/μL versus 8800/μL, $p<0.05$), higher blood eosinophil counts (788.5/μL versus 139.0/μL, $p<0.05$), higher creatinine clearance (77.3 mL/min versus 56.3 mL/min, $p<0.05$), higher levels of serum immunoglobulin (Ig)E (660 IU/mL versus 125 IU/mL, $p<0.05$), and IgG4 (361.5 mg/dL versus 84.0 mg/dL, p <0.05). In patients with EGPA, the most susceptible type to peripheral neuropathy, 80% of the patients had peripheral neuropathy. Comparison between patients with EGPA with peripheral neuropathy and those without demonstrated significantly younger age (56.0 years versus 80.0 years, $p<0.05$) and higher blood eosinophil counts (7832/μL versus 2340/μL, $p<0.05$) were characteristic for the presence of peripheral neuropathy. Patients with EGPA with motor neuropathy (n=8) showed higher white blood cell counts (26850//μL versus 8650//μL, p <0.05) and higher blood eosinophil counts (13134//μL versus 3436//μL, $p<0.05$) compared with those with only sensory neuropathy (n=4).

Conclusion: Our current study has shown that patients with EGPA are more prone to peripheral neuropathy than patients with MPA or GPA. Severe motor neuropathy was observed only in patients with EGPA and associated with more intense eosinophilic inflammation. Our results suggest that molecular targeted therapy that improves eosinophilic inflammation such as anti-IL-5 therapy is beneficial for peripheral neuropathy.

Background: Granulomatosis with polyangiitis (GPA) is the second most frequent vasculitis in Germany with an annual incidence of 34 per million and a prevalence of 210 per million [1]. GPA is characterized by its chronic course, frequent relapses, significant overall morbidity and mortality, and substantial socio-economic impact. Multiorgan involvement affecting the respiratory tract, kidney, and other organs is common. Limited variants also occur [2]. So far, prospective long-term observational data on the disease course of GPA are missing in Germany. Therefore, the Joint Vasculitis Registry in German-speaking countries (GeVas) has been established to follow the course of patients recently diagnosed with vasculitis or a change of their treatment due to a relapse (inception cohort). The GeVas registry allows long-term follow-up of a substantial cohort of vasculitis patients in a multicenter setting.

Objectives: To present the first data on the follow-up of newly diagnosed and relapsing GPA enrolled in the GeVas registry.

Methods: GeVas is a prospective, web-based, multicenter, clinician-driven registry for the documentation of organ manifestations, damage, long-term outcomes, and therapy regimens in various types of vasculitis. Recruitment started in June 2019. By January 2022, 17 centers in Germany were initiated and started enrolling patients. Meanwhile, more than 350 patients have been documented in the registry. Sites in Austria and the German-speaking cantons of Switzerland will be integrated soon [3].

Results: By mid-October 2021, the participating centers included 113 patients with GPA. The majority of patients were PR3-ANCA positive and affected by general symptoms, ENT, lung, renal, and neurological involvement. Patients commonly received cyclophosphamide or rituximab in combination with glucocorticoids for the induction of remission. Fewer patients received methotrexate or other immunosuppressants. Patient characteristics and therapy are summarized in Table 1.

Table 1. Patient characteristics (n = 113). *Unless otherwise specified.

Category	Feature	n (%)*
Age	Age (years); median [range]	60 [51 - 70]
Gender	Male	61 (54.0)
	Female	52 (46.0)
Reason for inclusion in the registry	Newly diagnosed vasculitis	57 (51.4)
	Relapse	56 (49.6)
ANCA status	PR3-ANCA	99 (87.6)
	MPO-ANCA	4 (3.6)
	ANCA negative	9 (7.9)
Organ manifestation	General symptoms	86 (76.1)
	ENT	69 (61.1)
	Lung/chest	66 (58.4)
	Renal	35 (31.0)
	Cardiovascular	7 (6.2)
	GI	3 (2.7)
	Neurological	27 (23.9)
Therapy	Glucocorticoid	102 (90.3)
	Rituximab	56 (49.6)
	Cyclophosphamide	37 (32.7)
	Methotrexate and other immunosuppressants, respectively	26 (23.0) and 19 (16.8), respectively

Conclusion: Here, we present the first interim analysis of the GeVas registry. Clinical manifestations of GPA reported herein show less frequent renal involvement in comparison with a recent report from another European registry (POLVAS) and an UK study [4, 5]. This is potentially related to the predominance of recruiting rheumatology centers thus far. By contrast, respiratory tract involvement is more frequent and PR3-ANCA less common in Japan [5]. Further data are prospectively documented and a follow up analysis is in progress.

AB0623 A REVIEW OF THE EVIDENCE BEHIND THE RECOMMENDATION OF RITUXIMAB FOR ANCA ASSOCIATED VASCULITIS

H. Amin[1], M. Bukhari[2]. *[1]Lancaster Medical School, faculty of health and medicine, Bailrigg, United Kingdom; [2]University Hospitals of Morecambe Bay NHS Foundation Trust, Rheumatology, royal lancaster infirmary, lancaster, United Kingdom*

Background: Cyclophosphamide (CYC) is currently used to induce remission in patients with ANCA-associated vasculitis (AAV). Once remission induction is successful Azathioprine (AZA) is given as maintenance (1). Concerns surround

the use of cyclophosphamide which has an undesirable safety profile, limiting its use in patients. AZA has shown to be effective at maintenance, however rates of relapse on AZA are high.

Rituximab (RTX) is a biologic with a high specificity to B cells. Its mechanism of action (B cell apoptosis) may mean that it can be used for both the induction and maintenance of remission, with a superior long-term safety profile.

Objectives: To conduct a systematic review of literature to determine the efficacy of rituximab as a remission inducing and maintaining agent.

Methods: A systematic review of literature was conducted by searching PubMed and Cochrane library with the search phrase "rituximab AND ANCA-associated vasculitis". The following criteria was then applied: randomised controlled trial (RCT) in the English language. Only original papers were accepted if it pertained to RTX for either induction or maintenance of remission.

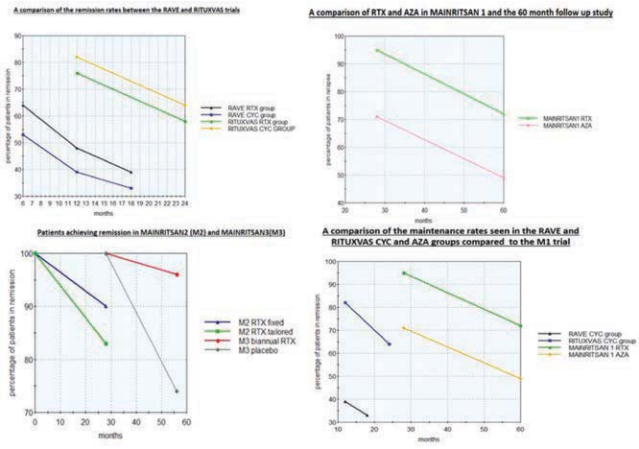
Results: 1008 papers were initially identified and after the search strategy was applied 9 RCTs were analysed.

The RAVE trial compared RTX to CYC in 197 patients with AAV in a double-blind double-dummy trial. The result of the RAVE trial indicated that RTX was as effective as CYC at maintaining remission. The RITUXVAS trial, which was partially blinded and had a sample of 44 patients also came to the same conclusion. Both the RAVE and RITUXVAS trials also showed that an initial dose of RTX was as effective as continuous immunosuppression over the trial length.

Further RCTs were published from the RAVE and RITUXVAS studies including a follow up of patients from the RITUXVAS trial at 24 months which showed no increased rates of relapse or adverse events between the groups. The RAVE study also showed that RTX was effective to be used on multiple occasions to induce remission irrespective of the initial remission inducing agent.

The MAINRITSAN1 study was a non-blinded randomised trial which compared RTX with azathioprine for maintenance in 115 patients with AAV. The results of this trial showed that RTX was superior than AZA at maintenance with only 5% on RTX compared with 29% on AZA relapsing. The long-term follow up of patients in the trial, showed that at 60 months, patients who received RTX were less likely to have relapsed.

The MAINRITSAN2 trial indicated that there was no difference between a fixed vs tailored RTX dose, meaning that a lower tailored dose was as effective as a higher fixed dose. The MAINRITSAN 3 paper was a double-blind trial that indicated that biannual RTX for maintenance was superior than placebo at maintaining remission.



Conclusion: RTX is as effective as CYC at inducing remission, with both the RAVE and RITUXVAS trials sharing similar conclusions.

Currently the research indicates that an initial dose of RTX can maintain remission at similar rates as continuous AZA, however its superiority is yet to be determined. The MAINRITSAN 1 trial was unblinded in its protocol with the data indicating it drastically overestimated the efficacy of both RTX and AZA. Therefore, more research is needed to validate the claim that RTX is superior than AZA at maintenance.

AB0624 PATIENTS WITH VASCULITIS HAVE A HIGH PREVALENCE OF CORONARY MICROVASCULAR DYSFUNCTION

Z. Wallace[1], B. Weber[2], S. Parks[3], C. Cook[4], D. Huck[2], J. Brown[2], S. Divakaran[2], J. Hainer[3], C. Bibbo[3], V. Taqueti[2], S. Dorbala[2], R. Blankenstein[2], K. Liao[5], A. Aghayev[3], H. Choi[4], M. Di Carli[6]. *[1]Massachusetts General Hospital, Harvard Medical School, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; [2]Brigham and Women's Hospital, Harvard Medical School, Heart and Vascular Center, Division of Cardiovascular Medicine, Department of Medicine, Boston, United States of America; [3]Brigham and Women's Hospital, Department of Radiology, Boston, United States of America; [4]Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; [5]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America; [6]Brigham and Women's Hospital, Heart and Vascular Center, Division of Cardiovascular Medicine, Department of Medicine, and Department of Radiology, Boston, United States of America*

Background: Vasculitides are a heterogenous group of diseases characterized by intense vessel wall inflammation, endothelial injury, and systemic inflammation. Several vasculitides are associated with high risk of cardiovascular (CV) disease, an important source of morbidity and mortality in this population. This excess CV risk is attributed both to a high burden of traditional risk factors and to inflammation, but this remains poorly studied. Indeed, inflammation is a known risk factor for CV disease and implicated in coronary microvascular dysfunction (CMD) which may precede obstructive coronary artery disease (CAD).

Objectives: We sought to assess whether vasculitis is associated with CMD in the absence of obstructive CAD.

Methods: We retrospectively identified subjects with systemic vasculitis who underwent symptom prompted rest/stress myocardial perfusion PET. Patients with an abnormal myocardial perfusion study (summed stress score ≥3) or LVEF<40% were excluded. Controls were identified from the same population and matched on age, gender and cardiovascular risk factors (CAD, hypertension, dyslipidemia, diabetes mellitus, and obesity). Coronary flow reserve (CFR), was calculated as the ratio of myocardial blood flow (ml/min/g) at peak stress compared to rest. CMD was defined as CFR <2.

Results: We studied 26 vasculitis cases and 66 matched controls. The most common vasculitides were giant cell arteritis (38%), ANCA-associated vasculitis (31%), and Takayasu's arteritis (12%). Median (IQR) time between diagnosis and PET was 6.5 (2.9, 14.2) years. Seven (27%) cases had active vascultis at the time of PET. Cases and controls were well-matched on age, sex, and CV risk factors (Table 1). Despite a similar prevalence of CV risk factors, coronary flow reserve (reflected by CMD) was abnormal in 38% of vasculitis cases compared to 15% of controls (p=0.004). The mean [SD] CFR was 19% lower in vasculitis cases vs controls (2.11 [0.5] versus 2.6 [0.7], p=0.003).

Table 1. The presence of coronary microvasculature dysfunction in patients with systemic vasculitis without obstructive coronary artery disease

Cohort characteristics	Vasculitis (n=26)		Control (n=66)	P-value
Age at PET, years	62 (18)		61 (17)	0.24
Time from Vasculitis Diagnosis to PET, years (median, IQR)	6.5 (2.9, 14.2)		n/a	
Female, n (%)	18 (72%)		43 (65%)	0.99
Vasculitis Characteristics				
Large Vessel (e.g., giant cell arteritis, Takayasu's), n(%)	13 (50%)		n/a	n/a
Medium Vessel (e.g., polyarteritis nodosa, Kawasaki's arteritis), n(%)	2 (8%)		n/a	n/a
Small Vessel (e.g., ANCA-associated vasculitis, Henoch-Schonlein Purpura), n(%)	11 (42%)		n/a	n/a
Cardiovascular Risk Factors	At Diagnosis	At PET	At PET	
Hypertension, n (%)	12 (46%)	20 (71%)	47 (80%)	0.47
Obesity, n (%)	3 (12%)	2 (32%)	2 (32%)	0.84
Diabetes, n (%)	3 (12%)	5 (20%)	13 (20%)	0.99
Dyslipidemia, n (%)	4 (15%)	15 (58%)	40 (61%)	0.99
Known CAD, n (%)	0 (0%)	1 (4%)	1 (2%)	0.48
Imaging Findings				
Rest myocardial blood flow, ml/min/g	1.0 (0.3)		1.0 (0.3)	0.8
Stress myocardial blood flow, ml/min/g	2.1 (0.6)		2.6 (1.0)	0.008
Coronary Flow Reserve, ml/min/g*	2.1 (0.5)		2.6 (0.7)	0.003
Coronary Microvasculature Dysfunction** (CMD), n (%)	10 (38%)		11 (15%)	0.004

Conclusion: Patients with systemic vasculitis, even in the absence of obstructive CAD, have a high prevalence of CMD compared with non-vasculitis patients. These differences were observed despite matching cases and controls on traditional CV risk factors, highlighting the importance of other factors, such as inflammation and vasculitis treatments on CMD and CV disease in this population. CMD is a known independent risk factor for CV mortality. Future prospective studies are needed to understand the relationship between vasculitis, systemic inflammation, and CMD.

Background: Cytomegalovirus (CMV) has been associated with atherosclerosis in patients with chronic renal failure, and may cause secondary nephrotic syndrome. Therefore, we hypothesized that the reactivation of CMV by immunosuppressive therapy in patients with vasculitis may affect renal function.

Objectives: The purpose of this study was to investigate relationships between CMV infection and renal function during ANCA-associated vasculitis remission induction therapy.

Methods: This retrospective cohort study enrolled microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA), and eosinophilic granulomatosis with polyangiitis patients at 25 sites in Japan who had a first or severe relapse between January 2017 and June 2020. Of these, patients with MPA or GPA who had a positive renal lesion score on BVAS (version 3) at baseline, or vasculitis findings on renal biopsy, CMV assayed by 48 weeks of treatment, were included. Patients were divided into two groups based on the presence or absence of a positive CMV antigen test during the remission induction phase (0–48 weeks of treatment). Outcomes were the rate of change in estimated glomerular filtration rate (eGFR) at 48 weeks after initiation of treatment in both groups, as determined by (eGFR at 48 weeks - eGFR at the initiation of treatment)/eGFR at the initiation of treatment; where lower values were associated with worse renal function. General linear models adjusted for age, gender, presence of diabetes or chronic kidney disease, and the use of rituximab or cyclophosphamide were generated.

Results: A total of 387 patients had CMV antigen measured during ANCA-associated vasculitis treatment, of which 164 had renal involvement and eGFR measured at 48 weeks. Seventy-seven (47.0%) were male and the median age was 75 years (range 69–80 years). CMV reactivation was observed in 44 patients (26.8%). The beta coefficient of multiple regression analysis with CMV positive as 1 and negative as 0 was 0.08 (95% confidence interval -0.13 to 0.29) (p = 0.47). The rate of change in eGFR was higher in the CMV positive group, but not statistically significantly.

Conclusion: Contrary to our hypothesis, renal prognoses tended to be better when CMV reactivation was observed. The patients in the CMV reactivation group may have been treated more aggressively, and some patients with a poor prognosis who were not followed up for 48 weeks dropped out. Further research investigating the adjustment of treatment methods is required.

AB0626 PREVALENCE OF FRAILTY IN AN INTERNET-BASED COHORT WITH A SELF-REPORTED DIAGNOSIS OF VASCULITIS – THE VASCSTRONG STUDY

S. E. Sattui[1], J. Stadler[2], C. Burroughs[3], K. Larson[2], P. A. Merkel[4], R. Spiera[5]. *[1]University of Pittsburgh, Medicine, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America; [2]Vasculitis Foundation, NA, Kansas City, United States of America; [3]University of South Florida, Health Informatics Institute, Tampa, United States of America; [4]PennMedicine, Medicine, Division of Rheumatology, Philadelphia, United States of America; [5]Hospital for Special Surgery Main Hospital, Medicine, Division of Rheumatology, New York, United States of America*

Background: Frailty is a syndrome characterized by an increased vulnerability to stressors and is associated with disability and early mortality. Frailty may be accelerated in patients with vasculitis. The prevalence of frailty in patients with vasculitis remains unexplored.

Objectives: To describe the prevalence of self-reported frailty in patients with vasculitis.

Methods: VascStrong is a longitudinal study utilizing the Vasculitis Patient-Powered Research Network (VPPRN), an internet-based prospective longitudinal cohort. Data elements collected included type of vasculitis, demographic, and use of medications. Frailty was measured by the FRAIL scale, a self-report measure which queries on 5 domains: 1. Fatigue, 2. Resistance (inability to climb 10 stairs), 3. Ambulation (inability to walk several blocks), 4. Illnesses (≥5/11 comorbidities), and 5. Loss of Weight (≥5% weight loss in the last year). Patients were classified as robust, pre-frail, and frail based on 0, 1-2, or ≥ 3 criteria, respectively.

Results: The survey collected information from October 8, 2021-January 15, 2022. For this preliminary analysis, 228 responses were included. Clinical characteristics and study data are outlined in Table 1. Prevalence of robustness, pre-frailty, and frailty was 28.5%, 47.8%, and 23.7%, respectively. The majority of patients with each form of vasculitis were rated as frail or pre-frail. Among the individual FRAIL domains, fatigue and loss of weight were the most frequent (48.7% and 42.5%, respectively) while illnesses, was the least common (3.5%). When compared to robust patients, frail and pre-frail patients were younger, more frequently female, more likely to be obese and reported more frequent use of glucocorticoids. Patients with urticarial vasculitis and Takayasu's arteritis were more commonly pre-frail or frail, compared to patients with other types of vasculitis.

Table 1. Characteristics for overall cohort and by frailty classification

	Overall N = 228	Robust N = 65	Pre-frail N = 109	Frail N = 54
Age, years, mean (SD)	57.6 (15.3)	62.4 (14.8)	55.1 (15.6)	57.1 (14.3)

Currently on glucocorticoids	104 (45.6%)	19 (29.2%)	52 (47.7%)	33 (61.1%)
Current glucocorticoid dose, prednisone equivalent (mg/d), mean (SD)	13.1 (18.0)	12.6 (17.1)	11.3 (18.6)	16.4 (17.4)

Data presented as n (%), unless specified otherwise *Other diagnosis: Behçet's disease, primary angiitis central nervous system, cryoglobulinemic vasculitis, IgA vasculitis, polyarteritis nodosa, and other/suspected diagnosis [a]Based on World Health Organization Body Mass Index categories

Conclusion: Self-reported frailty or pre-frailty is prevalent in the majority of patients with multiple forms of vasculitis. Future analysis will focus on identifying factors associated with frailty in patients with vasculitis, to allow earlier identification and prevention in this population at high-risk for frailty.

Acknowledgements: The investigators want to thank all participants.

EVALUATION OF INTERNAL CONSISTENCY, FEASIBILITY, AND RELIABILITY OF THE ITALIAN VERSION OF ANCA-ASSOCIATED VASCULITIS PATIENT-REPORTED OUTCOME (AAV-PRO_ITA) QUESTIONNAIRE: PRELIMINARY RESULTS FROM A MULTICENTER STUDY ON A LARGE COHORT OF ITALIAN PATIENTS

Background: The ANCA-associated vasculitis patient-reported outcome (AAV-PRO) questionnaire is a 29-item disease-specific PRO measure for AAV[1]. The Italian version of the AAV-PRO questionnaire (AAV-PRO_ita) was translated in collaboration with Oxford and Bristol University (UK) and was preliminarily tested on a single-center Italian cohort[2].

Objectives: The main objective of this multicentric study was to assess the internal consistency, feasibility, and reliability of the AAV-PRO_ita in a large cohort of Italian AAV patients. The secondary objective was to investigate the clinical characteristics of AAV patients associated with AAV-PRO_ita domains.

Methods: The AAV-PRO_ita is describes the following disease domains: (1) organ-specific and systemic symptoms and signs (SSS); (2) physical function (PF); (3) social and emotional impact (SEI). In this study, Italian-speaking AAV patients were recruited from Italian Centres (N=13) with a large experience in the diagnosis and treatment of systemic vasculitis, belonging to the Vasculitis Study Group of the Italian Society of Rheumatology. Inclusion criteria were: a confirmed diagnosis of GPA, MPA, or EGPA; ANCA positivity in at least once occasion or biopsy-proven AAV; and age ≥18 years old. Participants completed the AAV-PRO_ita at three different time-points: baseline, after 5-7 days, and at month 3.

Results: 229 AAV-patients (56.3% women) with a median age of 61 (IQR 51-72) were recruited and completed the questionnaires. The subtype of AAV was mainly GPA (131, 57.2%), followed by EGPA (58, 25.3%), and MPA (40, 17.5%). Median BVASv3 at baseline was 0 (IQR 0-3), whereas the median BVASv3 at the onset of disease was 14 (IQR 9-20). Participants had a median duration of disease of 67 (IQR 24-126) months. Patients who experienced at least one relapse, one hospitalization, and one severe infection were 40.2%, 53.3%, and 24%, respectively. 83% of the patients were on immunosuppressant therapy and 71.6% were still receiving glucocorticoids (GC).

AAV-PRO_ita questionnaire had good internal consistency (Cronbach's Alpha range 0.81-0.93) and good test-retest reliability (ICCs range 0.93-0.96). Item response rates were high overall (maximum 0.87% missing data), supporting the feasibility of the questionnaire.

Concerning the domains of the questionnaire, female AAV patients scored higher (i.e. worse) in all three domains, especially in the SEI domain (p-value<0.001). Older participants (≥65 years) scored higher in the PF domain (p-value<0.05) in all three times of self-completions of the questionnaire. The ongoing treatment also influenced the results. In fact, patients on GC showed higher scores in the PF domain (p-value=0.003) and SEI domain (p-value=0.021). The VDI value seemed to be related to AAV-PRO_ita scores more than disease duration or disease activity, especially in the SSS domain (ρ>0.3, p-value<0.001). Conversely, subtype of AAV did not influence the item scores.

Conclusion: The AAV-PRO_ita questionnaire is a new 29-item, disease-specific PRO measure for use in AAV in the Italian language. It is a self-administered Italian questionnaire with good internal consistency, feasibility, and reliability. AAV-PRO_ita proved to be a useful tool to explore the AAV patient's perception of quality of life, and it could become an important way of measuring the unmet needs of AAV patients.

SYSTEMATIC LITERATURE REVIEW INFORMING THE 2022 UPDATE OF THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF ANCA-ASSOCIATED VASCULITIS: FOCUS ON DIAGNOSTIC AND FOLLOW-UP PROCEDURES

B. Sanchez-Alamo[1], J. Schirmer[2], S. Monti[3], B. Hellmich[4], D. Jayne[5]. *[1]Lund University, Skåne University Hospital, Nephrology, Lund, Sweden; [2]University*

Medical Center Schleswig-Holstein, Clinic for Internal Medicine I, Section for Rheumatology, Kiel, Germany; [3]University of Pavia, Fondazione IRCCS Policlinico S. Matteo, Rheumatology, Pavia, Italy; [4]University of Tübingen, Medius Kliniken, Internal Medicine, Rheumatology and Immunology, Kirchheim-Teck, Germany; [5]University of Cambridge, Addenbrooke's Hospital, Department of Medicine, Cambridge, United Kingdom

Background: The 2008 and 2016 European Alliance of Associations for Rheumatology (EULAR) recommendations for the management of ANCA-associated vasculitis (AAV)[1,2] have supported clinicians with recommendations for the accurate diagnosis, monitoring and for the management of the long-term complications of patients with ANCA-associated vasculitis (AAV). Since the publication of the last EULAR guidelines, several high-impact research articles have provided further evidence to improve diagnosis and monitoring of AAV-patients.
Objectives: The aim of this systematic review was collecting evidence supporting the 2022 update of the AAV management recommendations.
Methods: The recommendations were developed based on the 2014 EULAR standardized operating procedures (SOP)[3]. Areas of interest were adopted from the 2016 recommendations and updated by identifying additional items through a Delphi exercise. Key questions were framed in the PICO (Population, Intervention, Comparator, Outcome) format. Keywords identifying topics of interest for the diagnosis and follow up were gathered based on the PICO questions and then incorporated into a search string. A systematic literature research (SLR) was performed according to the EULAR SOP. PubMed (Medline), Embase and the Cochrane Library databases were searched for articles providing data on the search questions. Abstracts of the annual meetings of EULAR, ACR, ERA-EDTA, ASN and the Vasculitis and ANCA Workshops were also screened, but restricted to randomized controlled clinical trials (RCTs).
After deduplication, publications were first sorted by title and abstract and then full text review was done for eligible articles. The data were extracted from included articles and grouped according to the PICO questions. Data extraction results were collected in evidence tables.
The Cochrane revised tool for assessing risk of bias for RCTs (RoB2), ROBINS-1 for observational studies, QUADAS II for diagnostic accuracy studies and AMSTAR II for meta-analyses were used for bias assessment. Evidence was categorized based on the GRADE system as per EULAR SOP[3].
Results: Based on the results of the Delphi, 3 topics related to diagnosis and follow-up were identified that were transformed into PICO questions: the impact of tissue biopsies and positive ANCA testing to support the clinical diagnosis of AAV and the impact of clinical parameters and biomarkers on disease-related outcomes and treatment-related adverse events (Table 1). Other items that received lower scores in the Delphi exercise were added in the format of subquestions (e.g. diagnostic imaging). Based on these research questions, search strings for the SLR were created.
The SLR was still ongoing at the time this abstract has been written and results of the SLR will be presented at the meeting.

Table 1. Topics of interest for diagnostic and follow-up testing identified in the Delphi exercise

Patients	Diagnostic / follow-up procedure	Outcome
Granulomatosis with Polyangiitis	Tissue biopsy	Confirmation of diagnosis of ANCA-associated vasculitis
Microscopic Polyangiitis Eosinophilic Granulomatosis with Polyangiitis	ANCA testing Clinical parameters Imaging Biomarkers	Disease-related outcomes Treatment-related adverse events

Conclusion: This SLR identified recent developments affecting key areas of AAV diagnosis and follow-up. The results of this SLR provide systematic evidence to inform the 2022 update of the EULAR recommendations for the management of AAV, which will also be presented at this meeting.

GLOMERULONEPHRITIS ASSOCIATED WITH ANCA AFTER COVID-19 VACCINE: A SYSTEMATIC REVIEW

A. Laskova[1], B. Mohammed[2], F. Ali[3], B. Syritsa[4]. *[1]AMITA Health Saint Joseph Hospital Chicago, Internal Medicine, Chicago, United States of America; [1]AMITA Health Saint Joseph Hospital Chicago, Internal Medicine, Chicago, United States of America; [3]University of Texas Health Science Center at Houston, Gastroenterology, Houston, United States of America; [4]AMITA Health Saint Francis Hospital, Internal Medicine, Evanston, United States of America*

Background: The COVID-19 pandemic has led to widespread vaccination with effective results and a great safety profile. However, as the vaccination rate has increased, more cases of autoimmune diseases after the COVID-19 vaccine have been described. We present a systematic review of ANCA-associated glomerulonephritis after the COVID-19 vaccine.
Objectives: To summarize the existing evidence on ANCA-associated glomerulonephritis after the COVID-19 vaccine.
Methods: We searched all studies from inception till January 27, 2022, that described ANCA-associated biopsy-proven glomerulonephritis after COVID-19 vaccine through Embase and Medline. Methodological quality was evaluated with the 4 domains tool. We included 13 patients from 2 case series and 9 case reports. We extracted demographics, history, lab results, outcomes. We then applied descriptive statistics.
Results: 46% of the patients were males and 54% were females. The median age was 74 years. 54% developed symptoms after the second dose of the 2-dose vaccine. The median interval between the vaccine and the symptom onset was 10.5 days. 85% had anti-MPO antibodies, and the rest – anti-PR3 antibodies. 31% of patients had persistent creatinine (Cr) elevation on follow-up, and 3 patients were requiring hemodialysis. Of those 3 patients, 1 patient had normal renal function prior to presentation, and the rest had chronic kidney disease. The summary of the cases is presented in Table 1.

Table 1.

Gender, age	De novo (1) or relapse (2)	AZD1222 (1), or mRNA-1273 (2), or BNT162b2 (3)	Outcome
M, 75[1]	2	1	Hemodialysis
M, 74[1]	2	1	Improved Cr
F, 82[2]	1	2	Improved Cr
F, 70[3]	1	2	Improved Cr
F, 78[4]	1	3	Improved Cr
F, 79[5]	1	3	Remission
F, 54[6]	1	3	Improved Cr
F, 78[6]	2	3	Hemodialysis
M, 58[7]	1	2	Remission
M, 63[8]	1	1	Improved Cr
F, 29[9]	1	3	Remission
M, 52[10]	1	2	Hemodialysis
M, 84[11]	1	3	Worsened Cr

Conclusion: Although the causality cannot be established on current evidence, the COVID-19 vaccine can probably trigger glomerulonephritis associated with ANCA, primarily anti-MPO type. We need a bigger cohort to identify patients predisposed for disease development or relapse after the COVID-19 vaccine.

AB0630 ASSESSMENT OF ORGAN DAMAGE ACCRUAL IN BEHÇET'S SYNDROME OVER 2-YEAR FOLLOW-UP: RESULTS FROM THE BODI PROJECT LONGITUDINAL EXTENSION.

A. Floris[1,2], R. Laconi[1,2], G. Espinosa[3], G. Lopalco[4], L. Serpa Pinto[5], N. Kougkas[6,7], J. Sota[8], A. Lo Monaco[9], M. Govoni[9], L. Cantarini[8], G. Bertsias[6], J. Correia[5], F. Iannone[4], R. Cervera[3], C. Vasconcelos[10], A. Mathieu[1], A. Cauli[1,2], M. Piga[1,2]on behalf of BODI project group. *[1]University of Cagliari, Medical Sciences and Public Health, Monserrato, Italy; [2]AOU University Clinic and University of Cagliari, Rheumatology Unit, Cagliari, Italy; [3]University of Barcelona, Department of Autoimmune Diseases, Hospital Clinic, Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]University of Bari , Rheumatology Unit, Bari, Italy; [5]Hospital Santo Antonio Centro Hospitalar do Porto, Unidade de Imunologia Clinica, Porto, Portugal; [6]University of Crete, Rheumatology, Clinical Immunology and Allergy Unit, Heraklion, Greece; [7]Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Hippokration University Hospital, Medical School, Thessaloniki, Greece; [8]University of Siena , Rheumatology Unit, Siena, Italy; [9]University of Ferrara, Rheumatology Unit - AOU S. Anna, Ferrara, Italy; [10]University of Porto, UMIB Abel Salazar Biomedical Sciences Institute, Porto, Portugal*

Background: Preventing accrual of organ damage is a major goal in the treatment of Behçet's Syndrome (BS). The BS Overall Damage Index (BODI) is the first damage assessment tool developed and preliminarily validated for BS.
Objectives: To assess the prevalence, extent, and determinants of organ damage accrual in the BODI validation cohort over 24 months of follow-up.
Methods: Overall, 189 patients from the multicenter BODI cohort underwent a 24 ±3 months follow-up (FU) visit. Demographics, ongoing medication, Behçet's Disease Current Activity Form (BDCAF) score, Physician (PGA) and Patient Global Assessment (PtGA) of disease activity, disease relapsing (defined by any treatment change due to increased disease activity), and the BODI score were recorded. Damage accrual was defined as any increase ≥1 in the BODI score between baseline and follow-up visit (Δ-BODI). Logistic regression models were built to identify factors associated with BODI damage accrual.
Results: The mean age (standard deviation) at enrolment and the disease duration was 46.2 (12.1) and 10.8 (8.3) years, respectively, and 92/189 (48.7%) patients were males. During 24 months, 36 (19.0%) patients had an increase in the BODI score of at least 1 point (mean increase of 1.7 points). The BODI score increased from 1.6 (2.1) to 1.9 (2.1), with a mean Δ-BODI of 0.3 (0.8). Overall, 61 new BODI items of damage were recorded (Figure 1); 22 (34%) were steroid-related (diabetes, osteoporotic fractures, cataract). Factors independently associated with increased BODI score were longer glucocorticoids exposure (OR 1.01 per month, 95%CI 1.01-1.02, p<0.001), and occurrence of flares (OR 3.1, 95%CI 1.1-8.9, p = 0.035), whereas stable treatment with conventional and/or biologic immunosuppressants was negatively associated with an increase in the BODI score (OR 0.19, 95% 0.07-0.97, p <0.001) (Table 1).

Table 1. Determinants of organ damage accrual over 2 years of follow-up.

	Univariate analysis			Multivariate analysis	
Candidate determinants	**Δ-BODI ≥1 (n 36)**	**Δ-BODI = 0 (n 153)**	**p**	**OR (95%CI)**	**p**
Males	16 (44.4%)	76 (49.7%)	0.572		
Age at enrolment	56.2 (42.9-62.0)	46.6 (35.4-53.1)	**0.001**	--	--
Disease duration	12.9 (7.1-22.0)	11.1 (5.4-21.2)	0.483		
Major organ involv.	22 (61.1%)	72 (47.1%)	0,129		
BDCAF at BL	3 (0-5)	2. (0-5)	0.365		
BDCAF at FU visit	3.0 (3-5)	3 (0-7)	0.188		
GC duration	112 (26.0-147.0)	24.0 (8.0-72.0)	**<0.001**	**1.012 (1.006-1.018**	**<0.001**
cIS or TNFì ever	24 (66.7%)	133 (86.9%)	**0.004**	**0.194 (0.073-0.972)**	**<0.001**
Relapse	9 (25.0%)	20 (13.1%)	**0.070**	**3.093 (1.066-8.972)**	**0.038**
BODI score at BL	1.0 (0-2.0)	1 (0-2)	0.579		

Continuous variables are presented as median (IQR). Dichotomic variable are presented as n (%). BODI, Behçet's Syndrome Overall Damage Index. FU, follow-up. cIS, conventional immunosuppressant. Δ-BODI increase of BODI score from baseline to the FU visit.

Conclusion: Despite the relatively high disease duration in the studied cohort, organ damage accrual was recorded in a relevant proportion of patients. BODI proved to capture the damage associated with major determinants such as inadequate control of disease activity and prolonged exposure to glucocorticoids.

Piga[1,2]on behalf of BODI project group. *[1]University of Cagliari , Department of Medical Sciences and Public Health, Cagliari, Italy; [2]AOU University Clinic and University of Cagliari, Rheumatology Unit, Cagliari, Italy; [3]University of Barcelona, Department of Autoimmune Diseases, Hospital Clinic, Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]University of Bari , Rheumatology Unit, Bari, Italy; [5]Hospital Santo Antonio Centro Hospitalar do Porto, Unidade de Imunologia Clinica, Porto, Portugal; [6]University of Crete, Rheumatology, Clinical Immunology and Allergy Unit, Heraklion, Greece; [7]Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Hippokration University Hospital, Medical School, Thessaloniki, Greece; [8]University of Siena , Rheumatology Unit, Siena, Italy; [9]University of Ferrara, Rheumatology Unit - AOU S. Anna, Ferrara, Italy; [10]University of Porto, UMIB Abel Salazar Biomedical Sciences Institute, Porto, Portugal*

Background: Behçet's Syndrome (BS) is a multisystem recurring inflammatory disorder characterised by a wide spectrum of clinical manifestations, which can vary from limited mucocutaneous lesions up to severe and even life-threatening events.
Objectives: To evaluate the impact of BS on the patients' work activity and productivity.
Methods: A sub-cohort of 148 patients from the original Behçet's syndrome Overall Damage Index (BODI) Project study was enrolled. The Work Productivity and Activity Impairment: General Health (WPAI:GH) questionnaire was administered. Demographics, disease duration, comorbidity, major organ involvement, ongoing therapy, Behçet's Disease Current Activity Form (BDCAF), Physician Global Assessment (PGA), Patient Global Assessment (PtGA), and the BODI were recorded. Multiple regression models were built to investigate the independent effect of BS features on WPAI.
Results: Overall, 97 (65.6%) out of 148 patients who completed the WPAI:GH questionnaire resulted working for pay; 22 out of 97 (27.8%) patients reported missing work in the past week due to their health, accounting for a mean (SD) of 34.4% (17.8) of their working time (absenteeism). The only factor significantly associated with absenteeism in multivariate analysis was the presence of ocular damage, as assessed by the BODI (β 0.255, p = 0.027).
Although 93 patients reported that they worked in the previous week, mean 27.3% (30.7) of their actual work productivity was impaired due to their health problem (presenteeism), with only 37 (38.5%) patients reporting no such loss. Factors associated with work impairment were female gender (β 0.319, p = 0.001), higher PtGA (β 0.298, p = 0.002), and an increased BODI score in the last 2 years follow-up (β 0.212 for one-point increased BODI score, p = 0.024).
Finally, 99 (66.9%) of the total 148 patients complained of a daily activity impairment, reporting that a mean of 33.3% (30.6) of their regular daily activities had been prevented due to their health problems. Factors significantly associated with patients' daily activity impairment were younger age at enrolment (β 0.187, p = 0.021), higher BDCAF disease activity (β 0.235, p = 0.002) and fibromyalgia (β 0.324, p = 0.033).

Conclusion: BS can lead to missing work time and significantly affect both the patient's work productivity and daily activities. Active disease seems to be one of the major determinants together with a higher burden of damage and the association of some specific comorbidities, such as fibromyalgia.

AB0632 INTRACARDIAC THROMBOSIS AND VASCULAR INVOLVEMENT IN BEHÇET'S DISEASE : TWO SIDES OF THE SAME COIN ?

S. Chadli[1], H. Khibri[1], W. Ammouri[1], M. Maamar[1], H. Harmouche[1], Z. Tazi Mezalek[2]. *[1]University Mohammed V - Faculty of Medicine and Pharmacy - University Hospital Center Ibn Sina, Internal Medicine, 10100, Morocco; [2]University Mohammed V - Faculty of Medicine and Pharmacy - University Hospital Center Ibn Sina, Internal Medicine and Clinical Hematology, Rabat, Morocco*

Background: Behçet's disease (BD) is a relapsing vasculitis that can affect vessels of all sizes and kinds. Intracardiac thrombosis (ICT) is a serious complication of the disease, which usually presents associated to vascular lesions. However, its mechanism of constitution in BD remains unclear and the link between these manifestations has yet not been fully clarified.
Objectives: Our first objective is to describe the clinical characteristics, imaging features, therapeutic management and outcome of these patients. And secondly, to shed some light on the relation between this rare condition and the vascular involvement of the disease.
Methods: This monocentric study was conducted in the University Hospital Center Ibn Sina of Rabat (Morocco), and retrospectively included 312 Behçet patients admitted to the Internal Medicine department between 2010 and 2021. Twelve patients with ICT related to BD were enrolled.
Results: Patients were mostly male (90%) with a mean age of 30 years. ICT was the presenting symptom of BD in half of the cases. In the other half, it was detected with a mean of 6.4 years after the disease onset. Six patients had a history of deep vein thrombosis (DVT) related to BD, either as a single episode (n=3), recurrent episodes (n=2), or as DVT associated to pulmonary artery occlusion (n=1). The most frequent symptoms were dyspnea (50%), chest pain (50%), dry cough (40%) and hemoptysis (30%). Four patients had signs of right cardiac failure. Peripheral vascular manifestations were noted in five patients. The other Behçet's flares simultaneously observed were mucocutaneous (80%), digestive (10%), ocular (10%) and articular (10%). Inflammatory parameters were raised in all patients with a median ESR of 49 mm/h and CRP of 51 mg/L. On echocardiography, ICT was always located in the right heart, with an extension to the inferior vena cava in half of the cases. Two patients had also the left cavities involved. Multiple thrombi were visualized in three cases. The associated cardiac lesions observed were pericarditis (50%), tricuspid insufficiency (50%), mitral insufficiency (10%), endomyocardial fibrosis (10%) and myocarditis (10%). The right cavities were dilated among five patients. Pulmonary hypertension was found in 60% of the cases. On CT Chest Angiography, 70% of the patients had pulmonary artery thrombosis and 50% of them had pulmonary artery aneurysms. The other vascular lesions detected were Budd Chiari syndrome with mesenteric ischemia (10%), subtotal internal jugular vein obstruction (10%) and cerebral venous sinus thrombosis (10%). All patients were treated with colchicine, glucocorticoids and immunosuppressants. Eleven patients were put under Cyclophosphamide and one under Methotrexate followed by a TNF- alpha inhibitor. Six patients were also on curative anticoagulation. No death or relapse was recorded to our knowledge. Five patients were declared on complete remission, two on partial remission.
Conclusion: ICT is a serious complication that usually occurs in the first years of the BD's onset, among young men with vascular manifestations. We believe that this strong association is highly suggestive that ICT in BD is a direct consequence of the underlying vasculitis.

AB0633 HEALTH-RELATED QUALITY OF LIFE IN ANCA VASCULITIDES AND RHEUMATOID ARTHRITIS PATIENTS: A CROSS-SECTIONAL COMPARATIVE STUDY

A. Panagiotopoulos[1], K. Thomas[2], E. Argyriou[3], A. Chalkia[4], N. Kapsala[2], C. Koutsianas[1], E. Mavrea[1], D. Petras[4], D. Boumpas[2], D. Vassilopoulos[1]. *[1]2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens School of Medicine, Hippokration General Hospital, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, Athens, Greece; [2]4th Department of Medicine, National and Kapodistrian University of Athens School of Medicine, Attikon General Hospital, Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, Athens, Greece; [3]Sismanoglio General Hospital, Rheumatology Unit, Athens, Greece; [4]Hippokration General Hospital, Nephrology Department, Athens, Greece*

Background: ANCA associated vasculitides (AAVs) are rare, serious forms of vasculitides. There are limited data regarding the quality of life in patients with AAVs compared to other chronic inflammatory diseases.
Objectives: The purpose of this study was to compare the quality of life between patients with AAV and those with a chronic inflammatory arthritis such as rheumatoid arthritis (RA).
Methods: Multicenter, cross-sectional study of AAV and RA patients followed in three tertiary referral centers. Data from 1007 healthy controls served as historic controls.[1] HRQoL was assessed with the Short Form 36 Health Survey (SF-36) which includes physical and mental component summary scores (PCS and MCS). Disease activity were assessed with the Birmingham Vasculitis Activity Score version 3 (BVAS 3, for AAVs) and the DAS28-ESR (for RA) respectively and organ damage/function with the Vasculitis Damage Index (VDI for AAVs) score and Health Assessment Questionnaire (HAQ for RA) scores, respectively.
Results: 66 patients with AAVs (GPA 62%, MPA 29% and EGPA 9%, females 56%, mean age 63.4 years, generalized disease 74%, mean disease duration 6.2 years, remission 73%) and 71 with RA (females 56%, mean age 63.3 years, remission 72%) were included. Both AAV and RA patients had significantly lower PCS and MCS scores compared to healthy controls ($p < 0.05$) while RA patients had lower PCS and MCS scores compared to AAV patients ($p < 0.05$). According to disease activity status, there was no difference in the SF-36 scores between those with active (BVAS > 1) and inactive (BVAS < 1) AAV, except for the energy-fatigue component (55.0 ± 21.8 vs. 67.2 ± 20.7, p= 0.038) whereas patients with active RA (DAS28-ESR > 3.2) had lower scores for all SF36 components compared to those with low disease activity (DAS28-ESR < 3.2). Additionally, active RA patients had lower both PCS and MCS scores compared to active AAV patients ($p < 0.05$). AAV patients with increased damage scores (VDI > 3) had lower PCS score compared to those with less organ damage (VDI < 3), (33.9 ± 10.1 vs. 49.1 ± 10.2, $p < 0.001$) while RA patients with increased damage/poor functionality (HAQ ≥ 0.75) had lower both PCS and MCS scores compared to those with less damage (HAQ ≤ 0.63), (35.0 ± 7.2 vs. 48.4 ± 8.6, $p < 0.001$) and (40.5 ± 8.6 vs. 48.2 ± 7.6, $p < 0.001$ respectively). Compared to patients with AAV, RA patients with increased damage had lower score for the pain component compared to AAV patients (37.7 ± 28.6 vs. 61.2 ± 29.5, p= 0.024).
Conclusion: In general, patients with AAV and RA, demonstrate impaired quality of life compared to healthy controls. In the AAV group, quality of life correlated more with organ damage and less with disease activity whereas in RA patients, quality of life correlated both with disease activity and damage. These data emphasize the need for more efficacious therapies for AAV patients that could prevent chronic organ damage and improve quality of life.

AB0634 VARIABILITY IN PHENOTYPE CLUSTERS IN BEHÇET'S SYNDROME: A SYSTEMATIC REVIEW

B. Macit[1], K. Akyuz[2], S. N. Esatoglu[3,4], G. Hatemi[3,4]. *[1]Kackar State Hospital, Department of Dermatology, Rize,Turkey; [2]Wayne State University School of Medicine, Department of Internal Medicine, Detroit, United States of America; [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul,Turkey; [4]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet's Disease Research Center, Istanbul,Turkey*

Background: The presence of distinct clinical phenotypes with clustering of certain organ manifestations is well-recognized Behçet's syndrome (BS). Differences in demographic features, treatment response, and possibly inflammatory pathways involved in the pathogenesis of different phenotypes have been proposed. However, studies from different BS cohorts have shown variability in the phenotypes that were defined.
Objectives: We aimed to explore the causes of variability in clinical phenotype clustering across different countries and cohorts.
Methods: An electronic search was carried out in PubMed to find articles published in or before November 2021, using the keywords of Behcet, cluster and factor analysis. Two reviewers independently performed a screening of titles, abstracts, and full-texts .
Results: Amongst 496 articles searched, 30 full-texts were assessed, and 10 studies were relevant for data extraction. Ten articles studied 12 different cohorts, 3 from China, 3 from Turkey, 2 from Japan, 1 from South Korea, 1 from Israel, 1 from Greece, and 1 from Italy. 9 out of 10 studies demonstrated clustering of organ manifestations (11 cohorts). There were important differences between the clusters that were identified in these studies (Table 1). Clusters including skin and mucosa manifestations were present in all cohorts, but the skin and mucosa manifestations that clustered together differed from cohort to cohort. Uveitis stood by itself in some studies, whereas it clustered with vascular and central nervous system (CNS) involvement in some cohorts, and certain skin and mucosa lesions in another. Papulopustular lesions (PPL) and arthritis showed a positive correlation in 4 cohorts whereas these manifestations were negatively correlated in 1 cohort. Moreover, no clusters were identified in 1 study. Potential causes of differences in clusters that we have identified in these studies were: study design (database vs multicenter vs single-centre cohort), statistical analysis method (hierarchical cluster vs factor analysis) patient population (pediatric vs adult vs late onset), setting (dermatology vs rheumatology), diagnostic criteria (ISG vs ICBD), disease duration, definition of organ involvement (such as PPL vs folliculitis, or CNS involvement vs dural sinus thrombosis, ascertainment of manifestations (confirmed gastrointestinal involvement vs any diarrhea, lack of ascertainment in diagnosis of nodular lesions as erythema nodosum vs superficial thrombophlebitis), time interval (manifestations throughout the disease course vs manifestations that were active during the last 3 months), and change in the natural history of BS over decades.
Conclusion: Differences in phenotype clusters may result from differences in study characteristics rather than real geographic or ethnic differences. A large multi-national study with uniform inclusion criteria is needed to better understand phenotype clusters and their implication towards management strategies in BS.

AB0635 CENTRAL NERVOUS SYSTEM INVOLVEMENT AND MIMICKERS IN ANCA ASSOCIATED VASCULITIS

Y. Yagiz Ozogul[1], S. N. Esatoglu[2,3], M. Ozogul[4], O. Kizilkilic[5], Y. Ozguler[2,3], V. Hamuryudan[2,3], G. Hatemi[2,3]. *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul , Turkey; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul,Turkey; [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet's Disease Research Center, Istanbul,Turkey; [4]Haydarpasa Numune Training and Research Hospital, Department of Radiology, Istanbul,Turkey; [5]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Radiology, Istanbul , Turkey*

Background: Central nervous system (CNS) involvement is rare in ANCA associated vasculitis (AAV). Besides, complications of immunosuppressive (IS) therapy or other conditions that mimic CNS involvement may occur in some AAV patients.
Objectives: We aimed to assess the clinical, laboratory and imaging features of our AAV patients with CNS involvement and conditions other than CNS involvement that caused neurologic signs and symptoms.
Methods: We reviewed the charts of our AAV patients with neurologic sign or symptoms and extracted data on their demographics, types of AAV, neurologic symptoms/signs, final diagnoses after neurologic work-up, and their outcome.
Results: Nineteen AAV patients (13 men, mean age: 46.6±16.6 SD years) with neurologic signs or symptoms were identified. Fifteen patients had GPA, 3 had MPA, and 1 had EGPA. Neurologic symptoms were present at disease onset in 9 patients while they developed within a mean follow up of 36.7 ± 40.1 SD months after AAV diagnosis in the remaining 10. At the time of the occurrence of neurologic symptoms, all patients had active disease (median (IQR) BVAS: 13.8 (9.5-18.5)). Eight patients (42%) also had accompanying peripheral nervous system involvement.
Final diagnosis was CNS involvement of AAV in 5 (26%) patients. These were ischemic cerebrovascular accident (CVA) in 2 patients, hemorrhagic CVA in 1 patient, and cranial neuropathy (peripheral facial nerve palsy) in 2 patients. Cranial MRI revealed T2 FLAIR hyperintensities in 2 patients with ischemic CVA. One also had border zone ischemic changes and the other had areas compatible with terminal branch ischemia. Corticosubcortical hematoma in the left parietal lobe and microhemorrhages in the right frontal lobe were observed in a patient with hemorrhagic CVA. Among the 2 patients with facial nerve palsy, cranial MRI was normal in one while the other had nonspecific increased T2 signals in the cerebral cortex. Cranial neuropathy resolved with high dose glucocorticoid (GC) treatment without sequel in 1 patient and regressed with high dose GC and cyclophosphamide (CYC) in the other. One patient with ischemic CVA was lost to follow-up, and the other recovered with high dose GC and CYC treatment without sequela. The patient with hemorrhagic CVA had died.
Neurologic symptoms were diagnosed to be due to other AAV manifestations in 6 (32%) patients. These were sinonasal involvement in 3 patients with sensorineural hearing loss (n=2), and blurred vision (n=1); orbital involvement in 2 patients with headache (n=2) and ocular involvement (scleritis) in 1 patient with blurred vision. Neurologic symptoms of these 6 patients recovered with immunosuppressive therapy including high dose GC (n=6), mycophenolate mofetil (n=2), methotrexate (n=2), rituximab (RTX) (n=1), and both CYC and plasmapheresis (n=1). Three patients (16%) had secondary complications affecting the CNS. One patient with seizures had posterior reversible encephalopathy syndrome (PRES)

CVS: Cardiovascular, DVT: deep vein thrombosis; EN: erythema nodosum; G: genital ulcers; GI: gastrointestinal J: joint; MC: mucocutaneous; NBS: Neuro-Behçet syndrome, O: oral ulcers; PF: pseudofolliculitis; PPL: papulopustular lesions; STM: superficial thrombophlebitis; U: uveitis; V: vascular

and recovered with CYC and anti-epileptic drugs. The second patient with blurred vision and headache had cerebral venous sinus thrombosis (CVST) and recovered with anticoagulant therapy. The third patient with muscle weakness died due to spondylodiscitis complicated with aortic pseudoaneurysm.
In 5 patients (26%), neurologic work-up did not lead to an underlying condition. The presenting symptoms of these patients were transient acute vision loss in 2, numbness of extremities in 1, syncope in 1 and vertigo in 1 patient. Neurologic symptoms resolved after high dose GC and RTX in the patient with vertigo. At the onset of neurologic symptoms, 3 patients were using IS therapy including azathioprine, MMF and CYC in 1 patient each. The fourth patient was off treatment. Neurologic symptoms were transient in these patients, and did not recur during our follow-up of 36, 52, 57, and 120 months.
Conclusion: CNS involvement appears to be rare in AAV and non-CNS entities including ocular, orbital and sinonasal involvement and complications such as PRES, CVST and infections may mimic CNS involvement in patients with AAV.

Piga[1,2]on behalf of BODI project group. *[1]University of Cagliari , Department of Medical Sciences and Public Health, Cagliari, Italy; [2]AOU University Clinic and University of Cagliari, Rheumatology Unit, Cagliari, Italy; [3]University of Barcelona, Department of Autoimmune Diseases, Hospital Clinic, Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [4]University of Bari , Rheumatology Unit, Bari, Italy; [5]Hospital Santo Antonio Centro Hospitalar do Porto, Unidade de Imunologia Clinica, Porto, Portugal; [6]University of Crete, Rheumatology, Clinical Immunology and Allergy Unit, Heraklion, Greece; [7]Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Hippokration University Hospital, Medical School, Thessaloniki, Greece; [8]University of Siena , Rheumatology Unit, Siena, Italy; [9]University of Ferrara, Rheumatology Unit - AOU S. Anna, Ferrara, Italy; [10]University of Porto, UMIB Abel Salazar Biomedical Sciences Institute, Porto, Portugal*

Background: Preventing accrual of organ damage represents a primary goal in the treatment of Behçet's Syndrome (BS), as it may result in impairment of other outcomes, including the health-related quality of life (HR-QoL).
Objectives: The objective of this study was to investigate whether the recent accrual of organ damage, rather than its extent at a single time point, correlate with an impairment of the HR-QoL.
Methods: A sub-analysis of data from patients recruited in the longitudinal phase of the BODI Project validation cohort was performed. The HR-QoL and damage were measured by the Short-form 36 questionnaire (SF-36) and the BS Overall Damage Index (BODI), respectively, at the baseline visit and at a follow-up (FU) 24 ±3 months later. Then the possible increase of damage over FU was assessed by calculating the difference between the BODI score (Δ-BODI) in the two visits. Then, the relationship between the Δ-BODI and the individual and summary domains of the SF-36 was analysed by building multivariate regression models, including age, gender, concomitant fibromyalgia and/or depression, current disease activity as assessed by the BDCAF, as confounding variables.
Results: From the BODI validation cohort, 147 patients were recruitable for this sub-analysis;73 (49.8%) were males. The mean (SD) age and disease duration at enrolment were, respectively, 46.2 (12.4) and 13.4 (10.1) years. BODI score did not influence the SF-36 domains assessed at the baseline visit. In contrast, a significant correlation was recorded between the Δ-BODI and the following SF-36 domains: physical function (PF) (β -0.158 for 1 unit increase in BODI score, p 0.025), role physical (RP) (β -0.150, p 0.044), general health (GH) (β -0.199, p 0.004), role emotional (RE) (β -0.180, p 0.001), mental health (MH) (β -0.244, p 0.001), and the mental components summary (MCS) (-0.203, p 0.008) (Figure 1). Gender, age, fibromyalgia and disease activity were also confirmed to significantly influence HR-QoL (Table 1).

Table 1. Multiple regression for the assessment of the relationship between Δ-BODI and SF-36 domains

	Δ-BODI	Male	Age	FBM	DPR	BDCAF
Physical function (PF)	-0.158 **(p 0.025)**	0.180 (p 0.010)	-0.299 (p<0.001)	-0.358 (p<0.001)	-- (p 0.552)	-0.141 (p 0.044)
Role-physical (RP)	-0.150 **(p 0.044)**	0.154 (p 0.039)	-0.212 (p 0.001)	-0.278 (p<0.001)	-- (0.086)	-0.251 (p<0.001)
Body-pain (BP)	-- 0.868	0.266 (p<0.001)	-0.286 (p<0.001)	-0.276 (p<0.001)	-- (p 0.799)	-262 (p<0.001)
General health (GH)	-0.199 **(p 0.004)**	0.187 (p 0.010)	-- (0.136)	-0.296 (p<0.001)	-- (0.861)	-0.352 (p<0.001)
Vitality (VT)	-- (p 0.868)	0.238 (p 0.001)	-0.178 (p 0.008)	-0.213 (0.002)	-- (p 0.855)	-0.371 (p<0.001)
Social function (SF)	-- (p 0.239)	0.299 (p 0.004)	-0.166 (p 0.024)	-0.242 (p 0.001)	-- (0.831)	-0.202 (p 0.010)
Role emotional (RE)	-0.180 **(p 0.003)**	0.158 (p 0.047)	-0.157 (p 0.048)	-0.233 (p 0.003)	-- (0.531)	-0.191 (p 0.016)
Mental health (MH)	-0.244 **(p 0.001)**	-- (p 0.142)	-- (p 0.142)	-0.292 (p<0.001)	-- (p 0.073)	-0.254 (p 0.001)
Physical Component Summary (PCS)	-- 0.105	0.229 (p 0.001)	-0.298 (p<0.001)	-0.296 (p<0.001)		-0.254 (p<0.001)
Mental Component Summary (MCS)	-0.203 **(p 0.008)**	-- (p 0.068)	-- (0.246)	-0.255 (p 0.001)	-- (0.122)	-0.302 (p<0.001)

FBM: fibromyalgia; DPR: depression

Conclusion: The recent accrual of organ damage, rather than its extent assessed in a single visit, is associated with impairment of different aspects of heath related quality of life, especially those mental related. Such phenomenon is similar to that observed in other systemic rheumatic disease, may be due to coping mechanisms.

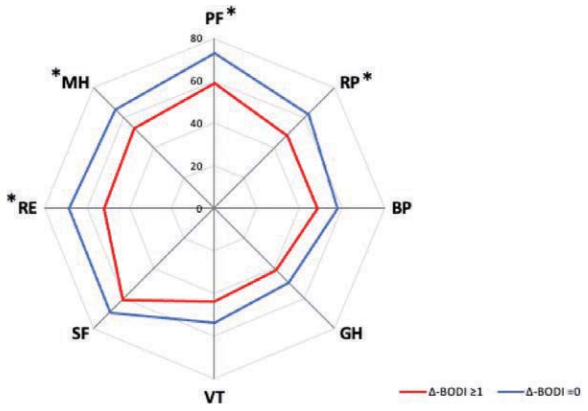

Figure. Impact of increase of damage accrual of 2 years of follow-up on different domains of the SF-36 questionnaire for measurement of the heath related quality of life. PF, physical function. RP, role-physical. BP, body-pain. GH, general health. VT, vitality. SP, social function. RE, role emotional (RE), MH, mental health. * p < 0.005 in univariate analysis using Mann Whitney test.

AB0637 THE ROLE OF ANTINEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA) IN ASSESSMENT OF DISEASE ACTIVITY IN SYSTEMIC VASCULITIS

L. Petelytska[1], O. Iaremenko[1], M. Nahirna[1]. *[1]Bogomolets National Medical University , The Department of Internal Medicine #3, Kyiv, Ukraine*

Background: Despite the proven diagnostic significance, the prognostic role of ANCA, in particular for assessing disease activity, remains questionable. Numerous studies have attempted to estimate the role of ANCA monitoring with different results and a lack of consensus on reported outcomes [1].
Objectives: To analyze the relationship between ANCA level and clinical or laboratory parameters of disease activity.

Methods: This is a retrospective analysis of 38 patients with ANCA-associated vasculitis (granulomatosis with polyangiitis – 25 patients, microscopic polyangiitis – 6 patients and eosinophilic granulomatosis with polyangiitis – 7 patients) from a single center observed from 2015 till the end of 2020. The diagnosis of ANCA-associated vasculitis was performed according to the ACR 1990 criteria or the Chapel Hill Consensus Conference 2012 nomenclature. The study included 20 women (52.6%) and 18 men (47.4%). The average age of patients was 49 (27-62) years, the mean duration of the disease was 26 (6-120) months. The clinical data, initial Birmingham vasculitis activity score (BVAS), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), ANCA (ELISA test) against proteinase-3 (PR-3) and myeloperoxidase (MPO) were evaluated. Spearman's correlation analysis was used to investigate the relationship between ANCA levels and ESR, CRP levels, BVAS activity index. The diagnostic value of ANCA in determining the active disease was evaluated by ROC analysis with an estimation of the area under the ROC curve (AUC). The definition of active disease included new, persistent, or worsening clinical signs and/or symptoms attributed to GPA, MPA, or EGPA and not related to prior damage [2].
Results: Positivity for MPO-ANCA was observed in 23.7% of patients, and for PR3-ANCA - in 76.3% of patients. The BVAS activity index averaged 16 (IQR-13) points. The mean CRP level was 47.9 (IQR-90.0) mg/L and the ESR level was 30.1 (IQR-33.5) mm/h. There was a positive correlation between the level of both ANCA and the BVAS index (r = 0.43; 95% CI 0.11-0.66; p <0.01), as well as the level of ESR (r = 0.37; 95% CI 0.05-0.63; p <0.05). No relationship was found between CRP level and ANCA level (r = 0.22; 95% CI -0.15-0.54; p> 0.05), but a positive correlation was observed between CRP level and index BVAS activity (r = 0.41; 95% CI 0.05-0.67; p <0.05). When using ROC-analysis to determine the value of ANCA in the assessment of active disease, it was found that the AUC is 0.93 ± 0.04 (95% CI 0.84-1.01; p <0.01), which indicates excellent ability ANCA diagnose patients with active disease (sensitivity - 87.9%, specificity - 80.0%).
Conclusion: The level of ANCA in patients with ANCA-associated vasculitis correlates with the Birmingham vasculitis activity score, as well as with the level of ESR. Determination of ANCA level can be used not only to diagnose ANCA-associated vasculitis, but also to assess disease activity.

AB0638 INTRAVENOUS IMMUNOGLOBULIN IN ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS. STUDY OF 28 CASES FROM A SINGLE UNIVERISTARY HOSPITAL AND LITERATURE REVIEW

F. Benavides-Villanueva[1], C. Corrales-Selaya[1], J. Loricera[1], V. Calvo-Río[1], S. Castañeda[2], N. Aviles Mendez[3], J. M. Blanco Madrigal[4], M. A. González-Gay[1], R. Blanco[1]. *[1]Marqués de Valdecilla University Hospital, Rheumatology , Santander, Spain; [2]Hospital de La Princesa, Rheumatology, Madrid, Spain; [3]Hospital Universitario Nuestra Señora del Perpetuo Socorro de Albacete, Rheumatology, Albacete, Spain; [4]Basurto University Hospital, Rheumatology, Bilbo, Spain*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) includes granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) or microscopic polyarteritis (MPA). Standard treatment is often accompained by significant adverse events. Intravenous immunoglobulins (IVIG) may constitute a therapeutic alternative, however, the data are scarce.
Objectives: To assess the utility and safety of IVIG in AAV.
Methods: Observational study of patients with AAV from Spanish referral center treated with IVIG. AAV diagnosis was based on a compatible clinical presentation and/or positive ANCA serology and/or histology. Disease activity was assessed with the Birmingham Vasculitis Activity Score (BVAS).
Results: We included a total of 28 patients; GPA (n=15), MPA (10), and EGPA (3). The main features are summarized in Table 1. The reasons for using IVIG were: **a)** relapse/refractory disease (n=20), or presence/suspicion of infection (8). We observed a rapid and maintained Clinical improvement, since first month of IVIG onset, yielding a BVAS score of zero in 56.5% of patients at 24 months (Figure 1). Serious Adverse event was only observed in 1 patient who developed congestive cardiac failure and had to stop the IVIG therapy.

Table 1. Main general features of 28 patients with antineutrophil cytoplasmic antibody-associated vasculitis treated with intravenous immunoglobulins.

GENERAL FEATURES	RESULTS	GENERAL FEATURES (Continuation)	RESULTS (Continuation)
DEMOGRAPHIC FEATURES		ANALITICAL FINDINGS	
Age of Diagnosis of AAV, mean±SD	57.1±18	CRP (mg/dL), median [IQR]	13.02
Men/ Women; n, (% men)	15/13 (53.6%)	ESR, mm/1st hour, median [IQR]	70.4
AAV Subtype, n (%)		PR3-ANCA, n (%)	11 (39.3)
GPA	15(53.6%)	MPO-ANCA, n (%)	12 (42.8)
EGPA	3(10.7%)	ANCA negative, n(%)	5 (17.8)
MPA	10(35.7%)	FFS at AAV diagnosis, n (%)	
CLINICAL MANIFESTATIONS, n (%)		0	10 (35.7)
Fever	15 (53.6%)	1	11 (39.3)
Constitutional symptoms	26 (92.85%)	2	7 (25)
ORL involvement	7 (25%)	PREVIOUS TREATMENT, n (%)	
Pulmonary involvement	19 (67.9%)	Cyclophospamide	13 (46.4%)
Renal involvement	25 (89.3%)	Methotrexate	6 (21.4%)
Cutaneous involvement)	6 (21.5%)	Azathioprine	3 (10.7%)
Ocular involvement	4 (14.3%)	Cyclophosphamide	13 (46.4%)
Joint involvement	4 (14.3%)	Mycophenolate mofetil	4 (14.3%)
Neurologic involvement	8 (28.57%)	Rituximab	5 (17.9%)

Abbreviations: ANCA:antineutrophil cytoplasmic antibody; EGPA: eosinophilic granulomatosis with polyangiitis; FFS: Five-Factors Score; GPA: granulomatosis with polyangiitis; MPA: microscopic polyangiitis

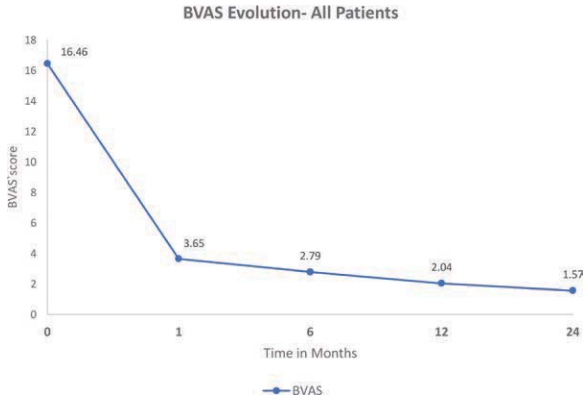

Figure 1. BVAS Evolution with IVIG treatment of all our patients.

Conclusion: IVIG seems to be an effectiveness and relative safe therapeutic option in relapse/refractory AAV or in presence of a concomitant infection.

AB0639 COMMON FEMORAL VEIN THICKNESS MEASUREMENT AS A DIAGNOSTIC TEST IN INCOMPLETE BEHÇET'S DISEASE

F. Alibaz-Oner[1], R. Ergelen[2], F. Temiz[3], S. Kutluğ Ağaçkıran[1], E. Soydemir[2], T. Ergun[4], H. Direskeneli[1]. *[1]Marmara University School of Medicine , Department of İnternal Medicine, Division of Rheumatology, İstanbul, Turkey; [2]Marmara University School of Medicine , Department of Radiology, İstanbul, Turkey; [3]Marmara University School of Medicine , Department of İnternal Medicine, İstanbul, Turkey; [4]Marmara University School of Medicine , Department of Dermatology, İstanbul, Turkey*

Background: Behçet's disease (BD) is characterized by recurrent oral and/or genital aphthous ulcers accompanied by cutaneous, ocular, articular, gastrointestinal and central nervous system lesions. Diagnosing BD can be a clinical challenge in patients presenting with a limited number of organ manifestations, especially with single major organ involvement. We reported the first controlled doppler ultrasound study showing increased common femoral vein (CFV) thickness in BD (1). We recently also showed that increased CFV thickness is a distinctive feature of BD, rarely present in other inflammatory or vascular diseases such as ankylosing spondylitis, systemic vasculitides, venous insufficiency, and non-inflammatory DVT with a specificity higher than 80% for the cut-off value of ≥ 0.5 mm. We suggest that CFV thickness measurement is an easy, non-invasive diagnostic test for BD (2).
Objectives: In this study, we aimed to assess the diagnostic performance of CFV thickness measurement in patients with 'Incomplete' Behçet's Disease diagnosed by expert opinion.

Methods: We included 28 patients with incomplete BD (15 male, 12 female) diagnosed with expert opinion and followed in the Marmara University Behcet's Clinic. Demographic, clinical characteristics and treatment data were recorded during routine visits. Common femoral vein wall thickness was measured by an experienced radiologist at the same day.
Results: Median age was 34.3 years and median disease duration 2 years (0-16). Four patients were newly diagnosed. At follow-up onset, oral ulcers were present in 22 (78.6%), genital ulcers in 6 (21.6%), papulopustular lesions in 4 (14.3%) and pathergy positivity in 5 (17.9%) patients. Ten (35.7%) patients had familial BD. While 24 (85.7%) patients had major organ involvement, 4 (14.3%) patients had mucocutaneous disease. Distrubution of major organ involvements were given in Figure 1.

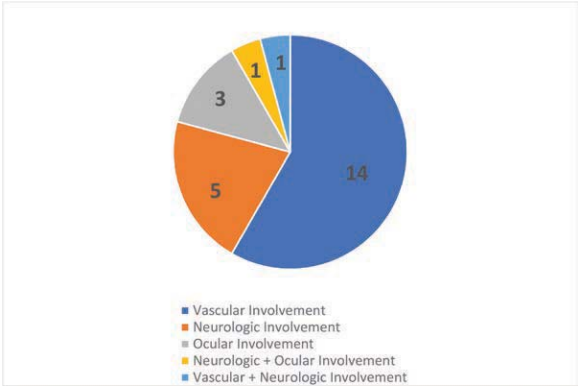

Figure 1. Distribution of major organ involvements (n) in study group

All patients except 1, had CFV thickness value above the cut-off value of ≥0.5 mm. Right CFV thickness was 0.71 (0.3-1.3) mm and left CFV thickness 0.72 (0.4-1.2) mm. Bilateral femoral vein thicknesses were similar in patients with and without an history of familial BD.
Conclusion: Diagnosing BD can be challenging in patients presenting with one major organ involvement such as oral ulcers and posterior uveitis, brain-stem disease or arterial aneurysms, especially in countries with a low prevalence. These patients are generally diagnosed as 'incomplete' BD by 'expert opinion'. Early diagnosis is of utmost importance in some of these cases, especially with venous thrombosis as their management differs from non-inflammatory venous thrombosis, necessitating immunosuppressive use rather than anticoagulant therapy. Our results show that CFV thickness measurement with Doppler US, a non-invasive, fast and cost-effective radiological modality, is a valuable diagnostic test in incomplete BD, especially with major organ involvement.

AB0640 PREVALENCE AND DETERMINANT FACTORS OF ENDOTHELIAL DYSFUNCTION IN ANCA ASSOCIATED VASCULITIS

A. L. Fedele[1], F. Melpignano[1], E. Porceddu[2], C. Tur[1], P. Tondi[2], A. Zoli[1], M. A. D'Agostino[1]. *[1]Division of Rheumatology-Catholic University of the Sacred Heart, Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze Mediche e Chirurgiche, Rome, Italy; [2]Division of Angiology-Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze dell'invecchiamento, neurologiche, ortopediche e della testa-collo, Rome, Italy*

Background: Atherosclerosis and its complications are one the leading cause of death in patients with anti-neutrophil cytoplasmic antibodies (ANCA)- associated vasculitis (AAVs), despite the recent remarkable improvements in prognosis. The mechanism by which atherosclerosis is accelerated in these diseases is not explained by the classical cardiovascular risk factors (CVRFs) and is still under investigation.
Objectives: To evaluate the prevalence of endothelial dysfunction (ED) in AAV patients and to identify the determinant factors of endothelial responses among vasculitis characteristics, such as ANCA status and organ involvement.
Methods: Thirty patients (15 men and 15 women) with AAVs [13 with eosinophilic granulomatosis with polyangiitis (EGPA), 7 with granulomatosis with polyangiitis (GPA), 10 with microscopic polyangiitis (MPA)] were enrolled in the study. For all subjects CVRFs, blood pressure, lipid profile, renal function, acute phase reactants, ANCA status and titers were recorded at diagnosis and at the enrollement in the study. Vasculitis disease activity was measured using the Birmingham Vasculitis Activity Score (BVAS) and organ damage was assessed with the vasculitis damage index (VDI). The prognosis was evaluated through the Five Factor Score (FFS). Patients were excluded from the study if they had previous cardiovascular or cerebrovascular events, liver failure, end stage renal disease under hemodyalisis, or cancer. Microvascular peripheral dysfunction was assessed by pulse amplitude tonometry (PAT) of the small digital artery. In particular, Log-transformed reactive hyperemia index (LnRHI) was evaluated using the EndoPAT2000 device: values of Ln-RHI < 0.51 were considered indicative of peripheral ED.
Results: At diagnosis, 23 subjects (76.7%) were ANCA positive (8 c-ANCA+, 15 pANCA+), and at the enrollment in the study 10 patients (33.3%) were still seropositive. Nineteen patients (63.3%) had inactive disease (BVAS=0), 7 (23.3%) were in low disease activity (1≤BVAS≤2) and 4 (13.3%) had an active disease (BVAS≥3). The presence of ED was documented in 9 AAV patients (30%). AAV patients with ED had higher C-reactive protein (CRP) values at diagnosis compared to subjects without ED (*p=0.05*). Moreover, patients with altered endothelial response were in higher percentage smokers (55.6%) and ANCA positive at enrollment (44.4%), compared to subjects with normal Ln-RHI (28.6%- p=0.12; 19%, p=0.15 respectively). There were no differences regarding age and other traditional CVRFs, disease duration, BMI, BVAS, VDI, FFS. There was an inverse correlation between CRP values at diagnosis and LnRHI (r=-0.42, *p=0.04*). In multiple logistic regression analysis, ANCA positivity at enrollment [OR (95% CI) = 15.68 (0.98-250.28)] (*p=0.05*), and higher CRP concentrations [OR (95% CI) = 1.03 (1.00–1.06)] (*p=0.03*) were independently associated with the presence of peripheral ED.
Conclusion: As observed in other chronic inflammatory autoimmune diseases, ED occurs in AAVs and is mainly related to the chronic systemic inflammation and seems to be also influenced by ANCA positivity, which is probably involved in the accelerated endothelial cell damage.
Further studies are needed to clarify the role of vasculitis related characteristics in the atherosclerotic process.

AB0641 AN ULTRASONOGRAPHIC STUDY OF THE SALIVARY GLANDS IN A COHORT OF PATIENTS AFFECTED BY CRYOGLOBULINEMIA VASCULITIS: PRELIMINARY RESULTS

A. Adinolfi[1], N. Ughi[1], D. A. Filippini[1], M. Chevallard[2], L. Belloli[1], C. Casu[1], M. Di Cicco[1], C. Gagliardi[1], M. C. Gerardi[1], M. Muscarà[1], E. Verduci[1], O. M. Epis[1]. *[1]Rheumatology Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; [2]Medicine Unit, Department of Medicine, Garbagnate Hospital, Milan, Italy*

Background: Xerostomia and xerophthalmia can occur in many diseases, rheumatological or not and are often reported by patients affected by cryoglobulinemia vasculitis[1], particularly if related to the Hepatitis C virus infection (HCV)[2]. On the other hand, the Ultrasound (US) was extensively used for detecting pathological findings of the salivary glands[3], possibly associated to many rheumatological diseases.
Objectives: The aim of this study was to detect, in patients affected by cryoglobulinemia vasculitis, the presence and the grade of pathological findings at level of the major salivary glands.
Methods: From January to December 2021, we enrolled consecutive oupatients patients affected by cryoglobulinemia (age ≥ 18 yo and a diagnosis of cryoglobulinemia vasculitis according to 2002 or 2011 classification criteria). Exclusion criteria were a previous diagnosis of other vasculitis/connective tissue diseases/inflammatory arthropathies, concomitant not rheumatological diseases or the intake of drugs possibly related to sicca syndrome symptoms. For each patient, the demographic, anthropometric and clinical history data, particularly about the cryoglobulinemia symptoms (either previous and ongoing) and past or current therapies have been collected. Furthermore, the values of erythrocyte sedimentation rate [ESR], C-reactive protein [CRP], Rheumatoid Factor [RF] and C4 serum complement fraction have been recorded. The presence and the titre of the cryoglobulins have been recorded. For each patient, the Schirmer's Test and the evaluation of the unstimulated whole salivary (UWS) flow were performed. The Schirmer Test was considered positive if < 5 mm/min at least in one eye and the UWS flow was defined pathological if < 1,5 ml/15 min. Each patient was submitted to the US examination (Esaote MyLab Twice) of both parotid and submandibular glands. Each gland was evaluated using a semiquantitative score 0-3, according to the OMERACT definitions[3]. The US score was considered pathological if ≥2. Thus, at patient level, a sum dichotomous score (normal/pathological>) was provided, defining it as "pathological" if any parotid or submandibular glands scored ≥ 2.
Results: We enrolled 20 patients, all females, with a mean age of 68.8 years (SD± 13.32) and a mean disease duration of 11.76 (SD±8.25). For 18 patients was reported a previous HCV infection. 16/18 HCV + subjects reached the remission of the

infection with undetectable HCV viremia. Among the patients enrolled, 10 referred at least one syndrome sicca symptom: 5 patients both xerostomia and xerophthalmia, 4 only xerostomia and 1 only xeropthalmia. Considering blood tests, the cryoglobulins were detected in 14, the ESR title was above the limit in 7 patients and the CRP in 3. The RF was detected in 12 subjects. The Schirmer's test was pathological in 9 patients while the UWS flow was under the limit in 3. As regards the US reports, 2 patients had pathological features scored as≥2, while 7 patients showed minor alterations scored as 1. So, according to the sum score, only 2 patients were classified as pathological. No correlations were identified between the clinical and the US data.

Conclusion: In this cohort of patients with cryoglobulinemia, the US mainly showed mild pathological features at level of the parotid and submandibular structure, suggesting that syndrome sicca symptoms could be related to different pathological mechanisms in these patients, possibly strongly associated to HCV infection. Further and larger studies are necessary to confirm our preliminary data.

AB0642 DIAGNOSIS OF CEREBRAL VASCULITIS: RETROSPECTIVE STUDY OF 68 CASES

A. Ben Salem[1], S. Arfa[1], F. Sghaier[1], H. Bouguila[2], Z. Chaari[1], A. Bchir[1], S. Younes[2], O. Berriche[1]. *[1]Taher sfar University hospital, Internal Medicine and Endocrinology, Mahdia, Tunisia; [2]Taher sfar University hospital, Neurology, Mahdia, Tunisia*

Background: Cerebral vasculitis, whether primary or secondary, is a group of heterogeneous pathologies characterized by a destructive inflammatory vascular wall lesion of the cerebral tissue. Its physiopathology remains poorly understood. Clinical polymorphism is a major characteristic of this disease.

Objectives: The aim of this work was to describe the epidemiological, clinical, radiological and etiological aspects of Cerebral vasculitis.

Methods: We conducted a retrospective descriptive study based of the records of 68 patients who were hospitalized in the Internal Medicine and Neurology Departments of the Taher Sfar University Hospital in Mahdia over a 12-year period from January 2008 to June 2021.

Results: A total of 68 patients were included: 46 female and 22 male (sex-ratio M/F: 0.47) with an average age of 50.8 ±12.7 [15-75 years]. The revealing symptoms were: Headaches in 52 patients (79.9%) followed by motor deficit in 21 patients (30.8%), sensitivity disorder in 24 patients (35.3%) and neurosensory disorders in 24 patients (35.3 %). These symptoms were insidious in 41 patients (61.2%). The neurological examination was pathological in 75 % of the patients, among them 19 patients (28.7%) had a walking disorder. Strokes were the revealing complication in 5 patients (7%).

Laboratory tests revealed an inflammatory syndrome in 37 patients (55.2%). The lumbar puncture was performed in 76.5% of cases. Cerebral spinal fluid showed aseptic meningitis in 5 cases and High protein level in 6 patients. The immunologic investigations showed that Antinuclear antibodies (ANA) were positive in 41 % and antiphospholipid antibodies were positive in 7.3%.

Cerebral Magnetic Resonance Imagining (MRI) revealed multiple patchy lesions hyperintense on T2 and FLAIR in the white matter in all cases: bilateral and asymmetric in 55 patients (80.9%) with subcortical distribution in 63% and periventricular localization in 45 %. Three patients had Leptomeningeal enhancement.

The etiologies of cerebral vasculitis were: Sjogren Syndrome in 33.8 %, Systemic lupus Erythematosus in 22%, Behcet disease in 19.1 %, Giant cell arteritis in 7.3%, antiphospholipid syndrome in 5.8%, Sarcoidosis in 4.4 %, Susac syndrome in 4.4 % and systemic sclerosis in 2.9 %.

Treatment was based on oral corticosteroids in 89.7 % of cases, associated with intravenous corticosteroids in 52.9% of cases. Immunosuppressive therapy was indicated in 42.4% of patients.

Prompt improvement was obtained in 48,3%, symptoms stability was noticed in 20 %. However, 30% of patients experienced relapse. Worsening of signs was seen in 1.7 %.

Conclusion: Cerebral vasculitis is a rare disorder with a non-specific clinical presentation. Therefore, its diagnosis is a challenge for clinicians who base their investigations on clinical and paraclinical arguments to attribute the neurological and systemic events to vasculitis. An early diagnosis and an appropriate treatment could improve its prognosis.

AB0643 ARE THERE ANY DISTINCTIVE FINDING IN ANCA-ASSOCIATED VASCULITIS RELATED PULMONARY INVOLVEMENT IN COMPARISON WITH CONNECTIVE TISSUE DISEAE OR IDIOPATIC PULMONARY FIBROSIS

E. Durak Ediboglu[1], Ş. Karasu[2], T. Ekici[2], M. O. Turan[3], Ö. Gerçik[4], D. Solmaz[1], C. Gümüş[2], S. Akar[1]. *[1]Izmir Katip Çelebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; [2]Izmir Katip Çelebi University, Department of Radiology, Izmir, Turkey; [3]Izmir Katip Çelebi University, Department of Pulmonary Dİsease, Izmir, Turkey; [4]Izmir Demokrasi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*

Background: Patients with ANCA associated vasculitis (AAV) have a wide spectrum of pulmonary involvement from parenchymal necrotizing granuloma formation, trecheobronchial inflammation, pulmonary capillaritis to interstitial lung disease. Pulmonary involvement is relatively common in connective tissue diseases (CTDs). Both rheumatologic disorders and idiopatic pulmonary fibrosis (IPF) might cause the usual interstitial pneumonia (UIP) pattern. However, little is known regarding the clinical and radiologic similarities/ dissimilarities of those diseases.

Objectives: We aimed to evaluate the thoracic computed tomography (CT) findings of patients with AAV, CTDs-related interstitial lung disease (ILD) or IPF.

Methods: Patients whose thoracic CT performed at the time of the diagnosis or relapse of AAV (n=64), at the time of the diagnosis of CTD related ILD (n=55) or IPF (n=52) were included in the analysis. Demographic, clinical and serological data were collected retrospectively. Radiological patterns of pulmonary involvement were evaluated by two expert pumonary radiologists and abnormal thoracic CT findings were classified according to Fleischner Society guidelines. Intra- and inter-observer variation were calculated. Multoniminal logistic reggresion was performed to identfy disease specific findings in thoracic CT.

Results: A total of 171 patients were included and of them 64 patients (62.5% with granulomatosis with polyangiitis, 37.5% with microscopic polyangiitis) in AAV group, 55 patients in CTD related ILD (50.9% with scleroderma, 40.0% with rheumatoid arthritis, 9.1% other or undifferensiye connective tisue disease) group and 52 patients in IPF group. Demographic and thoracic CT findings were summarized in Table 1. In univariate analysis according to Fleishner Society definition, patients with AAV had more common pulmonary noduls, cavities, consolidation. However, patients with AAV were less likely to have interlobular septal thickening (ILST), lymph node adenopathy (LAP) and reticulation compared to both CTD related ILD and IPF. In addition, among those groups of rheumatic diseases, cavities and alveolar hemorrhage were detected only AAV. In multinominal logistic reggresion, the presence of nodul and consolidation and the absence of ILST and mediastinal LAP were independent determinant findings in thoracic CT in patients with AAV in comparison with both CTD related ILD or IPF.

Table 1. Demoraphic characteristics and Thoracic CT findings of patients

	AAV patients (n=64)	CTD related ILD (n=55)	IPF (n=52)	p
Characteristics				
Age at diagnosis, yrs, mean (SD)	58.6 (15.0)	61.8 (12.0)	72.4 (9.4)	<0.001
Sex, male, %	70.3	30.9	75	<0.001
Smoking, ever, %	77.8	26.5	62.8	0.29
Chest CT findings according to Fleishner guideline, %				
Ground glass opasity	29.7	38.2	9.6	0.003
Reticulation	19.0	52.7	94.2	<0.001
Interlobular septal thickening	28.6	69.1	98.1	<0.001
Peribronchial thickening	11.1	20.0	3.8	0.03
Honeycombing	14.3	25.5	63.5	<0.001
Bronchiectasis	31.3	47.3	86.5	<0.001
Consolidation	45.3	12.7	5.8	<0.001
Micronodules	6.3	3.6	0	0.07
Nodules	45.3	10.9	3.8	<0.001
Cavities	23.4	0	0	<0.001
Eymphysema	18.8	7.3	19.2	0.96
Mosaic attenuation pattern	7.8	20	38.5	<0.001
Alveolar hemorrage	17.2	0	0	<0.001
Mediastinal lymph node adenopathy	26.7	53.7	57.7	0.002
Pleural effusion	14.1	1.8	0	0.001
Pericardial effusion	6.3	9.1	0	0.16

Conclusion: The results of this study show that in additon to clinical and labaratory characteristics, some thoracic CT imaging findings like the presence of nodules and consolidation and the abscence of LAP and ILST may be useful to differentiate pulmonary involvement of AAV from other relatively common rheumatologic conditions and IPF. In addition, alveolar hemorrhage and cavities may be particular manifestations of AAV.

Scleroderma, myositis and related syndromes

AB0644 INCIDENCE OF CARDIOPULMONARY COMPLICATIONS AND SURVIVAL IN EARLY SYSTEMIC SCLEROSIS (SSC) PATIENTS COMPARING BETWEEN THOSE WITH AND WITHOUT ELEVATED SERUM CREATINE KINASE (CK): INCEPTION COHORT STUDY

S. Wangkaew[1], J. Intum[1], N. Prasertwittayakij[1], J. Euathrongchit[2]. [1]*Chiang Mai University, Internal Medicine, Chiang Mai, Thailand;* [2]*Chiang Mai University, Radiology, Chiang Mai, Thailand*

Background: There has been no prior inception cohort data regarding incidence of cardiopulmonary complications and survival in early SSc patients comparing between those with elevated creatine kinase (baseline CK ≥ 500 U/L) and without elevated CK (baseline CK < 500 U/L).
Objectives: The aims of this study were to compare: (1) the prevalence of clinical manifestations; (2) incidence rate (IR) of cardiopulmonary complications and (3) survival, between early SSc patients with and without elevated serum CK levels, using inception cohort study.
Methods: We used an inception cohort of early SSc patients (disease duration from first Non-Raynaud's phenomenon≤ 3 years) seen at the Rheumatology clinic, Maharaj Nakorn Chiang Mai Hospital, Thailand, between January 1st 2010 and 31 December 2019. All patients were assessed for clinical manifestations, creatine kinase (CK) levels and underwent electrocardiography (ECG), echocardiography and high-resolution computed tomography (HRCT) at the study entry and every 12 months thereafter. Interstitial lung disease (ILD) was determined by HRCT. Myocardial disease was defined as presence of dilated cardiomyopathy, non-specific cardiomyopathy or suspected primary right ventricular dysfunction assessed by echocardiography.
Results: One hundred and forty-four patients (84 females, 115 diffuse cutaneous SSc [DcSSc] and 111 anti-topoisomerase I antibody-positive) with mean ± SD age of 53.3 ± 8.9 years, mean disease duration of 11.9 ± 9.2 months and mean follow-up duration of 6.2 ± 2.7 years were recruited. There were 29 early SSc patients with elevated CK (20.1%). Comparing with patients without elevated CK, SSc with elevated CK had significantly higher proportion of clinical manifestations as followings: male gender (58.6% vs. 37.4%, p = 0.038), DcSSc subtype (93.1% vs. 76.5%, p = 0.047) and shorter disease duration (8.2 ± 6.3 vs.12.8 ± 9.5 months, p = 0.009). At enrollment, the elevated CK group had significantly higher prevalence of arthritis (44.8% vs. 25.2%, p = 0.038), weakness (55.2% vs. 10.4%, p < 0.001) and higher modified Rodnan skin score (MRSS) (23.5 ± 10.1 vs. 17.5 ± 10.6, p = 0.005); At last visit, the elevated CK group had significantly higher cumulative prevalence of weakness (58.6% vs. 11.3%, p < 0.001), dysphagia (75.9% vs. 43.5%, p = 0.002), LVEF < 50% (48.3% vs. 12.2%, p < 0.001) and myocardial disease (55.2% vs. 21.7%, p < 0.001). The elevated CK group had significantly higher incidence rate (IR) of: LVEF < 50% (14.24 vs. 2.03 per 100 person-year; incidence rate ratio (IRR) 7.03, p < 0.001), myocardial disease (19.74 vs. 3.87 per 100 person-year; IRR 5.09, p < 0.001) and ILD (60.40 vs. 31.49 per 100 person-year; IRR 1.92, p = 0.006); compared to the non-elevated CK group. The survival rate of early SSc with elevated CK group at 1, 3 and 5 year were 86.2% and 82.5% and 74.3%, respectively. The median survival time of the elevated CK group was lower than those without elevated CK group (6.98 vs. 8.56 years, p = 0.012).
Conclusion: Our study cohort found that early SSc patients with elevated baseline CK levels are predominant in male gender, DcSSc subtype with shorter disease duration. The elevated CK group has more severe clinical presentations including higher MRSS, arthritis and weakness compared to the non-elevated CK group. In addition, significantly higher incidence rate of: LVEF < 50%, myocardial disease, ILD; and poorer survival are also obviously detected in the elevated CK group.

AB0645 NINTEDANIB IN TREATMENT OF PULMONARY FIBROSIS SECONDARY TO CONNECTIVE TISSUE DISEASE:

A. Laria[1], A. M. Lurati[1], D. Mazzocchi[1], K. Re[1], M. G. Marrazza[1], E. Zaccara[2], D. Bompane[2], A. Tamburello[2], L. Castelnovo[2], F. Bini[3], P. M. Faggioli[2], A. Mazzone[2]. [1]*ASST OVEST MILANESE– Presidio di Legnano e Magenta, rheumatology unit, magenta, Italy;* [2]*Internal Medicine Unit, Civil Hospital, Legnano, Internal Medicine Unit, legnano, Italy;* [3]*Pneumology Unit, Department of Medicine, Ospedale Salvini, Garbagnate Milanese, ASST Rhodense, Pneumology Unit, Department of Medicine, garbagnate milanese, Italy*

Background: Interstitial lung disease (ILD) is a common manifestation of systemic sclerosis and other Rheumatic Diseases, and is one of the major causes of mortality. Nintedanib, a tyrosine kinase inhibitor, has been shown to have antifibrotic and anti-inflammatory effects in preclinical models of systemic sclerosis and ILD.
Objectives: To evaluate efficacy and safety of Nintedanib in pulmonary fibrosis secondary to Connective Tissue Disease.
Methods: Ten patients with pulmonary fibrosis secondary to Connective Tissue Disease treated with Nintedanib were monitored at baseline, 6 and/or 12 months, with clinical assessment, chest CT scan and/or pulmonary function testing (PFT) with assessment of the diffusing capacity for CO (DLCO). 8/10 patients had a diagnosis of Progressive Systemic Sclerosis, while the remaining ones had Polydermatomyositis and Mixed Connectivitis. All patients were dyspnoic at baseline and presented with dry cough. All patients had pulmonary fibrosis according to high-resolution chest CT scan. All patients had been treated with at least one csDMARD or bDMARD (cyclophosphamide, azathioprine, cyclosporine, rituximab, tocilizumab), prior to receiving nintedanib. At baseline 2/10 patients were treated with Nintedanib monotherapy, 7/10 were in combination therapy with Mycophenolate, 1 patient received a combination therapy with cyclosporine.
Results: Compared to baseline values, 4/7 patients showed stationarity of the respiratory function parameters (DLCO), in 2/7 patients it was observed a significant improvement of the DLCO (with a change of 15%) while in only 1 patient there was a worsening over time. FVC remained stable over time except in 1 patient who got a significant improvement. In 5/9 patients cough improved (unchanged in the rest of patients). Dyspnea (NYHA scale) improved in 6/9 patients, remained stationary in 2/6 patients and became worse in 1 patient. 8/9 patients had a stable chest CT at 6 and / or 12 months, while only 1 patient witnessed a further worsening of the fibrosis. 50% of the patients showed good gastrointestinal tolerance to the full dose of nintedaninb. The other half had the dose reduced in order to improve gastrointestinal symptoms.
Conclusion: Our data show that patients with ILD associated with Rheumatic Diseases treated with nintedanib had a clinical benefit over dyspnea and cough symptoms and a stabilization of radiological findings 12 months after starting the treatment. Also, respiratory function parameters remained stable over time. Gastrointestinal adverse events, including diarrhea, were common in these patients, but therapeutic dose adjustment led to fast symptoms resolution and good tolerance.

AB0646 G- CSF TREATMENT FOR REFRACTORY DIGITAL ULCERS IN SYSTEMIC SCLEROSIS

S. Keret[1], G. Slobodin[1], A. Awisat[1], L. Kaly[1], I. Rosner[1], M. Rosenbaum[1], N. Boulman[1], A. Shouval[1], D. Rimar[1]. [1]*Bnai Zion Medical Center, Rheumatology, Haifa, Israel*

Background: Digital ulcers (DU) are a common manifestation of systemic sclerosis (SSc). Despite combination vasodilator therapy, refractory DU are not rare. Granulocyte-colony stimulating factor (G-CSF) had not been evaluated for SSc DU heretofore.
Objectives: To evaluate the efficacy and safety of G-CSF for refractory SSc DU.
Methods: Adult SSc patients with chronic resistant DU despite treatment with maximal tolerated doses of prostacyclin analogue, endothelin receptor antagonist and PDE5 inhibitor, were treated with three consecutive daily doses of G-CSF. Evaluation of DU healing, DUCAS score, antibiotics use, side effects and hospitalizations, was performed.
Results: Ten patients (90% females), mean age 53.5 ± 11.1 years were treated. Fifty percent of the patients had a diffuse SSc disease. All patients suffered from chronic (80%), or recurrent (20%) DU. G-CSF treatment resulted in complete resolution of most DU, after an average of 1.57± 0.76 months. DU recurrence occurred in two patients, after a mean period of two months. The number of DU decreased from 2.23±2.20 at baseline, to 0.84±0.80 at one month (p value= 0.04), and 0.50±0.67 at 3 months (p value= 0.015). DUCAS score dropped from 6.84±1.62 before the treatment, to 1.76±2.00 and 1.16±2.55 at one and three months, respectively (p value <0.0001). No serious adverse events were observed.
Conclusion: G- CSF treatment was found to be beneficial for refractory SSc DU, resulting in DU healing and sustained remission in most cases. No significant side effects were observed. Future trials are needed to evaluate the efficacy and safety of this therapy.

AB0647

CLINICAL PHENOTYPE IN SCLERODERMA PATIENTS WITH LIMITED AND DIFFUSE CUTANEOUS DISEASE BASED ON AUTOIMMUNITY

C. Sieiro Santos[1], C. Moriano[1], I. González Fernández[1], X. E. Larco Rojas[1], C. Álvarez Castro[1], E. Diez Alvarez[1]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Classically, anti-centromere antibodies (ACA) are associated with limited cutaneous involvement (lcSSc) and pulmonary hypertension, whereas anti-topoisomerase I (Sc70) are associated with diffuse skin involvement (dcSSc) and pulmonary fibrosis (ILD). Patients with lcSSc and Sc70 antibodies draw particular attention, which is why characterization of clinical phenotypes can help distinguish patient subgroups and assessing the prognosis of the disease.
Objectives: We aimed to characterize the clinical phenotype of patients with SSc based on autoantibodies.
Methods: We included patients with SSc, fulfilling the 2013 ACR/EULAR criteria, with disease duration ≤10 years. We have compared different subgroups of patients with lcSSc: Scl70-lcSSc (group1), ACA-lcSSc (group 2) and ANA-lcSSc (group 3), (Table 1). Next, we compared patients with Scl70-lcSSc (group 1) to Scl70-dcSSc (group 4) and ANA-lcSSC (group 3) to ANA-dcSSC (group 5). In the ANA subgroup we included patients with negative Scl70 and ACA antibodies. We have assessed the risk of ILD, myositis, scleroderma renal crisis, cardiac and gastrointestinal involvement, myositis, pulmonary hypertension (systolic pulmonary arterial pressure sPAP>45 mmHg at transthoracic echocardiography or sPAP>25 mmHg at right heart catheterization), cancer and all-cause-mortality.

Table 1. Clinical characteristics of patients with lcSSc

	Scl70-lcSSc	P value	ACA-lcSSc	P value	ANA-lcSSc
Female	9 (56.3%)	**0.03**	36 (83.7%)	0.80	12 (52%)
Time from RP to SSc (years)	1.28 (0.25-3.5)	**0.02**	6.23 (3-9)	**0.002**	4.91 (2-5)
Age at SSc onset	56.5 (48-66)	**0.04**	62.5 (54-73)	0.76	59.2 (44-66)
CRP elevation	30 (22-39)	**0.02**	22 (16-29)	0.21	10 (6-19)
mRSS	4 (2-4.2)	**0.03**	3.2 (2.1-4.0)	0.92	3.9 (2.5-4.2)
Joint synovitis	6 (37.5%)	0.47	12 (28%)	0.71	10 (43%)
Tendon friction rubs	2 (12.5%)	0.50	3 (7%)	0.19	0
Myositis	4 (25%)	**0.04**	2 (5%)	0.81	5 (21.7%)
Gastrointestinal involvement	6 (37.5%)	0.19	27 (63%)	**0.04**	16 (69%)
Renal crisis	4 (25%)	**0.04**	2 (5%)	0.18	2 (9%)
ILD	10 (63%)	**0.001**	7 (16%)	**0.04**	7 (30%)
Pulmonary hypertension	4 (25%)	0.47	7 (16%)		3 (13%)
Arrythmia	5 (21.7%)	0.08	6 (14%)	0.35	7 (30%)
Conduction defects	1 (6.3%)	0.59	5 (11.6%)	0.79	1 (4%)
Diastolic disfunction	7 (43.8%)	0.36	17 (39.5%)	0.77	9 (39%)
Immunosuppressants	10 (63%)	**0.01**	13 (30.2%)	0.52	12 (52%)
Steroids	9 (56%)	**0.04**	12 (28%)	0.98	13 (56.6%)
Cancer	8 (50%)	**0.04**	10 (23.2%)	0.22	7 (30%)
Mortality	3 (18.8%)	**0.04**	6 (14%)	0.82	5 (21.7%)

Results: 103 SSc patients were included: 72 (69%) females, 82 (79%) lcSSc and 21 (20%) dcSSc. Among lcSSc patients, 43 (52%) had ACA, 16 (19%) Scl70 and 23 (28%) ANA. Among dcSSC patients, 9 (43%) had Scl70 and 12 (57%) had ANA. Scl70-lcSSc patients had significantly shorter time from Raynaud's phenomenon (RP) to SSc diagnosis (p=0.02), younger age at SSc onset (p=0.04), higher mRSS (p=0.03), higher rate of myositis (p=0.04) and renal scleroderma crisis (p=0.04) than ACA-lcSSc patients. The risk of ILD in Scl70-lcSSC compared to ACA-lcSSC is 3.8 higher (95% IC 1.2-14.5) and 1.5 higher (95% IC 1.05-5.61) than ANA-lcSSC. All-cause mortality was higher in Scl70-lcSSC (p=0.04) compared to ACA-lcSSC. Scl70-dcSSC patients had a shorter time from RP to SSc diagnosis (p=0.02), higher CRP (p=0.04), mRSS (p=0.001), higher rate of myositis (p<0.05) and ILD (p=0.04) and all-cause mortality (p=0.04) than Scl70-lcSSc patients, while renal and cardiac involvement was similar. ANA-dcSSC patients also had a shorter time from RP to SSc diagnosis (p=0.03), higher mRSS (p=0.02) and higher rate of ILD (p=0.02).
Conclusion: Scl70-lcSSc patients show the major organ involvement, followed by ANA-lcSSc and ACA-lcSSc. Scl70-dcSSc and ANA-dcSSC patients exhibit more cutaneous involvement and ILD than Scl70-lcSSc and ANA-lcSSc. These results may provide new ways to help in early diagnosis, management and assessing the prognosis of the disease.

CANCER IN SYSTEMIC SCLEROSIS: ASSOCIATION BETWEEN ANTIBODIES AND MALIGNANCY AND RESULTS FROM A THIRD-LEVEL CENTER

C. Sieiro Santos[1], C. Moriano[1], I. González Fernández[1], C. Álvarez Castro[1], A. López Robles[1], M. Martín Martín[1], E. Diez Alvarez[1]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*

Background: Systemic sclerosis (SSc) is associated with increased risk of malignancy. Risk factors predisposing a SSc patient for development of malignancy are not well defined, and the pathogenic basis of the association is yet to be explained. Some autoantibodies have been associated with a close temporal relationship with cancer. The absence of malignancy screening guidelines tailored for SSc patients raise the importance of the need for more studies on the association of SSc and cancer.
Objectives: To study the prevalence of cancer in SSc and the association between SSc-specific and SSc-associated autoantibodies and cancer in a third-level center.
Methods: We conducted a retrospective cohort study by including patients diagnosed with SSc followed from 1980 to 2020 fulfilling the 2013 ACR/EULAR SSc criteria. Demographic features, clinical and immunological characteristics were retrieved. The primary outcome was cancer-associated SSc, defined as cancer occurring within 2, 3 and 5 years of first non-Raynaud SSc manifestation. The exposure was defined by the presence of SSc-specific/associated autoantibodies, including anti-centromere (ACA), topoisomerase I (Scl70), RNA polymerase III, fibrillarin, Th/To, PM-Scl, Ku, TIF1g, Ro52. Descriptive analysis was used to compare clinical characteristics of subjects with cancer to those without cancer. Univariate logistic regression was used to compare the odds of cancer-associated SSc between the autoantibody subgroups.
Results: Out of 103 SSc subjects, 27 (26%) had a history of cancer following SSc diagnosis. Mean age was 61.9 (57-69) years, 70% were female and 88% had a smoking history. Median time between cancer and disease onset was 6.33 (3-9) years. Among patients with cancer, 12 (44%), 8 (29%) and 7 (26%) were diagnosed within 2, 5 and 10 years of SSc onset. The most frequent types were breast cancer (n=9), gastrointestinal cancer (n=5), prostatic cancer (n=4), hematological (n=3) cancers, cervical/uterine cancers (n=2), non-melanoma skin (n=2), lung cancer (n=2). Patients with cancer were more likely to be Sc70+(OR 2.55, 95% CI1.03-6.3, p 0.04), anti-TIF1g (OR 19.5, 95% CI 5.6 – 68.3, p 0.001) and RNA pol III (OR 10.9 CI 95% 1.08-109.3, p 0.04), have a history of smoking (OR 7.24, 95% CI 2.6-197, p 0.001), myositis (OR 5.2 IC 95% 2.06-13.2, p 0.005) and older age at SSc onset (61.9 vs 57, p 0.04). Breast cancer was more frequent in anti-TIF1g (OR 3.75 IC 95% 1.8-17.5) and RNA pol-III (OR 7.14 IC 95% 1.56-90.8) subgroups. The risk of cancer-associated SSc was significantly increased among anti-TIF1g-positive subjects at 5 years after SSc onset (OR 2.1 CI 95% (1.45-9.94), p 0.04) and among RNA-pol III-positive subjects at 2 years after SSc onset (OR 3.5 95% CI (1.2-51.4), p 0.02) (Table 1).

Table 1. Logistic regression analysis for the risk of cancer within 2,5 and 10 years of SSc onset according to antibody positivity

	OR 95% CI for cancer diagnosis within 2 years of SSc onset	OR 95% CI for cancer diagnosis within 5 years of SSc onset	OR 95% CI for cancer diagnosis within 10 years of SSc onset
Anti-Scl70	1.56 (0.51-44.5)	1.41 (0.27-12.7)	2.1 (0.55-13.4)
Anti-centromere	1.72 (0.62-52.1)	1.52 (0.32-32.1)	1.69 (0.14-21.3)
Anti-TIF1g	3.9 (0.35-43.4)	**2.1 (1.45-9.94)**	0.42 (0.04-5.32)
ARN Pol III	**3.5 (1.2-51.4)**	1.9 (0.72-62.1)	-
Anti-PM Scl75/100	-	-	0.87 (0.04-1.98)
Anti-Ro52	2.5 (0.66-66.8)	2.0 (0.45-50.2)	0.63 (0.05-7.74)

Conclusion: Anti-Scl70, anti-TIF1g and RNA pol III were predictive of cancer-associated SSc for cancers. Breast cancer was the most frequent. Subjects with cancer were more likely to have a history of smoking, myositis and an older age at SSc onset. Autoantibodies should be taken into account in cancer screening. Larger studies are needed to define the risk of cancer-associated SSc in different autoantibody subgroups.

MYOSITIS SPECIFIC ANTIBODIES - WHO ORDERS THEM AND WHAT ARE THE RESULTS? A RETROSPECTIVE AUDIT OF TWO LARGE REFERRAL CENTERS

S. Shan[1], A. Foote[1], L. Schachna[2], M. Mian[1]. [1]*Northern Health, Rheumatology, Melbourne, Australia;* [2]*Austin Health, Rheumatology, Melbourne, Australia*

Background: Idiopathic inflammatory myopathies are a group of disorders associated with myositis-specific antibodies (MSA) and myositis-associated antibodies (MAA) (1). MSA and MAA are helpful in classifying clinical syndromes with both treatment and prognostic implications (2). Ordering of MSA and MAA has increased in recent years. We report the hospital services that ordered MSA and MAA and follow-up investigations performed in two large referral centers in Melbourne, Australia.
Objectives: To explore and investigate the testing patterns of MSA and subsequent follow up.
Methods: We identified all patients who underwent MSA and MAA testing between January 1 2019 and December 31 2020. Relevant demographic and clinical data were obtained by chart review.
Results: Over the 2-year study period, 294 MSA tests were ordered, alongside 275 ANA and 266 ENA. Of these, 60 (20.4%) were positive and 9 (3.1%) tested positive to more than one MSA. Interstitial lung disease (ILD) was the most common extra-muscular manifestation, 42 (14.2%) had muscle disease manifestations. Respiratory (41%), rheumatology (24%) and neurology (15%) were the top three specialties ordering the most MSA, with the highest proportion of positive MSA originating from rheumatology (38.5%). The rheumatology service was involved in 131 (41.0%) of the MSA ordered as the primary treating unit or as a consultation service. Anti-Scl100 was the most common MSA (n=10, 15.6%). Among the 60 patients with positive MSA, 39 (65%) was given a definitive diagnosis, 13 (21.7%) underwent MRI of muscles, 10 (16.7%) open muscle biopsy, and 5 (8.3%) a skin biopsy. Thirty-two (53.3%) of MSA positive patients underwent high-resolution CT chest; 26 (81.3) % had findings suggestive of a fibrotic process and 12 (20.0%) had a formal diagnosis of ILD. A cancer screen was performed in 23 (38.3%) of the MSA positive patients and no malignancy was identified within the cohort.
Conclusion: Among MSA studies performed in two large centers, 20.4% of results were positive. Respiratory ordered the most numerous tests predominantly to evaluate ILD, a higher proportion of tests recommended by the rheumatology service was positive.

LUNG MANIFESTATIONS OF DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS PATIENTS FROM INDIA

A. Samitinjay[1], S. N. Vithala[2]. [1]*Govt General and Chest Hospital, General Medicine, Hyderabad, India;* [2]*Govt General and Chest Hospital, Pulmonary Medicine, Hyderabad, India*

Background: Lung manifestations in diffuse cutaneous systemic sclerosis (dCSS) are well known. Data on these manifestations in Indian patients are scant or unknown. We aim to present the various lung manifestations in patients with dCSS.
Objectives: To study the clinical and radiological characteristics of pulmonary symptoms such as cough, dyspnea, or hemoptysis, in patients, previously diagnosed with dCSS, in accordance with ACR 2013 classification criteria.
Methods: This was a cross-sectional, point of care study, done at the Government General and Chest Hospital, Hyderabad, Telangana, India. The study was conducted from April 2019 to March 2020 and patients with a confirmed diagnosis of dCSS were included. Patients with known heart disease, diabetes mellitus, cancer, obesity, acute respiratory infections, and HIV infection were excluded.
7 patients were eligible for inclusion. All patients gave their consent to participate in this study. The study was also approved by the institutional ethics committee. All imaging studies were read and confirmed by consultant radiologists at our hospital.
Results: All patients received a confirmed diagnosis of dCSS less than 2 years from the time of presentation to our hospital. The shortest duration from diagnosis of dCSS to first manifestation of pulmonary symptoms was 6 months.
All patients were females. The mean age was 52 ± 14.6 years. All patients had chronic cough, lasting ≥ 1 month. 6 out of 7 patients had exertional dyspnea lasting for ≥ 1 month. None of the 7 patients reported hemoptysis, wheezing, or having a fever. Only 1 patient had anemia, and none had leukocytosis. All patients had their chest x-rays reported as normal.
6/7 (85.7%) patients had subpleural reticular shadowing limited to the lower lobes on HRCT chest, consistent with usual interstitial pneumonia (UIP) pattern. 3/6 (50%) patients with reticular shadowing also had honeycombing suggesting advanced/severe UIP. None of the patients had traction bronchiectasis. 2/6 patients (33.3%) with UIP, also had non subpleural ground glass opacities (GGOs) in the middle and lower zones, suggesting an overlap between UIP and NSIP (non-specific interstitial pneumonia).

Table 1.

S.No.	Age (years)	Sex	Duration from Diagnosis to first pulmonary manifestation	Pulmonary symptoms	CBC	Chest X-ray	HRCT Chest	ECG	2D-Echo	Spirometry	BAL
Patient 1	44	F	16 months	Cough + Dyspnea – 2 months	Normal	Normal	Advanced UIP	Normal	Normal	Restrictive	Normal
Patient 2	56	F	18 months	Cough + Dyspnea – 3 months	Normal	Normal	UIP	Normal	Normal	Normal	Neutrophilic
Patient 3	61	F	12 months	Cough + Dyspnea – 1 month	Normal	Normal	Advanced UIP	Normal	RVSP = 48 mm Hg	Restrictive	Lymphocytic
Patient 4	70	F	21 months	Cough + Dyspnea – 2 months	Normal	Normal	Normal	Normal	Normal	Normal	Lymphocytic
Patient 5	24	F	18 months	Cough + Dyspnea – 2 months	Normal	Normal	Advanced UIP + NSIP (overlap)	Normal	RVSP = 51 mm Hg	Restrictive	Neutrophilic
Patient 6	55	F	12 months	Cough + Dyspnea – 1 month	Normal	Normal	UIP	Normal	Normal	Normal	Not Performed
Patient 7	54	F	6 months	Dyspnea – 1 month	Anemia +	Normal	UIP + NSIP (overlap)	Normal	Normal	Restrictive	Neutrophilic

Notes in the column 'BAL' indicate the predominant cell type noted on cytology. RVSP = Right Ventricular Systolic Pressure

Findings on ECG, 2D-Echo, spirometry and bronchoalveolar lavage (BAL) are summarized in Table 1.

Conclusion: Although limited by a small sample size, UIP appeared to be the most common lung pathology in patients with dCSS. The duration from diagnosis of dCSS to first manifestation of pulmonary symptoms is much shorter in comparison to limited cutaneous systemic sclerosis [1] PAH is commoner with limited cutaneous systemic sclerosis than with dCSS. [2] BAL was neither useful for diagnosis nor required in preparing a therapeutic plan for these patients.

AB0651 CLINICAL IMPACT AND PROGNOSIS OF CRYOGLOBULINEMIA AND CRYOFIBRINOGENEMIA IN SYSTEMIC SCLEROSIS

S. De Almeida Chaves[1], P. Benedicte[2], T. Porel[1], E. Bories[3], D. Adoue[1], L. Astudillo[4], L. Alric[3], A. Huart[5], M. Michaud[6], D. Ribes[5], G. Prevot[7], L. Sailler[8], F. Gaches[6], G. Pugnet[3]. *[1]Hospital Purpan, Internal Medicine, Toulouse, France; [2]Hospital Purpan, Immunology, Toulouse, France; [3]Hospital Rangueil, Internal Medicine, Toulouse, France; [4]Clinic nephrologist Saint Exupery, Internal Medicine, Toulouse, France; [5]Hospital Rangueil, Nephrology, Toulouse, France; [6]Hospital Joseph Ducuing, Internal Medicine, Toulouse, France; [7]Hôpital Larrey, Pneumoogy, Toulouse, France; [8]Hôpital Purpan, Internal Medicine, Toulouse, France*

Background: Systemic sclerosis (SSc) is reported to be a secondary cause of cryoglobulinemia as well as cryofibrinogenemia. However, prevalence, clinical implication and associated pronostic of cryoprecipitates in SSc are unknown.

Objectives: To describe the prevalence, the phenotype and evaluate the prognosis of cryoglobulinemia and/or cryofibrinogenemia associated with systemic sclerosis.

Methods: We included all adult (≥18 years) consecutive SSc patients from the Systemic Scleroderma Toulouse Cohort (SSTC) [1] for whom a cryoglobulin and/or cryofibrinogen measurement was carried out at the immunology laboratory of the Toulouse University Hospital between June 1, 2005 and May 31, 2018 and at least one follow-up visit. We compared SSc-patients characteristics' with and without cryoglobulinemia > 50 mg/l and with and without cryofibrinogenemia. Survival analysis based on presence of cryoglobulin cryofibrinogen was performed using the Kaplan-Meier method. Univariable and multivariable Cox proportional hazards models (ascending step-by-step method) were used to determine baseline variables associated with cryoglobulin or cryofibrinogen presence.

Results: 166 patients were included in the study. 74.6% of patients were women, with a average age at diagnosis of 51.2 years-old. 24% were diffuse cutaneous subtypes and 71.6% limited cutaneous subtypes. Anti-centromere and anti-Scl70 were respectively positive in 44.5% and 21.6% of cases. All these patients were assessed for cryoglobulin detection and 75 cryofibrinogen detection in serum. 43.3% had a cryoglobulinemia >50 mg/l. 46.6% had cryofibrinogenemia. Patients with cryoglobulinemia >50 mg had more cardiac diastolic involvement (22.8% vs. 5.1% p=0.0395). In the multivariate analysis, diastolic involvement (HR=6.23; p=0.0331) was an independent predictor of cryoglobulin >50 mg/l. Survival at 10 years was better for patients with cryoglobulinemia >50 mg/l (log-rank 0.0363) (Figure 1). Survival at 5 and 10 years was 97.6% and 88.8% respectively in patients with cryoglobulinemia >50 mg/l versus 91.9% and 78.4% in patients with cryoglobulinemia <50 mg/l. In cox regression model adjusted for gender, age and type of systemic sclerosis, cryoglobulin >50 mg/l was negatively associated with mortality (HR: 0.09; p=0.03). The presence of cryofibrinogenemia was not associated with any clinical, biological or morphological features. In the multivariate analysis, no variable was predictive of the presence of cryofibrinogenemia in patients with SSc. The presence of cryofibrinogenemia had no influence on the mortality of these patients.

Conclusion: In SSc patients, the presence of cryoglobulin >50 mg/l is an independent predictive factor of cardiac diastolic involvement and is associated with a better survival. However, cryofibrinogenemia does not influence clinical phenotype or impact mortality in SSc patients.

AB0652 PREVALENCE OF INTERSTITIAL LUNG DISEASE AND PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS PATIENTS COHORT AT A RHEUMATOLOGY REFERRAL CENTRE IN THE UNITED ARAB EMIRATES

K. Saleh[1], N. Khan[1], A. Ghorab[1], M. El-Kaissi[2], A. Mubashir[3], M. Elarabi[3], H. Sabbour[4], R. Namas[3]. *[1]Cleveland Clinic Abu Dhabi, Respiratory Institute, Abu Dhabi, United Arab Emirates; [2]Cleveland Clinic Abu Dhabi, Radiology, Abu Dhabi, United Arab Emirates; [3]Cleveland Clinic Abu Dhabi, Rheumatology, Abu Dhabi, United Arab Emirates; [4]Cleveland Clinic Abu Dhabi, Cardiology, Abu Dhabi, United Arab Emirates*

Background: Scleroderma, also known as Systemic Sclerosis (SSc), is a connective tissue disease that affects multiple organ systems, including the cardiovascular and respiratory systems, namely, pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD) as the leading causes of death in this patient population.

Objectives: The purpose of this study is to determine the prevalence of PAH and ILD in a cohort of patients diagnosed with SSc.

Methods: We performed a retrospective chart review of clinical characteristics of all patients diagnosed with SSc Cleveland Clinic Abu Dhabi between April 2015 and April 2020. PAH was estimated by echocardiographic findings and diagnosed based on right heart catheterization (RHC) using 2019 World Symposium on Pulmonary Hypertension. The CT scan of the chest was read by a board-certified radiologist in chest radiology.

Results: Fifty individuals were diagnosed with SSc, with 46% having diffuse cutaneous systemic sclerosis and 54% having limited cutaneous systemic sclerosis. The majority of the patients (88%) were female, with a mean age of 41 ±13 years. The average period from presentation to diagnosis was 5 ±5.4 years. The majority of the cohort (86%) were from the United Arab Emirates. The average BMI was 26.0 kg/m^2. Patients' most prevalent symptoms are fatigue (80%), gastrointestinal symptoms (72%) followed by shortness of breath (58%) and cough (50%). Twenty-six out of fifty patients (52%) underwent a CT chest scan, with 19 (38%) having ILD. Eight patients had more than 30% fibrotic alterations, four patients had 10-30% fibrotic changes, and seven patients had less than 10% fibrotic abnormalities. Patients with more than 10% fibrotic changes were more likely to have usual interstitial pneumonia, whereas those with less than 10% fibrotic changes were more likely to have none specific fibrosis. The majority of patients (92%) had echocardiogram. All except one patient had a normal ejection fraction, and five had grade 1 left ventricular diastolic dysfunction. Five patients were described as having mild, 1 moderate and 2 severe PAH. Only 4 patients underwent RHC. One patient had group II PAH based on elevated wedge pressure. One had group 1 PAH with systemic sclerosis as the only cause for her PAH and two patients had group III PAH due to having more than 30 % pulmonary fibrosis and severe restrictive defect on spirometry. Therefore, the precapillary PAH prevalence was 6% (3/50).

Conclusion: While the prevalence of pulmonary fibrosis in our SSc patients reflects what has been reported in the literature, the prevalence of PAH is significantly lower than the reported 15-20%.[1] This is likely due to underdiagnosis of PAH considering the number of years of systemic sclerosis diagnosis on presentation to our clinic. A systematic approach is needed to assess for the presence and severity of PAH using tools as in Detect algorithm which has been validated and commonly used in Europe and North America to screen for PAH.[2] Validation of such algorithm is likely needed in middle eastern population before it is universally adopted.

AB0653 **THE ASSOCIATION OF AUTOANTIBODIES WITH MORBIDITY AND MORTALITY OF SCLERODERMA RENAL CRISIS IN JAPAN**

H. Tsuji[1], N. Kuramoto[2], T. Sasai[1], M. Shirakashi[1], H. Onizawa[3], K. Kitagori[1], S. Akizuki[1], R. Nakashima[1], R. Watanabe[4], A. Onishi[3], K. Murakami[5], H. Yoshifuji[1], M. Tanaka[3], M. Hashimoto[4], K. Ohmura[6], A. Morinobu[1]. *[1]Kyoto University Graduate School of Medicine, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; [2]Wakayama Medical University, Department of Rheumatology and Clinical Immunology, Wakayama, Japan; [3]Kyoto University Graduate School of Medicine, Department of Advanced Medicine for Rheumatic Diseases, Kyoto, Japan; [4]Osaka City University Graduate School of Medicine, Department of Clinical Immunology, Osaka, Japan; [5]Kyoto University Graduate School of Medicine, Division of Clinical Immunology and Cancer Immunotherapy, Center for Cancer Immunotherapy and Immunobiology, Kyoto, Japan; [6]Kobe City Medical Center General Hospital, Department of Rheumatology, Kobe, Japan*

Background: The morbidity of scleroderma renal crisis (SRC) and autoantibodies in systemic sclerosis (SSc) vary by races and regions. Anti-RNA polymerase III is associated with SRC in America and European countries. However, the association of autoantibodies with SRC had not been elucidated in Japan.

Objectives: We aimed to investigate the association of autoantibodies with morbidity and mortality of SRC in Japan.

Methods: The clinical characteristics and mortality of 330 patients with systemic sclerosis (SSc) at Kyoto University Hospital were retrospectively analyzed, focusing on anti-centromere, anti-RNA polymerase III, anti-topoisomerase I, and anti-U1-RNP. Logistic regression analyses were performed to examine the association of autoantibodies with the development and mortality of SRC. Kaplan-Meier survival analysis was performed comparing the groups classified by autoantibodies.

Results: Anti-centromere (n = 177/318, 56%), anti-topoisomerase I (n = 80/311, 26%), anti-RNA polymerase III (n = 27/204, 13%), and anti-U1-RNP (n = 24/305, 8%) were found in SSc patients (n = 330). SRC was observed in 24 out of 330 SSc patients, including anti-topoisomerase I (n = 12/24, 50%), anti-RNA polymerase III (n = 7/24, 29%), anti-U1-RNP (n = 5/24, 21%), and anti-centromere (n = 3/24, 13%). Anti-U1-RNP (odds ratio [95% confidence interval], 3.63 [1.11–10.2]), anti-RNA polymerase III (3.29 [1.16–8.70]), and anti-topoisomerase I (3.22 [1.37–7.57]) were associated with the development of SRC. All patients with SRC were treated with ACE inhibitors and the 1-year survival rate was 54%. Anti-topoisomerase I was associated with the 1-year mortality of SRC (6.00 [1.11–41.1]). When the survival rate was compared between the patients positive for anti-topoisomerase I (n=12) and negative for anti-topoisomerase I (n=12), the 1-year survival rate was 33% vs 75% (p=0.041), respectively (Figure 1A). Furthermore, the 1-year survival of anti-centromere (100%), anti-RNA polymerase III (83%), and others/not detected (50%) were shown in patients negative for anti-topoisomerase I (Figure 1B).

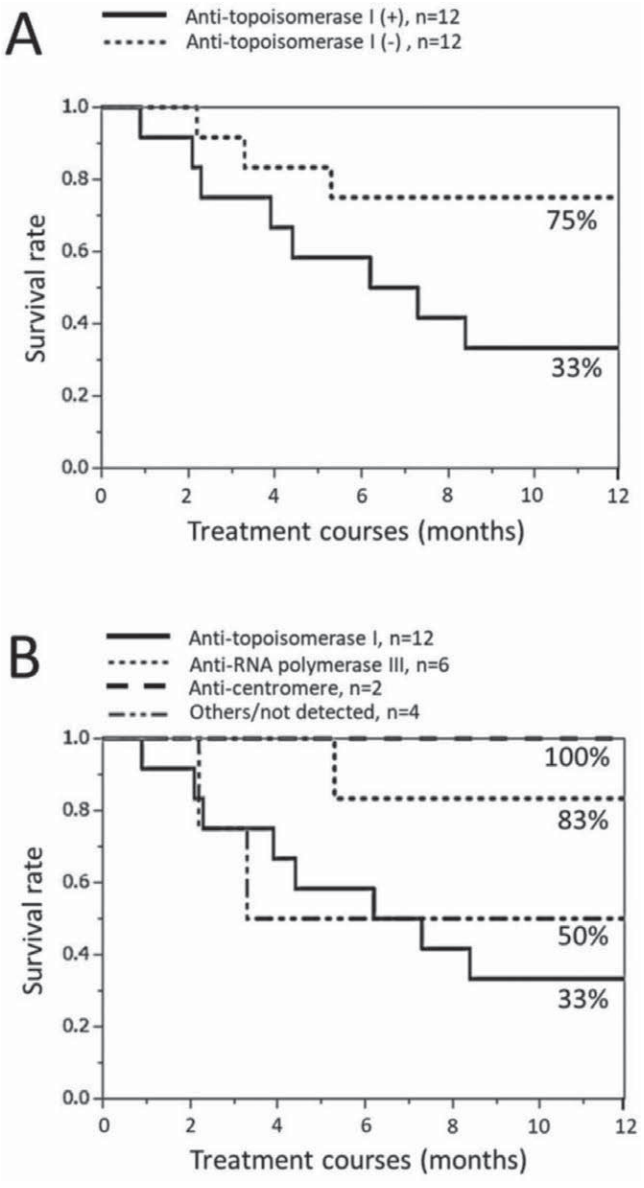

Figure 1. Overall survival of patients with SRC according to the type of autoantibodies. (A) The survival rates in SRC patients who were positive for anti-topoisomerase I (solid line, n = 12) and those who were negative for anti-topoisomerase I (dotted line, n = 12). (B) SRC patients negative for anti-topoisomerase I were classified as patients with anti-RNA polymerase III (dotted line, n = 6), anti-centromere (broken line, n = 2), and others/not detected (chain line, n = 4).

Conclusion: Specific SSc-related autoantibodies were associated with the morbidity and mortality in SRC.

AB0654 ELEVATED CIRCULATING LEVELS OF IL-33 IN SYSTEMIC SCLEROSIS PATIENTS WITH INTERSTITIAL LUNG DISEASE

R. Dacheva[1], G. Vasilev[2], K. Tumangelova-Yuzeir[2,3], D. Kyurkchiev[2,3], S. Monov[4,5]. *[1]University Hospital "St. Ivan Rilski", Diagnostic and Consultation Center, Sofia, Bulgaria; [2]University Hospital "St. Ivan Rilski", Laboratory of Clinical Immunology, Sofia, Bulgaria; [3]Medical University of Sofia, Department of Clinical Immunology, Sofia, Bulgaria; [4]University Hospital "St Ivan Rilski", Clinic of Rheumatology, Sofia, Bulgaria; [5]Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria*

Background: Systemic sclerosis (SSc) is a chronic autoimmune disease characterized by immune dysregulation, vasculopathy and progressive skin and internal organ fibrosis. Interstitial lung disease (ILD) remains a leading cause of morbidity and mortality in SSc patients. Interleukin 33 (IL-33) is a member of the IL-1 superfamily and has been previously described as a pro-fibrotic cytokine that exerts its function by inducing Th2 cells differentiation and stimulating the expression of TGF-β. Previous reports have revealed the role of IL-33 in numerous fibrotic diseases.

Objectives: The aim of the present study is to examine the serum levels of IL-33 and explore the possible correlation with clinical and laboratory features with a focus on pulmonary involvement in SSc patients.

Methods: A total number of fifty five (n=55) patients fulfilling the 2013 ACR/EULAR criteria for classification of SSc were enrolled in the study. Twenty five (n=25) age and sex matched healthy volunteers were used as controls. Detailed medical history, clinical and laboratory parameters were obtained for all included patients. Serum levels of IL-33 (pg/ml) were determined by enzyme-linked immunosorbent assay. GraphPad Prism 6,SPSS V.28 and RStudio were used for the performance of the statistical analysis.

Results: Of all included patients in the analyses, serum sample was obtained from 55 SSc patients, 51 women (92,7%) and 4 men (7,3%): thirty nine (n=39) with diffuse subset. Mean age was 56±12, mean disease duration was 5.5±6 years. No statistically significant difference was found between IL-33 levels in the patient group and healthy controls. Higher serum IL-33 levels were detected in patients with systemic sclerosis associated interstitial lung disease (SSc-ILD), median 27.9 pg/ml [IQR 4.8-52.9 pg/ml] compared to patients without SSc-ILD 1.12 pg/ml[1.12-45.8 pg/ml]. Decreased percent predicted forced vital capacity (FVC) and vital capacity (VC) correlated inversely with IL-33 levels (p<0,05). The ROC curve analysis with bootstrapping revealed diagnostic accuracy with AUC=0.65, p=0.05 for IL-33 circulating levels as a marker of interstitial lung involvement. A optimal cut-off value of 5 pg/ml was determined with respectively 75 % sensitivity and 60 % specificity.

Conclusion: IL-33 may be involved in the immunopathogenesis of pulmonary fibrosis. The results are consistent with previous studies. The present study is cross-sectional and further analyses and follow-up may be required to determine whether IL-33 may serve as a potential biomarker in the routine practice.

Background: Various nationwide studies have been already published to better understand Mixed Connective Tissue Disease (MCTD) (1,2). However, Portuguese data is not available.

Objectives: To characterize clinical and immunological features of a Portuguese cohort of patients with MCTD.

Methods: Retrospective, multicenter study including adult-onset patients with clinical diagnosis of MCTD and fulfilling at least one of the following classification criteria: Sharp, Kasukawa, Alarcón-Segovia or the Kahn's criteria. Positivity to other autoantibodies besides anti-U1-RNP were allowed. SPSS was used for statistical analysis and significance level was defined as 2-sided $p<.05$.

Results: A total of 98 patients were included, with a mean age at diagnosis and disease duration of 40.5±13.7 and 7.0±6.5 years, respectively. Most patients were female (87.8%) and Caucasian (70.4%). Raynaud's phenomenon (96.9%), arthralgia/arthritis (94.9/74.5%) and puffy fingers (60.2%) were the most common and early manifestations. Gastroesophageal (GE), respiratory and muscular

involvement were also prevalent, mostly during the follow up, affecting 30.6%, 34.7% and 43.9% of the patients, respectively. Clinical and immunological characteristics are described in Table 1. Males were older at symptom's onset (65.0 VS 46.7, *p*=.035), having more respiratory involvement (OR=4.5, 95% CI 1.3-16.4), and positivity to anti-ACPA (OR=20.0, 95% CI: 3.1-129.4). GE involvement occurred more often in Caucasian patients (OR=3.8; 95% CI: 1.0-14.1), while anemia of chronic diseases (OR=2.7; 95% CI: 1.0-7.2), myositis (OR=3.6; 95% CI: 1.3-9.9) and constitutional symptoms (OR=3.2; 95% CI: 1.2-8.3) were more frequent in Afro-American patients, whose were also younger at disease (34.1 VS 50.6, *p*=.01). After a median follow-up time of 4 (IQR 8) years, 4 deaths occurred (4.1%), mostly (75%) due to infectious complications.

Table 1. Clinical and immunological characteristics

Clinical Manifestations	At presentation	Follow-up
Mucocutaneous system		
Raynaud's phenomenon, n (%)	85 (86.7)	95 (96.9)
Puffy hands, n (%)	48 (49.0)	59 (60.2)

Legend: Anti-dsDNA: anti-double stranded deoxyribonucleic acid antibody; SLE: systemic lupus erythematosus, SSc: systemic sclerosis. *No information regarding cardiac catheterism, then compatible alterations in the echocardiogram.

Conclusion: Raynaud's phenomenon, puffy fingers and arthritis were the most common manifestations in Portuguese patients, with similar proportions found in literature (1,2). However, we reported some differences in mucocutaneous, renal and serosa involvement and higher prevalence of probable pulmonary hypertension (1,2), which may be explained by the heterogeneity of the inclusion criteria. Except for respiratory, myositis, GE and constitutional symptoms, there were no differences regarding gender and ethnicity. Here, we characterize the largest cohort of MCTD in Portugal.

CAROTID INTIMA-MEDIA THICKNESS AS POTENTIAL MARKER OF CARDIOVASCULAR RISK IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY.

F. S. Iaquinta[1], S. Di Napoli[2], R. Grosso[2], S. Naty[1], V. Cassano[3], D. Crescibene[3], G. Armentaro[3], A. Sciacqua[3], R. D. Grembiale[1]. [1]*"Magna Graecia" University of Catanzaro, Rheumatology Research Unit, Department of Health Sciences, Catanzaro, Italy;* [2]*"Magna Graecia" University of Catanzaro, Department of Health Sciences, Catanzaro, Italy;* [3]*"Magna Graecia" University of Catanzaro, Department of Medical and Surgical Sciences, Catanzaro, Italy*

Background: In several rheumatic diseases, persistent inflammatory state has been related to an accelerated atherosclerosis. Although the risk of cardiovascular (CV) events and atherosclerosis is increased in patients with Systemic Sclerosis (SSc), the exact underlying process has not been well defined. Indeed, inflammation is not a remarkable feature of systemic sclerosis pathogenesis as in other inflammatory rheumatic diseases.

Objectives: The aim of this study was to evaluate the carotid intima-media thickness (c-IMT) as potential marker of cardiovascular damage in SSc patients.

Methods: Between April and July 2021, 14 consecutive patients with SSc and 14 control subjects were enrolled in the study. Participants were aged > 18 and were able to provide written informed consent. Demographic, anthropometric and cardiovascular risk factors (smoking, arterial hypertension, diabetes and family history of CV events) were collected for each subject. Moreover, an evaluation of the sero-haematological characteristics was also performed. The c-IMT was assessed by the same qualified physician through a B-mode ultrasound examination. C-IMT values ≥ 0.9 mm were considered pathological.

Results: Demographic and clinical characteristics are shown in Table 1. Traditional CV risk factors were similar between groups, although BMI was significantly lower in SSc patients than controls (24±6 vs 26±2; *p*=0.019). Patients' median disease duration was 11 [5.0-16] years. Three patients had limited and 11 patients had diffuse disease according to LeRoy classification. Anti-nuclear antibodies were detected in all SSc subjects. Three patients expressed anti-centromere antibodies (ACA), other 3 are anti-Scl70 antibodies positive, only one patient showed anti-RNA polymerase III antibodies and 7 patients did not presented specific SSc autoantibodies. SSc patients had slightly increased c-IMT compared with controls, however the difference did not reach statistical significance (median c-IMT 0.84 [0.72-0.91] vs median c-IMT 0.68 [0.63-0.82], *p*=0.164).

Table 1.

	Controls (n=14)	SSc patients (n=14)	*p*

ERA, yes (%)	0 (0)	9 (64)	$2.71x10^{-4}$
HMG-CoA reductase inhibitors, yes (%)	6 (43)	4 (29)	0.430

Continuous data are presented as mean ± standard deviation or as median and interquartile range. Binomial data are shown as frequencies and percentages. The overall p-value was calculated by the Mann–Whitney non-parametric test for independent samples and by Chi-squared test as appropriate.

Conclusion: In our study patients with SSc had a non-significative increased c-IMT compared with controls (*p*=0.164), however different results have been reported in previous studies. Although it is not clear whether c-IMT may be considered a marker of cardiovascular damage in SSc, further studies are needed to clarify its role.

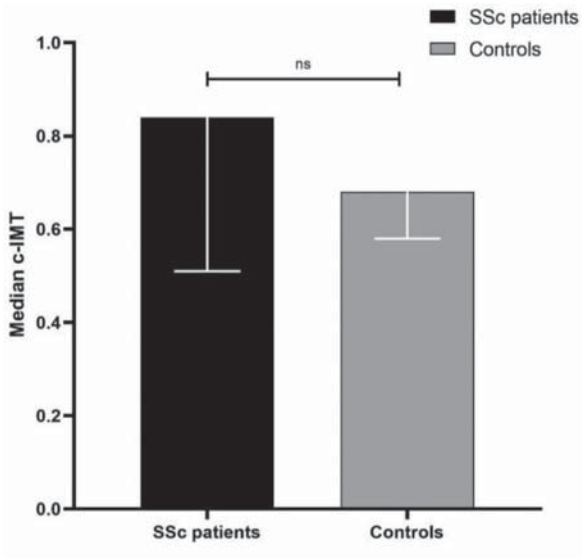

Figure 1. Median c-IMT among groups. Data are shown as median and range. P-values were calculated by the Mann–Whitney non-parametric test for independent samples.

SEVERITY AND IMPACT OF GASTROINTESTINAL SYMPTOMS IN PATIENTS WITH SSC-ILD TREATED WITH NINTEDANIB: DATA FROM SENSCIS-ON

D. Khanna[1], E. Volkmann[2], K. Highland[3], Y. Allanore[4], S. Jouneau[5], J. Seibold[6], A. James[7], M. Alves[8], O. Distler[9]. *[1]Division of Rheumatology, Department of Internal Medicine, Scleroderma Program, University of Michigan, Ann Arbor, MI, United States of America; [2]University of California, David Geffen School of Medicine, Department of Medicine, Division of Rheumatology, Los Angeles, CA, United States of America; [3]Cleveland Clinic, Department of Pulmonary, Cleveland, OH, United States of America; [4]Descartes University, APHP, Cochin Hospital, Department of Rheumatology A, Paris, France; [5]Competences Centre for Rare Pulmonary Diseases, Univ Rennes, CHU Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, F-35000 Rennes, Department of Respiratory Medicine, Rennes, France; [6]Scleroderma Research Consultants LLC, President, Aiken, SC, United States of America; [7]Elderbrook solutions GmbH, Statistics, Bietigheim-Bissingen, Germany; [8]Boehringer Ingelheim International GmbH, Department, Ingelheim am Rhein, Germany; [9]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland*

Background: Gastrointestinal (GI) involvement is a common manifestation of systemic sclerosis (SSc) and a frequent side-effect of drugs used to treat SSc. In the SENSCIS trial, nintedanib reduced the rate of decline in forced vital capacity (FVC) in patients with SSc-associated interstitial lung disease (SSc-ILD), with an adverse event profile characterised predominantly by GI events.

Objectives: To assess the severity and impact of GI symptoms on quality of life in patients treated with nintedanib in the open-label extension trial, SENSCIS-ON.

Methods: Patients with SSc-ILD who completed the SENSCIS trial or a drug–drug interaction (DDI) study of nintedanib and oral contraceptive were eligible to enter SENSCIS-ON. Patients who received nintedanib in SENSCIS (up to 100 weeks) and continued nintedanib in SENSCIS-ON comprised the "continued nintedanib" group. Patients who received placebo in SENSCIS and initiated nintedanib in SENSCIS-ON, or who received nintedanib for a short time in the DDI study, comprised the "initiated nintedanib" group. We assessed changes in scores on the UCLA Scleroderma Clinical Trial Consortium Gastrointestinal Tract (UCLA SCTC GIT) questionnaire v2.0 from baseline to week 52. This questionnaire comprises 7 scales measuring the severity and impact of GI symptoms: reflux, distension or bloating, faecal soilage, diarrhoea, constipation, emotional well-being, social functioning. Each scale is scored from 0 to 3 except for the diarrhoea scale (0 to 2) and constipation scale (0 to 2.5). The total score, the mean of the scores for the scales except constipation, ranges from 0 to 2.83, with higher scores indicating worse symptoms.

Results: The "continued nintedanib" group comprised 197 patients and the "initiated nintedanib" group comprised 247 patients (231 from SENSCIS). Of these, 178 and 218 patients, respectively, provided a total UCLA SCTC GIT score at baseline. At baseline, mean (SD) total scores were 0.33 (0.33) and 0.33 (0.34) in the continued nintedanib and initiated nintedanib groups, respectively. Mean (SD) scores on the 7 scales ranged from 0.16 (0.52) to 0.70 (0.73) in the continued nintedanib group and from 0.13 (0.43) to 0.64 (0.68) in the initiated nintedanib group. Increases (worsening) in scores were observed in both groups from baseline to week 52, except for on the constipation scale (Figure 1). Based on the total score, between baseline and week 52, the proportion of patients with moderate or severe or very severe GI symptoms increased, but 45.7% and 39.7% of patients in the continued nintedanib and initiated nintedanib groups, respectively, had no or mild GI symptoms at week 52 (Table 1).

Table 1. Changes in severity and impact of gastrointestinal symptoms based on UCLA SCTC GIT total score between baseline and week 52 of SENSCIS-ON

		Baseline				
Week 52		None or mild	Moderate	Severe or very severe	Missing	Total
	Continued nintedanib					
	None or mild	81 (41.1)	5 (2.5)	0	4 (2.0)	90 (45.7)
	Moderate	38 (19.3)	10 (5.1)	0	1 (0.5)	49 (24.9)
	Severe or very severe	13 (6.6)	14 (7.1)	7 (3.6)	1 (0.5)	35 (17.8)
	Missing	6 (3.0)	3 (1.5)	1 (0.5)	13 (6.6)	23 (11.7)
	Total	138 (70.1)	32 (16.2)	8 (4.1)	19 (9.6)	197 (100)
	Initiated nintedanib					
	None or mild	87 (35.2)	6 (2.4)	1 (0.4)	4 (1.6)	98 (39.7)
	Moderate	35 (14.2)	12 (4.9)	2 (0.8)	3 (1.2)	52 (21.1)
	Severe or very severe	8 (3.2)	7 (2.8)	4 (1.6)	1 (0.4)	20 (8.1)
	Missing	37 (15.0)	15 (6.1)	4 (1.6)	21 (8.5)	77 (31.2)
	Total	167 (67.6)	40 (16.2)	11 (4.5)	29 (11.7)	247 (100)

Data are n (%) of patients. None or mild=scores of 0 to 0.49; moderate=scores of 0.5 to 1; severe or very severe=scores of 1.01 to 3.

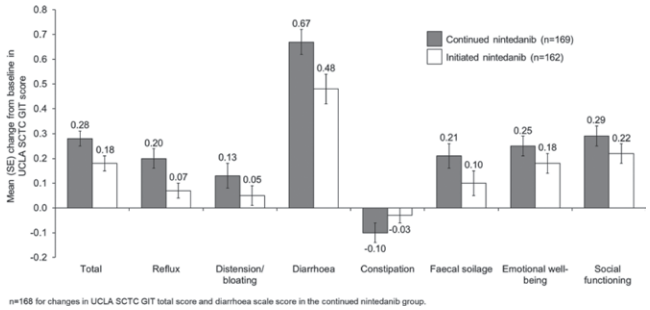

Figure 1. Changes in UCLA SCTC GIT scores from baseline to week 52 of SENSCIS-ON

Conclusion: In the SENSCIS-ON trial, the majority of patients with SSc-ILD treated with nintedanib had no or mild GI symptoms at baseline. A small worsening in GI symptoms was observed over 52 weeks. Diarrhoea had the greatest impact, reflecting the adverse event profile of nintedanib. Recommendations for the management of diarrhoea in patients treated with nintedanib should be implemented in clinical practice.

NOCEBO EFFECT ON DIARRHOEA REPORTED IN THE SENSCIS TRIAL OF NINTEDANIB IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD)

O. Distler[1], K. Highland[2], A. Azuma[3], C. Miede[4], M. Alves[5], P. Sfikakis[6]on behalf of The SENSCIS trial investigators. *[1]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland; [2]Cleveland Clinic, Department of Pulmonary, Cleveland, OH, United States of America; [3]Graduate School of Medicine, Nippon Medical School, Department of Pulmonary Medicine and Oncology,Tokyo, Japan; [4]mainanalytics GmbH, Statistics, Sulzbach (Taunus), Germany; [5]Boehringer Ingelheim International GmbH,TA Inflammation Med, Ingelheim, Germany; [6]National Kapodistrian University of Athens Medical School, 1st Dept of Prop. Internal Medicine & Joint Academic Rheumatology Program, Athens, Greece*

Background: Unfavourable effects observed after administration of placebo that may be attributed to factors such as expectation or conditioning are known as nocebo effects. Prior to initiation of the SENSCIS trial, diarrhoea was a known side-effect of nintedanib.

Objectives: To investigate whether a nocebo effect contributed to reporting of diarrhoea in the SENSCIS trial.

Methods: The SENSCIS trial enrolled patients with systemic sclerosis (SSc) with first non-Raynaud symptom in the prior ≤7 years and ≥10% extent of fibrotic ILD on high-resolution computed tomography. Patients were randomised to receive nintedanib or placebo until the last patient had reached week 52 but for ≤100 weeks. A follow-up visit was conducted 28 days after the end of treatment. Adverse events were reported by investigators irrespective of causality and coded according to the Medical Dictionary for Regulatory Activities. We analysed the incidence of diarrhoea adverse events in the on-treatment period (*i.e.,* events with onset between the first intake of trial drug intake and the last intake plus 7 days) and in the post-discontinuation period (*i.e.,* events with onset between the first day after the on-treatment period and the end of the follow-up period) in the nintedanib and placebo groups. Incidence rates were calculated as the number of patients with diarrhoea adverse events divided by the time at risk.

Results: In the on-treatment period (time at risk: 277.8 patient-years), the rate of diarrhoea adverse events in the placebo group (n=288) was 33.1 per 100 patient-years. In the post-discontinuation period (time at risk: 41.9 patient-years), the rate of diarrhoea adverse events in the placebo group (n=284) was 19.1 per 100 patient-years. In the on-treatment period (time at risk: 105.1 patient-years), the rate of diarrhoea adverse events in the nintedanib group (n=288) was 209.3 per 100 patient-years. In the post-discontinuation period (time at risk: 53.7 patient-years), the rate of diarrhoea adverse events in the nintedanib group (n=283) was 5.6 per 100 patient-years.

Conclusion: In the SENSCIS trial in patients with SSc-ILD, the rate of diarrhoea adverse events in the placebo group fell after trial drug was discontinued. This suggests that a nocebo effect may have contributed to the diarrhoea adverse events reported in the SENSCIS trial.

AB0659

RECRUITMENT AND PREVALENCE OF MIXED PHENOTYPE MACROPHAGES IS PROMINENT IN BRONCHOALVEOLAR LAVAGE (BAL) OF SYSTEMIC SCLEROSIS (SSC) PATIENTS WITH INTERSTITIAL LUNG DISEASE (ILD).

Y. Al-Adwi[1], T. J. Gan[2], J. Bosma[3], W. Abdulahad[3,4], I. M. Atzeni[1], M. Van der Leij[5], B. J. Kroesen[5], A. J. Stel[3], W. Timens[4], J. Burgess[4], H. Van Goor[4], J. Westra[3], D. J. Mulder[1]. *[1]University Medical Center Groningen, Internal Medicine (Vascular), Groningen, Netherlands; [2]University Medical Center Groningen, Pulmonary Diseases and Tuberculosis, Groningen, Netherlands; [3]University Medical Center Groningen, Rheumatology and clinical medicine, Groningen, Netherlands; [4]University Medical Center Groningen, Pathology and medical biology, Groningen, Netherlands; [5]University Medical Center Groningen, Medical immunology, Groningen, Netherlands*

Background: ILD is a major problem in SSc for which no disease-modifying therapies are available. Many observations suggest monocyte/macrophage involvement in SSc and might be a key component in the development of ILD. Macrophages polarize into M1 and M2 phenotypes and thereby orchestrate inflammation and subsequent fibrosis by responding to and producing a vast array of cytokines and chemokines. Differences in the levels of the chemokines might explain variations in the recruitment and activation of macrophages in affected organs. In SSc, monocytes with a mixed phenotype (expressing both M1 and M2 markers) are prominent in peripheral blood. No previous study has investigated the mixed phenotype macrophages locally on the lung level.

Objectives: a-to measure macrophage-related chemokines in BAL fluid obtained from SSc-ILD and SSc-no-ILD patients.

b-to investigate levels of M1 and M2 macrophage markers in BAL cells obtained from SSc-ILD and SSc-no-ILD patients.

Methods: A cross-sectional study in which BAL procedure was performed on 15 treatment-naïve SSc patients divided into two groups according to lung involvement determined by HRCT and lung function tests: SSc-no-ILD group and SSc-ILD group (Table 1). Levels of chemokines (CCL18, CXCL-10 and CCR2) were analysed using ELISA. mRNA expression levels of CD86 (M1; inflammatory macrophage marker) and CD206 (M2; fibrogenic macrophage marker) in cells isolated from BAL were assessed using RT-qPCR. In addition, immunofluorescence studies and flow cytometry analyses were performed to evaluate the expression of M1 (CD86) or M2 (CD206) markers in BAL macrophages.

Table 1. Patient characteristics

	no ILD	ILD
Number of patients	8	7
Age	57 (51-68)	60 (53-73)
Female	75%	57%
Raynauds phenomenon	100%	85%
Age start of Raynauds	36 (22-53)	56 (41-66)
Age start of non-Raynauds	50 (33-60)	49 (36-68)
Skin thickening	50%	43%
Digital ulcer at this moment	0%	29%
Digital ulcer in the past	38%	29%
Pitting scars	38%	43%
Telangiectasia	50%	43%
Calcinosis	13%	29%
Cardiac	25%	14%
Gastro-intestinal	88%	43%
Kidney	0%	0%

Results: Macrophages were the predominant immune cell population in BAL of SSc patients (73%). The levels of CCL18, CCR2 and CXCL10 were slightly elevated in the SSc-ILD group compared to the SSc-no-ILD (Figure 1.1). RT-qPCR data showed that CD86 expression was elevated in the SSc-ILD group while no difference was observed in CD206 expression between the two groups (data not shown). The SSc-ILD group had higher proportions of double-positive (CD86+, CD206+) macrophages than SSc-no-ILD which, in contrast, had higher proportions of CD86+, CD206- macrophages (Figure 1.2). These results were supported by fluorescent microscopy images in which the SSc-ILD group had higher CD86 and CD206 expression than the SSc-no-ILD (Figure 1.3). Double staining clearly showed a more prevalent mixed activation of macrophages in the SSc-ILD group.

Conclusion: In this pilot study, recruitment and activation of mixed phenotype macrophages was more prominent in SSc-ILD than in SSc-no-ILD. Although levels of chemokines were not profoundly different between both groups, studying extensively the macrophage activation patterns in BAL provided novel findings regarding differences between the two groups. Since SSc is characterised by inflammatory and fibrotic phases, the mixed polarization of macrophages we showed for the first time in SSc-ILD patients on an organ level is a key aspect in such disease and could potentially serve as a target for therapeutics.

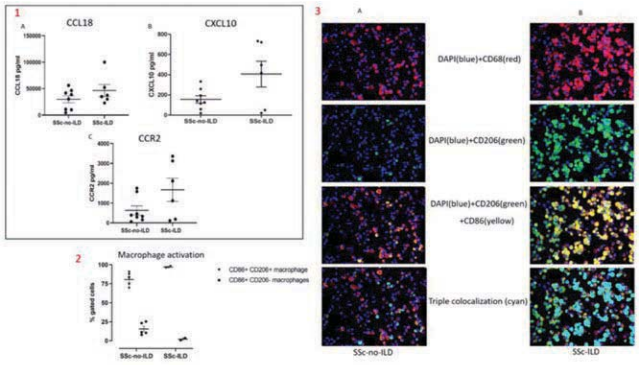

Figure 1: Macrophage-related chemokine levels, and M1/M2 analysis in SSc and SSc-ILD patients. (1) Protein levels in 6x concentrated BAL expressed in pg/mL. (A-C) elevated levels of CCL18, CXCL-10 and CCR2, respectively, in concentrated BAL of SSc-ILD patients compared to SSc-no-ILD, N=14. (2) Percentage of gated cells using CD86 and CD206 surface markers to distinguish M1 from mixed M1 and M2 macrophages in BAL cells, N=7. (3) Fluorescence microscopy images of cytospin preps stained with CD68 (pan-macrophage marker), CD86 and CD206 MoAB-conjugated fluorescence dyes, and DAPI for nuclei visualization (magnification: 20x). A) SSc-ILD cytospin prep showing prevalent staining of both CD86 and CD206 compared to SSc-no-ILD. B) SSc-no-ILD cytospin prep shows less activation of macrophages reflected by low prevalence of CD86 (yellow) and CD206 (green) stainings. No statistical testing was performed due to the small sample size.

AB0660 LONG-TERM EFFECT OF COMBINATION THERAPY WITH RITUXIMAB AND MYCOPHENOLIC ACID ON CARDIAC MANIFESTATIONS, PULMONARY FUNCTION AND SKIN FIBROSIS IN SYSTEMIC SCLEROSIS

E. B. Adjailia[1], H. Grasshoff[1], J. Y. Humrich[1], P. Lamprecht[1], G. Riemekasten[1]. *[1]University Medical Center Schleswig Holstein, Rheumatology and clinical immunology, Lübeck, Germany*

Background: Cardiac manifestations in systemic sclerosis (SSc) can be either due to the fibrotic and vascular process or secondary to pulmonary arterial hypertension (PAH), cardiac inflammation, or renal crisis. Despite being one of the leading causes of death in SSc, cardiac involvement and its therapeutic options have been poorly studied. According to the ACR/EULAR recommendations, therapy with cyclophosphamide (CP) is applied to patients with cardiac manifestations. However, in case of inadequate response to CP, there are no other therapeutics evaluated.

Objectives: The aim of this retrospective analysis was to explore the efficacy of a therapy with rituximab and mycophenolic acid (MPA), especially in cases of CP failure or therapy induced cardiac toxicity

Methods: 14 Patients with SSc and cardiac involvement (defined as troponin T elevation plus right- or left ventricular systolic or diastolic dysfunction, myocarditis, pericarditis, right heart failure secondary to PAH, or arrhythmias) were analysed. Two patients each showed concomitant myositis and rheumatoid arthritis, respectively. Twelve patients were initially treated with CP and two patients with methotrexate (MTX). Due to a disease progress (either cardiac involvement, skin fibrosis or lung function) a therapy with rituximab and MPA was initiated [1] These patients were followed for up to five years.

Results: Before initiation of CP or MTX electrocardiogram showed arrhythmias (atrial fibrillation, conduction blocks, multifocal ventricular extrasystoles (VES)) in 9 patients. Echocardiography revealed abnormalities in 10 patients including reduced left-ventricular ejection fraction (LV-EF), diastolic dysfunction, mitral regurgitation, or aortic aneurysm. 3 patients had PAH, 2 patients were diagnosed with post capillary pulmonary hypertension. Cardiac MRI revealed signs of myocarditis in 4 patients. 4 patients required cardiac resynchronization therapy or pacemaker implantation. Moreover, body plethysmography showed a reduction in forced vital capacity (FVC) in 12 patients, suggestive of restrictive lung disease. Under therapy with CP 11 patients had suffered from disease progress, 1 patient developed relapsing pneumonias and the 2 patients with overlap rheumatoid arthritis developed cardiac disease manifestations on MTX monotherapy. Consequently, rituximab 1000 mg q12weeks and MPA 1000 mg bid were initiated. Under this combination troponin T decreased in all patients (p=0.0002), LV-EF improved in 5, remained normal in 7 and deteriorated in 2 patients. The rate of VES improved in 8 patients. In one patient, myocarditis resolved completely (MRI). Moreover, pulmonary artery systolic pressure, measured by echocardiography, improved in all patients diagnosed with PAH under stable therapy. The modified Rodnan skin score improved in all patients, FVC improved in 7 patients, remained stable in 6 and decreased in the patient with overlap myositis. Rituximab infusions could be extended (1000 mg q24weeks) after 24-36 months of treatment in 11 patients. All patients showed peripheral blood depletion of B cells without noticed severe IgG deficiency. While 11 patients did not develop severe complications 2 patients died during follow-up of pneumonia and cardiogenic shock (overlap myositis), respectively and one patient developed a relapse of lung cancer with cerebral metastasis.

Conclusion: Therapy with rituximab and MPA is a promising alternative. However, its use requires risk stratification of patients with respect to adverse side effects which needs to be explored in future studies.

AB0661 NEUROPSYCHOLOGICAL OUTCOME OF CHILDREN BORN TO WOMEN WITH SYSTEMIC SCLEROSIS ASSESSED THROUGH A SELF-ADMINISTERED MULTIDISCIPLINARY QUESTIONNAIRE: RESULTS FROM A MONOCENTRIC COHORT

L. Moschetti[1], M. G. Lazzaroni[1], E. Pedretti[1], A. Bano[1], C. Nalli[1], F. Cucchi[1], A. Molinaro[2], J. Galli[2], E. Fazzi[2], F. Franceschini[1], A. Tincani[1], P. Airò[1], L. Andreoli[1]. *[1]ASST Spedali Civili, University of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy; [2]ASST Spedali Civili, University of Brescia, Obstetrics and Gynaecology, Brescia, Italy*

Background: In the last years, the rate of successful pregnancies has significantly increased in Systemic Sclerosis (SSc)[1] women. However, the long-term outcome of their children remains an unexplored issue.

Objectives: To evaluate the neuropsychiatric (NP) outcome of children born to SSc mothers.

Methods: An ad-hoc questionnaire, regarding different aspects of child's neurodevelopment (ND) (3 sections: childhood [0-5 years]; scholar age [6-11 years]; adolescence [12-18 years]), was created and administered to female SSc patients (ACR/EULAR 2013 criteria) attending our outpatient clinic during 2021 and who had at least 1 child. Children's NP characteristics were compared between 3 subgroups: A) born >10 years before SSc diagnosis; B) born ≤10 years before SSc diagnosis; C) born after SSc diagnosis. Results below are expressed as number/total number of answers collected for each question.
Results: 100 SSc women reported 189 pregnancies: 152 resulted in 154 live births (2 twin pregnancies).
At least one NP alteration was reported in 42/119 (35%) subjects, more frequently in group B (57%), as compared to group A (31%, *p:0.07*) and group C (30%, *p:0.09*) although not statistically significant (Figure 1). Sleep irregularities were the most frequently reported disorder (15/42, 36%). Comparisons between the 3 subgroups for every NP outcome evaluated are shown in Table 1: overall, a higher rate of NP alterations were reported in children belonging to group B.

Table 1. Analysis of NP outcomes: comparison of the 3 subgroups.

	A n=103	B n=19	C n=32
N° of subjects evaluated for DISORDERS IN CHILDHOOD	103/103	19/19	32/32
Sleep irregularities	6/79 (8)*	4/13 (31)*	5/27 (19)
Motor difficulties	0/77 (3)°	2/13 (15)°	2/26 (8)
Difficulty in relationships	0/78 (0)	1/11 (9)	2/26 (8)
Difficulty in non-verbal communication skills	0/78 (0)	1/11 (9)	2/26 (8)
Difficulty in verbal communication skills	1/77 (1)	1/12 (8)	2/26 (8)
Difficulty in social integration	6/77 (8)	3/12 (25)	1/25 (4)
Cognitive difficulties	0/77 (0)	1/12 (8)	0/26 (0)
N° of subjects evaluated for DISORDERS IN SCHOLAR AGE	103/103	17/19	17/32
Difficulty in school lessons/homework	7/77 (9)	3/12 (25)	0/15 (0)
Behavioral problems during school period	4/76 (5)	1/12 (8)	1/15 (7)
School year repetition	11/76 (15)	2/13 (15)	0/15 (0)
N° of subjects evaluated for DISORDERS IN ADOLESCENCE	101/103	14/19	11/32
Difficulty in managing anger and aggression	4/75 (5)	0/11 (0)	0/10 (0)
Behavioral alterations	0/75 (0)	0/11 (0)	0/10 (0)
Difficulty in conduct	2/73 (3)	0/11 (0)	2/10 (20)
Mood alterations	1/73 (1)	1/11 (9)	0/10 (0)
Alterations of the feeding behavior	1/75 (1)	0/11 (0)	0/10 (0)
Anxiety problems	1/75 (1)	1/10 (10)	0/10 (0)

Results are presented as number/total number (%) of answers collected for each question. Variables were compared with Chi Squared/exact Fisher test. **p=0.03*; *°p=0.02*.

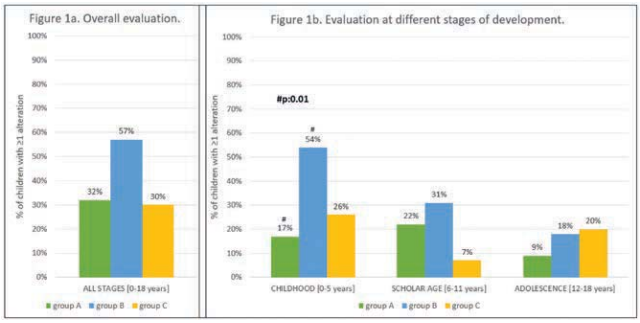

Figure 1. Children with ≥1 NP alteration: comparison of the 3 subgroups.

In addition, SSc mothers declared that 7/123 (6%) children underwent a NP evaluation leading to a diagnosis in 3 cases: 1 cognitive delay, 1 learning disorder (LD) and 1 autism spectrum disorder (ASD). These children were born 1 and 5 years before and 3 years after SSc diagnosis, respectively. The prevalence of these diagnoses (0.8%) does not differ from general pediatric population.
Conclusion: Children born to SSc mothers, had prevalence of major NP alterations (cognitive deficits, LDs, ASDs) similar to general pediatric population. A higher frequency of minor ND disorders, especially sleep irregularities, was observed in children within 10 years before maternal diagnosis, compared to the other groups, possibly suggesting an impact of maternal chronic disease on the relationship with child in the first years of life. To confirm these self-reported preliminary data, the extension of the study will consist in a systematic NP evaluation proposed to all the offspring of SSc mothers aged ≤18 years.

AB0662 **ELEVATED FECAL CALPROTECTIN IN EARLY SYSTEMIC SCLEROSIS**

V. Hamberg[1], J. K. Wallman[1], E. Mogard[1], E. Lindqvist[1], T. Olofsson[1], K. Andréasson[1]. [1]*Lund, Rheumatology, Lund, Sweden*

Background: Gastrointestinal (GI) morbidity is prevalent in systemic sclerosis (SSc), causing a reduction in quality of life and increased mortality, but has been difficult to assess objectively [1]. Elevated levels of fecal calprotectin (F-cal), a biomarker of GI inflammation, has previously been observed in patients with SSc [2]. F-cal has not been explored in early SSc and its diagnostic potential in the classification of SSc has not been studied.
Objectives: Our objectives were; 1) study F-cal levels in early SSc; 2) investigate the discriminatory power of F-cal; 3) explore F-cal in relation to GI features of SSc.
Methods: Consecutive referred patients with suspected new-onset SSc without concurrent non-SSc GI disease were invited to this study. Patients were classified as SSc if meeting ACR-EULAR criteria, or SSc mimickers if they did not. GI symptoms and use of NSAID or PPI was noted. F-cal was measured and levels >50ug/g were classified as elevated. F-cal was also measured in age- and sex matched controls without rheumatological disease.
Results: Of 137 patients, 92 were classified as SSc and 45 as SSc mimickers. Elevated F-cal was significantly more common in SSc patients compared to the control group (38% vs 7.3%; p < 0.001) but not compared to the SSc mimicker patients (38% vs 31%; p = 0.427). The median F-cal level was higher in SSc patients compared to controls (35 µg/g vs ≤30 µg/g; p ≤ 0.001) but not compared to the SSc mimicker patients (35 µg/g vs ≤30 µg/g; p = 0.248). Elevated F-cal was not associated with any GI symptoms. Elevated F-cal was more common in patients who used PPI (OR 7.14; 95% CI 2.56-29.93; p < 0.001).
Conclusion: In this study, we demonstrate that elevated levels of F-cal are prevalent already in the early stages of SSc. These results are in line with previous data suggesting that GI involvement may be present in early SSc.

Table 1. Frequency of GI features and association to F-cal elevation (n = 92)

GI features (n, %)	Normal F-cal, n = 57	Elevated F-cal, n = 35	Odds Ratio (95% CI)
Dysphagia	19 (35%)	12 (34%)	0.99 (0.41-2.41)
Reflux symptoms	33 (59%)	23 (68%)	1.46 (0.60-3.56)
Fecal incontinence	9 (16%)	3 (8.6%)	0.50 (0.08-2.22)
Patient-reported involuntary weightloss	11 (20%)	8 (23%)	1.21 (0.43-3.39)
Dilated esophagus on HRCT	8 (16%)	8 (28%)	1.95 (0.64-5.94)
NSAID use	12 (21%)	6 (17%)	0.78 (0.26-2.30)
PPI use	23 (40%)	29 (83%)	7.14 (2.56-19.93)

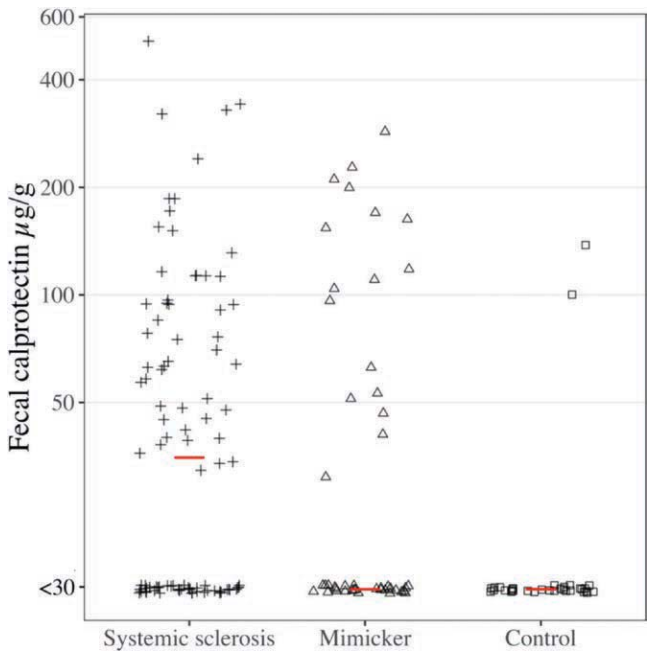

Figure 1. F-cal measurements by group. Median value represented by horizontal bar.

AB0663 BICENTRIC OBSERVATIONAL STUDY ON THE THERAPEUTIC MANAGEMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC SCLEROSIS OVERLAP SYNDROME

N. Lebel[1], C. Marcelli[2], I. Marie[3], H. Levesque[3], T. Lequerre[1], O. Vittecoq[1].
[1]Hospital Center University De Rouen, Rheumatology, Rouen, France;
[2]University Of Caen Normandie Hospital Center, Rhumatologie, Caen, France;
[3]Hospital Center University De Rouen, Medecine interne, Rouen, France

Background: The rheumatoid arthritis (RA)/systemic sclerosis (SSc) overlap syndrome is a rare and understudied association. It affects 5% of patients with SSc. Only open studies evaluating biological drugs (bDMARDs) have reported encouraging results, particularly on joint involvement. The management of these patients is therefore not codified.
Objectives: The objective was to analyze in real conditions the therapeutic strategy and the response to bDMARDs, with a focus on joint involvement.
Methods: We retrospectively analyzed over a 10-year period the clinical, biological, radiographic characteristics and therapeutic management of patients meeting the ACR/EULAR diagnostic criteria for RA and SSc in two academic centers. Response to bDMARDs was assessed according to EULAR and if unavailable according to therapeutic maintenance. The evolution of lung function test was also evaluated.
Results: Twenty-two patients were identified. Interstitial lung involvement was common (n=11). Only 7 patients were treated with csDMARD alone. The most commonly used drug was methotrexate. The use of bDMARDs was frequent (15/22), significantly greater in patients with rheumatoid factors (OR 26.7; p=0.004) and with a trend in patients with higher levels of anti-CCP (160 vs 15 IU; p=0.11) or diffuse interstitial lung disease (OR 10.6; p=0.063). Tocilizumab was the most selected therapy (n = 8) followed by rituximab (n = 5), abatacept, and anti-TNFs (n = 4 respectively). We evaluated 21 treatment sequences, 19 of which were evaluated according to EULAR response criteria. bDMARDS that inhibits the activation of lymphocytes (abatacept, rituximab) generally resulted in a good or moderate response (n = 9/10) with a significant decrease in DAS28 at 6 months (-1.75; p = 0.016). Cytokine inhibitors (tocilizumab, etanercept, infliximab) were less likely to achieve good or moderate control of joint involvement (n = 3/9) with a smaller decrease in DAS28 at 6 months (-0.79; p = 0.36). Two tocilizumab sequences were stopped early due to intolerance and could not be evaluated. One patient received tofacitinib with a good clinical response but was discontinued at 9 months for intolerance. Lung function test data did not change significantly on bDMARD.
Conclusion: In patients with rheumatoid arthritis (RA)/systemic sclerosis (SSc) overlap syndrome, bDMARDS that inhibits the activation of lymphocytes (abatacept, rituximab) resulted in more frequent and greater improvement in joint involvement than cytokine inhibitors (tocilizumab, etanercept, infliximab).

Nasonova Research Institute of Rheumatology, control unit, Moscow, Russian Federation*

Background: The low prevalence of pregnancy in women with systemic sclerosis (SSc) is due to multi-factorial causes, including premature ovarian insufficiency (POI). Anti-Mullerian hormone (AMH) is one of the primary parameters for assessing reproductive function and ovarian reserve. The levels of AMH correlates with the residual follicular pool among women of reproductive age.
Objectives: To assess AMH levels in SSc female patients of child-bearing potential, and analyze the relationship between AMH levels and disease severity, as well as the relationship between serum AMH levels and different therapeutic regimens.
Methods: The study group included 48 women with SSc aged 20-40 years, and the control group included 15 age-matched healthy women. Pts' mean age was 32,9 [28;37] yrs, disease duration was 6,3 [3;10] yrs. Diffuse cutaneous subset of the disease had 41,7%, limited in 41,7% and overlap in 16,6% pts. AMH levels was measured using ELISA. AMH reference values ranged within 1.0-10.6 ng /ml. Values <1.0 were interpreted as a decreased ovarian reserve.
Results: Mean AMH level was 2.8 ng/ml in SSc pts, and 3.1 ng/ml in the control group, showing no statistical difference. A decrease in ovarian reserve (AMH less than 1.0 ng/ml) was significantly more common in SSc pts compared to controls (45,8% vs. 13%, p<0,05).

Table 1. AMH and forms of SSc

form	diffuse, n=20	limited, n=20	overlap, n= 8	p
Mean AMH	1,1 [0,06-1,5]*	3,3 [0,4-5,6]*	2,3 [0,7;3,4]	* 0,03
AMH >1 ng /ml, n (%)	13 (65%)*	7 (35%)*	2 (25%)	*0,05

Mean AMH levels was significantly lower in the diffuse SSc in comparison with the limited SSc. A redaction of ovarian reserve (AMH less than 1.0 ng / ml) was more often observed in diffuse form of SSc compared to limited form (65% vs 35%), p=0.05.

Table 2. AMH and course of SSc

course	acute, n=5	subacute, n=19	chronic, n= 25	p
Mean AMH	1,2 [0,01-1,7]	0,9 [0,05-1,3]	3,5 [0,7;5,6]	0,01
AMH >1 ng /ml, n (%)	3 (60%)	13 (68,4%)*	6 (24%)*	*0,03

Mean AMH levels was significantly lower in acute and subacute course of SSc. A decrease of ovarian reserve was significantly more often observed in subacute course compared to chronic course of SSc (68% vs 24%, p=0,03).

CYC	CYC (+), n=14	CYC (-), n=34	p
Mean AMH	0,8 [0,08-1,07]	2,8 [0,4;3,6]	0,01
AMH >1 ng /ml, n	9 (64,3)	13 (32,2)	ns

Mean AMH levels was significantly lower in pts with SSc receiving CYC. Correlation analysis revealed a negative correlation between AMH and cyclophosphamide (CYC) therapy (r=-0.33, p>0.05), with erythrocyte sedimentation rate (r=-0.36), heart damage (r=-0.32) and gastrointestinal involvement (r=-0.31), digital ulcers (r=-0.33) and digital pitting scars (r=-0.28). Correlation with other clinical manifestations, immunological markers and immunosuppressive therapy of SSc wasn't found. In five patients who receivied CYC earlier, the levels of AMH was within normal values (the total dose of CYC did not exceed 4 g).

Conclusion: Ovarian reserve was significantly more often reduced in women with SSc compared to healthy controls. Mean AMH levels was significantly lower in the diffuse SSc compared to the limited SSc. Reduction of ovarian reserve was more often observed in diffuse form SSc. Mean AMH level was significantly lower in acute and subacute course of SSc. A decrease of ovarian reserve was significantly more often observed in subacute course SSc compared to chronic course. The levels AMH negatively correlated with CYC therapy, erythrocyte sedimentation rate, heart and gastrointestinal tract involvement, digital ulcers and digital scars. CYC therapy negatively affected the ovarian function, and most likely in a dose-dependent manner.

AB0665 TURKISH VALIDATION OF THE 'COCHIN (DURUOZ) HAND FUNCTION SCALE' IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Komac[1], D. Temiz Karadağ[1], E. Basaran[1], A. Yazici[1], A. Cefle[1]. *[1]Kocaeli University Faculty of Medicine, Rheumatology department, Kocaeli, Turkey*

Background: Hand impairment is the main challenge for patients with systemic sclerosis (SSc) and may arise from inflammatory arthritis, joint contractures, tendon friction rubs (TFRs), Raynaud's phenomenon (RP), digital ulcers (DU), puffy hands, skin sclerosis, acro-osteolysis, or calcinosis. There is not yet a tool which can objectively measure hand functions in scleroderma patients both in daily practice and for research purposes.
Objectives: To adapt and validate the Turkish version of Cochin (Duruoz) hand function scale (CHFS) and contribute to the development of outcome measures with good metric properties assessing hand disability in SSc (1).
Methods: Ninety one consecutive patients who fulfilled the 2013 ACR/ EULAR SSc classification criteria for SSc were enrolled in the study. Disease

related involvements and physical examination findings of the patients were recorded. Participants filled out the self-administered questionnaire of the Turkish version of the CHFS. Modified Rodnan skin scores of the patients were calculated, bilateral hand extension and fingertip-palm distances were measured, grip strength was evaluated with hydrolic hand dynamometer. We evaluated convergent validity by testing the correlation between CHFS and related components of Short Form 36 version 2 (SF-36v2) and Scleroderma Health Assessment Questionnaire (sHAQ). Discriminant validity was evaluated by stratifying patients according to hand related involvements and disease subtypes. Thirty of the patients re-filled the CHFS questionnaire two weeks after the first visit.

Results: Demographic data and disease characteristics of the patients shown in Table 1. For the convergent validity, the CHFS significantly correlated with the sHAQ, Raynaud visual analog scale (VAS), digital ulser VAS, overall disease severity VAS, hand grip, hand extension measurements and fingertip-palm distances (Table 2). The instruments could discriminate between disease subtypes (10[0-24] / 2[0-19], p=0,038) and between the patients with and without contractures (11[0-24] / 2[0-9], p=0,023) for the discriminant validity. We demonstrated high reproducibility for CHFS (ICC = 0,894, 95% confidence interval = 0,779-0,949).

Table 1. Demographic data and disease characteristics of the patients

Age (years)	**55.4±10.7**	**Total mRSS**	**6 ±5.1**
Sex (female)	79 (%86.8)	Right hand total mRSS	2.2±1.7
Diseasesubtype (diffuse)	25(%27.5)	Left hand total mRSS	2.2±1.7
PAH	6 (%6.7)	Right hand fingertip-palm distance (cm)	1.3±1
ILD	41 (%45.6)	Left hand fingertip-palm distance (cm)	1.2±1.2
ANA positivity	88 (%96.7)	Right hand extension (cm)	17.7±2.5
Arthritis	1 (%1.1)	Left hand extension (cm)	18±2.3
Sclerodactly	79 (%86.8)	Right hand hydrolic dynomometer pressure (kg)	21.7±8.6
Contracture	26 (%28.6)	Left hand hydrolic dynomometer pressure (kg)	20.4±7.6
Amputation	12 (%13.2)	SF 36 physical function	51.7 ±24
Active digitalulcer	3 (%3.2)	SF 36 role limitations due to physical health	52±42
Digitalulcerscar	23 (%25.3)	SF 36 role limitations due to emotional problems	57.3±33.4
Calcinosis	10 (%11)	SF 36 energy/fatigue	46±23.3
CHFS score	3 [0-13]	SF 36 emotional well-being	60.4±21.2
Raynaud's phenomenon VAS	0.8±0.9	SF 36 social functioning	70±26
Digital ulcer VAS	0.5±0.9	SF 36 pain	64±30
Overall disease severity VAS	0.9±0.9	SF 36 general health	44.3±21.7

PAH: Pulmoner arterial hypertension, ILD: Interstitial lung disease, ANA: Anti nuclear antibody, CHFS: Cochin hand function scale, mRSS: Modified Rodnan skin score, VAS: visual analog scale, SF36: short form 36

Table-2 Correlation of CHFC with hand measurements, scleroderma specific VAS's and sHAQ

	Cochin hand function scale	
	r	p
Right hand fingertip-palm distance	0,302	**0,004**
Left hand fingertip-palm distance	0,302	**0,004**
Right hand extension distance	-0,300	**0,004**
Left hand extension distance	-0,279	0,007
Right hand hydrolic dynamometer pressure	-0,462	**<0,001**
Left hand hydrolic dynamometer pressure	-0,511	**<0,001**
sHAQ global	0,703	**<0,001**
Raynaud's phenomenon VAS	0,302	**0,004**
Digital ulcer VAS	0,287	0,006
Overall disease severity VAS	0,432	**<0,001**
Right hand total modified Rodnan skin score	0,041	0,7
Left hand total modified Rodnan skin score	0,078	0,463

Conclusion: The Turkish version of the CHFS met the requirements of validity and reproducibility. With this study, we validated a scale which will contribute to the development of outcome measures with good metric properties assessing hand disability, disease evolution and treatment efficacy in our SSc patients.

AB0666 BODY COMPOSITION AND PHYSICAL FUNCTION AS POTENTIAL PROGNOSTIC BIOMARKERS IN PATIENTS WITH SIBM

K. Y. Jensen[1,2], J. Alcazar[3,4,5], A. N. Jørgensen[2,6], P. Aagaard[2], C. Suetta[3,7], L. P. Diederichsen[8,9]. *[1]Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; [2]University of Southern Denmark, Department of Sports Science and Clinical Biomechanics, Odense, Denmark; [3]Bispebjerg And Frederiksberg University Hospital, Department of Geriatric and Palliative Medicine, Geriatric Research Unit, Copenhagen, Denmark; [4]Universidad de Castilla-La Mancha, GENUD Toledo Research Group, Toledo, Spain; [5]CIBER of Frailty and Healthy Aging (CIBERFES), Faculty of Sport Sciences, Madrid, Spain; [6]University of Southern Denmark, Department of Clinical Research, Odense, Denmark; [7]Copenhagen University Hospital, Herlev and Gentofte, Department of Medicine, Geriatric Research Unit, Herlev, Denmark; [1]Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; [9]Odense University Hospital, Department of Rheumatology, Odense, Denmark*

Background: Sporadic inclusion body myositis (sIBM) is an acquired disease within the idiopathic inflammatory myopathy (IIM) spectrum, characterized clinically by progressive muscle atrophy, weakness and often severely impaired physical function leading to Sarcopenia. Despite of this, muscle mass and physical function is not routinely assessed in patients with sIBM.

Objectives: To investigate muscle mass, muscle power and physical function in patients with sIBM compared to healthy controls.

Methods: The study was a retrospective analysis of patients with sIBM (sIBM) and healthy age and gender matched controls (CON) from The Copenhagen Sarcopenia Study[1]. Appendicular lean mass (ALM) and skeletal muscle index (ALM/h^2) was assessed by DXA (iDXA, GE). Muscle strength and physical function was evaluated by maximal horizontal gait speed (GS), 30-s sit-to-stand test (30s STS) and maximal leg extensor power (LEP) (PowerRig). A linear mixed-effect model for all outcome variables was used for the statistical analysis. A linear mixed-effect model for all outcome variables was used for the statistical analysis, including sex and health condition as fixed factors, and performed using SPSS v20 (Inc., Chicago, Illinois, USA), and the level of significance was set at $\alpha = 0.05$ using two-tailed testing.

Results: In total, 22 patients with sIBM (18 men, age 69.8±4.6; 4 women, age 65.0±8.4) and 414 healthy age-matched controls (237 men, age 70.2±4.9; 177 women, age 65.5±5.4) were included. In men, ALM (sIBM: 21.4±3.1; CON: 25.3±3.6) and ALM/h^2 (sIBM: 6.9±0.9; CON: 8.0±1.0) was reduced in sIBM compared to CON ($p < 0.05$), while there was no differences in ALM (sIBM: 17.4±1.4; CON: 18.0±2.5) and ALM/h^2 (sIBM: 6.8±0.4; CON: 6.6±0.9) in women with sIBM compared to CON. In men, GS (sIBM: 1.05±0.23; CON: 2.20±0.50), 30s STS (sIBM: 6.1±3.8; CON: 17.8± 5.9) and LEP (sIBM: 79.4±57.3; CON: 255.8±81.3) was reduced in sIBM compared CON, respectively ($p < 0.05$). Likewise in women, GS (sIBM: 1.27±0.42; CON: 2.16±0.51), 30s STS (sIBM: 7.0±4.8; CON: 18.5±5.9) and LEP (sIBM: 76.5±23.4; CON: 163.7±51.6) was reduced compared CON, respectively ($p < 0.05$).

Conclusion: The present data demonstrate that muscle mass and physical function are reduced in patients with sIBM compared to healthy counterparts. Although data from larger studies are warranted, it may indicate that assessment body composition and physical function can be used as prognostic tools in these patients.

AB0667 EFFECT OF TEMPERATURE VARIATION ON SERUM KL-6 LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS

H. Hirose[1], T. Higuchi[1,2], K. Takagi[3], A. Tochimoto[1], Y. Kawaguchi[1], M. Harigai[1]. *[1]Tokyo Women's Medical University Hospital, Division of Rheumatology, Department of Internal Medicine, Shinjuku City, Japan; [2]Tokyo Women's Medical University, Division of Multidisciplinary Management of Rheumatic Diseases, Division of Rheumatology, Department of Internal Medicine, Shinjuku-City, Japan; [3]Adachi Medical Center, Tokyo Women's Medical University, Department of Internal Medicine, Adachi-Ciy, Japan*

Background: Serum Krebs von den Lungen-6 (KL-6) levels has much evidence as a biomarker about the progression and prognosis of interstitial lung disease (ILD), including systemic sclerosis (SSc)-associated ILD[1-4]. However, serum KL-6

levels often fluctuate regardless of the progression of ILD. This sometimes mislead the evaluation of the disease activity, however, the reason for the fluctuation has not been clarified.

Objectives: We tested the hypothesis that serum KL-6 levels are affected by ambient temperature in patients with SSc.

Methods: We defined the warm season (May–October) as the period when the ambient temperature was above the Tokyo metropolitan average ambient temperature announced by the Japan Meteorological Agency, and the cold season (November–April) as the period when the ambient temperature was below the average. ILD was classified based on chest CT findings. Among SSc patients who had visited our department since May 2018, we selected those who had data of serum KL-6 levels at least 3 times in warm and cold seasons from October 2014 to September 2021, respectively. Patients having malignancy were excluded after confirmation of the onset of malignancy using medical record retrospectively. The difference in serum KL-6 levels between warm and cold seasons was evaluated by Wilcoxon's rank-sum test.

Results: In total, 252 patients with SSc were included. Median age was 66.3 years, with median disease duration of 13.5 (8.9–19.2) years, diffuse cutaneous type of 94 (37.3%) patients, and concomitant ILD of 120 (47.6%) patients (Table 1). The median follow-up was 6.4 (4.4–6.8) years, with median KL-6 measurement of 24 (14–39) times. Serum KL-6 levels were significantly higher in the cold season than that in the warm season, with a greater difference in the group with ILD (536 IU/L vs. 492 IU/L, p = 0.0012) in the group with ILD, 364 IU/L vs. 345 IU/L in the group without ILD, p = 0.0028) .

Table 1. Patients characteristics

	With ILD (n=120)	Without ILD (n=132)	*P* value
Female, n (%)	110 (43.7)	128 (52.4)	0.1
Age, years (IQR)	65.8(56.1–73.4)	66.4(56.0–72.5)	0.77
Disease duration, years (IQR)	14.0 (9.8-21.0)	13.0 (8.7-18.0)	0.23
Modified Rodnan skin score (IQR)	10 (4-15)	6 (2-11)	0.0017
Diffuse SSc, n (%)	53 (40.2)	27 (20.5)	<0.001
Pulmonary hypertension, n (%)	4 (3.3)	3 (2.3)	0.71
ANA positive, n (%)	98 (81.7)	112 (84.8)	0.50
SSc-related autoantibody, n (%)	98 (81.7)	112 (84.8)	0.50
Anti-centromere antibody, n (%)	17 (14.2)	86 (71.7)	<0.0001
Anti-topoisomeraseI antibody, n (%)	63 (52.5)	8 (6.1)	<0.0001
Anti-RNA polymerase III antibody, n (%)	7 (5.8)	11 (8.3)	0.62
Anti-U1-RNP antibody, n (%)	15 (12.5)	13 (9.8)	0.54
KL-6, IU/L (IQR)	548 (384–876.8)	233 (191.3–302)	<0.0001
KL-6 measurement, times (IQR)	33.5(20-45)	18.5(12.3-28)	<0.0001
Steroid use, n (%)	68 (56.7)	22 (16.7)	<0.0001
Cyclophosphamide, n (%)	44 (36.7)	12 (9.1)	<0.0001
Other Immunosuppressive agents, n (%)	31 (25.8)		0.002

Conclusion: Our results suggest that cold ambient temperature may affect serum KL-6 levels in patients with SSc.

AB0668

ASYMMETRICAL DIMETHYLARGININE CORRELATES WITH WORSENING PERIPHERAL MICROANGIOPATHY IN SYSTEMIC SCLEROSIS

E. Pagkopoulou[1], S. Soulaidopoulos[2], E. Triantafyllidou[1], G. Kitas[3,4], A. Garyfallos[1], T. Dimitroulas[1]. *[1]Hippokration Hospital, Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Thessaloniki, Greece; [2]Hippokration General Hospital, National and Kapodistrian University of Athens, First Department of Cardiology, Athina, Greece; [3]Dudley Group of Hospitals, NS Foundation Trust, Dudley, United Kingdom, Department of Rheumatology,, Dudley, United Kingdom; [4]University of Manchester, Manchester, United Kingdom, Arthritis Research UK Centre for Epidemiology, Manchester, United Kingdom*

Background: Systemic sclerosis (SSc) is a connective tissue disease characterized primarily by, micro-angiopathy and endothelial dysfunction stimulate fibrotic process. Asymmetrical dimethylarginine (ADMA) is an endogenous nitric oxide (NO) inhibitor and represents a novel risk factor for vascular dysfunction. Nailfold Video Capillaroscopy (NVC) is a non-invasive and reliable technique for the evaluation of microvasculopathy in SSc.

Objectives: The aim of this study was to examine the possible association between ADMA and microvascular involvement in patients with SSc.

Methods: This was a cross-sectional study including consecutive SSc patients attending the Scleroderma Outpatient Clinic. ADMA was measured in serum samples by using commercial enzyme immunoassay ELISA kit (Aviva Systems Biology ADMA ELISA Kit). Participants underwent NVC with qualitative and semi-quantitative assessment and all parameters were measured in the distal row of each finger. The findings were classified in one of the three qualitative NVC patterns: early, active, and late.

Results: Eighty-one (92,6% women) SSc individuals with mean age 55.44±13.4 years and disease duration 6.78 [9.22] years were included in this analysis. Within-groups comparisons revealed a trend between higher ADMA levels and progressive micro-vasculopathy (1,29 [2,1]vs 1,57 [1,95] vs 2,41 [3,87]; for early, active and late patterns respectively, p=0.039) (Figure 1). Furthermore, ADMA concentration was significantly associated with the number of capillaries/mm (r= -0.235; p=0.035).

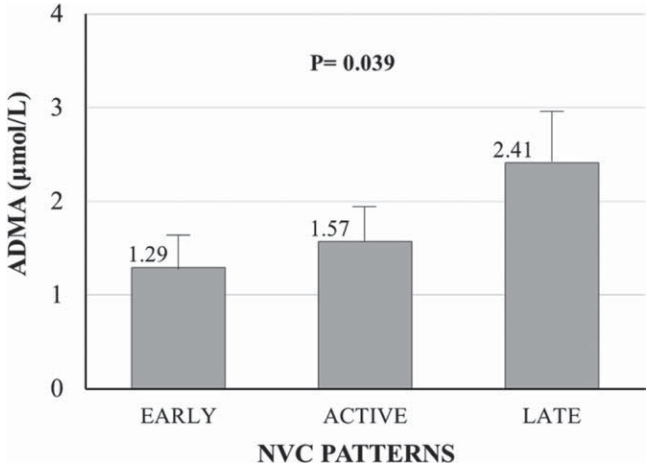

Figure 1. Serum ADMA levels in the early, active, and late NVC patterns

Conclusion: Serum ADMA levels were significantly associated with advancing stages of microcirculatory abnormalities suggesting that ADMA may have a role in promoting microvascular endothelial dysfunction in SSc individuals.

AB0669 **PREGNANCY OUTCOMES IN SYSTEMIC SCLEROSIS, SYSTEMIC LUPUS ERITHEMATOSUS AND BEHCET'S DISEASE**

R. Goloeva[1], Z. Alekberova[2], L. Garzanova[3], O. Koneva[3], A. Lila[2,4]. *[1]V.A. Nasonova Research Institute of Rheumatology, trobovinflammation laboratory, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, advisory department, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, laboratory of sistemic sclirosis, Moscow, Russian Federation; [4]V.A. Nasonova Research Institute of Rheumatology, systemic rheumatic disease, Moscow, Russian Federation*

Objectives: To clarify pregnancy outcomes in patients with systemic sclerosis (SSc), systemic lupus erythematosus (SLE) and Behcet's disease (BD) using retrospective analysis.
Methods: The study group included 48 women with SSc, 47 with SLE 45 with BD aged 20-40 years, and the control group - 15 age-matching healthy women. SSc pts' mean age was 32,9 [28;37] years, SLE pts' 32,3 [29;36] years, BD pts' 31,3 [27;35] years, disease duration 6,3 [3;10], 9,8 [3;16] and 6,0 [3;8] years respectively. Completed by all women issue-specific questionnaire covered clinical symptoms of SLE, SSc, BD and details of obstetric history (characteristics of menstrual and reproductive function, presence of genital and extragenital pathology, previous pregnancies outcomes; previous intrauterine interventions, a history of coagulopathy).
Results: Retrospective analysis of thematic maps of 48 patients with SSc revealed: 28 patients had 77 pregnancies, 44 of which ended with the birth of children (13 by caesarean section in 9 patients); 3 women had 4 premature births at 28-35 weeks, one of which ended with perinatal death of the baby; 33 incomplete pregnancies in 19 patients: 28 medical abortions up to 12 weeks of gestation at the woman's request; 5 pregnancy complications had 5 patients, spontaneous abortion - 3, undeveloped pregnancy - 2. The frequency of unfavorable pregnancy outcome was similar in patients with SSc and in the control group. Analysis of thematic maps of 47 patients with SLE: 27 patients had 68 pregnancies, 31 of which ended with the birth of children on time (12 by caesarean section in 9 patients); 3 women had 4 premature births at 27-33 weeks, two of which ended with perinatal death of the baby; 33 incomplete pregnancies in 18 patients: 15 medical abortions up to 12 weeks of gestation at the woman's request, two women had 3 abortions for medical reasons (high activity of SLE); 15 pregnancy complications had 9 patients, spontaneous abortion had 8 pts, undeveloped pregnancy was observed in 7 women. The frequency of unfavorable pregnancy outcome was similar in patients with SLE and in the control group. 118 pregnancies in 35 pts with BD resulted in 75 live birth (6 cesarean section in 3 pts). Thirty-nine incomplete pregnancies were observed in 26 patients. Ten patients had 20 medical abortions on request before 12 weeks of gestation, one patient had an abortion due to medical reasons (rubella on the 7 th week of gestation), two patients had premature birth at 28 and 32 weeks with subsequent perinatal death of the baby. Fifteen out of 35 pts had 20 adverse pregnancy outcomes: 8 spontaneous abortion, 12 missed miscarriage. Nine patients had 12 Missed miscarriage at 6-11 weeks of gestation, one patient had 3 missed miscarriage, two had 2, and the others had 1 missed miscarriage. Six patients had 8 spontaneous abortions (early miscarriage). In the control group of 15 women, 7 had 15 pregnancies, 13 live birth of healthy children on time.

Table 1. Pregnancy outcomes

Pregnancy, n	SSc, n=77 (%)	SLE, n=68 (%)	BD, n=118(%)	Control, n=15	*p*
Birth	44 (57,1)*	35 (51,5)*	77 (65)	13 (87)*	0,03
Abortion	28 (36,4)*	18 (26,5)*	21 (18)	0 *	0,01
Unfavorable pregnancy outcome	5 (6,4)	15 (22)	20 (17)	2 (13)	ns
Missed miscarriage	2 (2,6)	7 (10,3)	12 (10)	0	ns
Spontaneous abortion	3 (3,9)	8 (11,8)	8 (7)	2 (13)	ns

Patients with SSc and SLE were more likely to terminate pregnancy of their own volition compared to the control group.

Conclusion: Patients with SSc and SLE were more likely to terminate pregnancy on their own volition compared to the control group. Unfavorable pregnancy outcomes were similar in groups.

AB0670 **MIXED CONNECTIVE TISSUE DISEASE IN A TERTIARY CARE HOSPITAL**

L. Mendez Diaz[1], R. J. Gil Velez[2], I. Madroñal García[1]. *[1]Seville, RHEUMATOLOGY, Seville, Spain; [2]hospital virgen del rocio, RHEUMATOLOGY, seville, Spain*

Background: Mixed connective tissue disease is a rare syndrome characterized by the appearance of Raynaud's phenomenon, arthritis and edema in the hands, muscle weakness, dysphagia and dyspnea;It consists of the mixture of symptoms present in other collagen diseases such as erythematosus systemic lupus, scleroderma, polymyositis and rheumatoid arthritis, but without meeting diagnostic criteria for any of them.
Objectives: -Describe the clinical characteristics of a cohort of patients diagnosed with mixed connective tissue disease. -Study the evolution of these patients to other inflammatory autoimmune diseases. Disease conversion was defined as the appearance of new symptoms and autoantibodies compatible with another rheumatic disease.
Methods: Retrospective descriptive study of patients treated at our Hospital (2010-2020) by the Rheumatology and Internal Medicine service with a diagnosis of mixed connective tissue disease. The data was obtained through the review of medical records.
Results: 63 patients were included, of whom 56 were women (88%) and 7 men (12%). The average age of diagnosis is 37 +/- 13 years. At the end of the period, only 36.5% (23 patients) met criteria for mixed connective tissue disease. Of the 40 patients (65.5%) who underwent conversion to another autoimmune collagen disease, 65% (26 patients) met the criteria for systemic lupus erythematosus, 22.5% (9 patients) met the criteria for systemic sclerosis, 5% (2 patients) met criteria for rheumatoid arthritis and 7.5% (3 patients) for other systemic collagen pathologies. Of the initial sample of patients, 15 patients (23.8%) developed secondary Sjögren's disease. Regarding symptoms, in order of frequency, 50 patients (79.3%) of the sample presented myalgia, 39 patients (61.9%) sclerodactyly, 30 patients (47.61%) presented Raynaud's phenomenon, 10 patients (15.87%) esophageal alterations and 4 patients (6.3%) presented interstitial lung disease. Regarding treatment, 60% of the sample used corticosteroids, 52% hydroxychloroquine, 31.7% methotrexate, 23.8% mycophenolate, and 1.6% required rituximab. In the analyzed period, 2 patients died (3.17%), none as a result of their rheumatic disease.
Conclusion: The results obtained are consistent with those reported in the medical literature. The majority of patients with mixed connective tissue disease ended up progressing to another autoimmune collagen disease, mainly systemic lupus erythematosus and systemic sclerosis. According to our studies, stricter classification criteria would be convenient. However, more powerful and longer-term studies are needed to be able to draw conclusive conclusions.
Disclosure of Interests: None declared

AB0671 **HISTOPATHOLOGICAL, CLINICAL AND SEROLOGICAL FEATURES IN IIM PATIENTS FROM A SINGLE CENTER COHORT**

T. Vojinovic[1], M. Olivari[2], M. Fredi[1], F. Franceschini[1], I. Cavazzana[1]. *[1]ASST Spedali Civili of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, Brescia, Italy; [2]University of Brescia, Faculty of Medicine and Surgery, Brescia, Italy*

Background: Idiopathic inflammatory myositis (IIM) is a group of heterogeneous autoimmune diseases, characterized by myositis-specific (MSA) or myositis-associated autoantibodies (MAA). Muscle biopsy is the diagnostic gold standard, but correlations with elevated creatine level (CK) or MSA/MAA are unclear.
Objectives: To evaluate the association between specific histological findings and clinical and/or serological features in IIM patients from a single tertiary Rheumatology referral center.
Methods: We retrospectively analyzed demographic and clinical data from medical charts, of 184 patients affected by IIM followed-up for >1 year. Muscle biopsies of 89 IIM patients were retrieved from deltoid, biceps or quadriceps muscle, snap-frozen and stored at -80°C and processed for routine histology and histochemistry.
Results: The majority of our muscle biopsy cohort was represented by Dermatomyositis (DM) (39.3%), Polymyositis (PM) (29.2%) and Anti-synthetase syndrome (ASS) (13.5%), whereas the rest was composed of Overlap Syndrome (OS), Immune-Mediated Necrotizing Myopathy (IMNM) and Inclusion-Body Myositis (IMB) (13.5%, 2.2% and 2.2% respectively). DM presented perifascicular atrophy in 85% of cases and perivascular and perifascicular infiltration in only 40% of cases, similar to other types of IIMs. The overall histology finding was characterized by minimal inflammation and/or necrosis but major atrophy. In comparison, Polymyositis showed more endomysial infiltration and necrosis (Table 1). ASS was characterized by atrophy and perifascicular necrosis in 83% of cases, with perimysial and perivascular infiltration in 67% of cases. Those characteristics were observed both in anti-Jo-1+ (13.9%) as well as non-Jo-1+ ASS patients (13.2%). Non-Jo-1+ ASS patients presented endomysial infiltration, invading or enveloping the muscle fibers (not present in anti Jo-1+) (p: 0.036), with addition of rimmed vacuoles and aspecific clinical presentation. Moreover, in DM, anti-Mi2+ antibodies (9.3%) were significantly associated with perifascicular regeneration and endomysial infiltration, in comparison to both anti-TIF1γ+ (5.8%) and anti-NXP2+ patients (4.6%). No significant histopathological features were found in patients with anti-Ro52 autoantibodies (37.2%), that represented the most frequent MAA in our cohort.

Table 1.

BIOPSY CHARACTERISTICS	ASS 12 (%)	PM 35 (%)	DM 26 (%)	p [OR] ASS vs PM	p [OR] PM vs DM
diffuse atrophy	3 (25)	34 (97.1)	8 (30.8)	<0.0001 [0.010 (0.001-0.106)]	<0.0001 [76.5 (8.8-660.6)]
perifascicolar degeneration	----	29 (82.9)	15 (57.7)	----	0.044 [3.544 (1.09-11.5)]
prevalent necrosis	----	10 (28.6)	1 (3.8)	----	0.017 [10 (1.19-84)]
	Jo1 12 (%)	**PL7/PL12 5 (%)**	**p [OR]**		
endomysial infiltration (invading fibers)	0	3 (60)	0.015 [inf]		
	Mi2 8 (%)	**TIF1γ 5 (%)**	**NXP2 4 (%)**	**p [OR] Mi2 vs TIF1γ**	**p [OR] Mi2 vs NXP2**
perifascicolar regeneration	8 (100)	1 (20)	0	0.007 [inf]	0.002 [inf]
endomysial infiltrate (surrounding fibers)	6 (75)	----	0	----	0.061

Conclusion: No significant associations emerged between CK levels, different types of IIM and MSA. Some histological features seem to define subtypes of DM. A precise definition of autoantibody profile in IIM could define not only a clinical phenotype but also the muscle damage distribution.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.1893

AB0672 FUNCTIONAL CAPACITY AND QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS – DATA FROM MOSCOW REGISTER OF PATIENTS WITH SYSTEMIC SCLEROSIS

A. Klimenko[1], E. Zhilyaev[1], E. Mikheeva[1], N. Shostak[1], N. Babadaeva[1], A. Kondrashov[1], N. Demidova[1], D. Khorolskii[1]on behalf of Register of patients with idiopathic inflammatory myopathies, systemic sclerosis and mixed connective tissue disease in Moscow. *[1]Pirogov Russian National Research Medical University, Acad. A.I. Nesterov Department of Faculty Therapy, Moskva, Russian Federation*

Background: Systemic sclerosis (SSc) is a multisystem, connective tissue disease characterized by fibrosis of the skin and internal organ involvement, which can influence quality of life and functional capacity. SSc patients show some problems associated with reduced quality of life.

Objectives: Systemic sclerosis (SSc) is a multisystem, connective tissue disease characterized by fibrosis of the skin and internal organ involvement, which can influence quality of life and functional capacity. SSc patients show some problems associated with reduced quality of life.

Methods: In total, 51 patients with SSc were included: 50 women and 1 man (mean age: 63,2 ± 10,1 year, limited SSc 28/diffuse SSc 23, median duration since first non-Raynaud symptom: 10,1 years) who fulfilled the ACR/EULAR classification criteria (2013), filled in questionnaires assessing disability (HAQ, Health Assessment Questionnaire) and quality of life (SF-36, Medical outcomes study Short Form 36 - Physical Component Summary and Mental Component Summary).

Results: Average HAQ in patients with limited and diffuse SSc was 0,66±0,58 and 0,9±0,59. Data analysis showed that 59% of the patients were in the mild to moderate HAQ disability category ($0 \leqslant HAQ < 1$), 39% in the moderate to severe disability category ($1 \leqslant HAQ < 2$), and 2% in the severe to very severe disability category ($2 \leqslant HAQ \geqslant 3$). The SF36 mean scores of the total group were 34,8±8,7 on the Mental Component Summary and 37,0±13,1 on the Physical Component Summary.

Conclusion: Ssc and its complications decrease quality of life and functional capacity. Although validated in SSc, the HAQ disability index underestimates respiratory failure due to interstitial lung disease, gastrointestinal symptoms, cardiovascular complications and severity of Raynaud phenomenon. Alternative measures of functional impairment should be examined. Health-related quality of life, which was assessed by the SF-36 is reduced in both physical and mental domains. It should be taken into account by clinicians for further improvement of treatment and development rehabilitation program.

AB0673 OVARIAN RESERVE IN SYSTEMIC SCLEROSIS, SYSTEMIC LUPUS ERYTHEMATOSUS AND BEHCET'S DISEASE

R. Goloeva[1], Z. Alekberova[2], M. Cherkasova[1], O. Koneva[3], L. Garzanova[3], A. Lila[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, trobovinflammation laboratory, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, advisory department, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, laboratory of sistemic sclirosis, Moscow, Russian Federation*

Background: Anti-Mullerian hormone (AMH) is one of the key parameters for assessing reproductive function and ovarian reserve. The levels of AMH correlates with the residual follicular pool in women of reproductive age.

Objectives: To assess AMH levels in female patients of child-bearing potential with systemic sclerosis (SSc), systemic lupus erythematosus (SLE) and Behcet's disease (BD), and analyze the relationship between AMH levels and disease severity, as well as relationship between serum AMH levels and different therapeutic regimens.

Methods: The study group included 48 women with SSc, 47 with SLE 45 with BD aged 20-40 years, and the control group included 15 age-matched healthy women. SSc pts' mean age was 32,9 [28;37] years, SLE pts' 32,3 [29;36] years, BD pts' 31,3 [27;35] years, disease duration was 6,3 [3;10], 9,8 [3;16] and 6,0 [3;8] years respectively. AMH levels was measured using ELISA. AMH reference values ranged within 1.0-10.6 ng / ml. Values <1.0 were interpreted as a decreased ovarian reserve.

Results: Mean AMH levels were 3.4 ng/ml in SLE pts, 2.5 ng/ml in BD pts and 3.1 ng/ml in controls, showing no statistical difference. However, in patients with SSc mean AMH was significantly lower compared to control (2.2 ng/ml vs. 3.1 ng/ml, p=0,03).

Table 1. AMH in patients and control group

form	SSc, n=48	SLE, n=47	BD, n= 45	Controls,n=15	p
Mean AMH	2,2 [0,29-3,06]*	3,4 [0,64-5,4]	2,5 [1,1;3,7]	3,1 [1,9;4,9]*	0,03
AMH >1 ng /ml,n(%)	21 (43,7)*	13 (27,7)	8 (17,7)	2 (13,3)*	0,03

A redaction of ovarian reserve (AMH less than 1.0 ng / ml) was more often observed in SSc pts compared to controls (44% vs 13%), p=0,03. The mean AMH levels were significantly lower in pts with SSc receiving cyclophosphamide (CYC). Correlation analysis revealed a negative correlation between levels AMH and CYC therapy (r=-0.33, p<0.05), with erythrocyte sedimentation rate (r=-0.36), heart involvement (r=-0.32) and gastrointestinal involvement (r=-0.31), digital ulcers (r=-0.33) and digital pitting scars (r=-0.28). Correlation with other clinical manifestations, immunological markers and immunosuppressive therapy of SSc wasn't found. In five patients receiving CYC earlier, the level of AMH was within normal values, the total dose of CYC at them did not exceed 4g.

No correlation was found between AMH and activity SLE (SLEDAI 2K), disease duration, and clinical course. Correlation analysis of levels AMH and SLE therapy revealed a negative correlation between AMH and CYC therapy (r=-0.32, p<0.05), a positive correlation with hydroxychloroquine therapy (r=0.34, p<0.05). Correlations of AMH with the clinical picture of SLE and therapy with other immunosuppressive drugs have not been obtained. In patients with SLE, previously or currently received CYC, a significant decrease in average AMH was revealed 2,4 [0,4-4,3] vs 4,2 [1,3;5,7], and they also significantly more often had a low levels of AMH (<1 ng/ml), 47,4% vs 14,3% pts, p<0.05. In three patients who had received CYC earlier, the level of AMH was within normal values, the total dose of CYC did not exceed 5.6 g. When analyzing the levels of AMH with the clinical picture and BD therapy, no correlations were found.

Conclusion: Mean levels AMH and ovarian reduction of reserve was significantly lower in women with SSc pts compared to healthy controls. The levels of AMH negatively correlated in SSc pts with CYC therapy, erythrocyte sedimentation rate, heart damage and gastrointestinal tract involvement, digital ulcers and digital scars. The levels of AMH negatively correlated in SLE pts with CYC therapy. CYC therapy negatively affected ovarian function, and most likely in a dose-dependent manner. Behcet's disease does not seem to have much effect on the ovarian reserve.

PROVIDING PATIENTS WITH SYSTEMIC SCLEROSIS BY MEDICAL CARE IN RUSSIA: THE FIRST DATA FROM MOSCOW REGISTER OF SYSTEMIC SCLEROSIS

D. Khorolskii[1], N. Babadaeva[2], E. Zhilyaev[3], N. Shostak[4], A. Klimenko[3], A. Kondrashov[3], E. Pershina[5], D. Somov[6], E. Mikheeva[6]on behalf of Register of patients with idiopathic inflammatory myopathies, systemic sclerosis and mixed connective tissue disease in Moscow. *[1]Pirogov Russian National Research Medical University, Health Department of Moscow, Moskva, Russian Federation; [2]Городская клиническая больница № 1 им. Н.И. Пирогова, Moscow City Rheumatological Center, Moskva, Russian Federation; [3]Pirogov Russian National Research Medical University, Department of Faculty Therapy, Moskva, Russian Federation; [4]Pirogov Russian National Research Medical University, Department of Faculty Therapy, Moskva, Russian Federation; [5]Городская клиническая больница № 1 им. Н.И. Пирогова, Radiograpic studies department, Moskva, Russian Federation; [6]Pirogov Russian National Research Medical University, Department of Faculty Therapy, Moskva, Russian Federation*

Background: Systemic sclerosis (SSc) is a multisystem, connective tissue disease characterized by fibrosis of the skin and internal organ involvement, which can influence quality-of-life and functional capacity. [1] The mortality rate is increasing in the United States and Europe; as many as 3.08 persons are affected per 1 million. Changes in lungs and heart, pulmonary hypertension are the most significant reasons of death in patients with systemic sclerosis.[2]
Objectives: To estimate quality and completeness of medical care in patients with systemic sclerosis in Russia.
Methods: 66 patients included in the study. 61 female and 5 male (mean age: 62,48 ± 10,1), among which there were 24 limited SSc (lSSc) and 42 diffuse SSc (dSSc). All patients fulfilled the ACR/EULAR classification criteria. We estimated percentage of patients, who were examined by basic studies: capillaroscopy, functional lung tests, echocardiography, HRCT, fully immunologic study and right heart catheterization etc. and try to understand reasons of incompleteness of these assessments.
Results: Despite the presence of Raynaud's phenomenon in 85% of patients, capillaroscopy was performed only in 65.21% of them, examination of the esophagus was performed in only 22.92% of patients, with development of dysphagia in 50% of patients. HRCT was performed in 54.71% (25.76% NSIP, 9.09% UIP), right heart catheterization in 4.17% (signs of pulmonary hypertension according to ECHO detected in 42.86% of patients). FLT were performed in mostly patients (86.34%), but it wasn`t fully: measuring of DLCO was realized only in patients with severe desease (22.92% of patients). That explains its low mean level (61.37% from normal) as opposed to mean FEV1 (90.7% from normal) and FVC (89.47% from normal) level. Fully immunologic study was performed in 35.42% of patients, despite the fact that different autoantibodies showed up in 72.92% of patients (the most common were: antiScl70 41,67%, ACA 22,92%, ANF 52,08%).
Conclusion: According to the results of the study, we have identified a significant decrease in the quality of medical care despite the clinical recommendations and generally accepted standards. We suppose. that the main reasons for this situation are the complex healthcare problems: insufficient competence of doctors, lack of collaboration between related specialties, unavailability of a number of studies within the framework of free medicine and high cost of these studies for the patients themselves, and the lack of time for communication between the doctor and the patient to explain the seriousness of the disease and the nescessity of all parts of examination and treatment.

Background: Mixed connective tissue disease (MCTD) is a systemic auto-immune disorder, being probably the least common among the connective tissue diseases. Symptoms can be severe and could affect health-related quality of life (HRQoL). Identification of the burden of MCTD patients is of key importance to provide appropriate pharmacological and non-pharmacological care. No reports on HRQoL have been published in adult patients with MCTD.
Objectives: To perform an explorative study to evaluate HRQoL and its main determinants in MCTD patients, and compare HRQoL between MCTD and matched systemic sclerosis (SSc) patients.
Methods: MCTD patients fulfilling the Kahn criteria and participating in the MCTD prospective follow-up cohort of the Leiden University Medical Center were included. In addition, SSc patients matched for age, gender and disease duration were included for comparison. Data on disease characteristics, functional disability and HRQoL were collected annually for both disease groups. HRQoL was evaluated using the 36-Item Short Form Health Survey (SF36) and EuroQol (EQ5D). At baseline, HRQoL, as reflected by SF36 mental component score (MCS), SF 36 physical component score (PCS) and EQ5D were compared between MCTD and SSc patients. For MCTD patients, factors associated with HRQoL at baseline were identified using linear regression and change in HRQoL over 3 years was evaluated using linear mixed models. In addition, characteristics of MCTD patients who showed worsening of MCS and/or had PCS superior to the minimal clinical important difference of three points were identified.
Results: Thirty-four MCTD patients (121 visits; 82% female, mean age 42 years, median disease duration 45 months) and 102 SSc patients (424 visits; 82% female, mean age 45 years, median disease duration 49 months) were included. At baseline, MCTD-patients more often had ILD (47% vs. 34%, p=0.027), cardiac involvement (30% vs. 2%, p<0.001), synovitis (26% vs. 11%, p=0.004) and myositis (15% vs. 1%, p=0.001) compared to SSc patients, whereas SSc patients more often used immunosuppressive treatments except for hydroxychloroquine (MCTD:18% vs. SSc:7%, p=0.007).
Baseline HRQoL in MCTD was comparable to HRQoL in SSc, with mean SF36-PCS of 40.2 (SD:9.1) and mean SF36-MCS of 44.9 (SD:9.9), which is (nearly) one standard deviation lower than the general Dutch population. The SF36 subscore "general health perception" was the most impacted in both groups (MCTD: 38.5 [SD:7.0], SSc: 39.9 [SD:8.9]). The median EQ5DNL was 0.38 (IQR:0.14 – 0.54) and comparable between SSc and MCTD.
At baseline, in MCTD, ILD was significantly associated with SF36-PCS (β:6.98, 95% CI: 1.10 to 12.86) and SF36-MCS (β:-8.10, 95% CI:-14.93 to -1.26). Sclerodactyly was significantly associated with EQ5DNL (β:0.006; 95% CI:0.002 to 0.010) and SF36-PCS (β:0.12, 95% CI:0.03 to 0.21). No other significant associations were identified.
Over time, in MCTD, both the SF36-MCS and SF36-PCS improved significantly (MCS: β:2.35/year [95% CI:0.58 to 4.13], PCS: β:1.34/year [95% CI:0.03 to 2.65), whereas EQ5DNL was stable. Explorative analyses did not reveal a specific clinical characteristic with significant impact on the change of HRQoL over time. With an MCID of 3 points on the MCS and PCS, 7 MCTD-patients worsened on the MCS and 3 on the PCS. Patients who showed worsening of MCS over time tended to be older, more often had ILD, sclerodactyly and GI complaints, and had worse exercise tolerance. All these differences did not reach statistical significance. The patients who decreased PCS more often had ILD (100% vs. 41%, p=0.015), and used glucocorticoids more often (33% vs. 0%, p=0.046), were slightly older and had a worse exercise tolerance as compared to those who showed a stable/improving PCS over time.
Conclusion: Like in SSc, HRQoL is significantly impaired in MCTD, especially the general health perception of patients. Cardiac involvement, ILD, age and worse functional disability might specifically impact HRQoL in MCTD. However, these associations need further evaluations in larger cohorts.

ONE YEAR PROGRESSION OF INTERSTITIAL LUNG DISEASE IN CONNECTIVE TISSUE DISEASES. A DESCRIPTIVE STUDY IN A SINGLE TERTIARY CENTER.

C. L. Garcia Gomez[1], L. Vega[1], O. Ibarguengoitia[2], M. Enjuanes[1], I. Calvo[2], D. Montero[2], J. M. Blanco[1], M. L. García Vivar[1], E. Galindez[1], A. R. Inchaurbe[1],

I. Torre[1], I. Gorostiza[1], E. Cuande[1], M. E. Ruiz[1]. *[1]Basurto University Hospital, Rheumatology, Bilbo, Spain; [2]Galdácano Hospital, Rheumatology, Galdakao, Spain*

Background: Interstitial lung disease (ILD) in connective tissue diseases (CTD) is an important cause of morbidity and mortalitiy.
Objectives: To evaluate ILD in CTD (systemic sclerosis, myositis, Sjögren syndrome, rheumatoid arthritis, mixed connective tissue disease), sarcoidosis and interstitial pneumonia with autoimmune features and its progression in 12 months evaluated through high resolution computed tomography (HRCT) and pulmonary function test (PFT).
Methods: A retrospective single tertiary center cohort study in CTD-ILD outpatients seen between 2012 and 2021. Clinical, serological data, PFT and HRCT results were collected. ILD patterns were classified into: usual interstitial pneumonia (UIP), inconsistent UIP, nonspecific interstitial pneumonia (NSIP), fibrosing NSIP, organizing pneumonia, interstitial lymphoid pneumonia and associated to sarcoidosis. Progression of ILD was defined as:
->10% decline in FVC in PFT.
->15% decline in DLCO in PFT.
-Progression of fibrosis in HRCT.
IBM SPSS v23 was used for statistical analysis.
Results: 51 patients were collected. Baseline characteristics are shown in Table 1. Figure 1 shows ILD progression in 1 year.

Table 1. Baseline characteristics.

Sociodemographic characteristics		**Clinical features/affection–** *n (%)*	
Total	51	Raynaud	23 (45,1%)
Female-n (%)	42 (82,4%)	Skin	23 (45,1%)
Age- years (mean) IQR)	56 (27-82)	Ocular	13 (25,5%)
		Arthritis	16 (31,4%)
		Myositis	7 (13,7%)
		Renal	1 (2%)
		Esophagus	7 (13,7%)
		Hematological	3 (5,9%)
		PHT	7 (13,7%)
Smoking status- n (%)		**Symptoms at ILD diagnosis- N (41) %**	
Current	9 (17,6%)	Cough	31,4%
Former	13 (25,5%)	Toracic pain	11,8%
Never	29 (56,9%)	Dyspnea	47,1%
Comorbidities- n (%)		**Pattern HRCT- n (%)**	
Diabetes mellitus	5 (9,8%)	UIP	11 (21,6%)
Ischaemic cardiopathy	3 (5,9%)	Fib-NSIP	5 (9,8%)
Hypertension	15 (29,4%)	UIPincons	13 (25,5%)

		OP	2 (3,9%)
		LIP	2 (3,9%)
		Sarcoidosis	3 (5,9%)
Type of disease associated to ILD - n (%)		**Immunosupression- n (%)**	
Systemic Sclerosis	14(27,5%)	Methotrexate	20(39,2%)
Sjögren's Syndrome	7 (13,7%)	Mycophenolate mofetil	16 (31,4%)
Sarcoidosis	3 (5,9%)	Hydroxychloroquine	19(37,3%
Myositis	8 (15,7%)	Cyclophosphamide	4 (7,8%)
SLE	1 (2%)	Etanercept	6 (11,8%)
MCTD	3 (5,9%)	TNF inhibitors	4 (7,8%)
RA	12(23,5%)	Tocilizumab	2 (3,9%)
IPAF	4 (7,8%)	Azathioprine	10 (19,6%)
		Leflunomide	3 (5,9%)
		MP pulses	15 (29,4%)
		Rituximab	12 (23,5%)
		Abatacept	5 (9,8%)
		Tacrolimus	5 (9,8%)
Antibodies- n (%)			
Anti-myositis	6 (11,8%)		
Anti-sclerosis	15(29,4%)		
Anti- Ro	25 (49%)		
Anti- RNP	3 (5,9%)		
ANA	35(68,6%)		
RF	21(41,2%)		
Anti- Synt	6 (11,8%)		

Note.
POCD = Pulmonary Obstructive Chronic Disease
SLE = Systemic Lupus Erythematosus
MCTD = Mixed Connective Tissue Disease
RA = Rheumatoid Arthritis
IPAF = Insterstitial Pneumonia with Autoimmune Features
Anti RNP = Anti RiboNucleoProtein
ANA = Antinuclear Antibodies
RF = Rheumatoid Factor
Anti Synt =Anti-synthetase
PHT= Pulmonary Hypertension
UIP = Usual Interstitial Pneumonia
Incons-UIP = Inconsistent Usual Interstitial Pneumonia
NSIP = Nonspecific Interstitial Pneumonia
Fib-NSIP = Fibrosing Nonspecific Interstitial Pneumonia
OP = Organizing Pneumonia
LIP = Lymphoid Interstitial Pneumonia
TNF inhibitor = Tumor Necrosis Factor inhibitor
MP = Metyhprednisolone

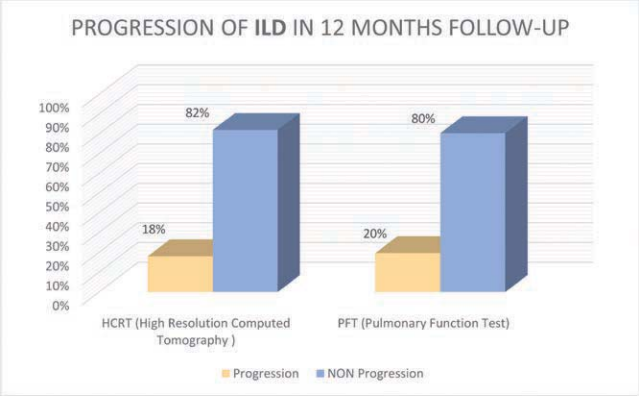

Figure 1.

During follow up, 1 patient with sarcoidosis died of COVID19 bilateral pneumonia.
Conclusion: In our series most patients were middle aged women. Anti-Ro antibodies and smoking status (former or current) were common among patients. Common clinical features were Raynaud (45%), skin affection (45%) and arthritis (40%). 47% of the patients expressed dyspnea at ILD diagnosis. 29,4% were treated with MP pulses, 23,5% with rituximab, 31,4% with mycofenolate mophetil. Fibrosing pattern in HRCT (UIP and fib-NSIP) was the most prevalent. 20% of the patients had progressive fibrosis under PFT criteria and 18% under HCRT. More studies of ILD-CTD are necessary to identify factors for progression and response to treatment and throw out more conclusions of prediction and prognosis of disease.

FREQUENCY AND RISK FACTORS OF OSTEOPOROSIS IN FERTILE WOMEN WITH SYSTEMIC SCLERODERMA

A. Sorokina[1], O. Dobrovolskaya[1], O. Nikitinskaya[1], N. Demin[1], N. Toroptsova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, osteoporosis laboratory, Moscow, Russian Federation*

Objectives: To determine the frequency and risk factors of osteoporosis (OP) in fertile women with systemic scleroderma (SSc)
Methods: 64 women (36,0 [31,5; 43,5] years old) with SSc were enrolled in the study: 35 (54,7%) with limited and 29 (45,3%) with diffuse cutaneous subtype without overlap rheumatic syndromes. The median disease duration was 5,0 [2,0; 9,0] years. Glucocorticoids (GC) were taken by 49 (76,6%) patients with the median duration of treatment 5,0 [2,0; 10,0] years. Dual energy X–ray absorptiometry (DXA) of the lumbar spine, the femoral neck and the total hip was performed. To estimate the value of the BMD the Z-score was used. Low BMD was considered at a Z-score < -2.0 SD. A univariate logistic regression analysis was performed to analyze the factors associated with OP.
Results: Low BMD was detected in 8 (12.5%) patients. 5 (7,8%) women had a history of low-trauma fracture, among them only 1 (1,6%) patient had low BMD and 4 (6,2%) persons - normal BMD.
A univariate logistic regression was performed to identify OP risk factors. Among traditional risk factors, low body mass index (BMI) associated with OP (OR 1,39 [1.04; 1.88], p=0,03) and falls during the past year (OR 5,25 [1.04; 26.36], p=0,04). Among specific ones – duration of SSc (OR 1,19 [1.02; 1.39], p=0,02), duration of GC using (OR 1,11 [1.00; 1.23], p=0,04), hand joint contractures (OR 8,54 [1.41; 51.63], p=0,02). There was no effect of smoking, treatment with proton pump inhibitors, family history of osteoporosis, age, subtype SSc, modified Rodnan score, digital ulcer, cutaneous calcification, esophageal hypotension, interstitial lung disease, diffusing capacity of the lung for carbon monoxide, force vital capacity, CRP, erythrocyte sedimentation rate, creatinine, presence of antinuclear antibody, anticentromere antibody or antitopoisomerase I antibody on the development of OP in fertile women with SSc.
Conclusion: Low BMD was detected in 12.5% of fertile women with SSc. Low BMI, falls during the past year, duration of SSs and GC taking, hand joint contractures associated with OP.
Disclosure of Interests: None declared

SUBCLINICAL ATHEROSCLEROSIS AND CARDIOVASCULAR RISK IN MYOSITIS PATIENTS AND HEALTHY CONTROLS: PRELIMINARY DATA FROM A SINGLE-CENTER CROSS-SECTIONAL STUDY

S. Oreska[1,2], H. Štorkánová[1,2], J. Kudlicka[3], V. Tuka[3], O. Mikeš[3], Z. Krupičková[3], M. Satny[3], E. Chytilova[3], M. Špiritović[1,4], B. Heřmánková[4], P. Cesak[5], M. Rybar[6], K. Pavelka[1,2], L. Šenolt[1,2], H. Mann[1,2], J. Vencovský[1,2], M. Vrablik[3], M. Tomčík[1,2]. *[1]Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic; [2]1st Faculty of Medicine, Charles University, Department of Rheumatology, Praha, Czech Republic; [3]General University Hospital and 1st Faculty of Medicine, Charles University, 3rd Department of Internal Medicine, Prague, Czech Republic; [4]Faculty of Physical Education and Sport, Charles University, Department of Physiotherapy, Prague, Czech Republic; [5]Faculty of Physical Education and Sport, Charles University, Department of Human Movement Laboratory, Prague, Czech Republic; [6]Charles University, Faculty of Mathematics and Physics, Prague, Czech Republic*

Background: Idiopathic inflammatory myopathies (IIM) are associated with systemic inflammation, limited mobility, and glucocorticoid (GC) therapy, which can negatively impact metabolic disorders, atherogenesis, and increase the cardiovascular (CV) risk.
Objectives: This study aimed to evaluate CV risk in IIM patients compared to healthy controls (HC) and explore its associations with disease-specific features.
Methods: 39 patients with IIM (32 females; mean age 56; mean disease duration 4.8 years; dermatomyositis 16, polymyositis 7, immune-mediated necrotizing myopathy 8, antisynthetase syndrome 8) and 39 age-/sex-matched HC (32 females, mean age 56) were included. Subjects with a history of CV disease (angina pectoris, myocardial infarction, cerebrovascular, and peripheral arterial vascular events) were excluded in both groups. Disease activity, damage, and muscle involvement (Manual Muscle Test (MMT)-8, Myositis Intention to Treat Activity Index (MITAX), Myositis Damage Index (MDI)) were assessed. Comorbidities and current treatment were recorded. All participants underwent examinations of carotid intima-media thickness (CIMT), pulse wave velocity (PWV), ankle-brachial index (ABI), and body composition (densitometry: iDXA Lunar, bioelectric impedance: BIA2000-M). The risk of fatal CV events was evaluated by the Systematic COronary Risk Evaluation (SCORE and SCORE2, charts for the European population; modified mSCORE according to the 2015 EULAR recommendation for inflammatory arthritis - only in IIM patients).
Results: In IIM, disease activity and damage were predominantly mild (MITAX 0.13, MDI 0.05). Compared to HC, there was no significant difference in the prevalence of traditional risk factors. Only PWV was significantly increased in IIM compared to HC (p=0.015). No other significant difference was observed between the IIM and HC regarding the CV examinations (CIMT, ABI, carotid plaques) and calculated SCORE and SCORE2 (p>0.05 for all). In IIM, age and mean arterial pressure were the most significant parameters that correlated positively with SCORE, SCORE2, and mSCORE; arterial hypertension was significantly associated with a higher SCORE, carotid plaque count/thickness, and PWV. Lipid profile parameters, body composition, and disease activity were significantly associated with CIMT and carotid plaques (p<0.05 for all). Antihypertensive treatment was associated with an increase in carotid plaque count (p=0.020), higher (favorable) ABI (p=0.004), while hypolipidemic treatment was associated with an increase in carotid plaque count/thickness (p=0.009, p=0.008). Diabetes was associated with lower (worse) ABI values (p=0.034), prediabetes with a higher carotid plaque count (p=0.036) and thickness (p=0.011), and a worse ultrasound examination related CV risk (p=0.006). Anti-Jo-1 positivity was associated with a lower (better) CIMT and lower SCORE (p<0.05 for all). There were no significant associations of CV risk with clinical manifestations, immunosuppressive treatment, and GC cumulative dose. However, exposure time to GC therapy was significantly associated with the carotid plaques count (p<0.001) and the carotid plaque thickness (p=0.003). In multivariate analysis, the age of the patients was the most significant factor affecting most of the parameters analyzed (SCORE and its modifications, PVW, CIMT, and the total count of carotid plaques). Other significant predictors were total cholesterol and atherogenic index of plasma (for ABI), mean arterial pressure (for PWV), and disease duration (for the total count of carotid plaques).
Conclusion: No significant differences in CV risk factors between IIM patients and HC were observed.In IIM, CV risk was associated with age, disease duration, duration of glucocorticoid therapy, lipid profile, and body composition, but not with clinical manifestations and disease activity.

INTRAVENOUS INMUNOGLOBULIN IN INFLAMMATORY MYOPATHIES: EXPERIENCE OF A SINGLE REFERRAL CENTER

C. Corrales-Selaya[1], F. Benavides-Villanueva[1], A. Herrero-Morant[1], D. Prieto-Peña[1], A. Corrales[1], M. A. González-Gay[1], R. Blanco[1]. *[1]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*

Background: Treatment of inflammatory idiopathic myopathies (IIM) is not well-stablished. Although the mechanism of action of intravenous immunoglobulins (IVIG) is not completely understood, they may be useful in rheumatic diseases, including IIM.
Objectives: To assess the efficacy and safety of IVIG in IIM.
Methods: Observational Single University study of IIM requiring therapy with at least one cycle of IVIG from January 2000 to December 2021. IIM, was diagnosed according to EULAR/ACR classification criteria **(1).** Efficacy outcomes were **a)** clinical features (muscular strength and cutaneous involvement), **b)** analytical parameters (Creatine Kinase) and, **c)** glucocorticoid-sparing effect. All of them were measured at 2-4 weeks, 3 months, 6 months, 1 year and 2 years after IVIG onset. Muscular Strength was measured in three muscle areas (upper limbs, lower limbs and neck flexor muscles) by using Medical Research Council Grading System. We classified clinical outcomes (muscular strength and dermatological) improvement in 3 categories: Complete improvement, Partial improvement and No improvement. IVIG schedule was a total of 2 g/kg administered in 1-5 days.
Results: We included 28 patients (22 females, mean age; 47.07±26.71 years) with IIM. The main clinical features are summarized in Table 1. Muscular weakness was present in 18 patients and cutaneous manifestations in 18 patients at baseline.

Table 1. General features of 28 patients with inflammatory idiopathic myopathies with IVIG treatment

GENERAL FEATURES		GENERAL FEATURES (continuation)	
Gender female / male, n (%)	22(78.6) / 6 (21.4)	**Clinical manifestations at IVIG onset;** n (%)	
Age (mean±SD)	47.07±26.71	Upper limbs involvement	17 (60.71)
Underlying IIM; n (%)		Lower limbs involvement	17 (60.71)
Dermatomyositis	12 (46.42)	Neck flexors muscular involvement	14 (50.00)
Amyopathic Dermatomyositis	1 (3.57)	Cutaneous involvement	18 (64.28)
Juvenile Dermatomyositis	6 (21.42)	Dysphagia	8 (28.57)
Polymiositis	2 (7.14)	Constitutional symptoms	9 (3.14)
Inmune-mediated necrotizing miopathy	5 (17.85)	Malignancy	2 (7.14)
Systemic sclerosis/myositis overlap syndrome	1 (3.57)	Respiratory disease	3 (10.71)
Toxic myopathy	1 (3.57)	Articular involvement	4 (14.28)
IIM duration, months (mean±SD)	28.74±38.75	Cutaneous vasculitis	2 (7.14)
Previous immunosupressants before IVIG; n (%)			
Methotrexate	9 (32.14)	**Concomitant Therapy with IVIG**; n (%)	
Azathioprine	4 (14.28)	Oral Corticosteroids at IVIG onset	18 (64.28)
Cyclophosphamide	1 (3.57)	Methotrexate	10 (35.71)
Mycophenolate mofetil	2 (7.14)	Azathioprine	4 (14.28)
Hydroxychloroquine	5 (17.85)	Mycophenolate mofetil	1 (3.57)
Rituximab	1 (3.57)	Hydroxychloroquine	5 (17.85)
Plasmapheresis	1 (3.57)		

An early and maintained improvement was observed in all outcomes: clinical (muscular strength (a) and cutaneous manifestations (b)), Creatine Kinase (c) and glucocorticoid-sparing effect (d) (Figure 1).

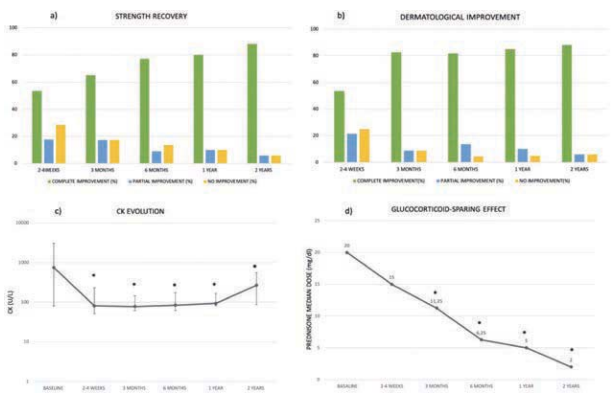

Figure 1. Efficacy Outcome.Figure 1. *p< 0.05 (Wilcoxon test).

After two years of follow-up, we observed the following adverse effects: headache (n=6), pruritus (n=3), allergic reaction (n=2) and arterial hypertension (n=1). No heart failure, renal insufficiency or thrombotic events were found.
Conclusion: IVIG seems effective and safety in IIM treatment.

AB0680 PSYCHOLOGICAL IMPACT OF AUTOLOGOUS STEM CELL TRANSPLANTATION IN SYSTEMIC SCLEROSIS PATIENTS AND INFLUENCE OF SUPPORT AND COPING STRATEGIES.

M. Schmalzing[1], N. Schwindl[2], L. Zerhusen[2], J. Henes[3], A. C. Pecher[3], H. P. Tony[1], M. Gernert[1], A. Kuebler[2], S. Kleih-Dahms[2], P. Ziebell[2], M. Fröhlich[1].
[1]University of Wuerzburg, Rheumatology/Clinical Immunology, Department of Internal Medicine II, Wuerzburg, Germany; [2]University of Wuerzburg, Institute of Psychology, Wuerzburg, Germany; [3]University Hospital Tuebingen, Centre for Interdisciplinary Clinical Immunology, Rheumatology and Auto-inflammatory Diseases and Department of Internal Medicine II (Oncology, Hematology, Immunology, Rheumatology), Tuebingen, Germany

Background: In severe cases of systemic sclerosis (SSc), autologous hematopoietic stem cell transplantation (aHSCT) is superior compared to cyclophosphamide with respect to effect on skin and lung manifestations, survival and quality of life. Nevertheless, major physical and psychological impacts have been found in a first qualitative study by Spierings et al. (2020) [1].
Objectives: Assessment of subjectively experienced physical and psychological impacts of aHSCT and exploration of potential interrelations of those impacts.
Methods: A SSc sample was assessed retrospectively after aHSCT in a two-step-approach. In the first step, 6 questionnaires were used: Global physical and mental health (SF-36 and Scleroderma Health Assessment Questionnaire = SHAQ), body image (Adapted Satisfaction with Appearance Scale = ASWAP), coping strategies (Freiburger Fragebogen zur Krankheitsverarbeitung = FKV-15), resilience (Resilienzskala = RS-11), and control beliefs (Fragebogen zur Erfassung von Kontrollüberzeugung zu Krankheit und Gesundheit = KKG). In the second step, semi-structured interviews based on Spierings et al. (2020) [1] were conducted and analysed via mixed methods qualitative content analysis following Mayring (2014).
Results: 19 patients (12 female, 7 male, mean age 53.47 years (SD = 9.50)) completed all questionnaires and interviews in a mean time of 6.56 years after aHSCT (SD = 3.90, range 1-12 years). A strong correlation was found between perceived physical impairment (SHAQ) and body image dissatisfaction (ASWAP) (Pearson's r = .63, p < .001). There was also a strong negative correlation between body image dissatisfaction (ASWAP) and the physical component of SF-36 (pcSF-36; r = -.59, p = .004) and a smaller correlation for the mental component of SF-36 (mcSF-36: r = -.38, p = .054). Depressive coping was negatively associated with SF-36 (pcSF-3: r = -.605, p = .003; mcSF-36: r = -.808, p < .001) (see Figure 1), whereas resilience was associated with a positive impact (pcSF-36: r = .622, p = .002; mcSF-36 r = .595, p = .004). In the qualitative content analysis of the interviews, all patients reported symptom improvements (mainly skin), which were associated with their coping strategies (depressive coping with fewer improvements, active coping with more improvements). Describing their emotional state during aHSCT, 7 patients verbalized "despair", 6 "loss of control", 5 "emotional instability", 4 "distress due to distance from home", 4 "loneliness", 3 "listlessness", 2 "concern for feelings of relatives", and 2 "depersonalisation". As valuable professional emotional support during aHSCT, 6 patients named nurses and 8 named physicians, while the crucial role of daily ward rounds of the specialised transplant team rather than the primary care team was emphasised. The additional support by a psychology team was not deemed necessary by 7 patients, while 4 patients would have wished such a support. 7 patients rated their physical and mental recovery after aHSCT as satisfying, 4 as better than expected, 4 as disappointing, and 3 as causing impatience.

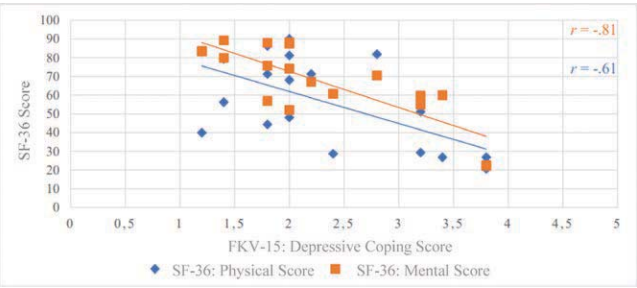

Figure 1. Correlation of SF-36 (physical and mental component) and FVK-15 (Depressive Coping Score) by Pearson's Correlation Coefficient

Conclusion: A transient negative impact of aHSCT on mental wellbeing of the majority of SSc patients is evident, but can be relieved by professional teams highly specialised in this particular treatment option.

AB0681 THE 2-YEAR IMPACT OF COVID-19 PANDEMIC ON MUSCLE STRENGTH AND PHYSICAL PERFORMANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS: A COHORT STUDY

L. Denardi Dória[1], R. Cavalheiro do Espírito Santo[1], L. Santos[1], D. Nóbrega de Moraes[1], É. Pena[1], J. Katarina Schoer Portes[1], A. A. Gasparin[2], N. Pamplona Bueno de Andrade[2], V. Hax[2], R. Xavier[1,2], R. Mendonça da Silva Chakr[1,2].
[1]Federal University of Rio Grande do Sul, Laboratório de Doenças Autoimunes, Porto Alegre, Brazil; [2]Hospital de Clínicas de Porto Alegre, Division of Rheumatology, Porto Alegre, Brazil

Background: Systemic sclerosis (SSc) patients are particularly prone to developing loss of muscle strength and worsening of physical performance due to decreased physical activity[1]. The lifestyle changes imposed by the SARS-CoV-2 outbreak have increased the incidence of sarcopenia in at-risk individuals[2]. However, the literature is scarce on the impacts of the COVID-19 pandemic on muscle strength and physical performance of SSc patients.
Objectives: (1) To assess the impact of the COVID-19 pandemic on muscle strength and physical performance of SSc patients and (2) to verify the associations of muscle strength and physical performance with inflammatory markers in a cohort study.
Methods: SSc patients who met the ACR / EULAR 2013 classification criteria were included. Patients followed between 2019 and 2021. Muscle strength was measured by handgrip strength (kg) and sit and stand (SST, seconds) tests. Physical performance was measured by timed up and go (TUG, seconds) and short physical performance battery (SPPB, points). Inflammatory markers were measured by C-reactive protein (CRP). T test for independent samples, Mann-Whitney U test of independent samples and Spearman's correlation coefficients were explored. The significance level was set at $p \leq 0.05$ for all analyses.
Results: Forty SSc patients concluded this study. At baseline, the mean age was 59 ±11.1 years old and the median disease duration was 13.1 (6.4-19.2) years. Patients had a median of 4.5 clinic visits (3.0-6.0) over the 2 years. The majority of patients were women (37, 92.5%). Ten patients (25%) had diffuse cutaneous disease, 30 patients (75%) non-diffuse cutaneous disease [25 patients (62.5%) had limited cutaneous disease, and 5 (12.5%) had *sine scleroderma* SSc]. The median of CRP was 2.9 (1.2-5.3). The median of handgrip strength was 20.0 (10.3-25.8) kg to the right hand and 19.0 (12.0-22.8) kg to the left hand. The median of SST was 14.4 (11.9-18.7) seconds. The median of TUG was 8.6 (7.7-9.5) seconds and the median of SPPB was 9.8 (9.0-11.0) points. The CRP was positively associated with SST (r=0.3, p=0.047) and TUG (r=0.3, p=0.029), and negatively with SPPB (r=-0.4, p=0.016). After 2 years of follow-up, the patients showed improvement in the left handgrip strength test (p=0.049) and SST (p=0.001). In physical performance, they showed improvement in the TUG test (p=0.005) and SPPB (p=0.001). The CRP was associated positively with TUG (r=0.4, p=0.033), no other associations were found.
Conclusion: Despite the COVID-19 pandemic and the restrictions imposed, in this population of patients with SSc, we did not detect any worsening in muscle strength and physical performance. Some of these parameters of muscle strength and physical performance were associated with the inflammatory marker CRP. More investigations are needed to assess the actual impact and possible associations.

Table 1. Baseline comparison and after 2 years of patients with SSc

		Baseline	After 2 years	*p*
CRP (mg/L),	median (IQR)	2.9 (1.2-5.3)	2.3 (1.0-5.1)	0.361
Handgrip (kg),	right, median (IQR)	20.0 (10.3-25.8)	20.5 (14.3-27.0)	0.072
	left, median (IQR)	19.0 (12.0-22.8)	19.0 (14.0-26.0)	0.049*
SST (seconds),	median (IQR)	14.4 (11.9-18.7)	11.6 (9.9-13.1)	0.001*
TUG (seconds),	median (IQR)	8.6 (7.7-9.5)	7.9 (7.1-9.2)	0.005*
SPPB (points),	median (IQR)	9.8 (9.0-11.0)	11.0 (10.0-12.0)	0.001*

SSc: systemic sclerosis; IQR: interquartile range; mg: milligram; L: liter; kg: kilograms grams; TUG: timed and up go; SST: sit and stand test; SPPB: short physical performance battery; PCR: C-reactive protein; and * significant difference of ≤0.05.

AB0682 FREQUENCY OF SEXUAL DYSFUNCTION IN SYSTEMIC SCLEROSIS, SANTO DOMINGO, DOMINICAN REPUBLIC

J. Santana Peralta[1], A. Cornelio[1], D. Garcia[1], R. A. Alvarez Santana[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Paulino[1], I. Mercedes[2], E. Rodriguez Bautista[2], T. Valdez Lorie[2], A. Feriz[2], R. Muñoz Louis[2]. *[1]Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic; [1]Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease.[1] Sexual function has been associated with a high prevalence of dissatisfaction.[2,3,4] Various factors have been implicated as causes of impaired sexual function.5 CSFQ-14 (Changes in Sexual Functioning Questionnaire) assesses changes in sexual functioning due to disease and/or treatment in [5] domains with a score range of 14-70; cut-off point indicating sexual dysfunction < 41 men and < 47 women.[6]
Objectives: To evaluate the frequency and degree of sexual dysfunction in patients with systemic sclerosis.
Methods: Prospective, observational, cross-sectional study of the cohort of the Rheumatology service at Hospital Docente Padre Billini. Patients were interviewed in November 2021. Inclusion criteria: > 18 years, diagnosis of SSc by ACR/EULAR 2013 classification criteria, at least 1 sexual relationship. Exclusion criteria: previous diagnosis of another autoimmune disease, depression, diabetes, treatment with antidepressants, antiepileptics, narcotics. Measurement of CSFQ-14, mRSS. Statistical analysis was performed with the Pearson correlation (r_p) with p=>0.05. The data was analyzed by SPSS V23.
Results: Of 63 patients, 54 met the inclusion criteria. 100% female, mean age 53+15.07 years, mean duration 11.3 years, lSSc 24.1% (13), dSSc 75.9% (41), single 50% (27), married 44.4% (24), widowed 5.6% (3). Frequency of sexual dysfunction 81.5% (44). Domains: pleasure 79.6% (43), desire/interest 37% (20), frequency desire 81.5% (44), arousal 46.3% (25), orgasm/completion 75.9% (41). Correlation CSFQ-14 with mRSS: Pleasure dysfunction: normal mRSS 2.3% (1), mild 23.3% (10), moderate 20.9% (9), severe 32.6% (14), terminal 20.9% (9). Desire/interest dysfunction: mild mRSS 35% (7), moderate 20% (4), severe 35% (7), terminal 10% (2). Frequency desire dysfunction: normal mRSS 2.3% (1), mild 25% (11), moderate 15.7% (12), severe 36.4% (16), terminal 20.5% (9). Arousal dysfunction: normal mRSS 4% (1), mild 16% (4), moderate 16% (4), severe 36% (9), terminal 28% (7). Orgasm/completion dysfunction: normal mRSS 2.4% (1), mild 22% (9), moderate 22% (9), severe 26.8% (11), terminal 26.8% (11). r_p=. 065 p> 0.05.
Conclusion: The study demonstrated a high frequency of sexual dysfunction in most of the population studied. The desire/frequency dysfunction domain turned out to be the one with the highest presentation, followed by the orgasm/completion domain. A statistically significant linear association between sexual dysfunction and cutaneous activity of the disease was evidenced.

AB0683 POLYNEUROPATHY IMPACT ON DISABILITY IN SYSTEMIC SCLEROSIS PATIENTS

K. Ivanova[1,2], O. Budreviča[3], D. Žukovs[4], E. Možeitoviča[4], V. Ķēniņa[5], N. Kurjāne[5]. *[1]Pauls Stradiņš Clinical University Hospital, Rheumatology centre, Rīga, Latvia; [2]Riga Stradins University, Department of Doctoral studies, Rīga, Latvia; [3]University of Latvia, Residency, Rīga, Latvia; [4]Riga Stradins University, Faculty of medicine, Rīga, Latvia; [5]Riga Stradins University, Department of Biology and Microbiology, Rīga, Latvia*

Background: Systemic sclerosis (SSc) is one of the most severe autoimmune rheumatic diseases with high morbidity and mortality rates [1]. Peripheral neuropathy in SSc is reported with a broad prevalence variable between 0.01% to 28% [2]. Developed in 1978, the Health Assessment Questionnaire Disability Index (HAQ-DI) for rheumatoid arthritis, nowadays is widely used to measure functional status in patients with SSc as well, but data are lacking in SSc patients with polyneuropathy (PN) [3].
Objectives: To determinate the impact of PN on disability in SSc patients.
Methods: This was cross-section study in patients with SSc. Study was conducted in two University hospitals in Latvia for adults. Study included patients diagnosed with SSc that met the ACR / EULAR 2013 accepted classification criteria and have been consulted by rheumatologists between 1st January 2016 and 31st July 2021. Patients who agreed to comply in the study were evaluated by one rheumatologist and were surveyed and clinically evaluated according to The European Scleroderma Trials and Research group accepted domains. Disease duration was defined as time from first non-Raynaud SSc symptom to date of examination. SSc subtype was evaluated in each patient by clinical presentation that included modified Rodnan score (mRSS) as well: limited cutaneous systemic sclerosis (lcSSc) with skin thickening distal to the elbow/knee and diffuse cutaneous systemic sclerosis (dcSSc) with skin thickening proximal to the elbow/knee. For neuropathic pain assessment, the Neuropathic Pain Diagnostic Questionnaire (DN4) was used. Peripheral neuropathy symptoms were assessed using total neuropathy score (TNS). Peripheral nerve conduction study (NCS) and quantitative sensory testing (QST) was used to detect PN.
Functioning and disability were assessed using HAQ-DI. All patients completed the HAQ-DI form in the same day as they were evaluated, filling the form in native language.
Results: From 109 acknowledged patients, 67 were able to come for a visit, 54 females, 13 males. Mean age for females 62.54±12.02 years, for males 58.69±14.50 years.
After assessment by rheumatologist, 50 were classified as lcSSc, 17 were classified as dcSSc. The overall ratio of lcSSC and dcSSc was 50:17, in females 41:13, in males 9:4. Disease duration ranges from 1 to 39 years (mean 15.49±10.18), 16.61±10.47 years for females, 10.85±7.55 years for males. Large fiber PN was diagnosed in 47.8% of subjects by NCS (n=32/67) and small fiber PN in 40.3% of subjects by QST (n=27/67), while 11.9% had neither (n=8/67). Mean HAQ-DI score was 1.22. There was no statistically significant difference in HAQ-DI score between males (1.08±0.89) and females (1.26±1.01), (p=0.13). As well there was no difference between HAQ-DI score in patients with large fiber/small fiber neuropathy and without neuropathy symptoms (p=0.6817). But we found that neuropathy symptoms (assessed by TNS) have moderately strong and statistically significant correlation with HAQ-DI (r=0.39, p=0.0012). As well we found moderately strong correlation between HAQ-DI and neuropathic pain (assessed by DN4) (r=0.45, p=0.00015).
Conclusion: PN is more common complication in SSc that was previously reported, with significant impact on QoL.

AB0684 FATIGUE ASSESSMENT IN SYSTEMIC SCLEROSIS, SANTO DOMINGO, DOMINICAN REPUBLIC

J. Santana Peralta[1], A. Cornelio[1], D. Garcia[1], R. A. Alvarez Santana[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Paulino[1], I. Mercedes[1], E. Rodriguez Bautista[1], T. Valdez Lorie[1], A. Feriz[1], R. Muñoz Louis[1]. *[1]Hospital Docente Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease.[1] Fatigue has been reported in 75% of SSc patients, and is the most problematic symptom due to impact on quality of life. Despite its high prevalence, origin is unknown.[2] Some studies associate it with the degree of disease activity and decreased quality of life. Fatigue is defined as a feeling of exhaustion, also as a reduction in physical and mental capacity,[3] scales such as FACIT-F (Functional

Assessment of Chronic Illness Therapy-Fatigue) are used, which evaluates the last 7 days, with a score of 0-52. For the severity analysis, 4 grades are used: no or mild fatigue (40-52), moderate (27-39), severe (14-26) and extreme (0-13).[4,5]

Objectives: To evaluate the frequency and degree of fatigue in systemic sclerosis.

Methods: Prospective, longitudinal, observational study of the cohort of patients of the Rheumatology service of the Hospital Docente Padre Billini. Patients were interviewed in November 2021. Inclusion criteria: ≥18 years, diagnosis of SSc according ACR/EULAR 2013 classification criteria. Exclusion criteria: previous diagnosis of fibromyalgia, depression or anxiety, treatment with antidepressants, antihistamines, beta-blockers. Measurement of FACIT-F, HAQ-DI, mRSS scales. Statistical analysis was performed with the Pearson correlation (r_p) with p=>0.05. The data was analyzed by SPSS V23.

Results: 54 met inclusion criteria. 100% female, mean age 53.3±15.1 years, mean disease duration 11.3 years, SScd 75.9% (41), SScl 24.1% (13), interstitial pneumonia 33.3% (18), gastrointestinal reflux disease 27.8% (15), HAP 20.37% (11). Frequency of fatigue 100% (54): moderate FACIT-F: 29.6% (16), severe FACIT-F 38.8% (21), extreme 31.5% (17). Correlation FACIT-F with mRSS and HAQ-DI: Moderate FACIT-F: mRSS mild 43.8% (7), moderate 12.5% (2), severe 18.8% (3), terminal 25% (4), HAQ-DI mild 25% (4), moderate 37.5% (6), severe 18.8% (3). Severe FACIT-F: mRSS normal 4.8% (1), mild 19% (4), moderate 91% (4), severe 33.3 % (7), terminal 23.8% (5), HAQ-DI mild 4.8% (1), moderate 19% (4), severe 47.6% (10). FACIT-F extreme: mRSS mild 7.61% (3), moderate 29.4% (5), severe 35.3% (6), terminal 17.6% (3), HAQ-DI moderate 11.8% (2), severe 52.9% (9). r_p=. 246 p>0.05

Conclusion: The study demonstrated a high frequency of fatigue. The most frequent degree was severe. A statistically significant linear association was observed between skin involvement and the degree of functional limitation.

AB0685 OXYGENATED HEMOGLOBIN AS PROGNOSTIC MARKER AMONG PATIENTS WITH SYSTEMIC SCLEROSIS SCREENED FOR PULMONARY HYPERTENSION

P. Xanthouli[1,2], O. Gordjani[1], C. Eichstaedt[1,3], N. Benjamin[1], F. Trudzinski[4], B. Egenlauf[1], S. Harutyunova[1], A. Marra[1,5], N. Milde[1], C. Nagel[1], N. Blank[2], H. M. Lorenz[2], E. Grünig[1]on behalf of Pulmonary Hypertension and Systemic Sclerosis. *[1]Thoraxklinik-Heidelberg gGmbH, Pulmonale Hypertonie, Heidelberg, Germany; [2]University Hospital Heidelberg, Division of Rheumatology, Department of Internal Medicine V: Hematology, Oncology and Rheumatology, Heidelberg, Germany; [3]Institute of Human Genetics, Laboratory for Molecular Genetic Diagnostics, Heidelberg, Germany; [4]Thoraxklinik-Heidelberg gGmbH, Pneumology and Critical Care Medicine, Heidelberg, Germany; [5]University of Naples Federico II,Translational Medical Sciences, Napoli, Italy*

Background: Oxygenated hemoglobin (OxyHem)[1] in arterial blood may reflect disease severity in patients with systemic sclerosis (SSc), particularly among those with pulmonary manifestations such as pulmonary hypertension (PH).

Objectives: Hence, the aim of this study was to analyze the predictive value of OxyHem in SSc patients screened for PH.

Methods: SSc patients were screened for PH including right heart catheterisation, laboratory and clinical assessment. They were followed for 3.2±2.6 (median 3.0) years. OxyHem was measured by multiplying the concentration of hemoglobin with oxygen saturation assessed in arterialized capillary blood. Kaplan-Meier analysis was performed using the defined threshold from Receiver Operating characteristic. Prognostic power was compared with known parameters of prognostic significance in SSc using uni- and multivariable analysis. Clinical parameters of patients with high and low OxyHem were compared by student's t-test.

Results: A total of 280 SSc patients were screened, 267 were included in the analysis (82% female, 59.8±13.4 years, 73.8% limited cutaneous SSc), 56 patients had manifest PH and 112 interstitial lung disease (ILD). Low OxyHem ≤12.5g/dl at baseline was significantly associated with a worse survival (p=0.046) among SSc patients. In the multivariable analysis the presence of ILD, age ≥60 years and diffusion capacity (DLCO) ≤65% were associated with worse survival among SSc patients. The combination of low DLCO and low OxyHem at baseline could predict the development of early pulmonary vascular disease at follow- up (sensitivity 79.6%).

Conclusion: This study detected for the first time that an OxyHem level ≤12.5 g/dl is a prognostic predictor in SSc- patients. Further studies are needed to confirm these results.

AB0686 THE IMPACT OF SYSTEMIC SCLEROSIS (SSC) ON WOMEN'S HEALTH EVALUATED WITH A NEW SSC-SPECIFIC PATIENT-REPORTED QUESTIONNAIRE.

M. G. Lazzaroni[1], L. Moschetti[1], E. Pedretti[1], F. Cucchi[1], A. Lojacono[2], F. Ramazzotto[3], C. Zanardini[3], S. Zatti[3], A. Tincani[1], F. Franceschini[1], P. Airò[1], L. Andreoli[1]. *[1]ASST Spedali Civili of Brescia, University of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy; [2]ASST Garda, Desenzano del Garda, Obstetrics and Gynaecology, Desenzano del Garda, Brescia, Italy; [3]ASST Spedali Civili of Brescia, University of Brescia, Obstetrics and Gynaecology, Brescia, Italy*

Background: Systemic Sclerosis (SSc) can strongly affect the quality of life of affected women. We aimed at designing a SSc-specific, patient-reported questionnaire to explore different aspects of women's health.

Objectives: The questionnaire was created together with Obstetricians-Gynecologists (70 questions, 5 sections) and administered to consecutive patients with SSc (2013 ACR/EULAR classification criteria) regularly attending our Clinic in May-December 2021. The Female Sexual Function Index (FSFI) questionnaire was also administered.

Methods: The questionnaire was created together with Obstetricians-Gynecologists (70 questions, 5 sections) and administered to consecutive patients with SSc (2013 ACR/EULAR criteria) regularly attending our Clinic in the period May-December 2021. The Female Sexual Function Index (FSFI) questionnaire was also administered.

Results: Questionnaires were proposed to 114 patients; among 100 who accepted to participate (median age 59.0 [43.0-67.0], median disease duration 11.0 [6.0-17.0] years), 48% had received SSc diagnosis during reproductive age (<45 years). The cutaneous involvement was limited in 75% and anti-centromere were positive in 44%. A regular gynecological follow-up was not declared by 60% of the patients. Considering patients with SSc-diagnosis in reproductive age: 73% never discussed contraceptive methods with their SSc-Clinicians; 63% desired a pregnancy after diagnosis, but 30% did not satisfied the desired family size; about 50% reported they did not know whether a woman with SSc could experience

disease worsening or take safe medications during pregnancy, and have children also affected by SSc. 77% of patients declared improvement or stability of SSc manifestations during pregnancy. Table 1 shows the comparison of pregnancies before and after SSc diagnosis, based on data reported by the patients. Regarding sexuality, 59% reported that SSc negatively affected it by vaginal dryness (67%), digital ulcers (37%), gastro-intestinal disease (37%) and dyspnea (20%). Among 39 patients completing FSFI, 67% had sexual dysfunction.

Table 1. Results are presented as median [IQR] or number/number available data (%) based on patients answering the question. Continuous variables were compared with Mann-Whitney test; categorical variables with Fisher's exact test.

	Total pregnancies (n= 189)	Pregnancies after diagnosis (n= 42)	Pregnancies before diagnosis (n= 147)	p-value OR [95% CI]
Maternal age at conception, years	28.0 [24.0-32.0]	32.0 [28.0-39.0]	27.0 [23.0-30.0]	*< 0.001*
Live births	152/189 (80.4)	31/42 (73.8)	121/147 (82.3)	*0.221*
Cesarean sections	36/135 (26.7)	17/31 (54.8)	19/104 (18.3)	*< 0.001 5.43 [2.30-12.9]*
Preterm births <37 weeks	32/109 (29.4)	7/32 (21.9)	25/77 (32.5)	*0.269*
Preterm births <34weeks	7/32 (21.8)	2/7 (28.6)	5/25 (20.0)	*0.632*
Birth weight, kilograms	3.3 [2.8-3.6]	3.1 [2.5-3.5]	3.3 [3.0-3.7]	*0.049*
≥ 1 Adverse Pregnancy Outcomes	15/113 (13.3)	8/31 (25.8)	7/82 (8.5)	*0.016 3.73 [1.22-11.39]*
Gestational hypertension	4/113 (3.5)	3/31 (9.7)	1/82 (1.2)	*0.062*
Preeclampsia	1/113 (0.9)	1/31 (3.2)	0/82 (0.0)	*0.274*
Eclampsia	0/113 (0.0)	0/31 (0.0)	0/82 (0.0)	*1.000*
HELLP syndrome	1/113 (0.9)	0/31 (0.0)	1/82 (1.2)	*1.000*
Gestational diabetes	3/113 (2.7)	2/31 (6.5)	1/82 (1.2)	*0.182*
Intra Uterine Growth Restriction	4/113 (3.5)	2/31 (6.5)	2/82 (2.4)	*0.302*
Perinatal deaths	2/134 (1.5)	0/32 (0.0)	2/102 (1.9)	*1.000*
Neonatal Intensive Care Unit Admission	11/134 (8.2)	6/32 (18.8)	5/102 (4.9)	*0.022 4.48 [1.27-15.84]*
Perinatal infections	8/134 (8.2)	3/32 (9.4)	5/102 (4.9)	*0.396*
Breastfeeding	92/132 (69.7)	22/32 (68.8)	70/100 (70.0)	*0.893*

Conclusion: The newly created specific questionnaire was instrumental to facilitate physician-patient communication about 'women's health', particularly in the field of sexuality which is characterized by a high frequency of dysfunction. Adverse outcomes are possible during SSc pregnancies and should be discussed during the multidisciplinary preconception counselling, along with measures to possibly reduce their risk.

AB0687 PROGNOSTIC MEANING OF RIGHT VENTRICULAR FUNCTION AND RESERVE IN PATIENTS WITH SYSTEMIC SCLEROSIS

P. Xanthouli[1,2], J. Miazgowski[2], N. Benjamin[2], O. Gordjani[2], B. Egenlauf[2], S. Harutyunova[2], R. Seeger[2], A. Marra[2,3], N. Blank[1], H. M. Lorenz[1], E. Grünig[2], C. Eichstaedt[2,4]. *[1]University Hospital Heidelberg, Division of Rheumatology, Department of Internal Medicine V: Hematology, Oncology and Rheumatology, Heidelberg, Germany; [2]Thoraxklinik-Heidelberg gGmbH, Pulmonary Hypertension, Heidelberg, Germany; [3]University of Naples Federico II, Translational Medical Sciences, Napoli, Italy; [4]Institute of Human Genetics, Laboratory for Molecular Genetic Diagnostics, Heidelberg, Germany*

Background: The delay of the diagnosis of pulmonary hypertension (PH) in patients with systemic sclerosis (SSc) leads to severe impairment of survival.

Objectives: The objective of this study was to investigate the prognostic impact of right ventricular (RV) function at rest and during exercise on survival in patients with SSc presenting for screening for PH.

Methods: Data from SSc patients who underwent routinely performed examinations for PH screening including echocardiography and right heart catheterization at rest and during exercise were analyzed. Uni- and multivariable analyses were performed to identify prognostic parameters in SSc and to compare them to known prognostic predictors.

Results: Out of 285 SSc patients screened for PH, 225 patients (81.3% female, mean age 58.1±13.0 years, 68% limited cutaneous SSc, WHO-FC II-III 74%, 24 manifest PH) were included in the analysis. During an observation period of 3.2±2.7 (median 2.6) years 35 patients died. Tricuspid annular plane systolic excursion ≤18 mm (p=0.0004), increase of cardiac index (CI) during exercise ≤ 2 l/min (p=0.0002), RV output reserve >3 mmHg/l/min (p=0.001), peak CI ≤ 5.5l/min (p=0.01), pulmonary arterial compliance >2 ml/mmHg (p=0.0005) and qualitative RV function at rest (p<0.0001) significantly predicted survival. In the multivariable analysis, RV function at rest, diffusion capacity for carbon monoxide < 65% predicted and CI increase <2 l/min/m^2 were identified as independent prognostic predictors and had >70% sensitivity and specificity to predict development of pulmonary vascular disease (PVD) during follow-up.

Conclusion: This study demonstrates that assessment of RV function at rest and during exercise may provide crucial information to identify SSc patients who are at a high risk of an impaired survival and development of PVD.

Background: Mixed connective tissue disease (MCTD) is a rare heterogeneous disease, characterized by overlapping features of classic connective tissue diseases. Myositis may be present in up to two-thirds of patients with MCTD and it is included in all diagnostic criteria available. Although some possible associations have been reported, to the best of our knowledge, no independent predictors of MCTD-related myositis have been described.

Objectives: To identify clinical and laboratorial predictors for muscular involvement in a cohort of Portuguese patients with MCTD.
Methods: Multicentre retrospective cohort study including adult-onset patients with a clinical diagnosis of MCTD and fulfilling at least one of the following diagnostic criteria: Sharp, Kasukawa, Alarcón-Segovia or Kahn criteria. Myositis was defined as proximal muscle weakness, creatine kinase elevation, electromyography (EMG) suggestive changes or a positive muscular biopsy. Univariate analysis was performed using Chi-Square, Fischer's Exact Test and Mann-Whitney Test, as appropriate. Multivariate analysis was performed using binary logistic regression modelling. The linearity of the continuous variables concerning the logit of the dependent variable was assessed via the Box-Tidwell procedure. Cases with missing information and outliers were excluded from the multivariate analysis to fulfil all assumptions necessary to assure the validity of the regression.
Results: A total of 98 patients were included, 43 (44.3%) of whom had muscular involvement at any time of the disease course. Concerning patients with MCTD-related myositis, the mean age at diagnosis was 34.8±12.5 years and the mean disease duration of 4.1±4.9 years. The majority of patients were female (90.7%) and of European ancestry (66.7%). EMG was performed in 24 patients, of whom 10 (41.7%) had a myopathic pattern. Seventeen patients were submitted to a muscular biopsy, of whom 8 (47.1%) had histological myositis features. Capillaroscopy was performed in 24 patients and 12 (50%) had a scleroderma pattern. African ancestry and leukopenia were positively associated with myositis at disease onset. Furthermore, fever at the onset of disease, younger age at diagnosis and shorter disease duration were positively associated with the occurrence of myositis at any phase of the disease. The multivariate analyses predicting myositis at diagnosis included 54 patients and at any time of the disease included 90 patients. These models explained 37.8% and 26.9% (Nagelkerke R2) of the variance in myositis and correctly classified 79.6% and 73.3% of all cases, respectively. African ancestry (OR 8.39, 95%CI: 1.43-49.37, p=0.019), leukopenia (OR 6.24, 95%CI: 1.32-29.48, p=0.021) and younger age at diagnosis (OR 1.07/year, 95%CI: 1.01-1.14, p=0.035) were identified as independent predictors of myositis at diagnosis. Fever (OR 6.51, 95%CI: 1.23-34.37, p=0.027) was an independent predictor of muscular involvement at any time of the disease in MCDT patients.
Conclusion: African ancestry, leukopenia and younger age at diagnosis are independent predictors of myositis at presentation in MCTD patients, while fever is an independent predictor of myositis at any time of the disease. While evaluating patients with MCTD, these predictive factors should be considered.

AB0689 CLINICAL COURSES AND PREGNANCY OUTCOMES OF EIGHT CASES COMPLICATED WITH POLYMYOSITIS/DERMATOMYOSITIS (PM/DM) IN SINGLE CENTER

R. Mino[1], H. Shimada[1], R. Wakiya[1], S. Nakashima[1], M. Kato[1], T. Miyagi[1], K. Sugihara[1], Y. Ushio[1], M. Mizusaki[1], T. Kameda[1], H. Dobashi[1]. [1]*Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Miki, Japan*

Background: Pregnancies complicated by a number of rheumatic diseases are known to be at high risk for the occurrence of adverse pregnancy outcomes (APOs). There have been several reports on the risk of APOs in systemic lupus erythematosus and rheumatoid arthritis, but few reports on polymyositis (PM)/dermatomyositis (DM) pregnancies. There are also insufficient reports on changes in the activity of PM/DM during pregnancy. Based on the findings reported in other rheumatic diseases, it is suggested that increased activity during pregnancy is associated with APOs in PM/DM (1-3). However, the risk factors for pregnancy outcome in pregnancies complicated by PM/DM, including the presence or absence of worsening of disease activity, have not been clarified.
Objectives: The purpose of this study was to analyze a case series of PM/DM complicated pregnancies in a single center to determine the changes in disease activity during pregnancy and pregnancy outcomes.
Methods: PM/DM patients who were managed from pregnancy to delivery at Kagawa University Hospital from March 2006 to May 2021 were included in this study. Clinical indices including duration of illness, disease activity, and treatment were extracted from medical records and retrospectively analyzed for association with pregnancy outcome.
Results: Eight PM/DM pregnancies were included in the analysis. The mean age at delivery was 28.3±3.8 years and the mean duration of disease was 6.3±3.2 years. Treatment at the time of pregnancy included glucocorticoids (GC) in 7 cases and immunosuppressive drugs in 5 cases. Creatinine phosphokinase (CK) levels were normal in all patients at the time of pregnancy, but increased during pregnancy in 4 (50%) patients. These 4 patients with elevated CK required treatment with increasing doses of GC, and the mean GC dose during pregnancy was 10.9 ± 6.0 mg/day. Table 1 shows the pregnancy outcomes of the 8 patients. There was one spontaneous abortion and seven live births. Among the live births, 2 were preterm and 4 were low birth weight. The mean gestational age at delivery was 35.3±5.2 weeks and the mean birth weight was 2297.7±1041.4g.

Table 1. Pregnancy outcomes of eight cases

Case no.	Outcome	Mode of delivery	Gestational age at delivery (weeks)	Birth weight of the newborn (grams)	Adverse pregnancy outcomes
1	Live birth	Cesarean section	26	590	Preterm birth, LFD, HELLP syndrome
2	Spontaneous abortion				
3	Live birth	Transvaginal delivery	30	1,299	Preterm birth, LBW
4	Live birth	Cesarean section	38	2,765	Hypertensive disorder
5	Live birth	Transvaginal delivery	37	3,290	–
6	Live birth	Transvaginal delivery	37	2,492	LBW
7	Live birth	Transvaginal delivery	39	3,456	–
8	Live birth	Transvaginal delivery	40	2,192	LBW
	7 live births 1 abortion		35.3±5.2	2,297.7±1,041.4	

The birth outcomes of the 2 patients who received continuous immunosuppressive therapy were full-term and normal weight infants. APOs, such as preterm delivery and low birth weight, occurred in cases with increased CK levels and increased GC doses.
Conclusion: In pregnancies of PM/DM patients, pregnancy outcome was less than favorable. An association between disease activity and the development of APOs during pregnancy in PM/DM was suggested. An association was also suggested between GC dose and the risk of developing APOs. As in other rheumatic disease pregnancies, continued use of pregnancy-appropriate immunosuppressive drugs and control of disease activity with lower glucocorticoid doses in PM/DM pregnancies may be important to achieve good pregnancy outcomes.

AB0690 CALCINOSIS CUTIS IN SYSTEMIC SCLEROSIS: CLINICAL AND BIOLOGICAL ASSOCIATIONS

G. M. State[1], N. D. Popescu[1], I. A. Berza[1], F. Negoi[1], A. Dima[1], M. Parvu[2]. [1]*Colentina Clinical Hospital, Department of Rheumatology, Bucharest, Romania;* [1]*Colentina Clinical Hospital, Department of Rheumatology, Bucharest, Romania*

Background: Calcinosis cutis (CC) is a rare disorder characterized by the abnormal deposition of calcium salts in the subcutaneous tissues of patients with normal calcium metabolism. Dystrophic calcinosis is a common and potentially debilitating manifestation in systemic sclerosis (SSc) patients. The CC was described to appear more frequently in newly diagnosed SSc patients with Raynaud's phenomenon, with ischemic ulcer or telangiectasia and in areas related to repeated trauma, but current data remains inconclusive [1,2].

Objectives: Our objective was to analyze the prevalence, clinical features, and biological associations of CC in SSc patients.
Methods: A retrospective analysis of patients hospitalized in the Rheumatology Department of the Colentina Clinical Hospital, Bucharest, Romania. Data of the patients fulfilling the 2013 American College of Rheumatology/ European League Against Rheumatism (ACR/EULAR) SSc classification criteria were collected. In all patients, clinical examination, including evaluation of the cutaneous involvement by the modified Rodnan skin score (mRSS) was performed. A CC diagnosis was sustained by radiographic and/ or ultrasound imaging.
Results: 44 SSc patients were included with female predominance (39 patients - 88.6%), and with mean (SD) age 58.8±11.3 years old, CC was found in 11(25.0%) of these patients, all feminine gender. Elbow (36.4%), hands and forearms (27.3%) were the most frequent sites affected by CC.
Overall, CC was not related to the SSc subtype, when comparing limited (lc) with diffuse cutaneous (dc) involvement (27.3% *vs.* 48.5%, p=0.219). However, patients with CC had more often lc SSc, 72.7% *vs.* 27.3%. Accordingly, SSc patients with CC had a significant lower mRSS score, 6 (1;7) *vs*. 9 (5; 15.5) points, p=0.001 and more frequently expressed positives anti-centromere antibodies (ACA), 72.7% *vs.* 57.1%, p=0.036. CC was also found not to be related to sclerodactyly, 54.5% *vs.* 75.8%, p=0.038. Regarding the nailfold capillaroscopy (NFC) exam, the CC was more often described in patients with late NFC pattern, 45.5% of cases.
In SSc patients with CC, there was reported more often intestinal transit disturbances 45.5% *vs*. 3.0%, p=0.015, even if overall there was no gastrointestinal involvement, 72.7% *vs.* 63.6%, p=0.582.
Regarding inflammation, the level of erythrocyte sedimentation rate (ESR) was lower in patients with CC 18 (13;33) *vs.* 33 (17.0; 58.5) mm/h, p=0.040, but not the C-reactive protein level 2.4 (1.7; 6.7) *vs.* 3.3 (1.2; 8.5) mg/L, p=0.866.
When comparing SSc patients with or without CC we did not found any significant difference regarding the presence of anti-Scl70 antibodies, p=0.432, rheumatoid factor, p=0.067, lupus anticoagulant or antiphospholipid antibodies, p=0.835. Also, no significant correlations were identified for CC in SSc and the following parameters: smoking, p=0.162, obesity, p=0.812, hypertension, p=0.371, diabetes, p=0.403, Raynaud phenomenon, p=0.539, telangiectasia, p=0.28, pulmonary hypertension, p=0.777, lung interstitial disease, p=0.315, digital ulcers, p=0.723, or digital starry scars, p=0.223.
Conclusion: The CC prevalence in SSc consecutive patients was 25.0%, more frequently with elbow localization. We've also found more frequent CC in patients with positive ACA serology and defined relations with many other SSc-related parameters.

AB0691 SYSTEMIC SCLEROSIS AT THE TIME OF COVID-19 PANDEMIC: A BIBLIOMETRIC STUDY

B. Doskaliuk[1], R. Yatsyshyn[2], I. Stoika[2], K. Fedorovych[2], O. Hotsaniuk[2], O. Drogomeretska[2]. *[1]Ivano-Frankivsk National Medical University, Pathophysiology, Ivano-Frankivsk, Ukraine; [2]Ivano-Frankivsk National Medical University, Internal medicine #1 clinical immunology and allergology, Ivano-Frankivsk, Ukraine*

Background: The Coronavirus disease 2019 (COVID-19) affects different organs and systems of the human organism. However, the main target remains the respiratory system and lungs in particular. Systemic sclerosis (SSc) is one of the systemic autoimmune diseases that can cause severe lung impairment. Considering the existence of common points of influence on the human organism, the overlapping of these two pathologies can significantly increase the negative impact on the patient's health.
Objectives: This study was aimed to analyze the common features of articles covering the link between COVID-19 and systemic sclerosis.
Methods: We retrieved the literature items in the scientific bibliometric database Scopus conducting our search on the 26th of January. We didn't set any time limits and did use the following keywords: "systemic sclerosis" OR "scleroderma" AND "Covid-19" OR "COVID-19" OR "coronavirus". The exclusion criteria were: absence of an abstract, literature items in form of conference papers, and articles dedicated to the rheumatological pathology in general with scarce mention of SSc. All selected papers were analyzed in view of the following characteristics: documents' type, authorship, journal, citations score, the origin of an article, language, and keywords. For data visualization, we have used software tool VOSviewer version 1.6.15 which make possible to build authors' and keywords' network (Figure 1 A and B) (the minimum keywords' threshold was 3 and the minimum author occurrence was 5).

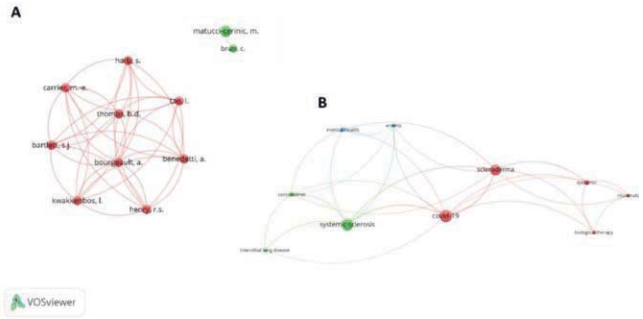

Figure 1.

Results: In the result of our comprehensive literature search only 206 items were obtained. After screening of title, abstract and keywords we omitted 166 articles as they met our exclusion criteria and were irrelevant for our study. The most (87.5%) of remained 40 articles were open access publications, which improves the articles' visibility and simplifies data sharing. The top journals covering this topic were: Annals Of The Rheumatic Diseases (n=7), Journal of Psychosomatic Research (n=4), Journal Of Scleroderma And Related Disorders (n=4), Clinical Rheumatology (n=3), Lancet Rheumatology (n=3) and Scandinavian Journal Of Rheumatology (n=3). The post productive authors originated from Italy (n of articles = 20); other countries with highest number of publications were: UK – 10; USA – 7; France – 7 and Netherlands – 6). The majority of papers were written in English and just one was in Chinese. The most prevalent research type among analyzed articles was Letter (47.5%), about a third of the articles were designed as Original Articles (35%), 7.5% were Notes, the number of Reviews and Editorials was 5% for each type. Based on the citations score, the most relevant article was dedicated to COVID-19 course in patients with SSc associated interstitial lung disease (SSC-ILD) using tocilizumab. The second highly cited paper highlighted a disease course of COVID-19 pneumonia in SSc patients treated with rituximab and the third actively cited article was World Scleroderma Foundation preliminary advice for patient management. It should also be noted that a lot of articles (n=7, 17.5%) were dedicated to the emotional wellbeing of SSc patients in time of COVID-19 pandemic.
Conclusion: Based on our literature analysis, it is the first attempt to overview comprehensively the papers focusing on SSc and COVID-19 overlap. The bibliometric studies offer an essential opportunity to emphasize the main features and trends in the particular topic and could be used by scientists as a guidance for forthcoming research.

AB0692 PREDICTORS OF ILOPROST INFUSION TOLERANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS

R. Bixio[1], E. Bertoldo[1], A. Giollo[2], G. Adami[1], A. Morciano[1], D. Bertelle[1], I. Gavioli[1], G. Orsolini[1], O. Viapiana[1], M. Rossini[1]. *[1]Università degli studi di Verona, Rheumatology section, Verona, Italy; [2]Università degli studi di Padova, Division of Rheumatology, Padova, Italy*

Background: Systemic Sclerosis (SSc) is an autoimmune disease characterized by vasospasm and microvascular involvement. Iloprost (ILO), a prostaglandin analogous, is used for the treatment of SSc-related Raynaud's Phenomenon and digital ulcers. The indicated dosage is 0-5-2 ng/kg/min for 6-8 hours and the maximum dose is decided upon the patient's tolerance.
Objectives: Our study aims to analyse ILO infusion tolerance and possible predictive factors in patients with SSc.
Methods: We evaluated patients with SSc beginning ILO iv treatment between 2004 and 2021. We assessed the maximum tolerated ILO iv infusion rate, the incidence of adverse events (AEs) and the need for symptomatic therapy during the dose-finding sessions. We collected relevant demographic and medical data at the beginning of ILO iv treatment. Statistical

analysis were performed to assess possible predictors of maximum tolerated ILO infusion rate and AEs.
Results: We retrospectively analysed 113 patients. The median ILO infusion rate at the end of the dose-finding process was 0.88 ng/kg/min (IQR 0.37). We found a significant inverse correlation between ILO infusion rate and body mass index (BMI) at the beginning of treatment. BMI was negatively associated with ILO infusion rate (β -0.29, p = 0.001) after correction for relevant confounding factors. Subjects in the upper BMI tertile (BMI above 25) had a lower tolerance to ILO compared with subjects in the lower BMI tertile BMI below 22 (p=0.002). Disease pattern, disease duration, age at the onset of disease, mean blood pressure, gender, smoking habits, combination therapy with calcium channel blocker or endothelin inhibitors were not predictors of ILO tolerance. AEs during ILO titration occurred in 47.8% of patients, of whom 22.2% presented concomitant hypotension. The most common AEs were headache, nausea, vomiting, diarrhoea, oedema, hypotension, and symptomatic therapy was needed in half of the patients at least once. Overweight patients (BMI >26) presented a 13-fold increased risk of developing AEs during ILO titration (adjusted odd ratio 13.979 95% CI 2.359-82.845).
Conclusion: Our study showed that only a higher BMI was associated with lower ILO infusion rate tolerance and higher AEs rate, underlying a possible BMI-dependent endothelial dysfunction possibly mediated by endothelin receptor expression. Individual ILO regimens still need to be tailored to the patient.

AB0693 EFFECTIVENESS OF RITUXIMAB IN PATIENTS WITH SYSTEMIC SCLEROSIS – EXPERIENCE IN A TERTIARY MEDICAL CENTER

N. Cristina[1], L. Groseanu[1,2], S. Petrescu[1], D. Nicoara[1], D. Opris-Belinski[1,2], D. Mazilu[1,2], A. Balanescu[1,2], R. Ionescu[1,2]on behalf of The Department of Rheumatology and Internal Medicine at Bucharest St. Mary's Hospital. *[1]St Mary Hospital, Internal Medicine and Rheumatology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, University of Medicine and Pharmacy, Bucharest, Romania*

Background: There is ample evidence of B cell involvement in the pathogenesis of fibrosis in systemic sclerosis (SSc), making it a promising target for the treatment of skin and lung fibrosis in SSc. However, data regarding the long-term use of B cell depletion in the treatment of this life-threatening connective tissue disease is scarce.
Objectives: The primary aim of this study was to evaluate the safety and efficacy of long-term B cell depletion and to define the changes on both cutaneous and visceral organ involvement after rituximab (RTX) therapy in SSc patients over time, in a tertiary hospital.
Methods: A prospective observational case-control study, conducted between 2016 and 2021, enrolled 10 SSc patients, who fulfilled the ACR/EULAR 2013 classification criteria for scleroderma and who had received RTX infusions at least once. All patients had been taking immunosuppressive therapy previously. The following clinical data were included into the analysis: disease activity by the EUSTAR activity index, skin fibrosis by the modified Rodnan Skin Score (mRSS), interstitial lung disease by lung function tests including forced vital capacity (FVC), diffusing capacity of the lung for carbon monoxide (DLCO) and high-resolution CT (HRCT). For the comparison of non-parametric data at two time points, Wilcoxon matched paired Student's t-test was used.
Results: The study included 10 patients (all female), with a mean age of 52.9 years, most of them with diffuse subset (9/10), treated with RTX between 2016 and 2021. Average duration of disease before the RTX therapy was 27.6 months. Mean baseline mRSS was 19.3 and mean EUSTAR activity index was 4.48. Seven patients received 2 courses of RTX for at least 6 months, four of which were evaluated 1 year after the beginning of RTX therapy. We found a statistically significant improvement in mRSS (p=0.02) and EUSTAR activity index values (p=0.02), when comparing baseline levels with those found at each follow-up visit. Furthermore, all the patients who were treated with RTX early in the disease course achieved better results at 6 months follow-up. There was no significant change in PFT's, DLCO and chest HRCT lesions in all patients, neither in the subgroup with early disease, nor in the subgroup with worsening, progressing pulmonary function, during the follow up period.
Conclusion: Our results suggest that B cell depletion, in patients with SSc, leads mainly to a clinically relevant decrease in skin involvement and to a stabilization of disease activity after 6 and 12 months of use. The study did not find a clear beneficial effect on pulmonary function during short-term follow-up. Despite these considerations, our results indicate that the course of lung disease did not worsen in our patients. At 6-year follow-up the safety of single and repeated courses of the drug was confirmed. While the study provides important insights into the use of RTX in SSc, it is limited by the low number of patients, the lack of a sufficient control arm and the single center design.

AB0694 VITAMIN D LEVELS IN SERUM OF PATIENTS WITH SYSTEMIC SCLEROSIS AND VERY-EARLY SYSTEMIC SCLEROSIS (VEDOSS)

G. Cuomo[1], M. C. Trotta[2], C. Di Vico[1], R. Ferrara[3], C. Romano[3], M. D'Amico[2]. *[1]Università degli Studi della Campania, Precision of Medicine, Naples, Italy; [2]Università della Campania Luigi Vanvitelli, Section of Pharmacology "L.Donatelli",, Napoli, Italy; [3]University of Campania Studies "Luigi Vanvitelli", Department of Medical and Surgical Sciences, Napoli, Italy*

Background: Systemic sclerosis (SSc) is a chronic disease characterized by autoimmunity, vasculopathy, and visceral and cutaneous fibrosis and very-early systemic sclerosis VEDOSS is characterized by Raynaud's phenomenon with SSc marker autoantibodies and typical capillaroscopic finding. Vitamin D has several functions in the immunological system, and different studies have suggested a potential role in triggering autoimmune diseases. (1,2)
Objectives: Our goal was to verify the difference of Vitamin D levels causal in SSC definite and VEDOSS population, and relationship between hypovitaminosis D and SSc characteristics
Methods: 42 adults with SSc were recruited: 24 with American College of Rheumatology criteria were affected by diffuse systemic sclerosis (4) and limited systemic sclerosis (20); 18 with VEDOSS criteria. Patients were evaluated from medical history and physical examination (modified Rodnan skin score and the presence / number of ulcers), biohumoral evaluation of routine, electrocardiogram, echocardiogram, pulmonary function tests, high resolution computed tomography of the chest, capillaroscopy. For the determination of total vitamin D levels (25-OH), the serum samples were suitably centrifuged at 4 ° C at 3500g. Vitamin D levels were then determined by a two-step chemiluminescence enzyme immunoassay (CLIA), with a maximum limit of 100 ng / ml.
Results: The 42 subjects recruited (4 men and 38 women); age 48.2 ± 11.5 years (mean ± SD). All subjects were ANA positive, with anti-Scl70 positivity in dcSSc patients (4) and anti-centromere lcSSc patients (18). Patients with VEDOSS showed optimal serum levels of vitamin D (33.93 ± 3.5 ng / ml). Conversely, patients with systemic sclerosis showed serum levels of vitamin D at the limit of sufficiency (21.75 ± 4.0 ng / ml). (Figure 1) In particular, in the group of patients with systemic sclerosis, vitamin D levels were significantly reduced by 1.5 times (P <0.05) compared to VEDOSS group. In patients with SSc the serum levels of vitamin D were inversely proportional to the presence of mega capillaries. Furthermore, a directly proportional correlation of the serum levels of vitamin D with the age of the patient. It is therefore possible to assume that higher levels of vitamin D delay the onset of the disease, while lower levels of vitamin D favor the onset of the same.
Conclusion: Considering our findings from this work, it is possible to consider the Vitamin D supplement in patients suffering from sclerosis, especially as an adjuvant in the initial phase of the disease, thus hypothesizing a slowdown in the progression of the disease and an improvement in prognosis.

AB0695

ANTI-TH/TO POSITIVITY IN SYSTEMIC SCLEROSIS: ANALYSIS OF PULMONARY INVOLVEMENT, ORGAN DAMAGE ACCRUAL AND MORTALITY IN AN ITALIAN MONOCENTRIC COHORT

L. Moschetti[1], M. G. Lazzaroni[1], I. Cavazzana[1], F. Franceschini[1], P. Airò[1]. [1]*ASST Spedali Civili, University of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy*

Background: Anti-Th/To antibodies, detected in 2-5% Systemic Sclerosis (SSc) patients, are associated to interstitial lung disease (ILD)[1] in half of the cases. However, long-term data on ILD as well as on organ damage accrual are lacking.
Objectives: To describe the clinical associations of anti-Th/To SSc patients, focusing on ILD, organ damage and mortality.
Methods: Monocentric retrospective study. 1) Description of clinical associations of anti-Th/To SSc patients (2013 ACR/EULAR criteria). 2) Case-control study: anti-Th/To vs anti-Topoisomerase (anti-Topo)1 patients (1:3; matched for sex and age at SSc onset) regarding a) ILD b) organ damage c) survival. ILD progression was assessed through pulmonary function tests (PFTs) at baseline (T0) and after 1 (T1), 5 (T5), 10 (T10) and 20 (T20) years. Organ damage was evaluated with SCTD-Damage Index (SCTD-DI)[2]. Continuous data are expressed as median [IQR].
Results: We identified 13 anti-Th/To patients (all Caucasians, F/M=10/3, median age at SSc onset: 50 [37-67] years). Anti-Th/To were assayed by RNA immunoprecipitation in 8/13 and by immunoblotting in 5/13 cases.
1) 2/13 patients had SSc/myositis overlap syndrome: 1 associated to anti-SRP, 1 negative for myositis specific antibodies and affected by a synchronous (±3 years from onset) cancer. All presented lcSSc, 77% esophageal symptoms, 46% digital ulcers (DUs), 40% ILD, 39% telangiectasias, 39% heart involvement (3 pericarditis, 1 myocarditis in patient anti-SRP+, 1 arrhythmia), 15% gastrointestinal symptoms, 15% myositis and 8% calcinosis. No patients presented synovitis, joint contractures, pulmonary arterial hypertension nor scleroderma renal crisis.
2a) Anti-Th/To ILD patients, as compared to 39 anti-Topo 1, less frequently required immunosuppression and never required antifibrotic or O_2 therapy (Table 1); ILD progression (%pFVC decline ≥10% or %pFVC decline 5-10% and %pDLCO decline ≥15%) was shown for 3/13, albeit, after a longer interval than in 8/39 anti-Topo 1 progressors (15 [10-15] vs 1 [1-6.3] years, p:0.05); none died because of ILD.

Table 1.

	anti-Th/To+ n=13	anti-Topo 1+ n=39	p-value
ILD on HRTC	4/10 (40)	28/33 (85)	**0.01**
Immunosuppressants	1/13 (8)	16/39 (41)	**0.04**
Antifibrotic and/or O_2	0/13 (0)	8/39 (21)	0.18
PH secondary to ILD	0/13 (0)	6/39 (15)	0.32
SSc-ILD related death	0/13 (0)	6/39 (15)	0.32
%pFVC T0	105 [85-114]	90 [81-114]	0.26
%pFVC T1	107 [97-112]	88 [80-108]	0.09
%pFVC T5	97 [84-114]	99 [83-111]	0.88
%pFVC T10	103 [91-114]	88 [80-112]	0.23
%pFVC T20	104 [83-111]	81 [74-103]	0.35
%pFVC <70% T0	0/13 (0)	3/39 (8)	0.56
%pFVC <70% T1	0/12 (0)	3/39 (8)	1.00
%pFVC <70% T5	0/10 (0)	3/33 (9)	1.00
%pFVC <70% T10	0/7 (0)	3/25 (12)	1.00
%pFVC <70% T20	0/5 (0)	1/8 (13)	1.00
Progressive fibrosis (PF)* [T1-T0]	0/12 (0)	5/39 (13)	0.32
PF* [T5-T0]	1/10 (10)	5/33 (15)	1.00
PF* [T10-T0]	1/7 (14)	4/25 (16)	1.00
PF* [T20-T0]	2/5 (40)	0/8 (0)	0.20

Continuous data are presented as median [IQR] and compared with Mann-Whitney test; categorical data are presented as number/number available data (%) and compared with Chi-square test/Fisher's exact test. *Progressive fibrosis= %pFVC decline ≥10% or 5-10% %pFVC decline and %pDLCO decline ≥15%.

2b) During 16 [6-20] years of follow-up, SCTD-DI score progressively increased, but remained low in all patients (SCTD-DI ≤5) and was significantly lower than in anti-Topo 1 (Figure 1*a*), mainly due to ILD, joint contractures and DUs in the latter group (85% vs 40%, p:0.01; 39% vs 0%, p:0.01; 77% vs 46%, p:0.08).

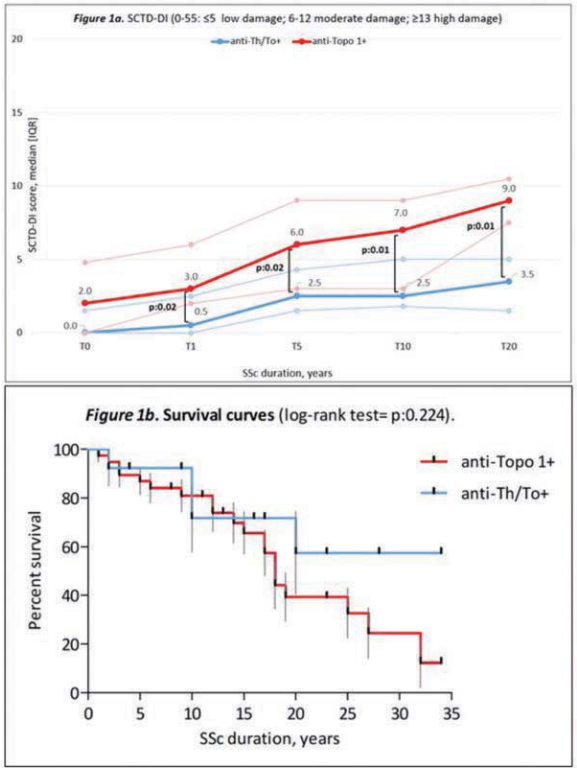

Figure 1.

2c) 4/13 patients died at 81 [75-86] years after 10 [8-13] years of disease duration, none due to SSc. The survival curves of the two groups are showed in Figure 1*b*.
Conclusion: In this cohort anti-Th/To patients showed a mild SSc phenotype, characterized by lower organ damage, more favorable long-term ILD functional outcome (although detectable in 40% of patients) and higher survival, as compared to matched anti-Topo 1 patients. Larger multicenter studies are needed to confirm these data.

PREVALENCE AND CLINICAL ASSOCIATIONS OF DIFFERENT AUTOANTIBODIES IN THE REUMA.PT SYSTEMIC SCLEROSIS COHORT: IS IT ALL REALLY SET IN STONE?

Background: Different autoantibodies (Ab) have been associated with distinct systemic sclerosis (SSc) phenotypes. Most of these associations have not been confirmed in Portuguese patients.

Objectives: To evaluate SSc immuno-clinical associations in the Rheumatic Diseases Portuguese Register (Reuma.pt) cohort.
Methods: Multicentre open cohort study including adult SSc patients registered in Reuma.pt up to February 2021. The associations between Ab expression and clinical data were established using Chi-Square, Fischer's Exact or Mann-Whitney U tests. The Bonferroni correction for multiple comparisons was applied to get $\alpha \leq 0.05$. Definite associations were defined by $p \leq 0.002$, and likely associations by $p \leq 0.05$.
Results: 1080 patients were included, with a mean age and disease duration of 60.2±14.6 and 12.4±10.0 years, respectively. Most were females (87.5%) and had white European ancestry (WEA, 93.2%). The most common disease subtypes were limited cutaneous (lcSSc, 57.4%), diffuse cutaneous (dcSSc, 17.7%), and very early diagnosis of SSc (VEDOSS, 12.3%). Most patients expressed antinuclear Ab (ANA, 93.4%), and the most frequent were anti-centromere (ACA, 54.6%), anti-topoisomerase I (Scl70, 21.8%), and anti-Pm/Scl Ab (PmScl, 4.7%).
ACA had definite positive associations with female sex, older age at diagnosis, lcSSc, lower modified Rodnan skin score (mRSS, median 0 vs 4), and isolated sclerodactyly, and likely associations with a higher diagnosis delay, WEA and VEDOSS. ACA had definite inverse associations with flexion contractures (FC), myositis, digital ulcers (DU), and interstitial lung disease (ILD), and likely inverse associations with pitting scars (PS) and oesophageal involvement (OI).
Scl70 had definite positive associations with male sex, dcSSc, higher mRSS, FC, DU, PS, ILD, and OI, and likely associations with younger age at diagnosis, tendon friction rubs, active scleroderma pattern in capillaroscopy, and heart involvement.
PmScl had a definite association with myositis and likely associations with male sex, calcinosis, joints involvement, and ILD. Anti-U1RNP Ab had definite associations with younger age at diagnosis, MCTD and myositis, and likely associations with a lower diagnosis delay, African ancestry and joint involvement. Anti-RNA polymerase III Ab (RP3) had likely associations with higher mRSS and renal involvement. Anti-U3RNP Ab had a definite association with dcSSc and likely associations with calcinosis and renal involvement. Anti-Th/To Ab had likely associations with male sex and myositis. Anti-Ku Ab had likely associations with systemic lupus erythematosus and mixed connective tissue disease (MCTD) overlap syndromes.
Conclusion: There was a higher prevalence of ACA and PmScl compared to other cohorts, most likely due to the high proportion of WEA patients. Most immuno-clinical associations described in the literature apply, including ACA with lcSSc and Scl70 with dcSSc, DU, PS and ILD. However, Scl70+ patients did not have an increased risk of renal involvement, and ACA+ patients did not have an increased risk for calcinosis, PAH or OI, contrary to what was described in the literature. New findings included the association of PmScl with ILD and Scl70 with an active pattern in capillaroscopy. Also, anti-U3RNP+ and Th/To+ patients did not have an increased risk of ILD or PAH, contrarily to what was previously reported. These nuances may be specific to the Portuguese SSc population or signal previously reported associations as geographically specific.

AB0697 DRAMATIC REDUCTION OF MORTALITY RATE BY TOFACITINIB IN ANTI-MDA-5 ANTIBODY-POSITIVE PATIENTS WITH RAPIDLY PROGRESSIVE INTERSTITIAL LUNG DISEASE

C. W. Tseng[1,2], M. Satoh[3], Y. M. Chen[1,2,4,5,6]. *[1]Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; [2]National Chung Hsing University, Department of Post-Baccalaureate Medicine, College of Medicine, Taichung, Taiwan, Republic of China; [3]University of Occupational and Environmental Health, Department of Clinical Nursing, School of Health Sciences, Kitakyushu, Fukuoka, Japan; [4]Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China; [5]National Chung Hsing University, Rong Hsing Research Center for Translational Medicine & Ph.D. Program in Translational Medicine, Taichung, Taiwan, Republic of China; [6]National Yang Ming Chiao Tung University, School of Medicine, College of Medicine, Taipei, Taiwan, Republic of China*

Background: Rapidly progressive interstitial lung disease (RP-ILD) is often seen in dermatomyositis patients with anti-melanoma differentiation-associated gene 5 (anti-MDA-5) antibody. They often have a poor prognosis with rapid decline in pulmonary function, leading to respiratory failure (1). Aggressive immunosuppressive therapy has been reported with improved prognosis, however; it may lead to opportunistic infections, including cytomegalovirus (CMV) or Pneumocystis pneumonia (PCP) infection (2, 3).
Objectives: This study aimed to evaluate the effectiveness of tofacitinib (TOF) in combination with CMV and PCP prophylaxis in anti-MDA-5-positive patients.
Methods: Medical records of 17 anti-MDA-5-positive RP-ILD patients enrolled during Mar 2017 to May 2021 were reviewed. RP-ILD was defined by the presence of deteriorated dyspnea, with a decrease in PaO2 levels and emerging radiographic anomalies within 4 weeks without evidence of infection (4). Chest CT was scored using Ichikado score (5). Clinical parameters including ferritin levels, white counts (WBC), Lactate dehydrogenase (LDH) levels, GAP scores (Gender, Age, and Physiology score for idiopathic pulmonary fibrosis) were recorded. Medications included cyclophosphamide (CyP), intravenous immunoglobulin (IVIG), mycophenolic acid derivatives (MPA), rituximab (RTX), and calcineurin inhibitor (CNI). Kaplan-Meier survival analysis and Log-rank test were used to evaluate one-year mortality differences (MedCalc version 19.6). The Ethics Committee approved our study (CE17038B).
Results: Six anti-MDA-5-positive RP-ILD patients were treated with tofacitinib; five had concomitant CMV prophylaxis with valganciclovir (VGCV); 4 had PCP prophylaxis with trimethoprim/sulfamethoxazole (TMP-SMX). Patients' demographic data are shown in Table 1. The median age, clinical manifestations, laboratory data, and chest CT scores were comparable between tofacitinib and non-tofacitinib groups. Prevalence of MPA use was higher in the non-TOF group. Kaplan-Meier survival analysis (Figure 1) indicated that patients with tofacitinib treatment (p=0.001), valganciclovir (p=0.003), and TMP-SMX (p=0.028) prophylaxis exhibited better 1-year survival rates compared with those without TOF therapy, VGCV, and TMP-SMX prophylaxis.

Table 1. Clinical characteristics of anti-MDA-5 antibody-positive patients with RP-ILD receiving tofacitinib vs non-tofacitinib treatment.

	Tofacitinib (n=6)	Non-tofacitinib (n=11)	*p* value
Age (years)	58 (42.3-77)	57 (50.0-62.0)	0.884
Female sex, n (%)	2 (33.3)	6 (54.5)	0.620

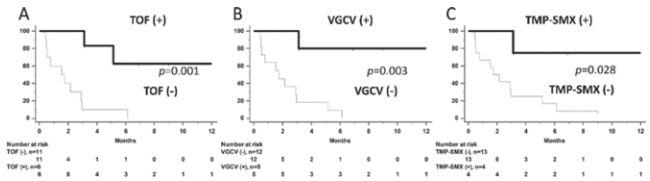

Figure 1.

Conclusion: The study demonstrated the efficacy of tofacitinib treatment in anti-MDA-5-positive RP-ILD. In addition, CMV and PCP prophylaxis appeared to improve in 1-year survival. Rheumatologists might consider TOF with prophylaxis as an option for anti-MDA-5-positive patients in daily practice.

AB0698 IMPACT OF ILOPROST WITHDRAWAL IN SCLERODERMA PATIENTS DUE TO COVID-19 PANDEMIC

L. Verardi[1], E. de Lorenzis[1,2], G. Natalello[3], L. Gigante[3], P. G. Cerasuolo[3], M. A. D'Agostino[3], S. L. Bosello[3]. *[1]Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Rome, Italy; [2]University of Verona-Verona, Italy., Ph.D. programme in Biomolecular Medicine-Cycle XXXV,, Verona, Italy; [3]Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Roma, Italy*

Background: Intravenous iloprost is currently recommended in the treatment of Raynaud's phenomenon (RP) refractory to oral therapy and of digital ulcers (DUs) related to systemic sclerosis (SSc). In real-life practice there is a huge heterogeneity about the Iloprost regimens used, because of a lack of specific recommendations. Coronavirus pandemic resulted in an unexpected emergency leading to sudden and synchronous withdrawal of programmed iloprost infusions for most SSc patients in March 2020, in order to limit virus dissemination. At the same time, lockdown forced people to stay at home, thus reducing the exposure to coldness. Both these unavoidable circumstances were close to an experimental condition, clearly non-replicable in routine conditions.
Objectives: The aim of the survey was to evaluate the consequences related to a sudden and simultaneous iloprost discontinuation in a cohort of SSc patients.
Methods: A telephone survey was carried out on SSc patients that interrupted Iloprost infusion at our centre. They were specifically asked to compare acral vascular symptoms just before Iloprost withdrawal, in February and just after the missed infusion in March (0-10 scale). Demographic and disease characteristics, severity and frequency of RP, new DUs onset or aggravation of those pre-existing were reported for each patient. Last available capillaroscopic images were also evaluated to assess the pattern.
Results: The analysis included 50 patients. After iloprost withdrawal, 11 patients reported a RP worsening because of enhanced intensity (4.6±2.1 vs 5.2±2.3, p=0.007). Only 8 patients of them also complained of an increased frequency (4.5±2.3 vs 5.0±2.4, p=0.07). None of the patients experienced digital ulcers for the first time during quarantine. Among the 27 patients with a history of digital ulcers, 9 reported worsening and 7 recurrences of DUs. Overall, 17 patients (34.0%) complained of a worsening of SSc vascular acral manifestations, namely RP or DUs. Disease and general features did not statistically correlate with worsening of RP except for reduced capillary density. Of note, each unit increase of capillary density corresponds to an average 44% decrease in the odds of RP worsening (OR 0.56, CI 95% 0.36-0.97, p=0.037). History of DUs - either active or former at the time of iloprost discontinuation - was the only clinical predictor of worsening of DU severity. As for RP worsening, the worsening of DU was associated with a lower capillary density.
Conclusion: Low capillary density can predict a worsening of both RP and DUs within a month after iloprost discontinuation in SSc patients. Further studies are needed to assess whether the capillaroscopy should be used to personalize iloprost regimen in SSc patients.

AB0699 DESCRIPTIVE STUDY OF A COHORT OF PATIENTS WITH DERMATOMYOSITIS IN A TERTIARY HOSPITAL.

R. J. Gil Velez[1], L. Mendez Diaz[1], I. Madroñal García[1]. [1]*Seville, Rheumatology, Seville, Spain*

Background: Idiopathic chronic inflammatory myopathies (IICM) are a heterogeneous group of rare diseases characterized by skeletal muscle inflammation. The incidence ranges from 1 to 60 new cases per 1,000,000 habitants/year and the prevalence between 2.4 and 34 per 100,000 habitants.The main symptoms are muscle weakness, which may be accompanied by contractures, pain, cramps or stiffness and symptoms related to localized disease in skin, lungs and other organs. Increased muscle enzymes and a myopathic pattern are seen on electromyography. Definitive diagnosis is made by muscle biopsy with lymphocyte infiltrates, necrosis and regeneration of muscle fibers.
Objectives: Description of the clinical characteristics of a cohort of patients diagnosed with dermatomyositis together with the study of the evolution: organic involvement, specific autoantibody profile and treatments performed in this population.
Methods: Descriptive study of a cohort of patients diagnosed with dermatomyositis at the Rocio Virgin University Hospital (Seville), during 2010-2022, obtained from medical records.
Results: Sixty patients were included, including 17 (28.3%), 43 (71.7%) women, whose mean age 58 +/-12 years, and mean time of diagnosis was 5 years. Among the types of inflammatory myopathies: dermatomyositis 37 (61.6%), amyopathic DM 6 (10%), antisynthetase syndrome 5 (8.3%), paraneoplastic 1 (1.6%) and rapidly progressive MDA5 7 (11.6%) Among the most frequent affections: pulmonary 20 (34%) being the most frequent NINE pattern 9 (45%), NIU 8 (40%); esophageal 20 (34%), cardiological 12 (20%).
Among the specific antibodies: ANA positive 24(40%), Ro 3(5%), La4(6.6%),JO1 6(10%),PL7 1(1.6%)PL12 1(1.6%),Mi2 1(,1.6%),SAE 3(5%),NXP2 2(3.3%),SRP 1(1.6%),MDA5 7(11.6%) and HMG-CoA 3(5%). Among the diagnostic tests MRI/electromyogram were positive 63% and 56.6% respectively. Biopsy was positive in 72%(42) of cases. The drugs used to induce remission were: cyclophosphamide 36 (60%), rituximab 12 (20%), immunoglobulins 6 (10%) and mycophenolate mofetil 6 (10%). As for the maintenance of remission: mycophenolate 54 (90%), methotrexate 3 (5%) and azathioprine 3 (5%). There was only one exitus caused by cardiac arrhythmia.
Conclusion: The results obtained have been in accordance with the published literature, with a clear association between specific autoantibodies and the different muscular and extramuscular manifestations. Among the remission inducers, the most frequent regimen used in our setting is the use of cyclophosphosmide/rituximab and maintenance of remission with azathioprine and mycophenonate. More studies on new therapeutic options are needed.

AB0700 HIGH BRONCHOALVEOLAR FLUID NEUTROPHILS INDEPENDENTLY PREDICT 15-YEAR MORTALITY IN SCLERODERMA PATIENTS WITH INTERSTITIAL LUNG DISEASE NAIVE TO IMMUNOSUPPRESSANTS

E. De Lorenzis[1,2], G. Natalello[1], L. Verardi[1], P. G. Cerasuolo[1], G. Alonzi[1], M. A. D'Agostino[1], S. L. Bosello[1]. [1]*Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Roma, Italy;* [2]*University of Verona-Verona, Italy., Ph.D. programme in Biomolecular Medicine-Cycle XXXV,, Verona, Italy*

Background: Scleroderma interstitial lung disease (SSc-ILD) has a variable and poorly predictable course. Data about the role of bronchoalveolar lavage fluid (BALF) analysis in prognostic stratification of SSc-ILD patients (pts) are conflicting.
Objectives: To assess BALF analysis role in prognostic stratification of SSc-ILD pts.
Methods: Forty SSc-ILD pts naive to immunosuppressants underwent comprehensive clinical evaluation, BALF analysis with total and differential leukocyte count, pulmonary function tests (PFTs), high-resolution computed tomography (HRCT) of the chest. All pts had fibrosing lung disease affecting more than 10% of lung volume on HRCT. Baseline alveolar and interstitial scores were computed. The 15-year crude mortality rate was retrospectively assessed.
Results: The enrolled pts (male 20%, aged 53.9±13 years) had a disease duration of4.3±3.4 years. Diffuse cutaneous involvement LeRoy variant was present in 47.5% of pts, while anti-Scl70 and anti-centromere antibodies were detected in 57.5% and 12.5% of pts, respectively. The average alveolar and interstitial scores were 6.5±4.8 and 6.2±2.7, respectively; 25% of the pts had FVC less than or equal to 80% and 35% had DLco less than or equal to 80%. During the follow-up, 18 pts (45%) received immunosuppressants. BALF neutrophilia (> 3%), eosinophilia (>1%) and lymphocytosis (>15%) were reported in 40%, 16% and 5% of pts, respectively. Twenty-five pts (62.5%) died within 15 years after bronchoscopy. Fifteen-year mortality was predicted by neutrophilia (HR 5.5, 95% IC 1.9-15.7), log-transformed total cell count (HR 2.5, 95% IC 1.1-5.7), absolute neutrophil (HR 1.8, 95% IC 1.3-2.5) and eosinophil (HR 1.3, 95% IC 1.1-1-6) cell counts, and macrophage (HR 0.1, 95% IC 0-0.6), neutrophil (HR 1.9, 95% IC 1.3-2.7), and eosinophil (HR1.3, 95% IC 1-1.7) percentages. Only absolute and relative neutrophil counts were independently associated with mortality also in regression models adjusted for demographics (age, gender), main disease traits (diffuse cutaneous variant, anti-Scl70 positivity), pulmonary function tests (FVC, DLco), HRCT involvement (alveolar and interstitial scores) and vascular complications (presence of pulmonary hypertension, digital ulcers).
Conclusion: High BALF neutrophils were associated with high 15-year mortality independently from established clinical risk factors. BALF analysis could improve prognosis prediction in SSc-ILD pts.

AB0701 FREQUENCY AND RISK FACTORS OF OSTEOPOROSIS IN MEN WITH SYSTEMIC SCLERODERMA

A. Sorokina[1], O. Dobrovolskaya[1], N. Demin[1], N. Toroptsova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, osteoporosis laboratory, Moscow, Russian Federation*

Objectives: To identify the frequency and risk factors of osteoporosis (OP) in men with systemic scleroderma (SSc).
Methods: 37 men with SSc were enrolled in the study: 19 (51,4%) with limited and 18 (48,6%) with diffuse cutaneous subtype. Patients with overlap rheumatic syndromes were not included. The median age was 56,0 [46,0; 61,0] years, the median duration of the disease was 6,0 [3,0; 9,0] years. 31 (83,8%) patients were treated with glucocorticoids (GC) > 3 months, the median duration of GC use was 3,7 [2,0; 7,0] years. Dual energy X–ray absorptiometry (DXA) of the lumbar spine (LS), the femoral neck (FN) and the total hip (TH) was performed. Osteoporosis (OP) was diagnosed with a T-score < -2.5 SD and osteopenia – with a T-score from -1SD to -2.5 SD at any region of interest. Z-score < -2 SD was used for diagnosis of OP in men < 50 years old. Spearman correlation between BMD and different factors was performed. Traditional and specific risk factors for OP were analyzed using univariate logistic regression analysis.
Results: The median LS BMD was 1,13 [1,03; 1,26] g/cm2, the FN BMD 0,95 [0,84; 0,99] г g/cm2 and the TH BMD - 0,99 [0,93; 1,06] g/cm2. Low BMD at least in one region of interest was detected in 19 (51,4%) patients: OP – in 8 (21,6%) (6 persons

50 years and older and 2 men < 50 years); osteopenia – in 11 (29,7%) men, without significant difference between the subtypes of the disease (p>0,05). 9 (24,3%) men had a history of low-trauma fracture, among them 2 (22,2%) patients had OP, 3 (33,3%) - osteopenia and 4 (44,4%) persons - normal BMD. 5 (27,8%) men with diffuse form and 3 (15,8%) - with limited cutaneous subtype had OP (p>0,05).
BMD in the LS correlated with uric acid (UA) (Rs = 0,59, p<0.05), BMD in the FN and BMD in the TH - with duration of the disease (Rs = -0,39, p<0.05 and Rs = -0,42, p<0.05, respectively), with duration of GC intake (Rs = -0,46, p<0.05 and Rs = -0,51, p<0.05, respectively), with the level of alkaline phosphatase (AP) (Rs = -0,54, p<0.05 and Rs = -0,46, p<0.05). In univariate logistic regression analysis, we found out that only the force vital capacity (FVC) was associated with OP (OR 15,19 [1.15; 199.79], p=0,04). There was no association between OP and other factors such as the duration of the disease or GC intake, the level of UC and AP.
Conclusion: OP was found in 21.6% of men with SSc. There was no statistically significant difference in the frequency of OP depending on the subtype of the disease. Among analyzed factors, only the FVC was positive associated with OP. Further research is needed.

AB0702 COEXISTENCE OF SYSTEMIC SCLEROSIS AND MICROSCOPIC POLYANGITIS ASSOCIATED WITH PULMONARY RENAL SYNDROME: A CASE REPORT AND LITERATURE REVIEW

Y. Jiang[1], Y. X. He[1], X. Liao[1], S. B. Wang[1], Y. F. Qing[1]on behalf of Institute of Research Center of Gout and Hyperuricemia of the Affiliated Hospital, North Sichuan Medical College. [1]*Affiliated Hospital of North Sichuan Medical College, Department of Rheumatology, Nanchong, China*

Background: Systemic sclerosis is a chronic immune disease characterized by varying degrees of fibrosis of skin and internal organs. Microscopic polyangitis, as a subtype of ANCA associated vasculitis, mainly involves small blood vessels, often manifested as necrotizing glomerulonephritis and pulmonary capillary vasculitis. Pulmonary renal syndrome is characterized by diffuse alveolar hemorrhage based on pulmonary capillary vasculitis and rapidly progressive glomerulonephritis, which can be derived from a variety of autoimmune diseases, of which ANCA associated vasculitis accounts for about 60%[1]. The cases of coexistence of systemic sclerosis and microscopic polyangitis associated with pulmonary renal syndrome in clinic are rare, which is often dangerous and is easy to miss diagnosis or misdiagnosis.
Objectives: To investigate the clinical characteristics, diagnosis and treatment of coexistence of systemic sclerosis (SSC) and microscopic polyangitis (M-PA) associated with pulmonary renal syndrome (PRS).
Methods: The clinical data, diagnosis and treatment process of a patient who has SSC combined with MPA and PRS were summarized and analyzed. And the literature was reviewed to explore the correlation of the pathogenesis and clinical experience of SSC complicated with MPA and PRS.
Results: The case is a middle-aged male who was diagnosed as SSc due to the hardening of the skin of both hands , Reynolds phenomenon, the anti-scl-70 antibody are positive. The patient suffered from repeated hemoptysis, progressive dyspnea, severe anemia and renal insufficiency, so he was diagnosed as MPA with PRS. After giving glucocorticoid, immunosuppressant and anti-infection treatment, his condition has improved. A total of 7 case reports were retrieved by reviewing the relevant literature.A total of 7 patients were reported.They were first diagnosed as SSc and then MPA with PRS, of which 4 cases improved after treatment and 3 cases died. Among the dead patients, 1 case was treated with penicillamine for 3 years, and the remaining 2 cases were only treated with steroids without immunosuppressants.In SSc, P-ANCA is closely related to vasculitis, and the prognosis of PRS secondary to P-ANCA may be very poor. Most of the diagnosis of MPA is only after patients have kidney or lung diseases.There is a certain correlation between them in pathogenesis. Glucocorticoids, immunosuppressants, biological agents, hemodialysis and plasma exchange are the main treatments.
Conclusion: Although the cases of SSc combined with MPA and PRS are rare, there are still many cases reported,which reminds us: ①When SSc patients have new symptoms such as renal insufficiency or lungs, they should be alert to new entities that may be combined with other autoimmune diseases to avoid missed diagnosis or misdiagnosis.②ANCA should be detected in SSc patients at baseline, which may be related to disease activity.③PRS has rapid progress and high mortality, whcih is an emergency that needs urgent treatment. Such patients should be treated with glucocorticoid, immunosuppression and plasma exchange immediately. However, if patients are complicated with SSc, they need to be extra careful when using high-dose steroids, which increases the risk of renal crisis.

AB0703 THE NEED FOR ANTI-OSTEOPOROTIC THERAPY IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Sorokina[1], N. Demin[1], O. Dobrovolskaya[1], N. Toroptsova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, osteoporosis laboratory, Moscow, Russian Federation*

Objectives: To determine the need for anti-osteoporotic therapy in postmenopausal women and men over 50 years of age with systemic sclerosis (SSc).
Methods: The study included 150 patients with SSc who met the ACR/EULAR 2013 criteria: 124 (82,7%) postmenopausal women and 26 (17.3%) men over 50 years of age. Median age was 59,0 [54,0; 64,0] years. The duration of the disease was 8,0 [5,0; 14,5] years. A history of fragility fractures was collected. FRAX was calculated in patients without prior fractures to identify patients at high risk of low-energy fractures. Dual-energy X-ray densitometry (DXA) was performed in persons at moderate risk of fractures, and 10-year probability of major osteoporotic fractures was recalculated with the inclusion of a hip neck T-score. DXA was also performed on all patients from the low-risk group who had 2 or more risk factors of OP.
Results: 36 (24%) patients had a history of fragility fractures: 21 (16.9%) women and 6 (4.3%) men - vertebrae fracture, 8 (6.5%) women - peripheral fractures, 1 (3.8%) man – hip fracture.
The calculation of the 10-year probability of fractures by FRAX showed that 21 (16,9%) women had a high risk, and another 60 women and 3 men had moderate risk of fractures. After the FRAX recalculation with the inclusion of the femoral neck T-score, only 26 (21,0%) women moved from the moderate-risk group to the high-risk group. All men and 48 women had a low risk of osteoporotic fractures according to FRAX, among them 12 (8,0%) people (4 men and 8 women) had osteoporosis by DXA.
Thus, among SSc patients 84 (67.7%) women and 11 (42,3%) men needed anti-osteoporotic treatment.
Conclusion: As a result of a comprehensive assessment of the risk of fractures and OP, it was found that 63.3% of patients with SSc needed anti-osteoporotic treatment.

LOW BODY MASS INDEX IN PATIENTS WITH RAYNAUD PHENOMENON IS ASSOCIATED WITH ENLARGED CAPILLARIES AND REDUCTION IN CAPILLARY DENSITY AT NAILFOLD VIDEOCAPILLAROSCOPY

G. Natalello[1], L. Verardi[1], C. Policola[2], L. Gigante[1], P. G. Cerasuolo[1], F. Sciarascia Mugnozza[1], G. Alonzi[1], E. De Lorenzis[1,3], S. Della Casa[2], M. A. D'Agostino[1], S. L. Bosello[1]. *[1]Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Roma, Italy; [2]Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Unit of Endocrinology, Roma, Italy; [3]University of Verona-Verona, Italy., Ph.D. programme in Biomolecular Medicine-Cycle XXXV,, Roma, Italy*

Background: Increased prevalence of peripheral vascular symptoms like Raynaud's phenomenon (RP) and acrocianosis is reported in anorexia nervosa (AN) and correlates with a more severe malnutrition.
Objectives: We aimed to characterize nailfold video capillaroscopy (NVC) abnormalities in patients with RP and BMI<18.5 kg/m2, according to adipokine levels, compared to subjects with RP and normal BMI.
Methods: We performed NVC in 21 female patients with primary RP with BMI<18.5 kg/m2, in 18 patients with primary RP and normal BMI, and in 18 patients classifiable as VEDOSS (Very Early Diagnosis of Systemic Sclerosis) and normal BMI, using a video-capillaroscope. Fingers two to four were evaluated bilaterally. Mean and minimum capillary density were registered for each patient, as well as maximum diameter and number of enlarged and giant capillaries, number of micro-haemorrhages and micro-thrombosis. We scored the frequency of enlarged capillaries considering the percentage of dilated capillaries out of the total. Demographic and clinical features of all patients were recorded.
Results: Patients with RP and low BMI presented a great number of elementary alterations on NVC; some of these modifications were typical of the scleroderma pattern. The percentage of enlarged capillaries was more than 33% of the total in 17(81%) patients with RP and low BMI with respect to 9(50%) of patients with RP and normal BMI (p=0.041). Furthermore, the number of megacapillaries was higher in patients with RP and low BMI compared to patients with normal BMI, while the maximum diameter of capillaries was comparable. Eight patients with low BMI presented a picture resembling an early scleroderma pattern (44%). The frequency of micro-thrombosis, micro-hemorrhages and microaneurysms were comparable in the twogroups. Patients with RP and low BMI presented a lower mean capillary and minimum capillary density compared to patients with RP and normal BMI (mean density: 7.4±1.4vs8.2±1.4,p=0.031; minimum density:4.8±1.0 vs5.4±1.0,p=0.05). Patients with RP and low BMI presented a comparable frequency of enlarged capillaries, number of megacapillaries when compared with patients with VEDOSS. Leptin and chemerin levels were lower in patients with low BMI with respect to patients with normal BMI (57.5±35.6vs124.2±92.0pg/mL, p<0.001; 46.9±11.9vs58.3±17.2 ng/mL, p=0.017, respectively); adiponectin levels were comparable.
Conclusion: Patients with low BMI and primary RP presented a great frequency of enlarged capillaries and a reduction of capillary density when compared with patients with normal BMI. The increased number of microvascular abnormalities on NVC in patients with low BMI reminds the NVC findings typical of early scleroderma, supporting the hypothesis of an endothelial dysfunction in such patients

CHANGES OF LUNG FUNCTION AND SKIN FIBROSIS IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS ON RITUXIMAB THERAPY - COMPARISON OF THE EFFICACY OF BIOSIMILAR ACELLBIA AND MABTHERA

L. Garzanova[1], L. P. Ananyeva[1], O. Koneva[1], O. Desinova[1], O. Ovsyannikova[1], M. Starovoytova[1], R. Shayakhmetova[1], A. Khelkovskaia-Sergeeva[1]. *[1]V A Nasonova Research Institute of Rheumatology, Laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: Rituximab (RTX) has shown itself as an effective option in treatment of interstitial lung disease associated with systemic sclerosis (ILD-SSc). However, there is not enough data on the effect of rituximab biosimilars in patients (pts) with SSc. Biosimilars could reduce price and increase pts access to expensive, but more efficient biologic therapy. The RTX biosimilar Acellbia (ACB) was registered in Russian Federation for all indications consistent with RTX.
Objectives: To study changes of lung function and skin fibrosis in pts with ILD-SSc on ACB therapy in comparison with original RTX (Mabthera (MBT) during 1 year of follow-up.
Methods: This prospective study included 62 pts received RTX as an addition to previous therapy, when it was ineffective. The mean follow-up period was 12.9±2.2 months. 31 pts received MBT (group 1) and 31 pts received ACB (group 2). All pts had ILD. In group 1 the mean age was 42.2±12.3 years, female-25 pts (81%), the diffuse cutaneous subset of the disease had 21 pts (68%). The mean disease duration was 5.3±3.5years. 91% of pts were positive for ANA and 77% of them were positive for antitopoisomerase-1. All pts received prednisolone at a dose of 11.2±3.9 mg/day, immunosupressants (IS) at inclusion received 39% of them. The cumulative mean dose of RTX was 1.5±0.5g. In group 2 the mean age was 48.7±11.3 years, female-23 pts (74%), the diffuse cutaneous subset of the disease had 16 pts (52%). The mean disease duration was 6.2±7.1years. 88% of pts were positive for ANA, 36% of them were positive for antitopoisomerase-1. All pts received prednisolone at a dose of 10.6±4.5mg/day, IS at inclusion received 42% of them. The cumulative mean dose of RTX was 1.4±0.5g. The results are presented in the form of mean values and standard deviations, delta(Δ)-difference between the baseline parameter and follow up point, median, lower quartile and upper quartile.
Results: There was an improvement of all evaluated parameters in both groups: decrease of Rodnan skin score (mRSS) and activity index(EScSG-AI), increase of forced vital capacity % predicted (FVC), diffusion capacity for carbon monoxide % predicted (DLCO) and 6-minute walk distance (Table 1). Both groups managed to reduce the mean dose of prednisolone. B-lymphocyte depletion persisted in both groups. When we compared changes (Δ) of the parameters between groups - no significant difference was obtained (Table 1).

Table 1. Changes of the main parameters at RXT therapy in delta (Δ); median; lower quartile; upper quartile.

Parameters	Group 1	P for Group 1 (between baseline and follow-up point)	Group 2	P for Group 2 (between baseline and follow-up point)	P between group 1 and 2
Δ mRSS	4.7±5.6 [2; 0; 10]	0.0001	4.3±4.1 [3; 0; 8]	0.0001	NS
Δ FVC, % pred	4.9±5.6 [5.8; 1.8; 7.8]	0.0001	4.7±5.5 [3.1; 0.9; 7]	0.0002	NS
Δ DLCO, % pred	2.3±5.1 [1.4; -0.6; 5.5]	0.03	2.5±3.8 [2; 0.8; 4.9]	0.001	NS
Δ Activity Index (EScSG-AI)	2±1.9 [2; 0; 3.5]	0.0001	1.8±1.5 [2; 1; 2]	0.0001	NS
Δ B-lymphocyte, absolute count	0,221±0,16 [0.185; 0.09; 0.33]	0.0001	0,216±0,17 [0.135; 0.09; 0.34]	0.0001	NS
Δ 6-minute walk distance, m	60.4±67.5 [42.5; 10; 91]	0.008	55.1±42.6 [52.5; 13; 90]	0.0003	NS
Δ Prednisolone, mg/day	2.03±2.1 [2.5; 0; 5]	0.0006	2.1±2.7 [2.5; 0; 5]	0.0004	NS
Cumulative mean dose of RTX, g, M±σ	1.5±0.5	-	1.4±0.5	-	NS

Conclusion: Our prospective study showed the similar effectiveness of ACB in comparison with MBT in ILD-SSc. There was a significant improvement of lung function tests and decrease of skin fibrosis. RTX has been shown the positive effect even at low doses (less than 2 g). ACB has shown a good efficacy for therapy ILD-SSc, but studies with a large number of patients are required.

AB0706

DEMOGRAPHIC, CLINICAL AND SEROLOGICAL CHARACTERISTICS IN IDIOPATHIC INFLAMMATORY MYOPATHIES. THE ROLE OF SPECIFIC ANTIBODIES

X. E. Larco Rojas[1], S. Sáez-Álvarez[2], P. Pérez-García[1], C. Sieiro Santos[1], I. González Fernández[1], C. Moriano[1], A. López Robles[1], M. Martín Martín[1], C. Álvarez Castro[1], E. Diez Alvarez[1]. *[1]Complejo Asistencial Universitario de León, Rheumatology, León, Spain; [2]Complejo Asistencial Universitario de León, Pathology, León, Spain*

Background: Idiopathic Inflammatory myopathies are a heterogenous group of diseases which main common characteristic is muscle injury. Specific autoantibodies related with different phenotypes have become an important diagnostic and prognostic tool. These antibodies may be associated with different histopathological features in muscle biopsies.
Objectives: To describe the demographic, clinical and serological characteristics of Idiopathic Inflammatory Myopathies (IIM); the most frequent corticoid sparing agents used and the frequency of associated neoplasms in a sample of patients with a compatible biopsy result. To compare these characteristics in patients with positive and negative ANA and the association of different biopsy patterns with specific myositis antibodies.

Methods: Muscle biopsies results that were compatible with inflammatory myopathy were collected from the Pathology Unit database of Leon´s hospital between January 2010 and March 2021.Demographic, clinical and serological characteristics, associated malignancies and treatments used were collected from clinical records.
Results: We included 30 patients in the study. Patient`s characteristics are shown in Table 1. Median age of diagnosis was 59 years. Arthritis and lung disease were found in 20% of patients. The patterns of lung involvement found in HRCT were NSIP in 2, UIP in 1, and bronchiectasis in 3 patients. Associated collagenopathies were found in 26,7%, being vasculitis the most frequent (2 patients). Associated Malignancies were found in 13,3%: lung carcinoma in 1, Urothelial carcinoma in 1, cervix carcinoma in 1 and prostate carcinoma 1 patient. Specific myositis antibodies were negative in 56,7%; positive ANA was found in 60%.

Table 1. Demographic, clinical, serological characteristics and treatment in the sample studied

Characteristics	Patients (n=30) Median; IQR or n(%)
Age at diagnosis (years)	59; 18,5
Sex F/M	17(56,7)/13(43,3)
Artralgias	11(36,7)
Arthritis	6(20)
Raynaud	3(10)
Lung disease	6 (20)
Skin disease	7 (23,3)
Autoimmunity biomarkers (+/-/ not done)	
ACPA	2(6,7) /3 (10) /25(83,3)
Positive Rheumatoid Factor	4(13,3) /13 (43,3) /13(43,3)
ANA	18 (60%) /12(40%)
Specific Myositis Antibodies	
Anti SRP	1(3,3)
Anti-HMG CoA reductase	5 (16,7)
Anti Jo1	2(6,7)
Negative	17 (56,7)
Not done	5 (16,4)
Biopsy pattern	
necrotizing	8 (26,7)
inflammatory	15(50)
Inclusion Bodies	4 (13,3)
dermatomyositis	3 (10)
Diagnosis	
Dermatomyositis	3 (10)
Statin Myopathy	5(16,7)
Inclusion body myopathy	3(10)
Polymyositis	8(26,7)
Immune-mediated necrotizing myopathy	2 (6,7)
Antisynthetase syndrome	1(3,3)
Other collagenopathies	8(26,7)
Treatment	
Methotrexate	11(36,7)
Azathioprine	3(10)
immunoglobulins	5(16,7)
Rituximab	5(16,7)
Mycophenolate	4(13,3)
Cyclophosphamide	2 (6,7)
None	11 (36,7)
2 or more treatments	8(26,7)
Associated malignancies	4 (13,3)

The median of levels at diagnosis of CK was: 1181; IQR:6252,5; aldolase 14,4; IQR: 34,65; AST 62; IQR:181,25; ALT 55,5; IQR:119,25; CRP 7,6; IQR 13,55. When compared, CK and ALT levels in patients with negative and positive ANA, this were higher in negative patients (6365; IQR:9592vs888;3045; P=0.044) and (182; IQR:287vs43; 85; P=0,035) respectively. Anti HMGCoA reductase antibodies were more frequently found in patients with necrotizing pattern in biopsies 5/8 patients; (62,5%); p=0.002. Methotrexate was the corticoid sparing agent most frequently used (36,7% of patients), 36,7% of patients were treated only with corticoids and 26,7% needed more than one treatment.
Conclusion: Specific myositis antibodies are helpful tools in the diagnosis when present, meanwhile biopsy can be an important tool when antibodies are negative. ANA positivity seems to be associated with milder disease at the muscular domain.

AB0707 CHANGES OF IMMUNOGLOBULIN G AND FREQUENCY OF INFECTIONS IN SYSTEMIC SCLEROSIS PATIENTS DURING LONG-TERM RITUXIMAB THERAPY

L. Garzanova[1], L. P. Ananyeva[1], O. Koneva[1], O. Ovsyannikova[1], O. Desinova[1], M. Starovoytova[1], R. Shayakhmetova[1], A. Khelkovskaia-Sergeeva[1]. [1]*V A Nasonova Research Institute of Rheumatology, Laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: Decrease of immunoglobulin G (IgG) could often be observed during rutuximab (RTX) therapy in systemic sclerosis (SSc) and other autoimmune diseases. Lower lever of IgG could be associated with an increased risk of secondary infectious complications. However, there are very few data on changes of IgG in SSc during long-term RTX therapy.
Objectives: To evaluate changes of Ig G and the frequency of infectious adverse events (AE) in SSc patients (pts) on RTX therapy during long-term follow-up.
Methods: Our prospective study included 78 pts with SSc received RTX therapy. The mean follow-up period was 50.2±23 months. The mean age was 48.2±13.7 years, female-64 pts (82%), the diffuse cutaneous subset of the disease had 48 pts (62%), limited - 24 (31%), overlap - 6 (7%). The mean disease duration was 5.4±3.4 years. 92% of pts were positive for ANA and 71% of them were positive for antitopoisomerase-1. All pts received prednisolone at a dose of 11.8±4.1 mg/day, immunosupressants at inclusion received 40% of them. The IgG was evaluated over the periods: at baseline (point 0), 12-18 mo (point 1), 24-60 mo (point 2) and 66-84 mo (point 3) after initiation of RTX therapy. IgG levels was measured using ELISA. Normal IgG reference values ranged within 7.0-16.0 g/l. AE were assessed and recorded by a physician at a hospital immediately after the infusion of RTX, then by patient reported outcome during the observation period. Severe AE were defined as those that required hospitalization for more than 24 hours and life-threatening situations. The results are presented in the form of mean values and standard deviations.
Results: There was a significant decrease of IgG during RTX therapy (Table 1). However, the level of IgG remained within normal limits. Initially lower level of IgG had 6 pts (8%). And further at point 1 there was 12 pts (15%) with decrease of IgG below normal limits, at point 2 - 12 pts (15%) and at point 3 - 5 pts (6%). When we compared the level of IgG between point 2 and 3 - no significant differences were found.

Table 1. Changes of IgG level during RTX treatment.

Parameters	Point 0 (n=78)	Point 1 (n=78)	Point 2 (n=76)	Point 3 (n=27)	P Point 0-1	P Point 0-2	P Point 0-3
IgG, g/l, M±σ	12.3±4.2	10.6±3.4	9.6±2.8	9.6±2.6	0.0001	0.0001	0.01
Cumulative mean dose of RTX, g, M±σ	-	1.8±0.5	3.9±1.3	4.8±2.1	-	-	-

AE was evaluated over the period of 335.4 patient-years (PY). Infectious AE were reported in 34 patients (44%), the overall frequency was 10.2/100 PY (95% Confidence Interval (CI) 7.1-13.8). No serious opportunistic infections were reported. The highest frequency of infectious AE was observed in the first 2-6 months after the first infusion of RTX, however these were mainly mild AE (82%). The frequency of serious infections was 1.8/100 PY (95% CI 0.7-3.8). There was a decrease of infectious AE in the follow-up period (4.4/100 PY, 95% CI 2.5-7.2 – at period from 24 month of RTX therapy).
Conclusion: In our study, a significant decrease of IgG was noted in SSc pts during the first 5 years of RTX therapy, but later its level stabilized and remained within normal limits. A decrease of IgG in the first year after the initiation of RTX therapy was accompanied by an increase in the frequency of infectious AE. However, with an increase of the cumulative dose of RTX, there was no increase in infectious AE. Monitoring of IgG levels may be useful for SSc pts on RTX therapy for early identification of the risk for developing infectious complications.

AB0708 ANALYSIS OF THE PERFORMANCE OF COMMERCIAL TESTS IN THE DETERMINATION OF MYOSITIS-SPECIFIC AND MYOSITIS-ASSOCIATED AUTOANTIBODIES: PREVALENCE AND CORRELATION WITH DIAGNOSIS OF IIM

E. Pedretti[1], F. Angeli[1], M. Fredi[1], I. Cavazzana[1], L. Andreoli[1], E. Garrafa[2], F. Franceschini[1]. [1]*ASST Spedali Civili of Brescia, Rheumatology and Clinical Immunology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy;* [2]*ASST Spedali Civili of Brescia, Central Laboratory of Chemical-Clinical Analysis, Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy*

Background: Idiopathic Inflammatory Myopathies (IIM) are a group of disorders sharing the common feature of immune-mediated muscle injury. In IIM autoantibodies specific for (MSA) or associated to (MAA) myositis are present in 60-65% of cases (1). Although only anti-Jo-1 (2) are included in the EULAR 2017 criteria, the presence of MSA allows to identify clinical and prognostic phenotypes.

Objectives: Aim of the work is to evaluate the positivity rate on sera analyzed by a line blot (LB) immunoassay able to detect MSA or MAA, the associated clinical diagnoses and the consistency with the antibody specificity.
Methods: 267 sera were analyzed using a commercial LB (Autoimmune Inflammatory Myopathies 16 Ag Profile EUROLINE) between March 2017 and March 2021. The diagnosis was identified by analyzing the medical records.
Results: A positivity for at least one MSA/MAA was found in 118/267 sera (44.2%); MAA isolated in 22% of cases and a double/multiple positivity for MSA in 12.7%. The distribution of antibody positivity and the associated clinical diagnoses are shown in Table 1.

Table 1. Autoantibody distribution and associated clinical diagnosis; for some patients there are multiple positivity

	Autoantibody specificity				Consistent diagnosis	
	Total positivity n. (%)	Isolated positivity n. (%)	Concomitant presence of at least one MAA n. (%)	Concomitant presence of MSA +/- MAA n. (%)	n. (%)	Type of IIM

DM: Dermatoyositis, PM: Polymiositis, ASS: Antisynthetase Syndrome, CAM: Cancer-Associated Myositis, CADM: Clinical Amyopatic Dermatomyositis, ILD: Interstitial Lung Disease

In our cohort, the most common antibodies were anti-Ro52kD, positive in 33 sera (28%), while the most frequent MSA were anti-Mi-2, positive in 27 sera (22.9%). MSA most frequently found as an isolated positivity were anti-Oj (75%), while anti-Jo-1 as an isolated positivity were present only in 25% of cases. Considering the 118 sera with at least one MSA/MAA a diagnosis of IIM was made in 52 cases (44%); in 11 cases others systemic autoimmune diseases were identified. The consistency between antibody specificity with the clinical diagnoses was analyzed: for some antibodies, as anti-Jo-1 (80%), anti-MDA5 (75%) and anti-Tif-1gamma (75%), LB results were consistent with clinical diagnoses; while for others, as anti-Mi-2 (18,6%) and anti-SRP (12,5%), the agreement was lower.
Conclusion: The use of LB in the diagnostic workout of IIM allowed the detection of MSA previously not found with routine methods. In our court low prevalence of anti-Jo-1 was found. This may be justified by the fact that anti-Jo-1 are included in the assays routinely used to identify anti-ENA antibodies, therefore these sera were not tested with an additional LB. With LB, a higher prevalence of double/multiple MSA positivity was found, compared to the 0.1% described with immunoprecipitation (IP) (3). LB give a semiquantitative result: low, medium or high titer, so the analysis of different titers, according with clinical data or IP, could be helpful in the interpretation of the co-existence of multiple MSA (4).

AB0709 SLEEP DISTURBANCES AND RHEUMATIC DISEASES – A CASE-CONTROLLED CROSS-SECTIONAL STUDY

S. P. Silva[1], C. Mazeda[1], J. P. Vilas[1], G. Eugénio[1], A. Barcelos[1]. [1]*Centro Hospitalar Baixo Vouga, Rheumatology department, Aveiro, Portugal*

Background: Rheumatic diseases may affect all aspects of life, including sleep[1]. Sleep disorders are common and potentially debilitating in these diseases, and the reason for this disturbance seems to be multifactorial.
Objectives: Evaluate the prevalence of sleep disturbance and its association with demographic-clinical factors in patients with Systemic Sclerosis (SSc) and Rheumatoid Arthritis (RA).
Methods: We conducted a cross-sectional study on patients, aged ≥18, who fulfilled the ACR/EULAR 2013 classification criteria for SSc and ACR/EULAR 2010 classification criteria for RA. Socio-demographic and clinical data was collected. Patients answered the Health Assessment Questionnaire (HAQ), Hospital Anxiety and Depression Scale (HADS), Functional Assessment of Chronic Illness Therapy (FACIT) Fatigue Scale and Pittsburgh Sleep Quality Index (PSQI) questionnaires. Sleep disorders were considered when PSQI was >5[2]. Differences between groups were assessed and variables with statistical significance in the univariate analysis were included in a multivariate logistic regression model, adjusted to age and sex. $p \leq 0.05$ was considered significant in all analysis.
Results: Fifty-six patients (28 with SSc and 28 with RA) agreed to participate in this study, of which 47 (83.9%) were female, with a median age of 61 years old (IQR 14). Most of our patients (73.2%) had a sleep disturbance, fatigue (80.4%) and disability (89.3%). Twenty patients (35.7%) suffered from anxiety and 10 (17.9%) from depression. A statistically significant association was found between sleep disturbances and the disease, its duration and body mass index (BMI). FACIT, HAQ and HADS-A, but not with HADS-D, were also associated (Table 1). When comparing diseases, there was no differences between gender, age, and BMI, however duration of disease was superior in RA patients (p<0.001) (Table 1). On the other hand, the SSc group showed worse mean scores in HAQ and PSQI compared with RA group (Table 1). Though, sleep disturbance was not associated with any clinical feature of SSc. Although SSc [3.882 (1.056-14.276), p=0.041], FACIT [0.883 (0.812-0.960), p=0.004], HAQ [4.223 (1.204-14.818), p=0.024] and HADS-A [1.257 (1.057-1.495), p=0.010] were predictors of sleep disorder in the univariate analysis, their effect disappeared in the multivariate logistic model.

Table 1. *Differences between sleep disorders and between Systemic Sclerosis and Rheumatoid Arthritis*

Characteristics	Without sleep disorder (n=15)	Sleep disorder (n=41)	P value	SSc group (n=28)	RA group (n=28)	P value
Age (year) Median (IQR)	55 (16)	61.50 (13)	0.059	60.50 (14)	61 (15)	0.941
Female gender N (%)	13 (86.7%)	34 (82.9%)	0.736	24 (85.7%)	23 (82.1%)	0.716
Disease duration (months) Median (IQR)	144.00 (156.00)	66.00 (60.00)	0.007*	60 (60)	120 (126)	<0.001*
BMI Median (IQR)	22.51 (6.47)	27.26 (6.95)	0.054	27.26 (7.92)	24.65 (6.06)	0.440
FACIT Median (IQR)	40.50 (12.25)	31.50 (18.00)	0.001*	33.00 (22.75)	36.00 (12.50)	0.522
HAQ Median (IQR)	0.438 (0.563)	0.813 (1.50)	0.022*	0.875 (1.625)	0.500 (0.563)	0.037*
HADS-A Median (IQR)	6.50 (5.50)	10.00 (5.00)	0.008*	9.50 (5.00)	8.00 (7.50)	0.229
HADS-D Median (IQR)	6.50 (5.00)	7.50 (5.00)	0.100	8.00 (4.75)	6.00 (5.00)	0.105
PSQI Median (IQR)				12.00 (7.25)	7.00 (7.50)	0.021*
Sleep disorder N (%)				24 (85.7%)	17 (60.7%)	0.035*

Legend: IQR - Interquartile Range.

Conclusion: In our cohort, sleep disturbances were highly prevalent, and we found a significant association between those and SSc, FACIT, HAQ and HADS-A. However, we didn't find a predictor of this disturbance in the multivariate analysis. New studies with large number of patients are warranted.

AB0710 STUDY OF THE GASTROINTESTINAL INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS

J. Bernardez Moreno[1], L. Berbel Arcobe[2], J. L. Tandaipan Jaime[3], J. Torguet Carbonell[1], G. Ghio[1], E. Riera Alonso[1], S. Martinez Pardo[1]. [1]*Hospital Universitari MútuaTerrassa, Rheumatology, Terrassa, Spain;* [2]*University General Hospital of Catalonia, Rheumatology, Sant Cugat del Vallès, Spain;* [3]*Hospital Dos de Maig, Rheumatology, Barcelona, Spain*

Background: Systemic Sclerosis (SSc) is a systemic autoimmune disease in which the gastrointestinal (GI) manifestation is one of the most frequent complications (90%), being esophagus and anorectal the most affected regions. The set of GI symptoms poses a diagnostic and therapeutic challenge, and the "Patient Reported Outcomes" (PRO) are good tools to address them. The UCLA GIT 2.0 validated questionnaire can be used as an instrument to measure the presence and severity of these symptoms, allowing screening, and improving subsequent management.
Objectives: To describe gastrointestinal (GI) involvement in patients with SSc.
Methods: Descriptive cross-sectional study conducted in a cohort of patients with SSc in a tertiary hospital. Sociodemographic, clinical, complementary tests and treatment variables were collected. Patients with established GI involvement needed to have urdergone some previous diagnostic test. The UCLA GIT 2.0 questionnaire was applied to all included patients, considering the presence of mild symptoms with a score of 0-0.49, moderate 0.49-1, and severe 1-3.
Results: 88 patients (90% women) were recruited, with a mean age of 61.3 years. They presented the subtypes of limited and diffuse SSc in 63.3% and 13.6%, respectively. The most frequent antibodies were anticentromere (ACA) in 52.3% of the patients, anti-Ro52 in 20.5% and anti-topoisomerase I in 14.8%. The most frequent manifestations were Raynaud's phenomenon in 98.8% of the patients followed by GI in 37.5% (gastro-esophageal reflux in 88.2%), diffuse interstitial lung disease in 18% and pulmonary hypertension in 10.22%. The most used treatment was proton pump inhibitors (PPI) in 47.7% of the patients. Patients with GI involvement presented the limited SSc subtype (72.7%) and ACA (60.6%) as main characteristics. Patients without digestive involvement had similar characteristics, but did not show a greater association with any specific antibody (p=0.321). 67% of the total number of patients presented a score greater than 0 in the UCLA GIT 2.0 questionnaire, with the reflux section being the most frequent (52.27%). In relation to the total score, they presented mild, moderate, and severe symptoms in 77.3%, 21.6% and 1.1% of the patients respectively. The rest of the results by categories are summarized in Table 1.

Table 1.

	Gastrointestinal involvement (n= 34)	Without gastrointestinal involvement (n= 54)
Subtype and antibodies		
Limited	24 (70,58%)	32 (59,25%)
Diffuse	5 (14,70%)	7 (12,96%)
ACA	20 (58,82%)	26 (48,14%)
ATA	5 (14,70%)	8 (14,81%)
Manifestations and treatment		
ILD	5 (14,70%)	11 (20,37%)
PAH	3 (8,82%)	6 (11,11%)
PPI	31 (91,17%)	11 (20,37%)
UCLA GIT 2.0 (median)		
Total score	0,30	0,05
Reflux	0,35	0
Swelling	0,62	0
Stain	0	0
Diarrhea*	0	0
Social functioning	0	0
Emotional well-being	0,22	0
Constipation ǂ	0	0

ILD (intersticial lung disease), PAH (pulmonary arterial hypertension), ACA (anti-centromere), ATA (anti-topoisomerase), PPI (proton pump inhibitors). *In the "diarrhea" subcategory the maximum score is 2. ǂ In the "constipation" subcategory the maximum score is 2,5.

Patients with GI pathology presented higher scores (moderate-severe) compared to those without pathology (p=0.009). In this last group, 34.5% of the patients presented GI symptoms according to the test, observing high scores in the bloating, reflux, and constipation sections in 25.2%, 16.6% and 14.8% of the patients respectively.
Conclusion: GI involvement tends to be one of the most frequent manifestations in our cohort and occurs more frequently in patients with limited skin involvement and ACA +. Patients with established GI pathology had higher scores on the UCLA test. The questionnaire may be useful in detecting undiagnosed patients, but more studies are necessary to establish this possible correlation.

AB0711 THE IMPACT OF ANEMIA ON SYSTEMIC ORGAN DAMAGE IN SYSTEMIC SCLEROSIS

Z. H. Li[1], T. Li[1], R. Mu[1]. [1]*Peking University Third Hospital, Rheumatology, Beijing, China*

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease with multiple organ damage. Scleroderma Clinical Trials Consortium (SCTC) has developed the Damage Index (DI) in SSc to quantify organ damage in SSc[1]. Anemia has been implicated as an independent prognosis factor for mortality and organ complications in systemic sclerosis (SSc), while the relationship between anemia and the weighted organ damage index has not been reported.
Objectives: To determine the degree and feature of organ damage in SSc patients with or without anemia in a population of patients from Peking University Third Hospital SSc cohort (PKUTH-SSc).
Methods: Patients were recruited from PKUTH-SSc between January, 2010 and December, 2021. The diagnosis of anemia was based on the reduced hemoglobin (Hb) concentrations (<120g/L for female and <135g/L for male). The demographics, clinical characteristics, laboratory parameters, autoantibodies medication and SCTC-DI were collected. Student's t-test and Chi-square were used.
Results: As shown in Table 1, a total of 155 patients were enrolled in PKUTH-SSc cohort, 70 (45.2%) patients developed anemia, older and lower BMI than non-anemia patients. The inflammatory indices, ESR and CRP, were higher in anemia patients, indicating anemia was more common in patients with active disease. Consistent with the result that the positive rate of anti-SSA and anti-SSB antibody was higher in anemia patient, the sicca symptoms were also reported in nearly half of anemia patients. In anemia patients, the Gastrointestinal system related damage, Oesophageal dysmotility, Pseudo-obstruction and weight loss, and renal damage were more frequently discovered. Moreover, anemia patients were more likely to develop moderate to high organ damage risk, demonstrating the necessary of regular organ damage follow-up for anemia patients.

Table 1. Clinical parameters and SCTC-DI of SSc patients with or without anemia

	Anemia N=72	Non-anemia N=83	*p* value
Age at baseline (years)	54.43±1.88	49.64±1.32	0.034*
BMI (kg/m2) (meanyear	20.49±0.40	22.46±0.39	<0.001*
ESR	32.48±3.06	16.67±1.83	<0.001
CRP	1.20±0.22	0.64±0.11	0.014*
Anti-SSA	22 (31.4%)	13 (15.3%)	0.017*
Anti-SSB	8 (11.4%)	1 (1.2%)	0.018*
Musculoskeletal and skin	2.22±.22u	1.11±.11u	<0.001*
Sicca symptoms	31 (44.3%)	22 (25.9%)	0.016*
Vascular	0.67±.67u	0.59±.59u	0.628
Gastrointestinal	2.09±.09r	1.31±.31r	<0.001*
Oesophageal dysmotility	27 (38.6%)	18 (21.2%)	0.018*
Pseudo-obstruction	5 (7.1%)	0 (0.0%)	0.017*
BMI<18.5 kg/m^2 or weight loss >10% in the last 12 months	40 (57.1%)	31 (36.5%)	0.010*
Respiratory	2.24±.24i	1.59±.59i	0.132
Cardiovascular	0.94±.94i	0.66±.66i	0.468
Renal	0.21±.21l	0.00±.00l	0.027*
History of SRC	4 (5.7%)	0 (0.0%)	0.040*
SCTC-DI	8.37±.37-	5.25±.25-	<0.001*
Moderate to high damage score	48 (68.6%)	31 (36.5%)	<0.001*

Conclusion: Anemia is associated with distinct organ damage behaviors and higher disease progression risk in SSc. Specifically Sicca symptoms and gastrointestinal, renal system were more common in SSc patients with anemia.

Background: A significant number of Systemic sclerosis (SSc) patients with Raynaud's phenomenon (RP) experience digital ischemic complications (DICs-digital ulcers, digital pitting/scars, gangrene and/or amputation).
Objectives: We reviewed the prevalence & risk factors for DICs in SSc-RP and compared treatment patterns among patients with & without DICs.
Methods: SSc patients meeting ACR/EULAR 2013 classification criteria that underwent an upper extremity arterial study between 2001-2018 were included. Clinical characteristics, treatment for RP, use of antiplatelet (aspirin 81 mg), statin therapy & occurrence of DICs, digital occlusive arterial disease (DOAD) on laser doppler flowmetry (LDF) and macrovascular disease (MVD) on duplex US were abstracted. Risk factors for DICs and their associations with therapy were evaluated.

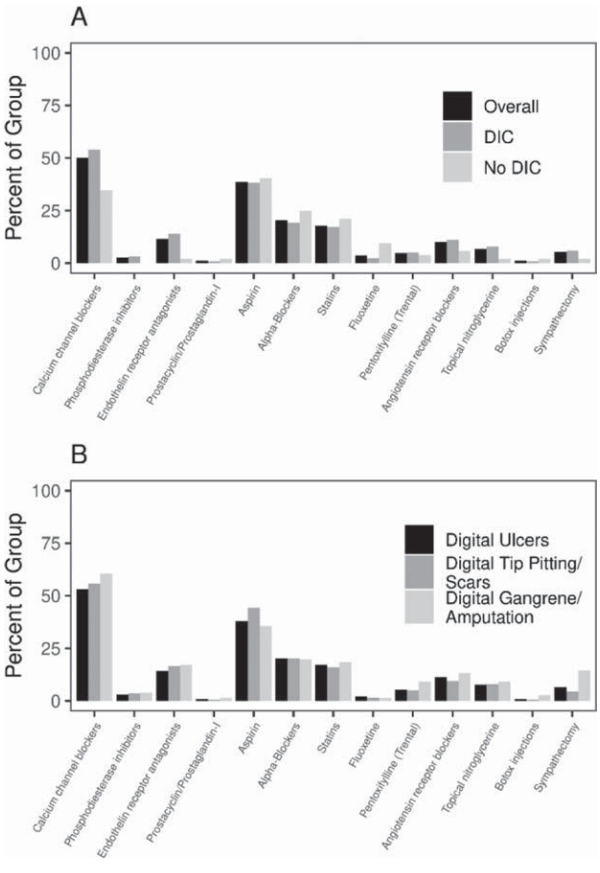

Figure 1.

Results: We identified 273 SSc patients (mean age 57±13 y, 81% F, 93% Caucasian, mean disease duration 4.8 ± 7.1 y). Cohort characteristics are described in Table 1. 79% (217/273) patients experienced DICs (digital ulcers 203, digital pitting/scar 138, digital gangrene 76). Patients with DICs had a higher prevalence of DOAD (89% vs 54%, p <0.001), MVD (32% vs 9%, p <0.001), ILD (41% vs. 27%, p=0.04), calcinosis (95/192 (49%) vs. 7/44 (16%), p<0.001), and pericardial effusion (25% vs. 12%, p=0.047), compared to those without DICs. No difference was noted between the 2 groups in regard to skin severity, smoking, BMI, hypertension, hyperlipidemia, diabetes, coronary artery disease, telangiectasias, pulmonary hypertension, renal crisis, GI dysmotility or myositis. Treatment patterns are described in Figure 1. Calcium channel blocker (CCB) and phosphodiesterase 5 inhibitor (PDE5I) use was higher among SSc patients with DICs than in those without DICs (CCBs: 53% vs. 34%, p=0.01; PDE5: 29% vs. 2%, p=0.01) likely due to confounding by indication. The use of aspirin or statins was not associated with DICs, even after adjusting for CV risk factors (ASA: OR 0.83, 95% CI 0.45-1.54; statin OR 0.67, 95% CI 0.28-1.62).
Conclusion: Our study confirms a high prevalence of DICs in SSc, with digital ulcers occurring in nearly 75% patients. A higher risk of DICs is associated with DOAD, MVD, ILD, calcinosis and pericardial effusion. While there is a significantly higher utilization of vasodilators among patients with DICs, the utilization of antiplatelet therapy and statins was not different among these groups. Whether this suggests a lack of evidence supporting their use in clinical practice, or inefficacy in preventing DICs remains unclear and warrants further study.

AB0713 **CALCINOSIS CUTIS - INDEPENDENT RISK FACTOR FOR ALL-CAUSE MORTALITY IN SSC PATIENTS**

N. Cristina[1], L. Groseanu[1,2], S. Petrescu[1], A. Balanescu[1,2], D. Opris-Belinski[1,2], D. Predeteanu[1,2], V. Bojinca[1,2], F. Berghea[1,2], I. Saulescu[1,2], D. Mazilu[1,2], A. Borangiu[1,2], M. M. Negru[1,2], C. Cobilinschi[1,2], M. Abobului[1,2], M. Duna[1], S. Daia-Iliescu[1,2], C. L. Constantinescu[1,2], V. Vlad[1], R. Ionescu[1,2]. [1]*St Mary Hospital, Internal Medicine and Rheumatology, Bucharest, Romania;* [2]*Carol Davila University of Medicine and Pharmacy, University of Medicine and Pharmacy, Bucharest, Romania*

Background: Calcinosis is a common and disabling complication of systemic sclerosis (SSc) with poorly understood pathogenesis and no effective treatment. Little is known about the etiology of this condition and management is essentially based on case studies and series.
Objectives: The objectives of this study were to describe the prevalence and characteristics of calcifications, and to investigate the relationships between calcinosis and clinical features in a population of patients with SSc.
Methods: This was a single center descriptive and retrospective study of patients treated at "Saint Mary" Clinical Hospital in Bucharest since January 2000 for SSc. Demographic and clinical features, including duration of disease progression, symptoms and parameters related to a specific organ involvement according to MEDS evaluation sheets, were evaluated in all patients. For testing

the association between nominal variables chi-square test was performed while independent t test was used to compare the differences between subgropus. Logistic regression analysis was used to predict the risk of all-cause mortality.
Results: 154 SSc patients were selected in the database, from which we identified a final group of 31 (20%) patients with calcinosis related to systemic sclerosis. The calcinosis cohort comprised 25 females and 6 males, with a mean age of 52.6 (±14.3) years, most of them with diffuse subset (16/31). Mean disease duration was 5.6 years (±3.1). Mean modified Rodnan skin score (mRSS) was 9.46 (±3.4) and mean adjusted EScSG activity index in the subgroup with calcinosis was 3.6 (±1.9). 45.16% (14/31) patients from the calcinosis subgroup developed interstitial lung disease (ILD) vs 43.9%; pulmonary hypertension was seen in 51.6% (16/31) cases vs 10.5% (13/123). As expected, calcifications were closely associated with vascular (p=0.004) and gastrointestinal (p=0.001) involvement and pulmonary hypertension (p=0.049). Moreover, associations were stronger for severe gastrointestinal involvement defined as chronic intestinal pseudo-obstruction (p=0.001). Females (p=0.024), patients with digital ulcers (p=0.004), those with disease duration longer than 10 years (p=0.001), those with pulmonary hypertension (p=0.049) and patients with gastrointestinal involvement (p=0.044) presented significantly more calcinosis. There were no significant associations between calcinosis and disease activity, myositis, interstitial lung disease, type of scleroderma or autoantibodies. Furthermore, in the logistic regression equation we identified calcinosis as a risk factor for all-cause mortality in SSc patients [OR:2.607 (CI:1.062,6,397), p=0.037].
Conclusion: Calcinosis cutis is a common manifestation is patients with SSc regardless of skin subset and type of autoantibodies. It seems to occur more often in patients with long-standing disease and is more commonly associated with vascular involvement such as digital ulcers and pulmonary hypertension. Furthermore, the present study has demonstrated that calcinosis could be an important prognostic factor when it comes to predict mortality. Given the fact that the management of calcinosis in scleroderma is an unmet need in almost half of patients with long-standing disease duration, systematic clinical trials are required to find effective measures to prevent this complication.

AB0714 LOW BONE MINERAL DENSITY AND INCREASED FREQUENCY OF OSTEOPOROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS – A CASE-CONTROL STUDY

K. Lillpers[1,2], K. Andréasson[1,2], F. Mcguigan[3], K. Åkesson[3,4], R. Hesselstrand[1,2]. *[1]Lund University, Department of Clinical Sciences Lund, Lund, Sweden; [2]Skåne University Hospital, Department of Rheumatology, Lund, Sweden; [3]Lund University, Department of Clinical Sciences Malmö, Malmö, Sweden; [4]Skåne University Hospital, Department of Orthopedics, Malmö, Sweden*

Background: Systemic sclerosis is an autoimmune disease characterized by fibrosis and vascular involvement. Osteoporosis, as a comorbidity among patients with systemic sclerosis is poorly described.
Objectives: The aim of this cross sectional case-control study was to investigate bone mineral density and prevalence of osteoporosis in patients with systemic sclerosis compared to controls.
Methods: We included 211 patients, 182 females and 29 males, with systemic sclerosis and 506 controls, individually matched for age and sex and from the same catchment area in the very south of Sweden. All participants underwent dual-energy X-ray absorptiometry (DXA). Bone mineral density (BMD, g/cm^2) and T-score were measured in lumbar spine L1-L4 and total hip. For patients, disease characteristics were obtained. Students T-test, one-way ANOVA or Chi-square test were used to compare groups and Pearson´s test for correlations. Osteoporosis (T-score ≤ -2.5) and osteopenia (T-score -1.0– -2.5) were defined using WHOs definitions.
Results: Systemic sclerosis patients had a mean (SD) age of 61.5 (13.5) and a mean (SD) disease duration from diagnosis of 9.2 (8.0) years. BMD (g/cm^2) was significantly lower in patients compared to controls: Total hip (SD) 0.874 (0.147) vs 0.941 (0.145) (p=<0.0001); lumbar spine 1.089 (0.170) vs 1.126 (0.195) (p=0.015). Total hip mean T-score difference between groups was -0.52 (95 % CI -0.67– -0.34). The frequency of osteoporosis was 14.7% vs 9.7% and of osteopenia 51.2% vs 41.2% in patients compared with controls (p=0.001). Only one (3.4%) of the male patients had osteoporosis but nearly half of them had osteopenia. In patients, we evaluated vascular features. Those with telangiectasias had lower total hip BMD than those without (p=0.026). Among patients with early disease (<2 years), a higher total hip BMD was observed compared to patients with longer disease duration (p=0.001). The difference was not seen in spine BMD. Features of fibrosis were not associated with BMD, ie there were no difference in BMD between patients with diffuse or limited disease or antibody status.
Conclusion: Patients with systemic sclerosis have lower BMD and osteoporosis is more frequent than among controls matched for age and sex.

AB0715 ANTI-MDA5 DERMATOMYOSITIS AFTER BNT162B2 VACCINATION

D. Astorri[1], L. Nalotto[1], E. Vaccaro[1], V. Carraro[1], L. Bernardi[1], L. Punzi[1,2], C. Bernardi[1]. *[1]Ospedale S.S. Giovanni e Paolo, Rheumatology Unit, Venezia, Italy; [2]Rheumatology Network, Veneto Region, Venezia, Italy*

Background: Background: Anti-Melanoma Differentiation-Associated gene 5 (MDA-5) Dermatomyositis (MDA5, DM) is a rare systemic autoimmune disease, characteristically associated with Rapidly Progressive Interstitial Lung Disease (RP-ILD) and cutaneous manifestations. Anti-MDA5 dermatomyositis may develop in genetically predisposed subjects after environmental exposure such as vaccines, infections and neoplasms (1). Myalgia is one of the main symptoms related to SARS-COV2 infection and sometimes may occurs after COVID-19 vaccine administration (2). However, only few cases have reported the occurrence of severe inflammatory myopathies after COVID19 vaccine administration (3)
Objectives: To describe a case of Anti-MDA5 Dermatomyositis occurred after BNT162b2 vaccine administration
Methods: This is a case of a 44 year-old-patient affected by Anti-MDA5 Dermatomyositis occurred after BNT162b2 vaccination referred at the Center for Rheumatic Diseases in Venice, Italy
Results: A 44 year-old-woman presented to the Center for Rheumatic Diseases in Venice, suffering from a cutaneus rash on her face, upper limbs, décolleté, gluteus and lower limbs occurred two days after the first dose BNT162b2 vaccination (Figure 1). A few days after the second dose of the vaccine the rash got worse and myalgias, strength deficiency and fatigue occurred. Elevated inflammatory and myocytolysis parameters were detected (Table 1). After chest HRCT a mild ILD was diagnosed. Muscle edema was detected with whole-body short tau inversion recovery (STIR)-MRI (Figure 1).The Skyn biopsy showed features of dermatomyositis with perivascular inflammatory infiltrates. 1 mg/Kg/die of prednisone was administered and then cyclosporine 3mg/kg/die was associated with clinical benefit.

Table 1. Clinical and laboratory characteristics of the patient

Age (years)	44
Sex	Female
Previous Rheumatological diagnosis	-
Previous Vaccination reaction	-
Time to onset COVID 19 vaccination	2 days
MMT-8*	124/150 (150/150)
Blood Tests	
Hb* (12-16 g/dl)	11,5 g/dl
CRP* (< 5 mg/L)	23,4 mg/L
AST* (31 U/L)	98 U/L
ALT* (1-34 U/L)	63 U/L
CPK * (10-145 U/L)	1085 U/L
Aldolase (0-7,6)	13,2 U/L
SARS-CoV-2 RT PCR	negative
Autoantibodies	
ANA*	1:1280 nucleolar
Myositis antibodies	Anti-MDA5
HLA- DRB1	03-04
HLA-DQB	02-03

MMT-8 MANUAL MUSCLE TESTING; Hb Hemoglobin; WBC withe blood cells count; CRP C-reactive proteine; AST Aspartate amino transferase; ALT Alanine amino transferase; CPK creatinine phosphokinase; ANA anti nuclear antibodies, ENA extractable nuclear antigens; HLA HumanLeukocyte Antigen

Conclusion: In rare cases COVID-19 vaccination could induce inflammatory myopathies (3). COVID-19 vaccine administration may have acted as a trigger for the myopathy driven by an autoimmune-mechanism. In such cases, it could be useful to investigate inflammatory myopathies, requiring blood tests (e.g. myocytolysis indices and anti myositis antibodies) and medical instrumental insights, in patients affected by skin manifestation and muscle pain occurred after vaccine administration. Although the association between vaccination and inflammatory

myopathies is presumptive, the temporal proximity of the BNT162b2 vaccine to the onset of the signs and symptoms related to the inflammatory miopathies may suggest a possible relationship between these two events. To the best of our knowledge this is the first case of Anti-MDA5 Dermatomyositis occurred after BNT162b2 vaccination.

AB0716 CHARACTERISTICS OF 4 CASES OF PL - 7 POSITIVE ANTISYNTHATASE SYNDROME: INTERSTITIAL LUNG DISEASE BEING A MORE COMMON FEATURE THEN MYOSITIS

C. Rosa[1], K. Chaudhuri[1], G. Kasavkar[1], A. Price-Forbes[1], S. Banerjee[1]. *[1]University Hospital Coventry & Warwickshire, Rheumatology, Coventry, United Kingdom*

Background: Anti synthetase syndrome is a heterogeneous group of auto immune diseases characterised by antibodies against aminoacyl t RNA synthetase, associated with interstitial lung disease, myositis, arthritis and Raynaud's phenomenon. Anti PL 7 antibody is rare, present in only 1-4% patients with anti synthetase syndrome.

Objectives: To describe clinical characteristics PL – 7 positive patients with anti-synthatase syndrome.

Methods: In this retrospective study, cohort of patients with inflammatory myositis were screened for anti PL-7 antibody positivity and 4 cases were detected. Diagnosis was made based on either 2017 EULAR/ ACR classification criteria and/ or Bohan and Peter criteria. [1, 2] Clinical manifestations, investigations including antibody profile, treatment and treatment response were described.

Results: Of the 4 patients, 3 were female and age of onset varied from 36 to 69 years. Only 1 patient presented with proximal muscle weakness while three patients with dyspnoea. Joint involvement and Raynaud's phenomenon was present in 2 patients. Two patients had scleroderma spectrum manifestations. Three patients had elevated CK during the disease course with maximum values being 228, 594 and 1200 with only one having muscle weakness. One patient had dermatomyositis and 2 patients had mechanic's hand. HRCT patterns were usual interstitial pneumonia(UIP), nonspecific interstitial pneumonia(NSIP) and fibrosing NSIP with organising pneumonia. Three patients had anti Ro antibodies. All patients were treated with steroids, one each received Cyclophosphamide and Azathioprine initially however all the patients ended up with Mycophenolate mofetil—which controlled disease effectively without flare.

Conclusion: In Anti PL – 7 positive patients, interstitial lung disease is much more common than myositis. Mechanic's hands and scleroderma overlap appear to be a common association. Additionally, antibody positivity with Anti Ro/Ro52 was also noted. One patient had features of dermatomyositis including facial rash which is extremely rare for PL7. All of these patients responded very well to Mycophenolate.

Background: Plain pelvic radiographs are the most common imaging modality used in the first line for diagnosis of axial Spondyloarthritis (axSpA). However, evaluation of the sacroiliac joint on two-dimensional plain radiographs may lead to misinterpretation among the evaluators.
Objectives: To investigate the diagnostic power of deep learning models in conventional radiographs of the patients with axSpA.
Methods: The study included 320 axSpA patients and 348 healthy controls (age; 34.5±15.3/38.2±10.6, p=0.072; gender (male) 53.8%/46.3%, p=0.064). Sacroiliitis was confirmed on sacroiliac MRI according to the Assessment of Spondyloarthritis International Society (ASAS) definition. The contrast equalization was preprocessed with the Clahel (Contrast-Limited Adaptive Histogram Equalization) filter. Then, classification was performed with Alexnet, VGG16, resnet101 and resnet50 models. As a result of the trials, the best result was achieved with resnet50. Four different filtering scenarios were applied (Clahel filter cliplimit 0.25, Clahel filter cliplimit 0.50, clahel filter 1.00 and no filter).Two different cropping processes were performed on the direct radiographs, and uncropped, cropped at pelvic borders, cropped images close to the sacroiliac joint were applied to the deep learning model. Meanwhile, all images were also evaluated by 3 rheumatologists for the presence of sacroiliitis.
Results: According to the results of 4 different scenarios studied with the Resnet50 model, the best result was obtained with the RESNET50 Model + Clahel filter clipLimit 0.50. With this model, after applying the clahel filter with a coefficient of 0.5 to the full resolution data, we achieved 0.8135 success in the separation of AS and normal. A kappa error of 0.0561, Cohen's Kappa Error = 0.6267, Fscore 0.8022 (AS), 0.8253 (normal) were obtained. After applying the clahel filter with a coefficient of 0.5 with Resnet50 to the pelvic data, we achieved 0.625 success in separation of AS and normal. Kappa error 0.0694, Cohen's Kappa Error=0.2400, Fscore 0.5399 (AS), 0.6838 (normal) values were obtained. After applying the Clahel filter with a coefficient of 0.5 with Resnet50 to the sacroiliac data, we achieved 0.61 success in the separation of AS and normal. Kappa error 0.0696, Cohen's Kappa Error=0.2131, Fscore 0.5517 (AS), 0.6549 (normal) values were obtained. As a result of the evaluation of the radiographs by the clinician, Cohen's kappa was 0.452 and accuracy was 0.73 for the first rheumatologist; Cohen's kappa 0.132 and accuracy 0.56 for the second rheumatologist and Cohen's kappa 0.362 and accuracy 0.68 for the third rheumatologist were found.
Conclusion: Application of RESNET50 Model + Clahel filter ('clipLimit', 0.5, 'Distribution', 'rayleigh') on uncropped images showed higher precision in diagnosing sacroiliitis from conventional radiographs compared to other filtering scenarios. Our results were found to have higher accuracy than the evaluation of three rheumatologists.

Table 1. Precision and kappa values of Resnet50 model, 4 different filtering scenarios and 2 different clipping operations

	Accuracy	Cohen's kappa (CI)
*RESNET50+no filter	0.7306	0.4509 (0.3234-0.5785)
*RESNET50 Model+ Clahel filter (0,25)	0.6943	0.3889 (0.2590-0.5189)
*RESNET50 Model+ Clahel filter (0,50)	0.8135	0.6267 (0.4186-0.7555)
*RESNET50 Model+ Clahel filter (1,00)	0.6839	0.3552 (0.2213-0.4890)
**RESNET50 Model+ Clahel filter (0,50)	0.625	0.2400 (0.1523-0.3245)
***RESNET50 Model+ Clahel filter (0,50)	0.610	0.2131 (0.1121-0.3430)

AB0718 **IMMUNE-APHERESIS IN PATIENTS WITH INFLAMMATORY MYOPATHIES, A CASE SERIES.**

K. Kastrati[1], H. Rajab[1], A. Rader[1], E. A. Aichner[1], T. M. Karonitsch[1], H. Kiener[1], D. Aletaha[1], M. Bonelli[1], H. Radner[1]. [1]*Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine 3, Vienna, Austria*

Background: Idiopathic inflammatory myopathies (IIM) comprise a heterogenous group of autoimmune diseases characterised by inflammation of muscle and affection of other organs, such as lung or skin. Some cases of IIM non-responsive to conventional treatment with glucocorticoids and DMARDs require treatment escalation. There are only limited data on efficacy and safety of immune-apheresis (IA) in IIM patients.
Objectives: This retrospective cohort study aims to determine whether IA is effective in treating therapy-refractory IIM.
Methods: Patients with active IIM undergoing IA (either plasma-exchange or immunoadsorption) at the Medical University Vienna were included in this explorative study. Patient characteristics and clinical data including serum levels of creatine kinase and concomitant medication were extracted from electronic medical records. As a primary endpoint, efficacy of IA was evaluated four weeks after initiation of IA, calculating absolute and relative change of CK-values as well as changes in steroid dose. Secondary endpoints included absolute and relative changes of CK-values at week 8 and week 12.
Results: From 2000 to 2021 25 IIM patients treated with IA were identified, 24 could be used for further analyses. Patient characteristics at start of IA are displayed in Table 1. Subtypes of IIM included dermatomyositis (DM 54.2%), polymyositis (PM 8.3%), Overlap-Myositis (20.8%), mmune-mediated-necrotising-myositis (IMNM 8.3 %), and antisynthetase syndrome (ASS 8.3 %). The majority of patients received concomitant steroid therapy (87.5 %) and DMARD therapy (62.5 %).

Table 1. Cohort descriptives:

Population, n (n= female%)	24 (n=19;79.2 %)	
Age at Baseline (years; mean [SD];)	42.5 [11.5]	
Subtyp Myositis (%,n)		
-Dermatomyositis	54.2 % (13)	
-Polymyositis	8.3 % (2)	
-Overlap-Myositis	20.8 % (5)	
-Immune mediated necrotising myositis	8.3 % (2)	
-Anti-Synthetase-Syndrom	8.3 % (2)	
Immune Apharesis within 4 weeks (number of cycles)	mean: 9.54, median: 9.5, [IQR: 8; 11.5]	
Previous DMARDs (%,n)		
-Any DMARDs		
-Mean number of previous DMARDs amongst all 24 patients	62.5% (15)	
-Azathioprin	33.3% (8)	
-Methotrexat	45.8% (11)	
-Rituximab	16.7% (4)	
-Mycophenolat mofetil	16.7% (4)	
-Cyclophosphamid	8.3% (2)	
-Ciclosporin	8.3% (2)	
-(Hydroxy)-Chloroquin	20.8% (5)	
-Etanercept	4.2% (1)	
-Infliximab	4.2% (1)	
Concomitant DMARDs (%,n)		
-Any DMARDs	62.5% (15)	
-Azathioprin	20.8% (5)	
-Methotrexat	20.8% (5)	
-Rituximab	4.2% (1)	
-Cyclophosphamid	4.2% (1)	
-Ciclosporin	4.2% (1)	
-(Hydroxy)-Chloroquin	8.3% (2)	
Concomitant Steroids % (n)	87.5% (21)	
-Dose prednisone at Baseline (mg/day; median [IQR])	25 [12.5; 50] (21)	
-Dose prednisone at week 4 (mg/day; median [IQR]	12.5 [0; 37.5] (22)	
CK-level at baseline (U/ml; median [IQR])	970.5 [157.5; 3795.5]	
Change in CK-values from baseline	*Absolute change*	*Relative change*
-to week 4 (n=24)	*median [IQR] U/ml*	*% [IQR]*
-to week 8 (n=16)	304.5 [28.8;2051]	49.1 [22.4; 79.3] %
-to week 12 (n=15)	648.5 [25.8; 3939.3]	70.0 [13.6; 87.7] %
	559 [-7; 3988]	63.8 [-5.8; 98.1] %

Until week 4 significant decrease in CK-values was observed in 21/24 patients (p<0.01; Figure 1), from median 970.5 [157.5; 3795.5] to 347[63; 1010] U/ml. Median [IQR] dose reduction of steroids was 12.5 [0; 12.5] mg/day absolute and 25% [0%, 100%] relative. No differences were observed within patients of different myositis subtypes. One patient died after 4 weeks, in 15 patients IA was maintained until week 12. Significant reduction in CK-values was observed from baseline to week 8 and 12 respectively (141 [78; 460], 111 [57;338]. Median and relative changes from baseline until week 12 are displayed in Table 1.

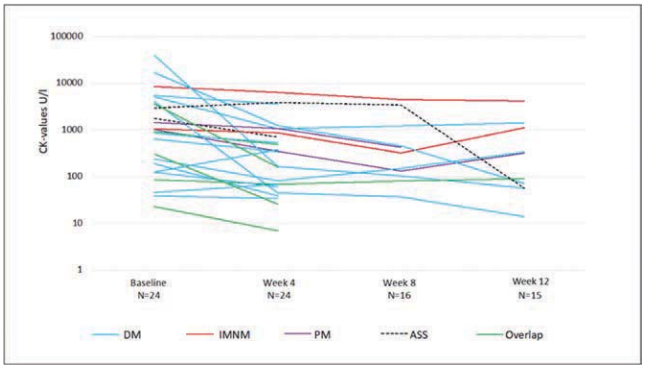

Figure 1. Individual response in CK-levels from baseline to week 12

Conclusion: Immune-apheresis seems an effective therapeutic option in refractory IIM, leading to decrease of CK-values and steroid dose.

AB0719 ECONOMIC BURDEN IN SCLERODERMA

L. Martin Calderon[1], M. Chaudhary[2], J. Pope[3]. *[1]Western University, Internal Medicine, London, Canada; [2]Western University, Medicine, London, Canada; [3]Western University, Rheumatology, London, Canada*

Background: Scleroderma (SSc) is a multi-system autoimmune disease, characterized by vasculopathy and fibrosis of the skin and internal organs, associated with substantial morbidity and disability. Patients with SSc commonly require considerable healthcare resources resulting in significant economic impact.

Objectives: The purpose of this systematic review is to provide a narrative summary of the economic impact and healthcare resource utilization associated with SSc.

Methods: MEDLINE and EMBASE were searched without language restriction from inception to January 20th, 2021. Studies were included if they provided information regarding total, direct, and indirect medical costs including medication, diagnostic test, and assistive devices costs. The cost of SSc complications was additionally collected. Included observational studies had risk of bias assessments through the Joanna Briggs Institute cross-sectional and case series checklists, and the Newcastle-Ottawa Cohort and Case-Control study scales.

Results: The search retrieved 1777 studies, of which 33 were included representing 20 cross-sectional, 10 cohort, and 3 case-control studies. Studies used various methods of calculating cost including prevalence-based cost-of-illness approach, bottom-up cost analysis, humanistic approach, and health resource units cost analyses. Overall scleroderma total annual medical cost ranged from USD $14,959-$23,268 in USA, CAD$10,673-$18,453 in Canada, €4,607-€30,797 in Europe, and AUD $7,060 to $11,607 in Oceania. Annual cost for SSc associated with interstitial lung disease and pulmonary arterial hypertension was USD $31,285-$55,446 and $44,454-$63,320, respectively.

Conclusion: Globally, SSc represents high patient and systemic economic burden. SSc-associated complications increase economic burden and are variable depending on geographical location, and access.

AB0720 ADULT ONSET STILL'S DISEASE: POINTS TO CONSIDER

L. Martin Calderon[1], J. Pope[2,3]. *[1]Western University, Internal Medicine, London, Canada; [2]Western University, Rheumatology, London, Canada; [3]St. Joseph's Hospital, Rheumatology, London, Canada*

Background: Adult-onset Still's disease (AOSD) is a rare and complex autoinflammatory disease of unknown etiology. AOSD has a heterogeneous presentation which can lead to diagnostic uncertainty with prolonged time prior to treatment. NSAIDs, glucocorticoids, conventional DMARDs, and biologics are used in the management of AOSD with varying results. Furthermore, factors associated with de-escalation of therapies remain unclear.

Objectives: To review the literature and create a consensus on points to consider in the diagnosis, prognosis, and treatment of AOSD.

Methods: A scoping review of the AOSD literature over the last 15 years was performed. MEDLINE and EMBASE were searched and studies included if they provided information regarding the epidemiology, differential diagnosis, diagnostic criteria, complications, prognosis, and initial, chronic, and refractory treatment approaches in AOSD. Following narrative information synthesis, a meeting was held with experienced clinicians across Canada for the creation of a consensus on points to consider in AOSD.

Results: The annual incidence and prevalence of AOSD is observed to be between 0.16 to 0.62 per 100,000 and 3.9 to 6.9 per 100,000, respectively. AOSD most commonly affects young adults and women. Women are more likely to have severe complications from AOSD including macrophage activation syndrome, disseminated intravascular coagulation, or thrombotic thrombocytopenic purpura. The Yamaguchi criteria remains the most widely used diagnostic tool with a sensitivity of 96.2% and specificity of 92.1%. Common presentation manifestations include intermittent high fevers (>39.0 degrees Celsius), arthralgias/arthritis, pharyngitis, lymphadenopathy, and a maculopapular rash. Other manifestations can variably involve the cardiovascular, respiratory, and GI systems. Common laboratory abnormalities include leukocytosis with neutrophilia, elevated ESR and CRP, elevated ferritin, and transaminitis. AOSD patients are most commonly ANA and Rf negative. Initial treatment includes NSAIDs, glucocorticoids, and conventional DMARDs. Disease refractory to initial therapy is managed through IL-1 and IL-6 inhibitors such as Anakinra or Tocilizumab. Elevated ESR, pericarditis, and non-response to corticosteroids are some of the factors associated with refractory and chronic disease requiring advanced therapies and long term follow-up.

Conclusion: AOSD is a multi-faceted autoinflammatory disease with a diverse presentation profile. Clinicians are recommended to consider AOSD, following exclusion of infections, malignancies, and autoimmune diseases, as a cause for fever of unknown etiology. Our review provides points to consider in the diagnosis and management of AOSD following expert consensus.

AB0721 FROM UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE TO IDENTIFIABLE DISEASE: PRECURSORS OF SYSTEMIC SCLEROSIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

L. Martin Calderon[1], J. Pope[2,3]. *[1]Western University, Internal Medicine, London, Canada; [2]St. Joseph's Hospital, Rheumatology, London, Canada; [3]Western University, Rheumatology, London, Canada*

Background: The pathogenesis of systemic lupus erythematosus and systemic sclerosis is characterized by derangements of the innate and adaptive immune systems, and inflammatory pathways leading to autoimmunity, chronic cytokine production, and chronic inflammation. Diagnosis is rooted in meeting established criteria. However, in pre-clinical states criteria is not fulfilled but biochemical and autoimmune derangements are present. Understanding the underlying processes responsible for disease pathogenesis in pre-clinical states, which place patients at increased risk for the development of established connective tissue diseases, presents a prognostic opportunity, and could enable timely treatment leading to limiting disease progression.

Objectives: We aim to describe the role of the innate and adaptive immune system in the pre-clinical states of UCTD-risk-SSc and prescleroderma, the underlying immune dysregulation in these pre-clinical states, and the evolution of antibodies from nonspecific antinuclear antibodies to specific prior to SLE development.

Methods: Our search strategy was developed alongside an experienced information specialist. We searched the databases EMBASE and MEDLINE with restrictions for the English language. Reference lists of all primary studies and review articles were searched for additional references. Studies reported in full-text and abstract formats were included.

Results: Multiple cytokines are observed to increase along a disease spectrum from UCTD-risk-SSc to classified SSc and include sICAM-1, CCL2, CXCL8, ang-2, CXCL16, e-selectin, and IL-13. The mechanism of action of these cytokines includes transmigration of lymphocytes endothelium, innate immune cell activation and signal propagation, and extracellular matrix deposition. The progressive nature of cytokine increase through a spectrum from pre-clinical to clinical emphasizes disease evolution and enables the discernment of patients who may warrant early intervention. Furthermore, there are disease markers which are observed to be predictive of established SSc and include sIL-2Rα, PIIINP, CXCL4, CXCL10, and CXCL11. Pre-clinical SLE is characterized by an evolving IFN signature and progressive SLE-specific antibody formation prior to disease classification.

Conclusion: The coordinated dysregulation of the innate and adaptive immune systems, and inflammatory signalling pathways leads to the pathogenesis of connective tissue disease. Our improved understanding of these underlying aberrations in pre-clinical stages of disease will serve to better identify patients at increased risk.

AB0722 ONE-YEAR CLINICAL EXPERIENCE ON THE USE OF NINTEDANIB IN SYSTEMIC SCLEROSIS: SAFETY PROFILE.

L. Magnani[1], A. Spinella[2], S. Testoni[2], G. Bajocchi[1], L. Dardani[1], C. Salvarani[1,2], D. Giuggioli[2]on behalf of Scleroderma Unit - MORE. *[1]ASMN-IRCCS Santa Maria Nuova, Rheumatology, Reggio Emilia, Italy; [2]University of Modena and Reggio Emilia, Rheumatology, Modena, Italy*

Background: Systemic Sclerosis (SSc) is a complex autoimmune disease characterized by vascular damage, immune activation and fibrosis of skin and internal organs (1,2). One of the most common and severe SSc manifestations is interstitial lung disease (ILD) (3).

Objectives: Evaluate tolerability and safety profile of Nintedanib in patients with SSc-related ILD.

Methods: We enrolled 11 consecutive patients (6 female, 5 male, Mean age 62.7 ± 8 SD, disease duration (from the first Non-Raynaud symptom) 8 years (± 7SD) who referred to our Scleroderma Units during the last twelve months. Patients fulfilled EULAR/ACR classification criteria (4) for SSc. Patient was assessed by means of clinical evaluation (baseline and every three months), High Resolution computed tomography (every six month, or sooner), respiratory function test (every three to six months), laboratory work up, nailfold videocapillaroscopy, echocardiogram, and clinical questionnaires (BORG and mMRC).

Results: NSIP was the most frequent HRCT pattern (5 pts, 45%), followed by UIP and UIP/NSIP pattern (respectively 3 pts & 3 pts, 27%). 9 patients showed more than 20% of HRCT pulmonary fibrosis involvement. Only 1 patient had a history of smoking. mRSS was 9.23 (±10SD) points with any significant improvement during the twelve months follow-up (10 ±10SD). 8 pts were on Micophenolate Mophetil (MMF) (7 of them on MMF + steroids), 8 patients were on steroids (mean dose 5 mg/day of Prednisone or equivalent), 3 on rituximab. Main FVC was 2347 ml [+/- 1051 ml] (61.3% predicted) remaining stable. The mmRC decrased from 2.36 at baseline to 2.27 at the end of the follow up and Borg ameliorated from 7.27 at baseline to 6. Two patients were on oxygen therapy (O2 3l/min) with any significant airflow adjustment. Three patients reported irrepressible diarrhea, one patient had a partial intestinal obstruction, one had pulmonary arterial hypertension worsening with an immediate drug withdraw, one patient presented nausea, one irritability. Three patients had a clinical irrelevant weight loss (less than 2 Kg).

Conclusion: we report a preliminary real-life experience on the use of Nintedanib in SSc-related patients, focusing in particular to its tolerability and safety profile. Nintedanib is well tolerated with a low rate of definitive discontinuation due to SAE. Diarrhea is a very frequent adverse event (approximately 5 episodes a day) and had led to dose reduction and/or treatment re-challenge in the majority of patients. Diarrhea seems to ameliorate reducing daily dose of MMF (1 gram/day) or precribing loperamide along with diosmectite and probiotics. FVC, mRSS, HRCT and capilalroscopy pattern remained stable. Further studies are desirable to confirm the usefulness of Nintedanib in progressive ILD, but based on our experience we support the combined use of the anti-fibrotic therapy plus immunomodulatory drugs in early stages of SSc-related ILD

AB0723 ANTI-TIF1-BETA AUTOANTIBODIES IN A PATIENT WITH CANCER-ASSOCIATED DERMATOMYOSITIS

J. B. Vulsteke[1,2], P. De Haes[3,4], M. Satoh[5], E. De Langhe[1,2], X. Bossuyt[6,7]. *[1]KU Leuven, Development and Regeneration, Skeletal Biology and Engineering Research Center, Leuven, Belgium; [2]University Hospitals Leuven, Rheumatology, Leuven, Belgium; [3]KU Leuven, Microbiology, Immunology and Transplantation, Leuven, Belgium; [4]University Hospitals Leuven, Dermatology, Leuven, Belgium; [5]University of Occupational and Environmental Health, Clinical Nursing, School of Health Sciences, Kitakyushu, Japan; [6]KU Leuven, Microbiology, Immunology and Transplantation, Clinical and Diagnostic Immunology, Leuven, Belgium; [7]University Hospitals Leuven, Laboratory Medicine, Leuven, Belgium*

Background: Anti-transcriptional intermediary factor 1-gamma (TIF1-gamma) autoantibodies are strongly linked to cancer-associated dermatomyositis (DM). In addition to anti-TIF1-gamma autoantibodies, autoantibodies to TIF1-alpha and TIF1-beta have been described, often coexisting with TIF1-gamma or other known autoantibodies [1,2]. Thus far, anti-TIF1-beta autoantibodies without other known autoantibodies have been identified in only 3 patients with dermatomyositis, of which none had cancer [1,2].

Objectives: To report on a patient with cancer-associated dermatomyositis and isolated anti-TIF1-beta autoantibodies.

Methods: Serum of a patient with cancer-associated dermatomyositis without known autoantibody specificity was evaluated by immunoprecipitation combined with liquid chromatography-tandem mass spectrometry (IP + LC-MS/MS). Mass spectrometry data were matched against the Uniprot Homo Sapiens database with the Mascot search engine using Proteome Discoverer. Additional immunoprecipitation of radiolabeled cell extract followed by autoradiography were performed. Clinical and laboratory data were retrieved from the electronic health record.

Results: TIF1-beta was identified in the immunoprecipitate of the serum of the patient by IP + LC-MS/MS, but not TIF1-gamma or TIF1-alpha. These results were confirmed by immunoprecipitation of radiolabeled cell extract (Figure 1A). The HEp-2 indirect immunofluorescence assay showed a nuclear fine speckled pattern (AC-4, maximum titre > 1/1280, Figure 1B), which corresponds to the subcellular localization of TIF1-beta [3]. The patient, a 64-year old male, presented with dermatomyositis with classical cutaneous and muscular involvement (max. serum creatine kinase level 370 U/l). A renal cell carcinoma was found during the diagnostic work-up for which a partial nephrectomy was performed. There was a good response of both cutaneous and muscular disease activity to treatment with hydroxychloroquine and methylprednisolone.

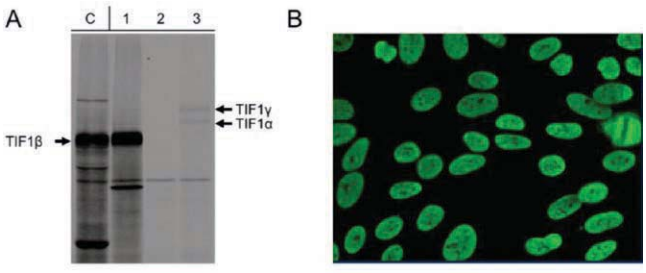

Figure 1. A Immunoprecipitation with ^{35}S-methionine labeled K562 cells with subsequent radiography. C Positive control with anti-TIF1-beta and anti-U1-RNP autoantibodies, 1 anti-TIF1-beta-positive patient (patient here described), 2 negative patient, 3 anti-TIF1-gamma/alpha-positive patient **B** Nuclear fine speckled pattern on HEp-2 indirect immunofluorescence assay, 40X magnification

Conclusion: Isolated anti-TIF1-beta autoantibodies should be considered in patients with dermatomyositis without known myositis-specific autoantibodies and can be associated with cancer.

AB0724 TO ASSESS THE SCLERODERMA CLINICAL TRIALS CONSORTIUM DAMAGE INDEX (SCTC-DI) IN PATIENTS WITH SYSTEMIC SCLEROSIS IN RUSSIAN COHORT PATIENTS.

O. Ovsyannikova[1], O. Koneva[1], L. Garzanova[1], L. P. Ananyeva[1], R. Shayakhmetova[1], O. Desinova[1], A. Khelkovskaia-Sergeeva[1], M. Starovoytova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Systemic sclerosis, Moscow, Russian Federation*

Background: Systemic sclerosis (SSc) is a multiorgan disease wherein the pathogenic processes of inflammation, vasculopathy and fibrosis lead to multiple disease manifestations. The course of SSc is often one of progressive damage to multiple organs including the skin, joints, heart, lungs, gastrointestinal tract and kidneys. The scleroderma clinical trials consortium damage index (SCTC-DI): a new instrument to quantify organ damage in systemic sclerosis [1].

Objectives: To assess the scleroderma clinical trials consortium damage index (SCTC-DI) in patients with systemic sclerosis in Russian cohort patients.

Methods: Data from 104 patients with systemic sclerosis (mean age was 51,7±12,5;64% have limited subset of the disease; 88% were female) all fulfilling the ACR criteria for SSc. Functional lung tests, high-resolution CT (HRCT), echocardiography, SSc activity (by the European Scleroderma Study Group (EScSG) activity index), HAQ, SHAQ, the six minute walk test (6MWT), scleroderma clinical trials consortium damage index (SCTC-DI) were evaluated. Other data collected including biological results (high-sensitivity C-reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR). Statistical analysis: descriptive data are presented as means (±SD) or medians (with interquartile range [IQR]) for continuous variables, while categorical variables are expressed as counts and percentages. Univariate comparisons were made with 2-sample t tests. we used the Spearman's rank-order (Spearman's p) correlations coefficients.

Results: A significant positive correlations were found between the SCTC-DI values and HAQ (r=0.31, p=0.003), SHAQ (r=0.28, p=0.0087), and values of EScSG activity index (r=0.31, p=0.0066) accordingly. The SCTC-DI values inversely correlated to values of 6MWT (r=-0.246, p=0.003). Moreover, the SCTC-DI values correlated inversely with forced vital capacity (r=-0.543, p<0.00000), forced expiratory volume in 1s (r=-0.487, p<0.00000) and diffusion capacity for carbon monoxide (r=-0.484, p<0.000001). A significant positive correlations the SCTC-DI values were found with pulmonary arterial pressure (PAP) (r=0.232, p=0.022), but didn't found any correlation with left ventriculi injection fraction (r=-0.104, p>0.05). Also we didn't find any correlations the SCTC-DI values with ESR levels and hsCRP levels (r=0.18, p>0.05 and r=0.15, p>0.05).

Conclusion: the SCTC-DI values correlate with dates of HAQ, SHAQ, EScSG activity index, values of 6MWT pulmonary function tests, supporting their use as measures of SSc severity.

Background: Systemic Sclerosis (SSc) is a complex autoimmune disease characterized by vascular damage, immune activation and fibrosis of skin and internal organs [1]. Raynaud phenomenon (RP) is frequently the first symptom of the disease and growing evidences are supporting the hypothesis the SSc may be a vascular disease, with a pivotal role of endothelial cells, particularly in the very early phase[2,3]. Robust data support the use of vascular active drug to treat RP and to prevent vascular complication[4–7].

Objectives: The use of prostacyclin analog (PA) is evertything but standardized, with different regimen used all around the Country. We report data on the use of PA in a multicentric regional reality to understand which regimen are prevalent (and why) and if there is the opportunity to standardized them.

Methods: We collected data from an online survey exploring different items related to the use of PA.

Results: Survey was fullfilled by 12 sites: 5 university hospital and 7 local hospitals, 7 driven by Rheumatologist and 5 from internal medicine specialists with/without concomitant rheumatologists. PA are ubiquitarly used for SSc-related digital ulcers (SSc-DU) and secondary RP but only a half of sites use it for primary RP. Seventy-five percent of sites (9/12) dispense PA at least once a month, but some other (1 each one respectively) on weekly basis, every other month or every 7 weeks. Drug administration may last from 2 to 5 consecutive days (mean 1.91+/- 1.5SD) with drug dose ranging from 0.5 to 2 ng/Kg/min with a minimum variability from site to site. Our regional hospitals may count on overall 68 spots, some available as beds (outpatient or inpatient), some as reclining chair or chair (outpatients only). University centers have usually more assigned personnel than local hospital (on average: 2 versus 1.5 physicians, 2 versus 1.2 nurse). Sites are able to offer meals (except one) and are able to accomodate from 1 to 12 patients at the same time (mean 3.45, +/- 3.2SD).

Conclusion: PA has known benefit in vascular involvement in SSc patients. Despite a multicenter palcebo-control study[8] defining time and dose of this drugs and subsequent data based on the same regimen[9], there is no homogeneity in treatment administration. The unequal treatment, based on our data, seems due to limited resources and personnel. High variability has been found in regimen duration and administration frequency.

AB0726 STUDY OF THE ASSOCIATION OF VARIOUS X-RAY SYMPTOMS OF INTERSTITIAL LUNG DISEASE (ILD) IN PATIENTS WITH SYSTEMIC SCLERODERMA(SSC) WITH INDICES OF LUNG FUNCTIONAL TESTS.

O. Koneva[1], L. Garzanova[1], O. Ovsyannikova[1], N. Kovaleva[1], L. P. Ananyeva[1], O. Desinova[1], M. Starovoytova[1], R. Shayakhmetova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: HRCT is the gold standard for confirming the presence of ILD. According to the literature data,there is an association between the prevalence of pulmonary involvement and the severity of PFTs.However,it remains unclear whether the nature of interstitial changes affects the degree of PFTs.
Objectives: To study the clinical significance of various X-ray symptoms in SSc-ILD during long-term follow-up.
Methods: The study included 37 pts with a SSc-ILD(average age-53.1±11.5 yrs, m/w- ¼, and d/l–1/1.8, SSc duration-10.9±9 yrs).For all pts at the time of inclusion in the study and after an average of 34±2.3 months,there were examined FVC,DLC,HRCT.All pts received immunosuppressive therapy-(IST). The analysis of HRCT data was conducted at 5 levels.The severity of changes by type of ground-glass,reticular changes,traction bronchiectases,and honeycombs were evaluated(0–3 points).The dynamics of X-ray changes and PFTs was assessed in the general group and in pts with the prevalence of ILD up to 20%(group A,n=23) and more than 20%(group B, n=14).
Results: At the time of inclusion in the study,the total CT score of ILD on average for the group was 9.6±8.2.FVC was normal(94±19.5%);a moderate decrease in DLC was detected(57.3±20.2%).The prevalence of ILD significantly correlated only with the DLC(R=-0.35, p<0.05). When included in the study,reticular changes were most often observed(the score was 4.6±3.5). Alterations by type of ground-glass were somewhat less common(the score was 3.2±3.1).The score of traction bronchiectases was 1.68±2.3.Changes by type of honeycombs were found in only 5 patients,of which only 1 patient was from the group A. Against the background of IST,values of FVC and DLC remained stable in the group as well as in the groups A and B,and the total CT score did not change.In patients of the group B,both the total CT score and the average score of ground-glass and reticular changes,and traction bronchiectases score were significantly higher. To assess the clinical significance of various X-ray symptoms,a correlation analysis of the total score of each of them with the PFTs data in groups A and B was executed. No significant correlation between the score of X-ray signs and values of FVC was detected. DLC significantly inversely correlated with the total score of each HRCT symptom, with the exception of ground-glass.At the same time,strength of the correlation was approximately the same for reticular changes, bronchiectases, and honeycombs in both groups.
Conclusion: The severity of the alveolar-capillary membrane functional disorders is primarily due to the prevalence of fibrotic changes.The variant of fibrotic changes has no significant importance.Changes by type of ground-glass to a lesser extent affect the degree of reduction in DLC.The best surrogate indicator reflecting the prevalence of interstitial changes was DLC.

AB0727 STUDY OF THE INDICATORS DYNAMICS OF THE PULMONARY FUNCTIONAL TESTS (PFTS) AND X-RAY PICTURE AGAINST DURING THE 36-MONTH IMMUNOSUPPRESSIVE THERAPY (IST) OF INTERSTITIAL LUNG DISEASE (ILD) IN PATIENTS WITH SYSTEMIC SCLEROSIS (SSC)

O. Koneva[1], L. Garzanova[1], O. Ovsyannikova[1], N. Kovaleva[1], L. P. Ananyeva[1], O. Desinova[1], M. Starovoytova[1], R. Shayakhmetova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: HRCT is the gold standard for confirming ILD.However,the role of HRCT for estimating the effectiveness of therapy is not determined in full.
Objectives: To assess the dynamics of X-ray changes and PFTs during IST in pts with SSc and different prevalence of ILD according to HRCT.
Methods: The study included 37 pts with signs of ILD(the average age-53.1±11.5 yrs,the ratio of m/w- ¼, d/l–1/1.8,the SSc-duration-10.9±9 yrs).For all pts at the time of inclusion in the study and after an average of 34±2.3 months were studied FVC,DLC and HRCT.The pts received IST during the follow-up period.The ILD dynamics was assessed as follows:improvement,deterioration and no dynamics. The analysis of HRCT data was conducted at 5 levels.The severity of changes by type of ground-glass,reticular changes,traction bronchiectasis,and honeycombs were evaluated(0–3 points).The dynamics of X-ray changes and PFTs was separately assessed in pts with the prevalence of interstitial changes up to 20%(group A,n=23) and more than 20%(group B,n=14) of the total area of lung tissue.
Results: In the general group during the IST CT-improvement was noticed in 13(34.2%),deterioration–in 9(24.3%) pts.There was no dynamics in 15(40.5%) pts. On average,values of FVC and DLC remained stable.None of the pts with improvement of HRCT showed a deterioration of FVC.Among pts with the X-ray picture deterioration,in 2 cases,there was a decrease in FVC by 5% or more;in other cases,indicator stabilized.The mean CT score did not change during the therapy.In group B,the total CT score and the average score of ground-glass,reticular changes,and traction bronchiectasis were significantly higher.Changes by type of “honeycombs” were mainly revealed in group B.During the IST,positive X-ray was detected in 6(42.9%) pts of group A, in 7(30.4%) pts of group B(p=0.06),and negative X-ray dynamics–in 4(17.4%) pts of group A, in 5(35.7%) pts of group B(p>0.05).During the IST,the mean values of DLC and FVC did not significantly change in both groups.
Conclusion: Semi-quantitative evaluation according to HRCT in pts with SSc-ILD did not reveal any dynamics in the total score of structural changes during IST,which coincided with stable indices of PFTs.Pts with less common pulmonary involvement during therapy were more likely to demonstrate positive CT-dynamics. With an increase in the prevalence of ILD,signs of fibrosis increased.Most pts had unidirectional dynamics of values of FVC and CT-changes,which confirmed the possibility of effective use of HRCT to assess the conducted therapy.

AB0728

COMPARATIVE RESULTS OF LONG-TERM (FOR 36 MONTHS) USE OF RITUXIMAB AND IMMUNOSUPPRESSANTS IN PATIENTS WITH SYSTEMIC SCLERODERMA WITH INTERSTITIAL LUNG DISEASE IN REAL CLINICAL PRACTICE

O. Koneva[1], L. Garzanova[1], S. Glukhova[2], O. Desinova[1], L. P. Ananyeva[1], O. Ovsyannikova[1], M. Starovoytova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, laboratory of inflammatory arthritis, Moscow, Russian Federation*

Background: Immunosuppressants (IS) is considered as a drug of choice for the treatment of interstitial lung disease (ILD) in the patients with systemic sclerosis (SSc). However, the IS use leads to rather limited and transient improvement of the pulmonary fibrosis. In this context the search for novel, more efficacious agents have been continued, such as attracting much attention rituximab (RTM).

Objectives: To compare the dynamics of pulmonary function parameters and skin fibrosis in patients with SSc associated with ILD, who received RTM and IS for 3 years in real clinical practice.

Methods: 158 pts with the SSc-ILD were enrolled into the study. All pts received low- and moderate-dose glucocorticoids regimens. **Group A** (n=100) **received IS's** (31/31% mycophenolate mofetil, 27/27% cyclophosphamide, 15/15% methotrexate; 27/27% other drugs; the patient's average age was 49.5±12.2 years, with female proportion 87%; SSc duration 8.6±7.2 years; diffused/localized forms 1/ 2.8). **Group B (n=58) received RTM a total dose** 3.0±1.2 g, 22 patients received RTM in combination with ISs (11/19% mycophenolate mofetil, 11/19% cyclophosphamide; average age 48.0±13.2 years, female proportion 86%, SSc duration 6.4±4.9 years, diffused/localized forms 1.5/1). The therapy duration in both groups was 36 months. The time courses of forced vital capacity (FVC), diffusive lung capacity (DLC), modified skin count (mRss, points), activity index (EScSG, points), HAQ were assessed in the study.

Table 1.

Parameters	Group A n=100		Group B n=58		p
FVC1 M ± SD	95.2±17.0	P=0.3	76.8±20.7	P=0.0003	
FVC1 M ± SD	96.5±18.9		83.8±22.2

EScSG 2,M ± SD	1.8±1.3		1.4±		
Dose of glucocorticoids 1, mg	8.8±4.8	P=0.16	11.4±4.0	P=0.002	
Dose of glucocorticoids 2, mg	8.1±3.7		9.1±2.9		
FVC increment by ≥10%, n/%	16/16		17/29.3		0.04
FVC decrement by ≥10% n/%	14/14		4/6.7		0.18
DLCO increment by ≥10%, n/%	6/6		5/8.6		0.5
DLCO decrement by ≥10% n/%	14/14		5/8.6		0.3

*1 = before treatment, 2 = after treatment; M ± SD = mean value and standard deviation; * = significant difference between the vales measured before and after the treatment*

Results: In Groups A and B the therapy was associated with significant decrease in mRss and stabilization of the diffusive lung capacity. During the follow-up period in Groups A no change of the other studied parameters was observed.
In Groups B the therapy was associated with significant decrease in HAQ and EScSG. Evaluation of FVC time course in Group B revealed significant FVC increase with median increment about 5.6%. In Group B 10% FVC increase was found in the third of the patients thus exceeding respective parameter in Group B (16%). The patient percentage with FVC decrease by ≥10% in group B was less common compared to group A. During RTM therapy it was possible to significantly reduce the dose of glucocorticoids. RTM and immunosuppressants administration for 36 months in the patients with SSc and ILD effectively alleviated skin induration and stabilized DLCO.

Conclusion: Only RTM significantly improved FVC and the patient's quality of life and decreased of the activity index. RTM demonstrated a steroid-saving effect. The study findings substantiate potential use of RTM as a first-line agent for the treatment ILD progressive phenotype in SSc. The immunosuppressants use as a single-agent therapy is more preferable in patients with less pronounced ILD.

AB0729

CLINICAL AND INSTRUMENTAL CHARACTERISTICS OF PATIENTS WITH SYSTEMIC SCLEROSIS IN DIFFERENT INTERVAL SEPARATED BY SCLERODERMA CLINICAL TRIALS CONSORTIUM DAMAGE INDEX (SCTC-DI) IN RUSSIAN COHORT PATIENTS.

O. Ovsyannikova[1], O. Koneva[1], L. Garzanova[1], A. Khelkovskaia-Sergeeva[1], O. Desinova[1], M. Starovoytova[1], R. Shayakhmetova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Systemic sclerosis, Moscow, Russian Federation*

Background: Systemic sclerosis (SSc) is a complex disease having an incidence of 1-2 cases per 100,000. In SSc, inflammation leads to organ failure due to severe fibrosis of the skin and internal organs. At late stages, this disease is characterized by a profound decline in the quality of life and premature death [1]. The course of SSc is often one of progressive damage to multiple organs including the skin, joints, heart, lungs, gastrointestinal tract and kidneys. The scleroderma clinical trials consortium damage index (SCTC-DI): a new instrument to quantify organ damage in systemic sclerosis [2].

Objectives: To use the scleroderma clinical trials consortium damage index (SCTC-DI) for pts with systemic sclerosis and highlight pts with different disease severity in Russian cohort patients.

Methods: Data from 96 patients with systemic sclerosis (mean age was 51,3±12,2; 63% have limited subset of the disease; 88% were female) all fulfilling the ACR criteria for SSc. Functional lung tests, high-resolution CT (HRCT), echocardiography, SSc activity (by the European Scleroderma Study Group (EScSG) activity index), HAQ, SHAQ, the six minute walk test (6MWT), scleroderma clinical trials consortium damage index (SCTC-DI) were evaluated. Total scores of SCTC-DI were categorized into groups (low damage score<5, moderate damage score 6-12, high damage score ≥13). Other data collected including biological results (high-sensitivity C-reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR). Statistical analysis: descriptive data are presented as means (±SD) or medians (with interquartile range [IQR]) for continuous variables, while categorical variables are expressed as counts and percentages. Univariate comparisons were made with 2-sample t tests.

Results: pts were divided into 3 groups in depend on total score of SCTC-DI. 77pts (80%) were into group 1 (with low damage score); 17 pts (18%) were into group 2 (with moderate damage score) and 2 pts (2%) were into group 3 (with high damage score). Baseline characteristics of the groups are presented in Table 1

Table 1.

parameters	Group1(n=77) (M±SD)	Group2 (n=17) (M±SD)	Group3 (n=2) (M±SD)	P
Age (months)	51.7±12.3	54.1±12.2	47±11.3	>0.05
SSc forms	43 (55%)	12 (70%)	1 (50%)	>0.05
Lim				
Gender: fem	69 (88%)	14 (82%)	2 (100%)	
Duration of dis.(years)	8.9±7.6	12.4±7.1	15±7	>0.05
HAQ	0.83±0.68	1.14±0.653	1.62	>0.05
SHAQ	1.174±0.704	1.3±0.76	1.5	>0.05
6MWT	412±170	358±187	108	>0.05
EScSG	1.81±1.44	2.14±1.44	0.5	>0.05
hsCRP	6.63±14.8	3.7±2.57	20.7±18.1	>0.05
MED[25;75‰]	2.93 [1.2;5.62]			
ESR	16.7±21.4	20±31.6	71.5±92.6.8	>0.05
MED[25;75‰]	12 [7;19]	14 [12;23]	71.5 [6;137]	
PAP	34.7±10.8	38±13.1	40±19.75	>0.05
Left ventriculi infection fraction	69.9±7.3	66.7±5.7	64.5±3.5	>0.05
FVC	97.3±14.68	64.7±17.3	43.3±5.8	Gr1 vsGr2 Gr1vs Gr3 p<0.0001
DLco	60.9±16	36.4±9.5.3	44.3	Gr1 vsGr2 p<0.0001
FEV1	96.8±14.9	66.3±20.1	46.7±7.2	Gr1 vsGr2 Gr1vs Gr3 p<0.0001

We didn't find a lot of significant differences in between groups, but it could be noted that group 3 was younger and the severity of the parameters increased in groups moderate and high damage. We found that mean value of FVC, DLco and FEV1 were significant increased in group1.

Conclusion: the pts with moderate and high damage scores of SCTC-DI had worse clinical and instrumental characteristics than pts with low damage score. We could try to use scores of SCTC-DI as measures of SSc severity.

AB0730 SCCA-IGM AS A PREDICTOR OF INTERSTITIAL LUNG DISEASE PROGRESSION IN SYSTEMIC SCLEROSIS

E. Zanatta[1], A. Martini[2], A. Cuberli[1], A. Biasiolo[2], P. Pontisso[2], A. Doria[1]. *[1]University of Padova, Rheumatology Unit, Department of Medicine, Padova, Italy; [2]University of Padova, Unit of Internal Medicine and Hepatology (UIMH), Department of Medicine, Padova, Italy*

Background: Interstitial Lung Disease (ILD) is the major determinant of morbidity and mortality in patients with systemic sclerosis (SSc). The course of lung involvement is extremely variable in SSc-ILD. Squamous Cell Carcinoma Antigen 1 (SCCA1) is a cysteine protease inhibitor that plays a crucial role in inflammation and fibrosis. It may be detected in serum in the form of an IgM-linked immune complex (SCCA-IgM), and we previously demonstrated that it is increased in patients with SSc-ILD (1).

Objectives: We aimed to investigate the association between SCCA-IgM serum levels and ILD progression in a cohort of SSc patients.

Methods: Ninety-seven patients with SSc (2013 ACR/EULAR criteria) from the Rheumatology Unit of Padua University Hospital were consecutively enrolled in the study. Clinical, serological indices and organ involvement (pulmonary, cardiac, gastrointestinal and articular) were evaluated at the time of the SCCA-IgM assay. Pulmonary involvement was investigated by high-resolution CT (HRCT) and respiratory function tests (PFTs). Serum immune complex levels were measured by a validated ELISA assay (Hepa-IC, Xeptagen, Venice, Italy) and expressed in arbitrary units/mL (AU/mL). Follow-up period was defined as the time between baseline (i.e. SCCA-IgM blood sampling) and last PFTs and/or HRCT performed at least after 24 months. SSc-ILD progression was defined by HRCT and/or PFTs worsening. Progression on PFTs: FVC decline ≥ 10% from baseline or FVC ≥ 5-9% decline plus DLCO decline ≥ 15%; radiological progression: ILD worsening on HRCT evaluated by the same experienced thoracic radiologist.

Results: Among the 97 SSc enrolled patients (mean age 55.4±12.5 yrs), 82 (84.5%) were female, 35 (36%) affected by diffuse cutaneous form of SSc (dcSSc) and 41 (42.3%) had ILD diagnosed by HRCT. The mean follow-up was 34.6 ± 1.8 months, with PFTs and/or HRCT data available in 86 patients, 37 (43%) of whom had ILD at baseline. Patients with ILD who progressed during follow-up were more frequently affected by dcSSc (p = 0.003), and tended to have lower values of total lung capacity (p=0,091). The median SCCA-IgM values were significantly higher in patients with progressive ILD vs. those with stable ILD: 301 (57-526) vs. 45 (34-236), respectively (p = 0.017), Figure 1. At Cox regression multivariate analysis, SCCA-IgM serum levels was the only variable independently associated with ILD progression [HR 1,003 95% CI 1,000-1,006, p=0.02].

Conclusion: In conclusion, our preliminary data support SCCA-IgM as a potential candidate biomarker for progressive ILD in patients with scleroderma.

AB0731 THYROID DISORDERS ASSESSMENT: AN UNMET NEED IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES?

M. Diomedi[1,2], C. Cardelli[1,2], S. Barsotti[2,3], E. Laurino[1,2], A. Tripoli[2], L. Carli[2], M. Mosca[1,2]. *[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy; [3]Ospedale di Livorno, Medicina Interna, Livorno, Italy*

Background: Thyroid diseases (TD) might compromise health status of patients, in particular owing to their possible impact on cardiovascular risk, bone mineral density (BMD) and muscle function. The prevalences of Hashimoto thyroiditis (HT), multinodular goiter (MNG) and Graves' disease (GD) in general population correspond respectively to about 12%, 10% and 1.3%; it is well known HT represents a risk factor for the development of thyroid papillary cancer (TPC). Idiopathic inflammatory myopathies (IIMs) are rare systemic autoimmune disorders, with a pleiotropic clinical picture. TD are a known comorbidity of patients with connective tissue diseases; in particular, they might increase the risk of osteoporosis (OP) and fragility fractures (FF) in patients with SLE[1]. A recent study described the association between IIMs and both hyper- and hypo-thyroidism[2].

Objectives: To evaluate the prevalence of TD in a monocentric cohort of patients with IIMs, exploring possible correlations with serology, organ involvement and comorbidities.

Methods: We retrospectively analyzed medical records of consecutive patients diagnosed with IIM according the EULAR/ACR 2017 criteria and regularly followed at our specialistic outpatient Myositis Clinic from January 2018 to December 2021. We collected data about demography, subset and duration of disease, organ involvement, serology, thyroid dysfunction and other comorbidities. As TD, we took into account the occurrence of HT, MNG and GD. Intergroups comparisons were assessed by using Chi-square, t-test and ANOVA. P values <0.05 were considered significant.

Results: The clinical charts of 151 patients were examined: 101 (66,9%) were female, the mean age was 65,1±14,0 years and the mean disease duration was 8,5±6,5 years. Clinical diagnosis were the following: 69 (45.7%) polymyositis, 59 (39.1%) dermatomyositis, 11 (7.3%) clinically amyopathic dermatomyositis, 10 (6.6%) inclusion body myositis, 2 (1.3%) juvenile dermatomyositis. Seventy-five patients (49.7%) had a TD; in particular, 39/151 (25.8%) had MNG, 34/151 (22.6%) had HT and 2/151 (1.3%) GD. The presence of a TD was significantly related with esophagus' involvement (p=0.037), Raynaud's phenomenon (RP) (p=0.045), sicca syndrome (SiS) (p<0,001), OP (p<0,001) and cataract (p=0,017). In particular, HT and MNG occurrence was respectively associated with a higher risk of OP (p<0,001) and of sicca syndrome (p<0,001). Interestingly, TD were significantly less frequent in patients with anti-Mi2beta autoantibodies (p=0,003) and anti-Jo1 autoantibodies (p=0,026). No further significant correlations emerged.

Conclusion: Our study showed nearly half of our IIMs patients had a TD, with a prevalence of both MNG and HT significantly higher than in general population; besides, owing to the retrospective nature of our study, these data could be underestimated. In addition to correlating with RP and SiS, TD showed a significant association with esophagus involvement; this result should be confirmed and clarified with future analyses. Moreover, in our cohort, TD were confirmed as a risk factor for a compromised BMD; in particular, HT was significantly associated with the occurrence of OP. Further studies are needed to corroborated our data in other cohorts of IIM patients

and to explore if TD represent a risk factor for FF also in IIM; finally, since HT is a risk factor for TPC, an evaluation of its occurrence in our cohort should be designed. However, our data seem sufficient to underline the need to regularly screen IIM patients for thyroid function, aiming at optimizing their quality of care, both for activity and damage domains of their autoimmune disease.

AB0732 ABATACEPT AS THERAPY OPTION IN SYSTEMIC SCLEROSIS (SSC) PATIENTS AFTER YEARS OF GRAZER- PROTOCOL TREATMENT- OUR EXPERIENCE

M. D'orazio[1], M. Daher[1], A. Lackner[1], S. Kielhauser[1], S. Zenz[1], J. Gretler[1], J. Thiel[1], H. P. Brezinsek[1], F. Fürst-Moazedi[1]. *[1]Medical University of Graz, Rheumatology and Immunology, Graz, Austria*

Background: Previous studies have provided evidence that T cells may play a significant role in the pathogenesis of systemic sclerosis (SSc) and observational studies reported that Abatacept, which interferes with T cells activation, appeared to be safe and effective in SSc-patients with skin and muscle involvement. So far, there was no significant effective treatment for SSC-ILD. We have recently demonstrated the effectiveness of intensified –RTX- long term treatment ("Grazerprotocol" with 500 mg RTX in week 0 and 2, every 3 months +/- MMF) in SSc patients with severe organ involvement and/or progressive form non responding to methotrexate or cyclophosphamide. However, no data are available concerning how long Patients with a stable disease need to be treated. B-cell-depletion therapy over years for SSC in remission might represent a risk factor for infections. Additionally, the parenteral administration is associated with an increase in health care and patients are bound to regular hospital visits, which is a limiting factor for life quality.

Objectives: We aimed to investigate if subcutaneous Abatacept could be used as a maintenance treatment in SSc-patients reaching a stable disease activity after a treatment with RTX administered according to our Grazer protocol over several years.

Methods: In this retrospective analysis, we retrieved data from 20 patients who fulfilled the diagnosis criteria for systemic sclerosis (SSc) according to the European League Against Rheumatism Scleroderma Trial and Research standards, who started a treatment with abatacept (ABA) after years of 500 mg RTX therapy every three months +/- MMF (Grazer protocol). The following clinical parameter were evaluated: modified Rodnan Skin Score (mRSS), Systemic Sclerosis Activity Score (SScAS), Systemic Sclerosis Severity Score (SScSS) and lung diffusing capacity for carbon monoxide (DLCO). Lab parameters like IgG, ANA, ENA and inflammation parameters were routinely assessed. Clinical data from baseline visit (BSL) (before ABA treatment start) and follow-up visit (FU) (after 6 months of treatment) were collected.

Results: We included 20 SSc patients in this retrospective analysis who changed from RTX to Abatacept. The majority were female (n=16; 94.1%), with a mean age ±SD of 54.8 years ±11 and an average disease duration of 7.7 years ±4.5. In 17.9% (n=4) treatment needed to be stopped due to disease flare after three months (lung n=2, skin and tendons n=2).

However, interestingly, Abatacept further decreased significantly mRSS between baseline visit and follow-up visit regarding the affected skin of the fingers. Thus, the mRSS went from 3.9±3.4 to 2.5±1.8 ($p<0.05$). As expected, no significant difference in the EUSTAR-SScAS, or ScSS or DLCO was found. No infections were observed during the abatacept follow-up period and Immunoglobulins remained within the normal range.

Conclusion: Abatacept might be a feasible option as a maintenance therapy after intensive immunomodulation with RTX and may give our patients the possibility to further improve their quality of life.

The fact that 4 patients experienced a relapse after switching to Abatacept warrants further studies to find prognostic factors.

AB0733 MUSCULO-ARTICULAR SYNDROME IN PATIENTS WITH SYSTEMIC SCLEROSIS-POLYMYOSITIS/ DERMATOMYOSITIS OVERLAP SYNDROME.

O. Desinova[1], M. Starovoytova[1], A. Khelkovskaia-Sergeeva[1], L. P. Ananyeva[1], O. Koneva[1], R. Shayakhmetova[1], L. Garzanova[1], O. Ovsyannikova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: Systemic Sclerosis-polymyositis/dermatomyositis overlap syndrome (SSc-PM/DM) occurs in 10 to 37% of cases and has great differential diagnostic difficulties. Muscle damage in SSc-PM/DM is represented by myositis with primary inflammatory and necrotic alterations in muscle fibers by type of PM/DM.

Objectives: To evaluate joint and muscle damage in patients with SSc-PM/DM.

Methods: 112 pts had idiopathic inflammatory myopathies, of which 73 pts with SSc-PM/DM (51 pts with lSSc and 22 pts with dSSc, male/female 24/49, mean age 44±14,5 years, average disease's duration 7 (2;9) years) had the standard clinical examination, intramuscular electromyography (IM-EMG) and manual muscle testing (MMT-8).

Results: All pts had polyarthralgia, 40% pts - arthritis. Damage to periarticular tissues with the formation of flexion contractures was observed in 70% pts, of which 16% - contractures of large joints (knee and elbow). X-ray changes in the hands and feet (distal osteoporosis, narrowing of the joint spaces, and smoothness of the phalangettes) were observed in all pts, 13% of pts had erosions associated with osteoarthritis. There was noticed significantly frequent development of flexion contractures in pts with dSSc ($p<0.05$) and high skin score ($p<0.05$). Osteolysis peculiar to SSc was detected in 23.5% of pts, and soft tissue calcinosis in the area of the phalangettes, and metacarpophalangeal joints – in 32% pts. Calcifications, specifically associated with PM/DM, in the soft tissues of the shoulder and pelvic girdle, large joints were revealed in 6% pts. A direct correlation was revealed between the duration of the disease and the development of calcinosis and osteolysis ($p<0.05$). Myalgia and proximal muscle weakness was in all pts, dysphagia – in 43% pts, and dysphonia – in 19% pts. Patients with a moderate degree of muscle weakness (MMT-8 76-115 points) prevailed and topped 41% and patients with severe disabling functional disorders (MMT-8 ≤75 points) showed 37%, of which 4% of pts were completely immobilized. In 18% of pts, PM was detected during physical and/or laboratory examination (MMT-8 ≥ 116 points). Analysis of IM-EMG of changes confirmed the presence of primary muscle inflammatory process (all patients had a decrease in motor unit action potential (MUAP) and spontaneous activity, polyphasia – in 93% of pts. A correlation was observed with laboratory and immunological signs of disease activity: between ESR and spontaneous activity ($p<0.02$), CPK titers and polyphasia ($p<0.01$), the presence of a-Pm-Scl and a decrease in MUAP ($p<0.03$).

Conclusion: Muscular syndrome in SSc-PM/DM has clear clinical symptoms, and the underlying symptom of involvement is sharp muscle weakness with movement disorders intrinsic to PM/DM. However, such disorders do not lead to complete immobility, as in PM/DM, and they are combined with other manifestations of SSc. Articular syndrome in pts with SSc-PM/DM is mainly represented by periarticular changes, in some pts with osteolysis and calcinosis common to SSc.

AB0734 **THE DYNAMICS OF LUNG FUNCTION IN PATIENTS WITH SYSTEMIC SCLERODERMA ASSOCIATED WITH INTERSTITIAL LUNG DISEASE DURING A THREE-YEAR FOLLOW-UP PERIOD.**

M. Starovoytova[1], O. Desinova[1], L. P. Ananyeva[1], O. Koneva[1], L. Garzanova[1], O. Ovsyannikova[1], R. Shayakhmetova[1], A. Khelkovskaia-Sergeeva[1]. [1]*VA Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: Nowadays ILD is one of the most common manifestations of SSc and the leading cause of death of patients. 25% to 30% of patients develop progressive ILD.
Objectives: To assess the course and outcomes of interstitial lung disease (ILD) in systemic sclerosis (SSc) based on lung function after three years of follow-up.
Methods: The study included 82 patients with SSc associated with ILD. There were 70 (85%) women and 12 (15%) men, whose average age was 49.86±12.30 years, 49 (60%) patients with limited SSc, 24 (29%) patients with diffuse SSD, 7 (9%) patients with overlap syndrome; median disease duration was 7 (4;11) years. The great majority of patients had a chronic course of the disease. The patients had systemic manifestations, vascular disorders and lesions of the musculoskeletal system. According to the results of CT scan of the thoracic organs, 28% of patients had more than 20% of pulmonary involvement. All patients took glucocorticoids (GCs); the average dose of prednisone was 8.6±4.6 mg. 50 (61%) patients took immunosuppressants (IS).
The diagnosis was set according to ACR/EULAR criteria. The patients were examined twice in accordance with generally accepted approaches. To identify and assess the dynamics of ILD, there was used high-resolution computed tomography (HRCT) Their lung function was assessed by data obtained due to spirometry (in particular, forced vital capacity, FVC) and diffusing capacity of the lungs (DCL); Doppler echocardiography was also conducted.
Results: In the group of patients with SSc, a significant improvement was noticed in some indicators demonstrating the peculiar manifestations of the disease. Therefore, skin induration (a decrease in skin score) decreased from the initial 5.8±5.2 to an average of 4.6±3.9 points after three years, p=0.0001. Functional capacities of the lungs and heart did not deteriorate. There was a trend towards an increase in FVC by 5.7% (from 91.8±19.1 to 96.15±18.26, respectively). However, these data were not clinically significant. Systolic pulmonary artery pressure (sPAP) also remained stable, mm Hg (31.83±8.10 and 33.57±9.03, respectively), indirectly indicating the absence of progression in pulmonary involvement. These positive alterations were the basis for reducing the daily dose of GCs in some patients. The reduction in dose of GCs was small but statistically significant (8.64±4.58 and 7.86±3.33, respectively, p=0.007).
Conclusion: Therefore, due to the study, stabilization of lung function and the absence of progression in the SSc-ILD group were noticed, which emphasizes the importance of continuous monitoring and follow-up of patients and continuation of therapy.

AB0735 **INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC CONNECTIVE TISSUE DISEASES: DYNAMICS OF LUNG FUNCTION AFTER THREE YEARS OF FOLLOW-UP**

M. Starovoytova[1], O. Desinova[1], L. P. Ananyeva[1], R. Shayakhmetova[1], A. Khelkovskaia-Sergeeva[1], O. Koneva[1], L. Garzanova[1], O. Ovsyannikova[1]. [1]*VA Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: Interstitial lung disease (ILD) is one of the most common and severe manifestations of connective tissue diseases, such as systemic scleroderma (SSc), dermato- and polymyositis (DM/PM), mixed connective tissue disease (MCTD), etc.
Objectives: To compare the course and outcomes of ILD in SSD, MCTD and DM/PM, immunoinflammatory myopathies (IIM) after three years of follow-up.
Methods: The SSc group consisted of 82 patients, the IIM group – 61 patients, and the MCTD group – 20 patients. In all the studied groups, women predominated. The oldest patients were found in the IIM group, and the average age was 51±12.88 years. The duration of the disease varied from 0.5 to 18.5 years. A longer course of the disease was observed among patients with MCTD, the median was 10.6 (6.9; 18.5) years. When assessing the initial parameters of lung function tests, significantly lower values of FVC and DCL were recorded in the IIM group (on average, 82±21.5 and 51.1±16.2, respectively), and higher values in the MCTD group (95.4± 20 and 67.5±15). All patients took GCs, the highest doses were taken by patients with IIM. The great majority of patients received immunosuppressants, of which 100% of patients were in the MCTD group.
Results: Despite the fact that the indices of FVC and DCL in the SSc group were initially lower (on average 91.8±19.1 and 59.2±19.5, respectively) than in the MCTD group. The dynamics of Δ FVC over three years against the background of ongoing therapy was discordant: Δ FVC in the SSc group significantly increased [0.6 (-8; 4.9)], in the MCTD group, it decreased [-5.7 (-10.3; 10.9)]. The mean value of DCL over the follow-up period remained practically the same; the dynamics between the groups was also discordant: it slightly increased in patients with SSc [1.1 (-3.8; 4.6)] and decreased in patients with MCTD [-1.6 (-11.2; 12.6)]. FEV1 decreased in both SSD and MCTD groups, but the alterations were not significant. In the group of patients with IIM during the follow-up period, there was a significant increase in the mean values of Δ DCL, FVC and FEV1 [9.8 (4-16), 13.9 (3.2-28.5), 10.2 (2-26.8)].
Conclusion: Therefore, due to the study, positive dynamics in lung function in patients with ILD was noticed in the IIM group, stabilization of the pathological process and the absence of progression in the SSc group were achieved, and, despite the initially higher values of FVC and DCL, negative dynamics was detected in the group of patients with MCTD. It is likely that the positive dynamics of lung function in patients with IIM is due not only to an improvement in the condition of the lungs, but also to an increase in muscle strength. A peculiarity of the group of patients with IIM is the high frequency of intake of rituximab in this group (40 patients).

AB0736 **ASSOCIATION BETWEEN ERYTHROCYTE DISTRIBUTION WIDTH AND SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE**

L. L. Holguín Arias[1], L. Sorrentino[2], A. Brigante[1], D. Yucra[1], A. Hamaui[1], M. Rivero[3], M. S. Menendez[4], C. Soliz[1], M. D. L. P. Menendez[5], R. Gomez[6], M. Iudici[7], A. Benitez[6], J. Gamba[6], C. Peon[6], D. Dubinsky[1]. [1]*SANATORIO GÜEMES, Rheumatology, CABA, Argentina;* [2]*SANATORIO GÜEMES, rheumatology, CABA, Argentina;* [3]*Hospital Municipal de Alberti, Rheumatology, Buenos Aires, Argentina;* [4]*Hospital Municipal de Chivilcoy, Pneumology, Buenos Aires, Argentina;* [5]*Hospital Aleman, Pneumology, CABA, Argentina;* [6]*Hospital Posadas, Rheumatology, CABA, Argentina;* [7]*Hospital Beau-Séjour, Rheumatology, Geneva, Switzerland*

Background: Interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH) account for 60% of deaths related to scleroderma (SSc). The erythrocyte distribution width (RDW) has been used as a marker of poor prognosis in different pathologies. In SSc, RDW has been found to be elevated in PAH and has been proposed as a predictor of cardiorespiratory compromise.
Objectives: The aim of this study is to evaluate the association between increased RDW and the presence of EPI in patients with SSc.
Methods: This is a multicenter, retrospective, cross-sectional study of patients diagnosed with SSc (ACR/EULAR 2013) from January 2011 to August 2021. Other concomitant autoimmune diseases, malignancy, active infections, iron-deficiency or pernicious anaemia and transfused patients were excluded. The diagnosis of PID was made by high-resolution computed tomography (HR-CT) and the extension evaluated by Goh criteria. A review of medical records was conducted, collecting clinical and demographic characteristics, interstitial pattern by HR-CT, assessed, acute phase reactants, capillaroscopy, functional respiratory tests (PFT) and echocardiographic resolution. Patients diagnosed with PAH by right heart catheterization were not excluded in this study but recorded.
Results: Seventy-five patients were included, with a mean age of 59.4 (SD 14.1 CI95% 56-6), from which 67 (89%) were women. A median of 8 years of disease evolution was observed RIC 8). Limited SS was observed in 50 (66%) and diffuse SS in 24 (32%). EPI was observed in 50 (66%) of which NSIP 25 (33%), NSIP-f 15 (20%) and UIP 10 (13%). The extension of the disease was limited in 25 (33%) and extensive in 19 (25%). Capillaroscopic findings were normal in 2 (3.4%), nonspecific in 1 (1.7%), early SD in 9 (15.3%), active SD in 22 (37.3%), and late SD in 25 (42.4%); in sixteen patients there was no capillaroscopy.
We observed an increase in RDW in the EPI group with a statistically significant difference OR 6.06 CI95% 2-17 (p 0.001). The median RDW is higher in patients with ILD and PAH than in healthy people (p<0.0001). We found a low negative correlation between RDW / FVC r (63) -.25 p 0.042 and RDW / FEV1 r (63) .30 p 0.015.
Conclusion: In the present study we have been able to evidence that there is a statistically significant relationship between the percentage of RDW and the presence of PID. When analysing the association between patients without pulmonary compromise, ILD and PAH and the percentage of RDW, we were able to find a statistically significant difference between the three groups. It is necessary to continue with studies with a larger number of patients to grant robustness to the results.

AB0737 CAPILLAROSCOPIC PATTERNS IN PATIENTS WITH SYSTEMIC SCLEROSIS- RHEUMATOID ARTHRITIS (SSC-RA) OVERLAP SYNDROME.

O. Desinova[1], M. Starovoytova[1], L. P. Ananyeva[1], O. Koneva[1], R. Shayakhmetova[1], L. Garzanova[1], O. Ovsyannikova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: Nailfold capillaroscopy is useful for the diagnosis and follow-up of autoimmune rheumatic diseases. Impaired microcirculation is one of the leading factors in local and general pathogenesis of SSc. Nail-fold video-capillaroscopy (NFVC) stands as the most informative and at the same time simple method used for evaluation of capillary circulation.
Objectives: To identify characteristic and specific for SSc-RA capillaroscopic features.
Methods: Both hand II – V fingers of 32 pts with SSc-RA were subjected to widefield NFC, evaluated using a binocular 20x magnification Olympus microscope and analyzed in view of specific skin lesions discriminating diffuse and limited SSc forms.
Results: SSc-specific dilatations of capillary loops were the most common for SSc-RA and were found in all pts SSc-RA. 1/3 pts had signs of active scleroderma pattern, such as capillary loss or “avascular areas” (37,5%) and hemorrhages (28%). The morphological capillary abnormalities such as varying degrees of capillary loops tortuosity/vascular inhomogeneity were present in 69% of examined nailfolds, branching bushy behavior of capillary loops predominated. Architectural disorientation/disarrangement of capillary loops was seen in 37,5% of them. Mega-capillaries and formation of subcutaneous plexus were presented infrequently in 16%. Ramified/bushy capillaries ($p<0.04$) were significantly more frequent in patients with lab signs of inflammatory ($p<0.03$).
Conclusion: Thus, widefield NFVC revealed a “mixed” nature of capillaroscopic changes, combining features specific for SSc (capillary dilation, avascular areas, hemorrhages) and for RA (various changes in capillary loops).

AB0738 DO COSMETIC SILICONE IMPLANTS TRIGGER SYSTEMIC SCLEROSIS?

A. Lercara[1], A. Sulli[1], C. Pizzorni[1], E. Gotelli[1], S. Paolino[1], A. Cere[1], M. Cutolo[1]. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology,, University of Genova, IRCCS San Martino Polyclinic Hospital, Department of Internal Medicine, Genova, Italy*

Background: The pathogenesis of systemic sclerosis (SSc) is thought to result from interactions between epigenetic features and environmental factors, leading to the onset and progression of the disease in genetically susceptible patients (1). Case reports of women with silicone breast implants who developed SSc have been published, but case-control and prospective studies in connective tissue diseases often failed to find an increased risk of SSc associated with silicone cosmetic surgery (2,3). These studies have several limitations, including heterogeneous cohorts of enrolled patients not selective for SSc, non-homogeneous disease duration or disease stage at study entry. For these reasons, the possible effect of silicone implants as immune adjuvants is highly suspected but remains unclear (4).
Objectives: Retrospective study of SSc patients, to find out who developed SSc after silicone cosmetic surgery.
Methods: The clinical files of 140 female patients with systemic sclerosis were retrospectively evaluated and clinical data collected.
Results: Five patients showing a history of silicone cosmetic surgery (3.6%) before SSc development were identified. The brief clinical histories of the five patients are below reported, showing very similar outcomes after silicone implant. 1. TC 47-year-old female underwent cosmetic breast prosthesis: twelve months later she experienced Raynaud’s phenomenon (RP) and diffuse cutaneous SSc after 10 further months; antinuclear antibodies were positive with a speckled and nucleolar pattern, but specific SSc-related autoantibodies negative. 2. LS 28-year-old female underwent cosmetic breast prosthesis: twenty-two months later RP appeared and anticentromere antibodies (ACA) positive aggressive diffuse SSc was diagnosed one year later. 3. PJ 38-year-old female underwent cosmetic breast prosthesis: eleven months later she experienced RP and after 10 further months, aggressive diffuse cutaneous SSc; antinuclear antibodies were positive with a speckled patter, but specific SSc-related autoantibodies were negative. 4. CM 58-year-old female who underwent cosmetic lip silicone application: one year later she complained of simultaneous onset of RP and very aggressive diffuse cutaneous SSc with anti-topoisomerase positivity; she died during follow-up. 5. BS 33-year-old female who underwent cosmetic breast prosthesis: twenty months later she complained of RP and after ten further months, limited cutaneous SSc with ACA positivity; SSc clinical condition partially improved and its progression stopped after prosthesis removal. Globally, after silicone implant, RP occurred in a mean time of 15±5 months and SSc in 23±8 months.
Conclusion: This study reports a prevalence of 3.6% of silicone cosmetic surgery before SSc onset, interestingly with a close and similar temporal association between silicone implant and disease development. This finding suggests a possible role of silicone in SSc pathogenesis (ASIA syndrome). Specifically addressed large clinical studies or big-data studies need to rule out this matter.

AB0739 AMINAPHTONE TOLERABILITY AND SAFETY IN SCLERODERMA PATIENTS: A FOUR-YEAR FOLLOW-UP

A. Cere[1], E. Gotelli[1], A. Lercara[1], C. Pizzorni[1], S. Paolino[1], E. Alessandri[1], M. Cutolo[1], A. Sulli[1]. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Department of Internal Medicine, Genova, Italy*

Background: Recent studies show that Aminaphtone is effective in the treatment of Raynaud’s phenomenon (RP) symptoms in patients with systemic sclerosis (SSc), and an increase in peripheral blood perfusion was demonstrated by Laser speckle contrast analysis in treated patients (1,2). Unfortunately, the drug is only available in a few countries.
Objectives: To evaluate long-term tolerability and safety of Aminaphtone in SSc patients with secondary RP.
Methods: Seventy SSc patients (EULAR/ACR criteria) (mean disease duration 8±7 years, mean age 61±10 years) who started Aminaphtone treatment due to active RP were enrolled and followed for at least 4 years. Patients were also taking various concomitant treatments, including immunomodulators, cyclic intravenous iloprost, endothelin receptor antagonists and aspirin. None was taking sildenafil or selexipag. Survival of Aminaphtone in therapy was assessed along with possible drug-related side effect. The Raynaud condition score (RCS) to asses disease severity and blood examinations were routinely performed.
Results: The mean follow-up of patients was 49±11 months. Aminaphtone was orally administered at 75 mg twice daily, as standard initial posology in our clinical practice. During the follow-up, six patients (8,6%) referred headache as side effect and had to reduce Aminaphtone posology to 75 mg per day, while maintaining clinical benefits. No other side effect related to the drug was observed during the follow-up. Seven patients increased the posology to 75 mg three times daily due to poor effectiveness, and further seven patients increased the posology to 75 mg three times daily only during the colder months of the year. Conversely, thirty-five patients reduced the dosage to 75 mg once daily only during the hottest months of the year, due to partial remission of the RP. During follow-up, blood tests did not reveal any significant alteration ascribable to Aminaphtone. A subjective improvement of Raynaud’s symptoms (assessed by the RCS) was already evident after 1-2 months of treatment in fifty-six patients (80%). Globally, the patients referred a sustained improvement followed by stabilization of Raynaud’s symptoms during the follow-up.

Conclusion: During an average observation period of four years, Aminaphtone showed a good tolerability and safety profile along with sustained efficacy in patients with SSc-related RP, without disabling or serious side effects. A randomized controlled trial for Aminaphtone use in the management of SSc-related RP is desirable to better assess the clinical efficacy of the drug over time.

AB0740 INTERSTITIAL LUNG DISEASE SYSTEMIC SCLEROSIS: AN EAST-EUROPEAN EUSTAR CENTER EXPERIENCE

D. M. Artene[1,2], C. Ancuta[1,2]on behalf of EUSTAR. [1]*Rehabilitation Clinical Hospital IASI, Rheumatology, Iași, Romania;* [2]*"Grigore T. Popa" University of Medicine and Pharmacy of Iași, Rheumatology, Iași, Romania*

Background: Systemic sclerosis (SSc) is a complex autoimmune connective tissue disorder defined by multifaceted visceral involvement. Still considered the leading cause of morbidity and mortality, interstitial lung disease (ILD) remains one the most common complication of SSc that involves vascular, immunological, and fibrotic processes.

Objectives: We aimed to assess the relationship between demographic, clinical features and risk factors for the development of lung fibrosis in patients with SSc as well as the specific management.

Methods: We performed a retrospective observational study in a series of 45 patients with SSc and ILD followed-up in East-European EUSTAR center (Department of Rheumatology 2, Clinical Rehabilitation Hospital, Iasi, Romania). We analyzed the frequency of known risk factors associated with progressive interstitial lung disease such as diffuse cutaneous SSc, male sex, presence of anti-topoisomerase I and absence of anti-centromere antibodies as well as risk factors for mortality in SSc-ILD including older age, male sex, extent of disease on high-resolution computed tomography (HRCT), lower pulmonary function tests (PFTs), lower diffusing capacity of the lung for carbon monoxide (DLCO).

Results: The study included 35 females, 10 males, with the mean age of 55.5 years. The diagnosis of interstitial lung disease was based on HRCT findings (bibasilar ground glass opacities, crazy-paving pattern, nodules, honeycombing and traction bronchiectasis, mosaic pattern, air trapping, pulmonary artery and lymph node enlargement). Symptoms of the ILD (dry cough, different stages of dyspnea, VELCRO crackles) were reported in 14 cases (25.45%). Furthermore, 25 patients had a significant decline in PFTs and DLCO, being associated with extensive pulmonary fibrosis on HRCT ($p<0.05\%$). Almost all patients with SSc-ILD had diffuse cutaneous involvement and anti-Scl-70 antibodies positivity. Despite identifying a higher percentage of women with ILD (35/45, 63.63%), the extent and progression of pulmonary fibrosis was more significant in males. The treatment for SSc-ILD with ongoing evidence of disease progression based on PFT decline or radiographic deterioration has focused on immunosuppressive therapies, particularly cyclophosphamide and only in selected cases on antifibrotic agents.

Conclusion: It is important to identify the risk factors for developing ILD, in order to complete the diagnostic and staging parameters early so that the treatment can be initiated as soon as possible in progressive pattern. Our data showed that the extent of pulmonary fibrosis in HRCT was associated with low values of PFTs and DLCO, and men had a more severe prognostic than women. ILD-SSc was more frequent in patients with diffuse cutaneous involvement than limited cutaneous subtype, and in those with anti-Scl-70 positivity.

AB0741 LUNG FUNCTIONS IN IDIOPATHIC INFLAMMATORY MYOPATHIES PATIENTS WITH INTERSTITIAL LUNG DISEASE DURING ≥ 3 YEAR OF FOLLOW-UP.

A. Khelkovskaia-Sergeeva[1], L. Garzanova[1], M. Starovoytova[1], O. Desinova[1], L. P. Ananyeva[1], O. Koneva[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: Interstitial lung disease (ILD) is the most common internal organ manifestation of idiopathic inflammatory myopathies (IIM) that can severely affect the course of the disease.

Objectives: To describe lung functions in IIM patients with ILD during ≥ 3 year of follow-up.

Methods: Our prospective study included 44 pts with IIM fulfilling Bohan and Peter criteria and having ILD. The mean follow-up period was 46.2±11.2 months. The mean age was 52.3±11.7 years, 34 (77.3%) pts were female. The median disease duration was 1.125 [0.16-18] years, 24 (54%) of pts were positive for a-Jo-1 antibody. All pts had the standard examination including anti-Jo-1 antibodies (anti-Jo-1) assay; forced vital capacity (FVC) and carbon monoxide diffusion capacity (DLCO) evaluation as well as high-resolution computed tomography (HRCT) scanning of the chest were performed at baseline, and 36 and more months.

Results: 61% with antisynthetase syndrome, 17% dermatomyositis (DM), 5% amyopathic DM, 15% with overlap myositis and 2 % with necrotizing myopathy were included. 70% patients had nonspecific interstitial pneumonia, 23% organizing pneumonia (OP) and 7% OP, transformed to diffuse alveolar damage.

All pts received prednisolone at a dose of 11.8±4.1 mg/day, immunosupressants at inclusion received 75% pts: cyclophosphamide 54%, mycophenolate mofetil 16.9% and combination 4.54%; Rituximab was administered in case of intolerance or inadequate response to GC and other immunosuppressive drugs in 37 pts (84%)(1-8 courses). 7 patients died, ILD progression was the cause of death in 4 cases

Table 1. Changes of the main parameters at the baseline and in 3 years

parameters	pts	baseline	in ≥ 3 years	p
a-Jo-1	23	177.2 ±41.7	90.5±76.7	0.000003
FVC	37	83.3±21.7	96.7±21	0.0001
DLCO %	37	52.4±14.9	60.8±17,3	0.001
Prednison, mg/day	37	23.04±12.8	5.9±2.3	0,000000001

Conclusion: Active immunosuppressive therapy improves lung function in IIM patients. However, some forms of ILD have a fatal course.

Disclosure of Interests: None declared

DOI: 10.1136/annrheumdis-2022-eular.4947

AB0742 THE DYNAMICS OF LUNG FUNCTION IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE ASSOCIATED WITH INTERSTITIAL LUNG DISEASE DURING A THREE-YEAR FOLLOW-UP PERIOD

R. Shayakhmetova[1], L. P. Ananyeva[1], O. Koneva[1], M. Starovoytova[1], O. Desinova[1], O. Ovsyannikova[1], L. Garzanova[1], A. Khelkovskaia-Sergeeva[1]. [1]*V.A. Nasonova Research Institute of Rheumatology;, laboratory of systemic sclerosis, Moscow, Russian Federation*

Background: Nowadays ILD is one of the most common manifestations of systemic rheumatic diseases and one of the leading cause of death of patients.

Objectives: To assess the course and outcomes of interstitial lung disease (ILD) in mixed connective tissue disease (MCTD) based on lung function after three years of follow-up.

Methods: The study included 20 patients with MCTD associated with ILD. The diagnosis was set according to Kasukawa criteria (1987). There were 19 (95%) women and 1 (5%) men; average age was 44.73±15.26 years; mean disease duration was 13.7±9 years. All patients took glucocorticoids (GCs) and immunosuppressants (IS); the average dose of prednisone was 10.2±5mg. To identify and assess the dynamics of ILD, there was used high-resolution computed tomography (HRCT). Their lung function was assessed by data obtained due to spirometry (in particular, forced vital capacity, FVC) and diffusing capacity of the lungs (DCL); Doppler echocardiography was also conducted.

Results: In the group of patients with MCTD there was a chronic course of the disease with a gradual addition of symptoms, musculoskeletal pathology prevailed. After three-year follow-up period there was a decrease in clinical manifestations (arthritis, myositis, proximal muscle weakness). Functional capacities of the lungs and heart did not deteriorate. DCL remained stable 67.5±15 and 66.9±13.8, respectively. Systolic pulmonary artery pressure also remained stable (31.4±4.5 and 32.8±5.2, respectively), indirectly indicating the absence of progression in pulmonary involvement. These positive alterations were the basis for reducing the daily dose of GCs in some patients. The reduction in dose of GCs was small but statistically significant (8.64±4.58 and 7.86±3.33, respectively, $p=0.007$). There was a trend towards a decrease in dose of prednisone (from 10.2±5 to 8±4,5, respectively). However, these data were not clinically significant.

Conclusion: Due to the study,there were no significant changes in the main indicators in patients with MCTD. All indicators remained stable, indicating the absence of clinically significant progression of lung damage on the background of therapy with GCs and IS. There was no significant change in the daily dose of GCs, but there was a decreasetendency

AB0743 BIOMARKERS IN SYSTEMIC SCLEROSIS: A 23-PLEX CYTOKINE/CHEMOKINE ANALYSIS

C. Perricone[1], G. Cafaro[1], R. Ilenia[1], S. Calvacchi[1], E. Marcucci[1], S. Cipriani[1], O. Bistoni[1], R. Gerli[1], E. Bartoloni Bocci[1]. [1]*University of Perugia, Rheumatology, Department of Medicine and Surgery, Perugia, Italy*

Background: Systemic Sclerosis (SSc) is a rare inflammatory disease of unknown etiology associated with multi-organ involvement. Biomarkers remain urgently needed as tools for differential diagnosis, prognosis, disease progression, and as therapeutic response predictors in SSc. Ideally, for widespread utility, biomarkers should be easy to sample and analyse.
Objectives: We aimed at evaluating potentially pathogenic circulating key cytokines/chemokines in a monocentric cohort of SSc patients.
Methods: Sera were drawn from SSc patients and 23 cytokines/chemokines (CCL2/MCP-1, IP-10/CXCL10, Flt3 Ligand, IFNa2, IL6, IL7, IL12, IL13, IL15, IL17A, TNFa, IL-1Ra, CXCL13, IL21, IL23, IL33, TSLP, IL-2RA, IL1RII, TNFRII, BAFF, CCL19/MIP-3B 66, MMP-8) were quantified using Luminex multiplex immunoassay (Bio-Rad-BioPlex 200 System-Lumine x-Map technology R&D Systems, USA) following the manufacturer's instructions and customized procedures. Data were acquired using Bioplex manager v 6.1. P value ≤ 0.05 was considered to be significant. Data were analyzed using GraphPad Prism V.8 (GraphPad Software, Inc.) software.
Results: Clinical and demographic features of 17 SSc (5 dcSSc, 12 lcSSc) patients are reported in Table 1. Mean±SD age was 55±14.68 years, mean±SD disease duration was 89.47±95.34 months. We found that MCP-1 levels inversely correlated with PAPs (r=-0.55, P=0.03) and IP10 with anti-Scl70 (r=-0.561, P=0.004), Figure 1. No other associations were found

Table 1.

	N	%
Sex	2M/15F	11.8/88.32
Age (years, mean±SD)	55±14.68	
Disease duration (months, mean±SD)	89.47±95.34	
Cigarette smoke	8	47
Raynaud's phenomenon	17	100
Skin thickening	14	82.4
Ulcers	2	11.8
Rodnan's Skin Score (mean±SD)	5.9±6.6	
Articular involvement	2	11.8
Heart involvement	0	0
Paps max (mmhg, mean±SD)	28.3±5.9	
Pulmonary involvement	5	29.4
DLCO min (%, mean±SD)	90.24±21.2	
Gastrointestinal involvement	3	17.6
ANA	17	100
Rheumatoid factor	4	23.5
Anti-Scl70 (U/ml, mean±SD)	33.2±59.3	
Anti-CENP(U/ml, mean±SD)	55.9±48.9	
Anti-SSA	2	11.8
Anti-SSB	1	5.9
Anti-Sm	1	5.9
Anti-RNP	1	5.9
Elevated Blood Pressure	4	23.5
Obesity	1	5.8
Any DMARD	5	29.4

Conclusion: We confirm a potential pathogenic role for MCP-1 in SSc. The -2518 promotor polymorphism in the MCP-1 gene has been already associated with disease susceptibility and an increased expression of the molecule both in peripheral blood and in the skin has been described. Intriguingly, MCP-1 seems to drive skin fibrosis while the role played in pulmonary involvement is more controversial. Indeed, similarly to our results, Scala et al. found an inverse correlation between pulmonary fibrosis and MCP-1 from T cell lines (1). At the same extent, the observation that IP-10 has an inverse correlation with anti-Scl70 levels is not novel and the usage of this chemokine as a marker of lcSSc has been already suggested. In this view, Zhu et al. found that Scl-70 negative patients have a higher expression of IP-10 than Scl-70 positive (1,878 (2,964) ng/L vs 1,030 (2,196.6) ng/L, P<0.05) (2). Finally, this is the first report on MMP8 in SSc and we suggest that MMP8 - a collagenase and marker of idiopathic pulmonary fibrosis involved in the migration of fibroblasts - can represent a promising biomarker for SSc diagnosis.

AB0744 "REACTIVE" MYOSITIS FOLLOWING ANTI-SARS-2 VACCINATION IN TWO PATIENTS CARRYING HLA-B*35 HAPLOTYPE

L. Punzi[1,2], D. Astorri[1], G. Carretta[3], C. Bernardi[1], A. Viola[4,5]. [1]*Ospedale S.S. Giovanni e Paolo, Rheumatology Unit, Venezia, Italy;* [2]*Rheumatology Network, Veneto Region, Venezia, Italy;* [3]*Azienda-Unità Locale Socio Sanitaria 3 (ULSS3) Serenissima, Chief medical officer, Venezia (Mestre), Italy;* [4]*University of Padova, Department of Biomedical Sciences, Padova, Italy;* [5]*Istituto di Ricerca Pediatrica (IRP), Fondazione Città della Speranza, Padova, Italy*

Background: The anti-SARS2 vaccination is considered the best way to reduce the frequency and the subsequent effects of COVID19 pandemic. To this aim, the most used in western countries are mRNA vaccines BNT16162b2 (Pfizer-BioNT) and mRNA-1273 (Moderna). With both these vaccines the risk/benefits balance is largely favorable and severe adverse effects are almost rare. In keeping, although transient myalgia and arthralgia are frequently seen, myositis have been until now rarely reported.
Objectives: To report two cases of myositis occurring in two patients after BNT16162b2 vaccine administration evaluated at the Center for Rheumatic Diseases in Venice, Italy.
Methods: In these patients clinical examination, blood and instrumental investigations for myositis and, in addition HLA typing, were performed. Patients were followed for at least six months after the onset of symptoms.
Results: The first patient, a 54-year-old male, complained of high-grade fever 4 days after the I dose of BNT16162b2 (Pfizer-BioNT) followed, by mild fatigue, muscle soreness and increasing weakness. He was sent to the emergency department of the local Hospital. The physical examination confirmed the muscle weakness. Blood investigation revealed an increase of AST: 509 U/L (NV< 37), ALT:189 U/L (NV <78), LDH 609, CPK 11394 U/L (NV<, 309), Myoglobin 3571 ng/ml (VN <96), CRP 1.6 mg/dl. Prednisone (PN) was started (50 mg orally day) and tapered to 5 mg in two weeks. At high doses, the symptoms slightly improved, but when < 10 mg, all the symptoms reappeared. Thus, he was hospitalized again. The new examination confirmed the increase of all indices of myositis; antinuclear antibodies and myositis antibodies were absent and PN was restarted at 10 mg/day without benefit; echocardiography and TC scan were negative. He was then sent to our observation. We increased the dose of PN at 1 mg/PN/kg and we required HLA typing. Two weeks later symptoms disappared almost completely and then we tapered PN 5 mg/day weekly. At present the patients is completely well and muscle indices negative since two months. HLA typing revealed the presence of B*35 and DRB1*15.
The second case was a 29-year-old female presented with a history of complaints appeared two days after the vaccination with BNT16162b2 administration (Pfizer-BioNT) characterized by three days of high-degree fever, followed by sever weakness, especially in the arms. The family doctor decide to hear our advise. At the initial presentation arm strenght was very decrease and the patient was accompanied. We required a serie of investigations which revealed: CPK 8950 U/L (NV 250), CRP 3.5 mg/dl increased; antinuclear and anti-myositis antibodies absent; cardiac (Ultrasound) and thoracic (CT) investigation and electromyography negative. HLA typing revealed the presence of haplotypes B*35 and DRB1*15. PN (50 mg orally day) was started; two weeks later she improved and both muscle indices and CRP negative. Thus, we reduce the dosage at 25 mg/day with tapering 5 mg weekly. She was completely remitted at end of PN cycle. At present, three month later she is well.
Conclusion: The rare occurrence of some particular side effects is not predictable. Our cases of severe myositis which in both cases completely remitted in some months are associated with haplotypes HLA-B*35 and DRB1*15. These are both binding sites linked to high-affinity interactions to S-protein T-cell epitope which account for high potentials to trigger immunogenic responses to the S protein of SARS-CoV-2 (1). Furthermore classically, HLA-B35 is associated with reactive arthritis and self-limiting, unclassified rheumatism (2).

AB0745 SYMPTOMS OF GASTROINTESTINAL DISORDERS IN SYSTEMIC SCLEROSIS PATIENTS WITH DIFFERENT DISEASE SUBTYPES AND ANTIBODIES

M. Vujovic[1], P. Ostojic[1,2]. [1]*Institute of Rheumatology, Rheumatology, Belgrade, Serbia;* [2]*School of Medicine, University of Belgrade, Belgrade, Serbia*

Background: Gastrointestinal tract is the second most commonly affected organ system in approximately 90% of patients with systemic sclerosis (SSc) and has a negative impact on health-related quality of life (1,2).
Objectives: This study aims to analyze frequency and severity of gastrointestinal symptoms, their impact on social functioning and emotional wellbeing and compare results among patients with limited cutaneous (lcSSc) and diffuse cutaneous systemic sclerosis (dcSSc), as well as in patients with anti-centromere antibodies (ACA) and anti-topoisomerase I antibodies (ATA).
Methods: 42 patients with SSc were included in this study, 31 of them with lcSSc and 11 patients with dcSSc. ACA were detected in 26, and ATA in 16 patients. The *UCLA-SCTC-GIT 2.0 self-assessment questionnaire* (3,4) was used to assess presence and severity of gastrointestinal symptoms in our patients. It consists of seven scales: reflux, distension/bloating, diarrhea, fecal soilage, constipation, social functioning and emotional wellbeing.
Results: There was no difference in percentage of patients with lcSSc and dcSSc who used proton pump inhibitors (27.27%: 32.25%), as well as in patients with ACA and ATA (34.61%: 25%). Symptoms of gastroesophageal reflux (lcSSc: dcSSc = 64.5%: 81.8%), distension/bloating (lcSS: dcSSc = 61.3%: 81.8%), constipation (lcSSc: dcSSc = 45.2%: 45.5%) and fecal soilage (lcSSc: dcSSc = 6.4%: 18.2%) were found equally frequent ($p>0.05$) in patients with lcSSc and dcSSc. However, symptoms of diarrhea were found significantly more frequent in patients with dcSSc (lcSSc: dcSSc = 16.1%: 45.5%, $p=0.04$). The mean index value for diarrhea was significantly higher in patients with dcSSc (dcSSc: lcSSc = 0.45: 0.11, $p=0.02$), indicating more severe symptoms in diffuse form of disease. We did not notice a significant difference in frequency or severity of gastrointestinal symptoms in patients with ACA and ATA. Mean index values of social functioning and emotional wellbeing did not differ significantly in patients with lcSSc and dcSSc, as well as in patients with ACA and ATA.
Conclusion: Unlike other gastrointestinal manifestations, diarrhea is significantly more common and more severe in patients with dcSSc. No significant difference in frequency and severity of gastrointestinal symptoms was found in patients with ACA and ATA. Impact of gastrointestinal tract symptoms on social functioning and emotional wellbeing was similar in both forms of disease and antibodies.

AB0746 MALIGNANCY IN DERMATOMYOSITIS

I. Naceur[1], I. Arbaoui[1], T. Ben Achour[1], M. Khanfir[1], I. Ben Ghorbel[1], M. Lamloum[1], F. Said[1], M. H. Houman[1]. [1]*Faculty of Medicine,Tunis-El Manar University, Internal medicine departement, La Rabta Hospital,Tunis,Tunisia*

Background: Link between dermatomyositis (DM) and malignancy is well established. Compared with general population, the incidence of cancer is estimated to be 5 to 7 times higher in patients with DM. However, criteria suggestive of associated malignancy still lack.
Objectives: The aim of our study was to describe clinical, biological, therapeutic features and outcomes of DM associated with malignancy.
Methods: We conducted a retrospective study of patients with DM diagnosed in an internal medicine department over a period time of 12 years. Cases of DM associated with malignancy were retained.
Results: Among 38 patients diagnosed with DM, malignancy was found in 10 (26.3%). Sex-ratio M/F was 0.3. The mean age at DM diagnosis was 40,22 years (range: 30-75 years) and the mean age at malignancy diagnosis was 43,19. In five cases the diagnosis of neoplasia was concomitant to the DM diagnosis. In the other 5 cases, the diagnosis of DM preceeded the neoplasia with a mean delay of 26 months [9-82 months].
The main clinical manifestations were: Gottron's papules (n=8), skin ulcers (n=7), periungual erythema (n=7), erythredema of the face with orbital rim (n=5), impaired general condition (n=4),Raynaud's with mega capillaries (n=2), skin necrosis(n=1) and subcutaneous calcinosis(n=1)., Muscular damage was found in 7 patients. Signs of severity such as swallowing disorders and false deglutition routes were found in 4 patients. Biological data showed acceleration of erythrocyte sedimentation rate (ESR) (n=4) and elevated muscle enzymes (n=7). Immunological features showed positivity of anti-Mi-2 antibodies in two cases, anti-transcription intermediary factor 1-gamma (TIF1-γ) antibodies in one case, simultaneous positivity of anti Jo1 and anti SRP in one other case. Associated cancers were: Breast cancer (n=5),Colon carcinoma (n=2), Lung cancer(n=1), Cancer of the cervix(n=1) and T-cell lymphoma(n=1). In addition to specific oncological treatment, all patients received high doses of corticosteroids. It was associated with methotrexate in 4 cases. Two patients received intravenous immunoglobulin. A relapse was observed in 4 cases although a durable remission of associated neoplasia. Outcomes were fatal in 3 cases due to the underlying cancer. Three patients were lost to follow-up.
Conclusion: In our series, breast neoplasm was the most frequent cancer associated with DM. Despite oncological treatment, DM can remain progressive.

AB0747 ORAL MICROBIOME IN RHEUMATIC DISEASES.WHAT INVOLVEMENT?

M. T. Ceccherini[1], S. Bellando-Randone[2], S. Guiducci[2], E. Romano[2], D. Carboni[2], K. El Aoufy[2], G. Lepri[2], L. Cometi[2], L. Tofani[3], M. Matucci-Cerinic[2,4], D. Melchiorre[2]. [1]*University of Florence, Department of Agriculture, Food, Environment and Forestry (DAGRI), Florence, Italy;* [2]*University of Florence, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy;* [3]*University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy;* [4]*San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare diseases,, Milan, Italy*

Background: The concept of core-microbiome in health is useful for investigating the possible role of the oral microbiome in autoimmune disease, such as Rheumatoid Arthritis, Spondyloarthritis, Sjogren Syndrome or Systemic Sclerosis (SSc), whose pathogenesis has not been fully understood. Environmental factors and certain genetic backgrounds have been proposed. Among the various environmental factors, the microbiota stands out, the entire composition of microorganisms, mainly bacteria but also fungi and viruses, which populate the human body.
Objectives: The aim of the study was to verify whether there were quantitative differences between the microorganisms present in the oral cavity, in particular between the *lactobacillus* spp., of patients with SSc compared to those present in the oral cavity of healthy subjects taken as controls.
Methods: Twenty-nine SSc female patients (mean age 62.) classified according to the ACR/EULAR2013 criteria and twenty-three female healthy subjects (HS, mean age 57.6) were enrolled and underwent tongue and gum swab sampling. Quantitative PCR was conducted in triplicates using *Lactobacillus* specific primers *rpo*B1, *rpo*B1o and *rpo*B2 for RNA-polymerase β subunit gene.
Results: Our data showed *Lactobacillus*spp.*rpo*B sequences significantly lower in the tongue of SSc patients than in HS ***(p=0.0211)***.The statistical analysis in HS highlighted a significant lower amount of *rpo*B on the gums than on the tongue.
Conclusion: Our preliminary data show that the number of *Lactobacillus* on the tongue in SSc patients is about half that of HS. These data make it more likely that *Lactobacillus* in SSc patients may play a protective role. Further investigations will also be needed in other autoimmune diseases.

AB0748

ANTI-FIBROTIC THERAPY IN PROGRESSIVE PULMONARY FIBROSIS ASSOCIATED WITH SYTEMIC SCLEROSIS: CHARACTERISTICS OF SSC-ÎAH PATIENTS RECEIVING NINTEDANIB AND ADVERS EVENTS DURING TREATMENT

Y. Yalçınkaya[1], S. Amikishiyev[1], N. Aliyeva[1], B. Artim-Esen[1], A. Gul[1], Z. Bingol[2], G. Okumuş[2], M. Inanc[1]. *[1]Istanbul University, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul University, Department of Pulmonology, Istanbul, Turkey*

Background: Nintedanib, an intracellular inhibitor of tyrosine kinases, has been recently approved for interstitial lung disease associated with systemic sclerosis (SSc-ILD). Nintedanib has shown antifibrotic and antiinflammtory effects in animal models of fibrosing ILDs.

Objectives: We aimed to evaluate clinical charcteristics of progressive SSc-ILD patients receiving anti-fibrotic therapy who were resistant to standart immunosuppressives (ISs) and adverse events during treatment period in this cohort.

Methods: Fifteen patients fulfilling ACR/EULAR (2013) classification criteria for SSc and receiving nintedanib for progressive ILD despite standart ISs included into this retrespective analysis.

Results: Demographics and clinical characteristics of SSc patients were summarised in Table 1. Median age, duration of Raynaud's and duration of non-Raynaud symptom were 49 (35-72), 8 (1-30) and 4 years (1-21), respectively. ILD was evident median 2 years (0.5-20) after onset of Raynaud's and 1 years (0.5-11) after onset of non-Raynaud symptom. Before pulmonary involvement, 7 patients received methotrexate and 1 patient cyclophosphamide (CYC) for diffuse cutaneous involvement. After evident ILD, 6 patients received CYC, 5 patients mycophenolate mofetil (MMF) and 4 patients azathioprine as first ISs for SSc-ILD. Median FVC(%) and DLCO(%) were 56 (39-67) and 44 (20-67) before antifibrotic therapy. Thirteen patients (%92,8) received ≥2 ISs before nintedanib. Duration of evident ILD to onset of antifibrotic therapy was median 5.5 years (2-11). Nintedanib was prescribed concomitantly with MMF in 8 or rituksimab-MMF in 6 patients. Median follow-up of antifibrotic treatment period was 7 months (2-18). Advers events during nintedanib were summarised in Table 2. One patient was deceased due to small cell lung cancer at 9.month of nintedanib.

Table 1. Characteristics of SSc-ILD Patients Receiving Nintedanib

	n (%)
Females	12 (80)
Clinical Characteristics	
Diffuse Cutaneous SSc	13 (86.7)
Limited Cutaneous SSc	2 (13.3)
Synovitis	3 (20)
Digital ulsers	8 (53.3)
Pulmonary arterial pressure >30 mmHg (echo)	5 (30)
Gastrointestinal involvement	10 (76.9)
Serology	
ANA	13(86.7)
Anti-Scl70	10 (66.7)
Immunosuppressives	
CYC	8 (53.3)
MMF	14 (93.3)
AZA	7 (46.7)
MTX	6 (40)
RTX	6 (40)
Low dose steroids	15 (100)

Table 2. Advers Events during Nintedanib Treatment inSSc-ILD patients

	SSc-ILD (n=15)
Any advers events n(%)	8 (53.3)
Diarrhoea	5 (30)
Nausea/ vomiting	1 (6.7)
Abdominal pain	3 (20)
Weight decreased	3 (20)
Yorgunluk	2 (13.3)
Cough	3 (20)
Infections (pneumonia)	3 (20)
Liver test abnormalities	4 (26.7)
Malignancy	1 (7.1)
Dose reduction and reescalation	7 (46.7)
Dose interruption	2 (13.3)

Conclusion: Nintedanib was prescribed in progressive SSc-ILD patients who had predominatly diffuse cutaneous involvement, anti-SCL70 positivity and exposed to multiple standart ISs. Duration of ISs were higher than 5 years before antifibrotic therapy. Gastrointestinal (GI) advers events were frequent during nintedanib requiring dose reduction in half of the patients. Nintetanib can be used in progressive SSc-ILD patients considering some difficulties in such a disease with GI involvement. Efficacy analysis of the antifibrotic therapy needs further studies including long term follow-up.

ANTI-PM/SCL 75 AND ANTI-PM/SCL 100 ANTIBODIES: DOES THE NUMBER MATTER?

B. Santos[1], A. Basto[2], A. Reboredo[3], A. Barcelos[1]. *[1]Centro Hospitalar Baixo Vouga, Aveiro, Rheumatology Department, Aveiro, Portugal; [2]Abel Salazar Biomedical Sciences Institute - University of Porto, Animal Science, Porto, Portugal; [3]Centro Hospitalar Baixo Vouga, Aveiro, Clinical Pathology Department, Aveiro, Portugal*

Background: Anti-polymyositis/Scl (PM/Scl) antibodies have been associated to systemic sclerosis (SSc), PM and PM-SSc overlap syndrome. Although not specific and with some uncertainty about their true prevalence, they have been linked to the clinical presentation and prognosis of SSc rather than traditionally related impact of the extent of the cutaneous involvement[12].

Objectives: The aim of this study is to describe the demographic, clinical and laboratorial data associated with the presence of anti-PM/Scl and to compare the differences against the two major antigenic components: 100 and 75 kDa proteins (anti-PM/Scl-75 and anti-PM/Scl-100).

Methods: A retrospective study including patients with positive anti-PM/Scl antibody followed in rheumatology department from January 2017 to December 2021 were analyzed. Demographic, clinical, immunological and nailfold capillaroscopy data at presentation and during follow-up were collected. Descriptive, Student's t and Fisher test were estimated.

Results: Fifty six patients were positive for anti-PM/Scl antibodies. Of these, 38 (68%) were female with a median age at presentation of symptoms was 47 ± 16 years. Asymptomatic carrier of anti-PM/Scl75 and anti-PM/Scl100 were present in 15 (27%) and 7 (13%) of the patients, respectively. SSc and PM were the diagnosis most found, 34% and 9%, respectively. Arthralgias/Arthritis and Raynaud phenomenon (RP) were the first clinical features most presented followed by respiratory symptoms and constitutional symptoms. Relating to cumulative organ complications, peripheral vascular involvement was the most affected (RP, 30%) followed by musculoskeletal (MSK) and lung (interstitial lung disease - ILD, 21%) and skin involvement (limited cutaneous form, 20%). All patients were positive to antinuclear antibodies by indirect immunofluorescence.

Comparing patients with positive anti-PM-Scl75 and anti-PM-Scl100 showed a statistically significant difference at the presence of RP (as first or cumulative manifestation) and early pattern on nailfold capillaroscopy (p= 0.049 and p=0.039, respectively). A statistically significant difference was also found in an asymptomatic patient (p<0.001) – Table 1.

Table 1. Demographic, clinical and immunological comparison between PM/Scl75 and PM/Scl100 antibody profile

	Anti-PM-Scl75 N = 37	Anti-PM-Scl100 N = 25	*p*-value
Sex, male/female*	11 (29.7)/26 (70.3)	7 (28.0)/18 (72.0)	0.558
Age (start of symptoms)*	46 ± 16	48 ± 18	0.759
Age (at diagnosis)*	49 ± 17	50 ± 19	0.872
Diagnosis			
Asymptomatic	15 (40.5)	7 (28.0)	**<0.001**
Systemic sclerosis	10 (27)	12 (48)	0.078
Myositis	3 (8.1)	3 (12.0)	0.463
Overlap Syndrome	1 (2.7)	2 (4)	0.648
Manifestation			
Raynaud phenomenon	9 (24.3)	13 (48.0)	**0.049**
Arthralgias/arthritis	20 (54.1)	14 (56)	0.544
Limited cutaneous	6 (16.2)	5 (20.0)	0.477
Diffuse cutaneous	0 (0.0)	2 (8)	0.159
Myositis	4 (10.8)	4 (16.0)	0.410
ILD	6 (16.2)	6 (24.0)	0.329
Nailfold capillaroscopy pattern			
Normal pattern	28 (75.7)	12 (48)	**0.025**
Early pattern	5 (13.5)	9 (36.0)	**0.039**
Active pattern	3 (8.1)	5 (20.0)	0.163

All values are presented as number (percentage) and those with * are presented as mean ± SD. ILD, interstitial lung disease.

Conclusion: Anti-PM/Scl antibodies are frequently associated to MSK and RP symptoms as first and cumulative clinical manifestations followed by ILD and limited cutaneous form of SSc. Between anti-PM/Scl 75 and 100 serological profile, anti-PM/Scl100 is more associated to RP and abnormal nailfold capillaroscopy pattern.

BACK PAIN AND MORNING STIFFNESS AS MEDIATORS OF TOFACITINIB TREATMENT EFFECT ON FATIGUE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A MEDIATION ANALYSIS

L. E. Kristensen[1], P. C. Taylor[2], V. Navarro-Compán[3], M. Magrey[4], J. C. Cappelleri[5], A. G. Bushmakin[5], A. Yndestad[6], O. Dina[7]. [1]*Copenhagen University Hospital, Bispebjerg and Frederiksberg, The Parker Institute, Copenhagen, Denmark;* [2]*University of Oxford, Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom;* [3]*University Hospital La Paz, IdiPaz, Madrid, Spain;* [4]*Case Western Reserve University, Division of Rheumatology, Cleveland, OH, United States of America;* [5]*Pfizer Inc, Inflammation and Immunology, Groton, CT, United States of America;* [6]*Pfizer Inc, Inflammation and Immunology, Oslo, Norway;* [7]*Pfizer Inc, Inflammation and Immunology, New York, NY, United States of America*

Background: Fatigue is a prevalent symptom of ankylosing spondylitis (AS)[1] and can contribute to higher levels of disease, disability and poor health-related quality of life.[2] Back pain and morning stiffness are also commonly reported symptoms.[3] Tofacitinib is an oral Janus kinase inhibitor for the treatment of adult patients (pts) with AS. In randomised studies, pts with active AS treated with tofacitinib experienced greater improvements in fatigue, back pain and morning stiffness at Week 12 and 16 of treatment compared with placebo (PBO).[4,5] Treatment of these symptoms is a priority for pts with AS and their healthcare providers, however, the mechanisms underlying the interrelationships between fatigue, back pain, morning stiffness and treatment are unclear.

Objectives: To describe the interrelationships between fatigue, back pain, morning stiffness and tofacitinib treatment in pts with AS, using mediation modelling.

Methods: Data from Phase 2 (NCT01786668)[4] and Phase 3 (NCT03502616)[5] studies of pts with active AS treated with tofacitinib 5 mg twice daily (BID) or PBO were used. Mediation modelling, a statistical method to assess the extent to which the effect of an independent variable on a dependent variable is indirect, via identified mediators, or direct, capturing all other (unmeasured) effects, was applied.[6,7] The initial model included: treatment as the independent binary variable (tofacitinib 5 mg BID vs PBO); fatigue (measured by Functional Assessment of Chronic Illness Therapy-Fatigue) as the dependent variable; mediators included back pain (measured by total back pain/nocturnal spinal pain [numerical rating scale, 0–10]) and morning stiffness (represented by the mean of Bath Ankylosing Spondylitis Disease Activity Index questions 5 and 6).

Results: Pooled data from 370 pts were included in the analysis. The initial model showed that 57.5% ($p<0.001$) of the tofacitinib treatment effect on fatigue was mediated via back pain and morning stiffness (indirect effect); mediation via morning stiffness alone was 49.7% ($p<0.01$), and 21.2% ($p=0.02$) via back pain alone. The effect of treatment attributable to factors other than back pain and morning stiffness (ie, direct effect) was not statistically significant (-28.4%; $p=0.33$). As a result, the initial model was re-specified to exclude the direct treatment effect on fatigue. In the re-specified model (Figure 1), 44.0% ($p<0.0001$) of the indirect effect of tofacitinib on fatigue was mediated via back pain and morning stiffness; mediation via morning stiffness alone was 40.0% ($p<0.001$), and 16.0% ($p<0.01$) via back pain alone. Analyses of the individual study data gave results generally consistent with those from the pooled data.

Conclusion: Overall, indirect pathways via morning stiffness accounted for ~84% of the effect of tofacitinib treatment on fatigue: (1) treatment affects morning stiffness, which impacts fatigue; and (2) treatment affects morning stiffness, which affects back pain and, ultimately, back pain affects fatigue. The indirect pathway via back pain alone accounted for ~16% of treatment effect on fatigue. These results suggest that in tofacitinib-treated pts with AS, improvements in fatigue are fully mediated through combined treatment effects on morning stiffness and back pain.

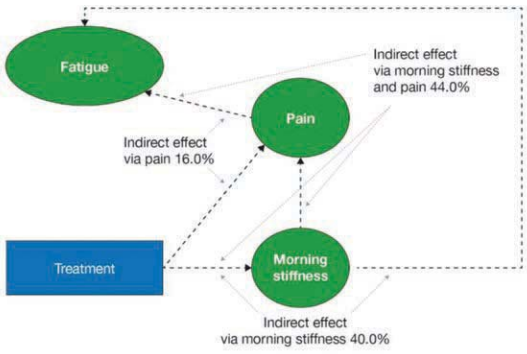
Figure. Re-specified mediation model results



- - ► Indirect effect of treatment on fatigue via back pain and morning stiffness

The mediation models were based on pooled data from Phase 2 (NCT01786668) and Phase 3 (NCT03502616) studies. Treatment is represented by a binary variable (tofacitinib 5 mg BID vs placebo). Pain is represented by total back pain due to AS on average during last week and pain at night due to AS on average during last week.
AS, ankylosing spondylitis; BID, twice daily

HOW DOES BODY MASS INDEX AFFECT SECUKINUMAB TREATMENT OUTCOMES AND SAFETY IN PATIENTS WITH ANKYLOSING SPONDYLITIS? – REAL WORLD DATA FROM THE GERMAN AQUILA STUDY

U. Kiltz[1], J. Brandt-Juergens[2], P. Kästner[3], E. Riechers[4], D. Peterlik[5], C. Budden[6], H. P. Tony[7] on behalf of on behalf of the AQUILA Study Group. [1]*Rheumazentrum Ruhrgebiet, Herne and Ruhr-Universität Bochum, Herne, Germany;* [2]*Rheumatologie, Schwerpunktpraxis, Berlin, Germany;* [3]*Ambulantes Rheumazentrum, Medizinisches Versorgungszentrum, Erfurt, Germany;* [4]*Medizinische Hochschule, Hannover, Hannover, Germany;* [5]*Novartis Pharma GmbH, Immunologie, Hepatologie & Dermatologie, Nürnberg, Germany;* [5]*Novartis Pharma GmbH, Immunologie, Hepatologie & Dermatologie, Nürnberg, Germany;* [7]*Medizinische Klinik II - Rheumatologie/Immunologie, Universitätsklinikum Würzburg, Würzburg, Germany*

Background: Obesity is a risk factor for worse overall health in people with ankylosing spondylitis (AS)[1]. The German non-interventional study AQUILA provides real-world data in AS on the influence of body mass index (BMI) on therapeutic effectiveness and safety under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits IL-17A.

Objectives: The aims of this interim analysis are to describe selected baseline (BL) demographics and to evaluate secukinumab treatment outcomes on disease activity and global functioning and health and to report safety profile depending on the BMI of AS patients (pts).

Methods: AQUILA is an ongoing, multi-center, non-interventional study including up to 3000 pts with active AS or psoriatic arthritis. Pts were observed from BL up to week (w) 52 according to clinical routine. Real-world data were assessed prospectively and analyzed as observed. Validated questionnaires were used to collect data on disease activity (Bath Ankylosing Spondylitis Disease Activity Index, BASDAI) and global functioning and health (Assessment of SpondyloArthritis-Health Index,

ASAS-HI). For calculation of proportion of pts that experienced (serious) adverse events ((S)AEs), all AS pts were included that received at least one dose of secukinumab. This interim analysis focuses on BMI subgroups ≤*25* kg/m^2 (normal weight), >*25 to* ≤*30* kg/m^2 (overweight) and >*30* kg/m^2 (obese) in AS pts.

Results: At BL, BMI data were available for 667 AS pts: 33.6% (n=224) normal weight, 39.9% (n=266) overweight and 26.5% (n=177) obese AS pts (Table 1). In all BMI subgroups the proportion of men was higher, even doubled among overweight AS pts. As BMI increased, so did age and comorbidities/extraarticular manifestations (EAMs, Table 1).

Table 1. Overview of baseline characteristics in AS pts depending on BMI

Demographics	BMI ≤25 kg/m^2 (N=224)	BMI >25 to ≤30 kg/m^2 (N=266)	BMI >30 kg/m^2 (N=177)
Male*	123 (54.9)	178 (66.9)	94 (53.1)
Age, years**	43.3 (12.1)	47.5 (12.3)	49.2 (11.0)
BASDAI**	4.8 (2.0)	5.5 (1.8)	5.5 (2.0)
ASAS-HI**	7.4 (3.7)	7.7 (3.3)	8.1 (3.6)
Comorbidities/EAMs*			
Heart-related disease	4 (1.8)	12 (4.5)	12 (6.8)
Coronary heart disease	4 (1.8)	10 (3.8)	8 (4.5)
Stroke	1 (0.4)	0 (0.0)	2 (1.1)
Heart insufficiency	1 (0.4)	4 (1.5)	8 (4.5)
Uveitis	11 (4.9)	17 (6.4)	13 (7.3)
Depression	88 (55.3)	121 (58.2)	73 (54.9)

*variables are given as n (%); **variables given as mean (SD)

Mean BASDAI developed similarly over time with lowest scores for normal weight and highest scores for obese AS pts (Figure 1A). Mean improvement from BL to w52 was 1.3 (27.1%) for normal weight, 1.5 (27.2%) for overweight, and 1.2 (21.8%) for obese AS pts.

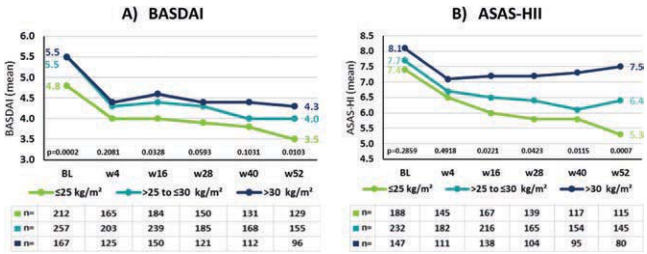

Figure 1. Disease activity and global functioning under secukinumab treatment in AS pts stratified by BMI

Mean ASAS-HI at BL was similar for all BMI subgroups (≤*25*: 7.4; >*25*-≤*30*: 7.7; >*30*: 8.1); the best improvement was observed in normal weight, the least in obese AS pts (Figure 1B). Mean improvement from BL to w52 was 2.1 (28.4%) for normal weight, 1.3 (16.9%) for overweight, and 0.6 (7.4%) for obese AS pts.

The occurrence of AEs/SAEs with or without suspected relationship to secukinumab increased with increasing BMI. For example, the percentage of SAEs in normal weight was 21%, in overweight 26.7% and in obese AS pts 30.9% (data not shown). There were no events with fatal outcome or unexpected safety signals in either subgroup.

Conclusion: In a real-world setting, secukinumab improved disease activity and global functioning and health in all BMI subgroups of AS pts; normal weight AS pts had numerically better ASAS-HI and BASDAI scores than obese AS pts. Altogether, real-world data of this interim analysis show that secukinumab is an effective treatment with a favorable safety profile up to 52 weeks in AS pts in all BMI subgroups.

AB0752

HOW DOES TIME TO DIAGNOSIS AND GENDER AFFECT TREATMENT OUTCOMES IN PATIENTS WITH ANKYLOSING SPONDYLITIS OR PSORIATIC ARTHRITIS? – REAL WORLD DATA FROM THE GERMAN AQUILA STUDY WITH SECUKINUMAB

K. Benesova[1], O. Hansen[1], U. Kiltz[2], J. Brandt-Juergens[3], P. Kästner[4], E. Riechers[5], D. Peterlik[6], C. Budden[6], A. Boas[6], S. Welle[6], H. P. Tony[7].
[1]Medizinische Abteilung V - Rheumatologie, Universitätsklinikum, Heidelberg, Germany; [2]Rheumazentrum Ruhrgebiet, Herne and Ruhr-Universität Bochum, Herne, Germany; [3]Rheumatologie, Schwerpunktpraxis, Berlin, Germany; [4]Ambulantes Rheumazentrum, Rheumatologie, Erfurt, Germany; [5]Medizinische Hochschule, Hannover, Hannover, Germany; [6]Novartis Pharma GmbH, Immunologie, Hepatologie & Dermatologie, Nürnberg, Germany; [7]Medizinische Klinik II - Rheumatologie/Immunologie, Universitätsklinikum, Würzburg, Germany

Background: In both, ankylosing spondylitis (AS) and psoriatic arthritis (PsA), women typically have a longer delay in diagnosis.[1,2] There is scientific evidence that prognosis for AS and PsA improves when diagnosed early. The German non-interventional study AQUILA provides real-world data on the influence of time to diagnosis and gender on treatment outcomes under secukinumab, a fully human monoclonal antibody that selectively inhibits interleukin-17A.

Objectives: The aims of this interim analysis are to describe selected baseline (BL) demographics of AS and PsA patients (pts) and to evaluate the impact of time to diagnosis and gender on secukinumab treatment outcomes, such as disease activity and global functioning and health.

Methods: AQUILA is an ongoing, multi-center, non-interventional study including up to 3000 pts with AS or PsA. Pts were observed from BL up to week (w) 52 according to clinical routine. Real-world data were assessed prospectively and analyzed as observed. Validated questionnaires were used to collect data on disease activity (Bath Ankylosing Spondylitis Disease Activity Index, BASDAI), global functioning and health (Assessment of SpondyloArthritis-Health Index, ASAS-HI) in AS, and skin and joint-related disease activity (Psoriasis Area and Severity Index, PASI; tender/swollen joint counts, TJC/SJC) and impact of disease (Psoriatic Arthritis Impact of Disease - 12 items, PsAID-12 score) in PsA pts. This interim analysis focused on the subgroups of male and female AS and PsA pts stratified by time to diagnosis after disease onset (˂1 year [y] and ≥1y for early and late diagnosis, respectively).

Results: At BL, 609 AS and 1145 PsA pts were included with information on time to diagnosis (Table 1); only 18.7% of AS and 25.8% of PsA pts were diagnosed within one year. Of interest, both female AS and PsA pts as well as male PsA pts with increased BMI tended to be diagnosed later (Table 1). Regarding BASDAI scores, male AS pts diagnosed late had increased disease activity at BL and throughout the study (Figure 1A); female AS pts diagnosed late showed reduced total treatment effect with increasing time to diagnosis (Figure 1B). Similarly, both male and female AS pts diagnosed late had slightly increased ASAS-HI at BL and throughout the study (Table 1). For PsA pts, there was no difference in skin- (PASI, Figure 1C/D) and joint-related (Figure 1E/F) disease activity with respect to time to diagnosis. Furthermore, there was no difference in PsAID scores (data not shown) between early- and late-diagnosed PsA pts.

Table 1. Overview of selected BL characteristics in AS and PsA pts stratified by time to diagnosis

	AS (N=609)			
	Time to diagnosis ˂1 year (n=114)		**Time to diagnosis ≥1 year (n=495)**	
	Male (n=63)	**Female (n=51)**	**Male (n=301)**	**Female (n=194)**
Age, years	43.1	46.3	45.9	47.7
BMI	27.7	25.9	27.3	27.8
BASDAI	4.7	5.0	5.3	5.2
ASAS-HI	6.7	8.0	7.4	8.2
	PsA (N=1145)			
	Time to diagnosis ˂1 year (n=295)		**Time to diagnosis ≥1 year (n=850)**	
	Male (n=126)	**Female (n=169)**	**Male (n=363)**	**Female (n=487)**
Age, years	50.1	51.8	52.3	53.1
BMI	28.7	29.4	29.3	28.8
PASI	6.5	6.2	7.0	7.2
PsAID	4.6	5.2	4.8	5.3
TJC/SJC	5.9/3.3	7.3/3.2	7.0/3.7	7.3/3.8

All variables given as mean

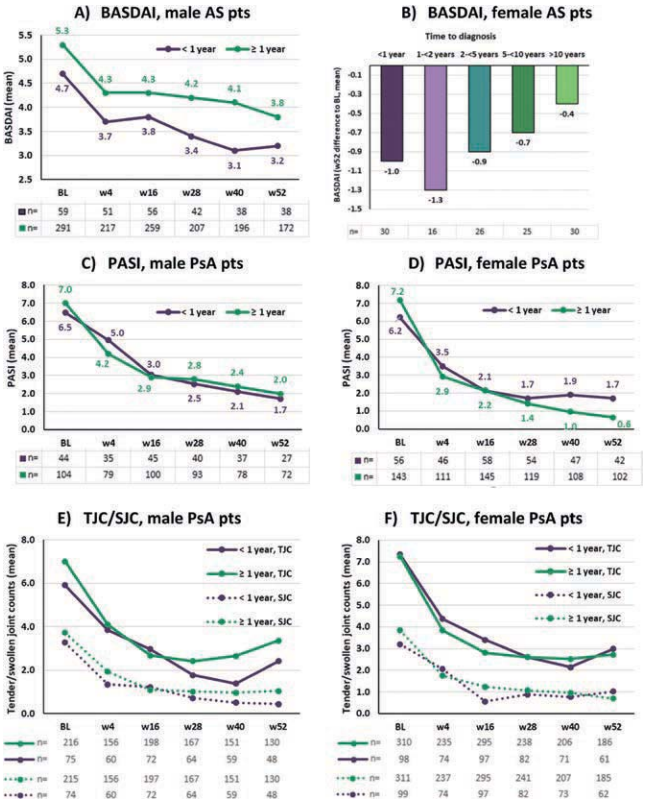

Figure 1. Disease activity in early- and late-diagnosed AS and PsA pts

Conclusion: In a real-world setting, secukinumab improved disease activity and global functioning in both AS and PsA pts. Both, male and female AS pts had a higher treatment response when diagnosed early. Interestingly, delay in diagnosis appeared to be BMI-dependent in female AS pts and PsA pts of both genders. However, in contrast to AS, treatment response of early- and late-diagnosed PsA pts did not differ in the further course.

AB0753 REAL LIFE DOSE REDUCTION OF BIOLOGICAL THERAPY IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES. UTILITY OF THE REDOSER TOOL

S. Manrique Arija[1], A. M. Cabezas-Lucena[1], F. Godoy-Navarrete[2], M. Morales-Águila[1], R. Redondo[1], N. Mena-Vázquez[1]. *[1]UCG of Rheumatology at the Hospital Regional Universitario de Málaga (HRUM). Institute for Biomedical Research in Malaga (IBIMA). Malaga University1, UCG of Rheumatology, Málaga, Spain; [2]UGC of Rheumatology, Hospital Universitario de Jaén, UCG of Rheumatology, Jaen, Spain*

Background: The long-term use of standard dosing of TNFi therapy is costly and not without side effects, including infections, tuberculosis and potential malignancies(1,2,). Hence, we undertook this study to determine whether dose reduction of TNFi therapy may be possible in a realworld setting and if REDOSER tool(3) is an appropriateness criteria for reducing the dose of BT.

Objectives: Describe the percentage of patients with inflammatory rheumatic diseases (IRD) who continue with dose reduction of biological therapy (BT). Evaluate relapse in clinical practice after 2 years of follow-up. Identify factors associated with relapse.

Methods: Retrospective observational study. Patients with axial spondyloarthritis (axial SpA), psoriatic arthritis (PSA) and rheumatoid arthritis (RA) in BT dose reduction. Inclusion criteria: Axial SpA according to ASAS criteria, APS according to CASPAR criteria and RA according to ACR2010 criteria, who have started reducing the dose of BT treatment between 2009-2019 at the Hospital Regional Universitario de Málaga, Spain. Protocol: patients with TB are followed prospectively in a monographic consultation with a pre-established protocol. The day of dose reduction = baseline visit (v0). *Variables:* **Maintained dose reduction:** % of patients who maintained dose reduction from the start of optimization to the index date (data collection). **Relapse at 12 and 24 months**: % of patients who, after starting dose reduction, returned to the previous or usual dose. Other variables: Demographic, time to diagnosis and evolution of the disease, clinical-analytical: disease activity (DAS28, DAPSA and BASDAI) and physical function (HAQ, BASFI). Previous treatments. Appropriateness criteria for reducing the dose of BT according to REDOSER (1): 1.appropriate, 2. inappropiate, 3. uncertain. Statistical analysis: Descriptive, bivariate, multivariate logistic regression (VD: relapse).

Results: One hundred twenty-nine patients with axial SpA, PSA and RA in BT dose reduction were included. The mean time from the start of BT to dose reduction was 38.1 months (16.6-73.1). The mean time in dose optimization was 19.5(±15.7) months. At the end of follow-up, 70.2% of the patients (87pts) achieved a sustained dose reduction. At 12 months and 24 months, 12.4% and 11.6% of patients relapsed, respectively. At the end of follow-up, there were no differences between baseline inflammatory activity and after 24 months in dose reduction measured by the different indexes: DAS28 (1.9[0.7] Vs 2.1[1, 7], p=0.323; DAPSA (5.4[4.9] Vs 4.8[4. 7], p=0.718, and BASDAI (1.5[1.1] Vs 1.4[1.3], p=0.867). Retrospectively, we evaluated the appropriateness of optimization according to the REDOSER tool (1) at the end of follow-up and it was observed that 85% of patients who maintained the dose reduction had an appropriate REDOSER and 14.5% uncertain and none inappropriate p<0.001.

Conclusion: Dose reduction of BT in IRD is possible in most patients, maintaining low disease activity or remission at 24 months, compared to baseline.
Relapse was associated with a longer evolution time of the IRD, a longer diagnostic delay, a higher inflammatory activity measured by the respective indices and a uncertain or inappropriate result of the REDOSER tool. This tool can be very useful used prior to the assessment of TB dose reduction

AB0754 REAL WORLD EVIDENCE ON DISEASE ACTIVITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TUMOUR NECROSIS FACTOR INHIBITORS AND/OR NONSTEROIDAL ANTI-INFLAMMATORY DRUGS IN ROUTINE CARE: RESULTS FROM THE "INVISIBLE" STUDY

J. Brandt-Juergens[1], J. Haschka[2], R. Finsterwalder[3], A. Casier[4], A. Kill[5], S. Dierckx[6]. *[1]Specialized practice for Rheumatology, Rheumatology, Berlin, Germany; [2]Karl Landsteiner Institute for Gastroenterology and Rheumatology, Rheuma-Zentrum Wien-Oberlaa, Vienna, Austria; [3]Novartis Pharma GmbH, Immunology, Hepatology & Dermatology, Vienna, Austria; [4]N.V. Novartis Pharma S.A., Immunology, Hepatology & Dermatology, Vilvoorde, Belgium; [5]Novartis Pharma GmbH, Immunology, Hepatology & Dermatology, Nuremberg, Germany; [6]CHU UCL Namur- Site Godinne, Rheumatology, Yvoir, Belgium*

Background: Ankylosing Spondylitis (AS) is an inflammatory rheumatic disease affecting the axial skeleton (1), with a prevalence of up to 0.5% in Europe (2; 3), and occurs in men twice as often than in women (4). 80% develop AS symptoms before the age of 30 (4). Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) and biological Disease-Modifying Antirheumatic Drugs (DMARDs) such as Tumour Necrosis Factor inhibitors (TNFi) are the first choice in pharmacological

treatments for AS patients (5; 6). Data on disease activity and disease control in AS patients treated in real life settings are limited.

Objectives: To evaluate the average disease activity status in the study population and assess the percentage of AS patients with a suboptimal treatment response following at least 12 weeks of treatment with TNFi and/or NSAIDs.

Methods: INVISIBLE was a real-world evidence study in Germany, Austria and Belgium. Adult patients with confirmed diagnosis of AS for at least 6 months and ongoing treatment with TNFi and/or NSAIDs for at least 12 weeks prior to enrolment were included. Primary data were collected at a single visit and medical history data from available patient files.

Results: 747 adult AS patients were included. 67% of patients were male, mean symptom duration 18.2 years. 77% of 696 patients were HLA-B27 positive. Appr. 23% of patients received NSAIDs, 42% received TNFi, 30% received both NSAIDs and TNFi, 5% received other treatment for at least 12 weeks prior to enrolment. Mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS) scores were 3.4 and 2.2, respectively. Appr. 40% of patients achieved a BASDAI score ≥4 and appr. 50% an ASDAS ≥2.1. Patients with a BASDAI score ≥4 achieved higher scores in most physician and patient reported outcomes. Overall appr. 35% of patients were not satisfied with their current symptom state according to Patient Acceptable Symptom State (PASS). Of patients with a BASDAI score ≥4 appr. 61% were not satisfied according to PASS.

Conclusion: Results from the non-interventional study INVISIBLE showed that a high proportion of AS patients receiving NSAIDs and/or TNFi have high disease activity according to BASDAI and ASDAS in real life settings. These results suggest that in some patients, disease control and treatment response are suboptimal under current treatment strategy.

Table 1. Demographics and Disease Characteristics

	Total (N=747)		BASDAI <4 (N=445)		BASDAI ≥4 (N=292)	
	N	Result	N	Result	N	Result
Age in years, mean (±SD)	746	47.9 (±13.1)	445	46.7 (±13.4)	292	49.6 (±12.3)*

AB0755 HIP DENERVATION AND INTRA-ARTICULAR HYDRATION IN AXIAL SPONDYLOARTHRITIS PATIENTS WITH HIP DAMAGE

A. Elsaman[1], A. Khalifa[1], A. Maaty[2]. *[1]Sohag University Hospital, Rheumatology and rehabilitation, Sohag, Egypt; [2]Suez canal university, Rheumatology and rehabilitation, Ismailia, Egypt*

Background: The hip joint is frequently affected in axial spondyloarhritis (SpA) of the adults with destructive effect in untreated patients. About 35% of axial SpA patients had either unilateral or bilateral hip arthritis. Destruction is more common with early-onset, active disease, or enthesitis [1, 2].

Objectives: The aim of this study is to evaluate the effect of hip denervation (HD) and intra-articular hydration (IAH) on pain, function score, hip mobility scores in a cohort of axial SpA patients with grade 3 and 4 hip BASRI score.

Methods: We enrolled 40 patients who fulfilled ASAS criteria for axial SpA. All had hip involvement with grade 3 or 4 BASRI score at baseline.

They were divided into 4 groups; group one received placebo, group 2 HD, group 3 IAH, and group 4 received HD and IAH. They all were assessed at baseline and after 4 weeks and 12 weeks. Outcome measures included; VAS, semi-quantitative scores of tenderness for the hip, range of motion, and Harris functional hip score (HHS).

Results: A significant improvement of VAS pain, tenderness score, ROM, HHS were detected in group 4 versus other groups ($p < 0.05$). Group 2 had significantly lower scores of tenderness and pain compared to group 3 ($p < 0.05$). In contrast, the patients of group 3 show better ROM and HHS than the patients of group 2 ($p < 0.05$). At 4- and 12-week, all therapeutic groups (2, 3, and 4) show considerable improvement in comparison to placebo (group 1) ($p < 0.05$).

Conclusion: HD and IAH can improve pain and function in damaged hip of axial SpA patients, especially when concurrently used.

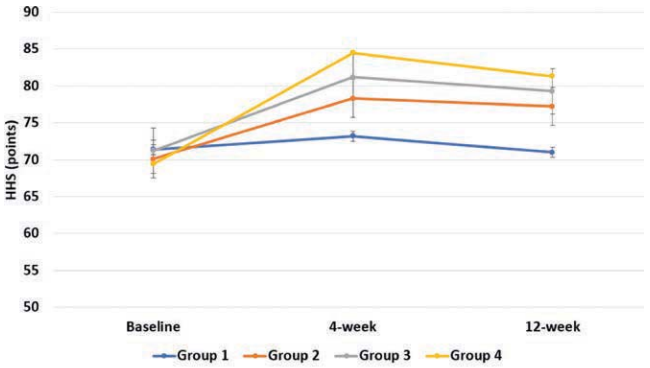

Fig. 1 HHS in all the studied groups during follow up.

AB0756 FIRST SPANISH STUDY ON THE EFFECTIVENESS OF ULTRASOUND-GUIDED INJECTION OF CORTICOSTEROIDS INTO THE SACROILIAC JOINT OF PATIENTS WITH SPONDYLOARTHRITIS.

M. A. Ramírez Huaranga[1], D. Castro-Corredor[2], A. E. Plasencia Ezaine[1], M. Paulino Huertas[2], R. Arenal Lopez[1], J. Anino-Fernández[2], C. C. Ramos Rodriguez[3] on behalf of REUDOL. *[1]Hospital General Universitario de Ciudad Real, Interventional Rheumatology, 13001, Spain; [2]Hospital General Universitario de Ciudad Real, Rheumatology, 13001, Spain; [3]Hospital General Universitario de Ciudad Real, Pathology, Ciudad Real, Spain*

Background: Sacroiliitis may be the main manifestation or a complication of any of the variants of spondyloarthritis. The few studies performed in patients with spondyloarthritis mainly evaluate the improvement in pain using a visual analog scale (VAS) and are limited by the need for an operating room and guidance based on fluoroscopy, tomography, or magnetic resonance. The advent of new ultrasound devices has meant that during the last decade, alternative approaches have been proposed for ultrasound-guided injection of the sacroiliac joint.

Objectives: To determine clinical improvement (Bath Ankylosing Spondylitis Activity Index [BASDAI], Ankylosing Spondylitis Disease Activity Score [ASDAS], acute-phase reactants, and the VAS score) after ultrasound-guided injection of corticosteroids into the sacroiliac joint of patients with spondyloarthritis.

Methods: We performed an observational, descriptive, and retrospective study at Ciudad Real General University Hospital (HGUCR), Ciudad Real, Spain. We reviewed the register of procedures carried out between June 1, 2020 and May 31,

2021 and included all patients with spondyloarthritis and inflammatory low back pain despite treatment with nonsteroidal anti-inflammatory drugs, biologics, or both. All patients underwent ultrasound-guided injection of the sacroiliac joint with corticosteroids (betamethasone chronodose 6/6 mg in each joint). We excluded patients whose clinical history did not contain the study variables and in whom modifications to pharmacologic treatment could have reduced the effectiveness of the injection. The outcome measures were presence of adverse effects/complications, reduction in the VAS score for inflammatory pain (>0=3 points), reduction of ≥1.1 points in the ASDAS score, reduction of ≥2 points in the BASDAI score, and reduced CRP and ESR values. These data were analyzed by comparing means (*t* test) for the variables VAS, BASDAI, ASDAS, CRP, and ESR. The potential association between the variables and a favorable clinical response was evaluated by calculating the odds ratio. The protocol was approved by the Research and Ethics Committee of Integrated Care Management, Ciudad Real, Spain.

Results: We analyzed 32 patients with spondyloarthritis (age 42.69±8.19 years; female sex, 56.25%) with a VAS score of 7.88±0.79, BASDAI of 5.43±1.48, and ASDAS of 3.27±0.86 before the procedure. At 2-3 months, 75% of patients had improved: VAS 3.81±2.33 (–4.07, p<0.0001) and BASDAI 3.24 ± 1.6 (–2.19, p<0.0001). At 5-6 months, 59.37% had improved: VAS 4.63±2.31 (–3.25, p<0.0001), BASDAI 3.57±1.67 (–1.86, p<0.0001), and ASDAS 2.27±0.71 (–1.0, p<0.0001). Bone marrow edema resolved in 87.5% of cases compared with the previous magnetic resonance scan. Analysis of factors potentially associated with improved clinical response as measured using the VAS, BASDAI, and ASDAS did not reveal a significant association with the variables analyzed (age, time since diagnosis, grade of sacroiliitis by radiography, presence of HLA B27 (+), peripheral and extra-articular manifestations, type of treatment). However, all the patients whose symptoms improved (EVA, BASDAI, and ASDAS) had had bone marrow edema on their magnetic resonance scan <1 year before the treatment. Only 5 patients experienced injection site pain, which lasted 1-2 days. No other adverse effects were reported.

Conclusion: Ultrasound-guided injection of corticosteroids into the sacroiliac joint of patients with spondyloarthritis and active sacroiliitis leads to an improvement in symptoms that is maintained at 5-6 months. The procedure is effective, safe, inexpensive, and easy to apply.

AB0757 THREE-YEAR DYNAMICS OF INFLAMMATORY CHANGES IN THE HIP JOINTS IN AXIAL SPONDYLOARTHRITIS.

E. Agafonova[1], D. Timokhina[1], S. Erdes[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory spondyloarthritis, Moscow, Russian Federation*

Background: Almost half of the patients with axial spondyloarthritis (axSpA) in Russia diagnosed hip joint lesions (HJ), but the causes and rates of progression are not studied. Until now, it remains unclear whether synovitis detected on MRI and ultrasound of hip joint is a predictor of radiological progression of coxitis.

Objectives: To assess the dynamics of inflammatory changes in the hip joint using instrumental research methods during 3-years observation and their relationship with the activity of axSpA.

Methods: 45 patients (mean age 30,07±7,1 years) with a diagnosed with axSpA (ASAS criteria 2009), which were observed for at least 3 years. Among them, AS according to the modified New York criteria (1984) - 40 (89%) patients and 5 (11%) were diagnosed with nr-axSpA. The median duration of the disease was 36 [19;108] moth, BASDAI 4,3 [3,1;6,8], BASFI 2,0 [0,6;4,7]. All patients underwent clinical, X-ray, ultrasound and MRI examination of the hip joint during the entire observation period. For ultrasound, coxitis was considered an increase in the cervical-capsular distance (CCD) of more than 7 mm. For MRI inflammatory changes were taken as osteitis of the acetabulum and / or femoral head and synovitis in STIR mode.

Results: At the time of inclusion of 45 patients, clinical signs of hip joint lesions were present in 66 (86%) patients, and after 36 months in 36 (80%) (p>0,05). The median CCD at the time of inclusion was 7,3 [6,6;7,9] mm, and after three years 6,6 [5,9;8,6] mm (p> 0.005). According to ultrasound, at the time of inclusion, 36 (80%) of 45 patients had coxitis, and after 3 years, 26 (58%) (p <0,005). Analysis of MRI changes initially showed the presence of synovitis in 42 (93%), and osteitis in 13 (29%) patients, and after 3 years synovitis persisted in y 25 (56%) (p <0,05), osteitis in 12 (27%) (p>0,005) and in 19 (42%) MRI patients, signs of active inflammation were arrested. Among all examined patients at the beginning of the study, the coincidence of signs of synovitis according to ultrasound and MRI data was noted in 35 (78%) cases. X-ray coxitis at the time of inclusion was detected in 11 (24%) patients, and after 2 years in 32 (68%) (p<0,05). The patients were divided into two groups ΔBASRI hip> 0 and ΔBASRI hip = 0. (Table 1)

Table 1. Characteristics of patients with axSpA at the time of inclusion in the study who had X-ray progression of coxitis after 36 months of observation.

Parametrs	ΔBASRI hip=0 n=15	ΔBASRI hip >0 n = 30	p
The duration of the disease, m., Me [25;75‰]	48 [12;120]	30 [24;108]	>0,05
Age, years, Me [25;75 ‰]	30,5 [23;34]	30,5 [25;35]	>0,05
BASDAI, Me [25;75 ‰]	6,7 [4,2;8,6]	4,2 [2,4;5,9]	<0,05
BASFI, Me [25;75 ‰]	4,4 [1,8;8,1]	1,7 [0,6;3,1]	>0,05
ASDAS (SRP), Me [25;75 ‰]	2,6 [1,6;3,9]	2,8 [2,1;4,2]	>0,05
ESR, mm/h, Me [25;75 ‰]	15 [7;30]	14,0 [7;27]	>0,05
SRP, mg/l, Me [25;75 ‰]	14,8 [10;56,0]	22,8 [3,7; 31,8]	>0,05
Peripheral arthritis, n %	11 (73%)	20 (67%)	>0,05
US synovitis n%	9 (60%)	23 (77%)	>0,05
Pain in HJ n%	28 (85%)	38 (86%)	>0,05
Synovitis in MRI, n%	15 (100%)	27 (90%)	>0,05
Osteitis in MRI, n%	3 (20%)	10 (34%)	>0,05
Therapy bDMARDs	9 (60%)	9 (30%)	<0,05

Conclusion: X-ray progression of coxitis in axSpA practically does not depend on the activity of the disease, nor on local signs of inflammation in the HJ, detected by ultrasound and MRI. X-ray progression of HJ lesions is less common in patients receiving bDMARDs therapy.

AB0758 GOLIMUMAB AFTER DISCONTINUATION OF NON-TNF INHIBITORS IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES: FOUR-YEAR RETENTION RATE IN THE SPANISH BIOBADASER REGISTRY

M. Pombo-Suarez[1], D. Seoane-Mato[2], F. Diaz-Gonzalez[3], F. Sánchez-Alonso[2], L. Cea-Calvo[4], M. Sánchez-Jareño[4], V. Jovani[5], P. Pretel[6], F. J. Manero Ruiz[7], I. Castrejon[8]on behalf of BIOBADASER Investigators. *[1]Santiago de Compostela University Hospital, Rheumatology, Santiago de Compostela, Spain; [2]Spanish Society of Rheumatology (SER), Research Unit, Madrid, Spain; [3]Canarias University Hospital, Rheumatology, Santa Cruz de Tenerife, Spain; [4]MSD Spain, Medical Affairs, Madrid, Spain; [5]Alicante General University Hospital, Rheumatology, Alicante, Spain; [6]Príncipe de Asturias University Hospital, Rheumatology, Alcalá de Henares, Spain; [7]Miguel Servet University Hospital, Rheumatology, Zaragoza, Spain; [8]Gregorio Marañón University Hospital, Rheumatology, Madrid, Spain*

Background: Treatment options for rheumatic diseases have evolved to include mechanisms of action beyond tumor necrosis factor inhibitors (TNFi). While non-TNFi biologics and targeted synthetic disease-modifying antirheumatic drugs (tsDMARDS) have been studied as first-line therapy or after TNFi discontinuation, data on the use of TNFis after discontinuation of these drugs is scarce.

Objectives: We assessed the probability of retention (persistence or drug survival) of golimumab in patients with rheumatic diseases when used after discontinuation of non-TNFi biologicals or tsDMARDs.

Methods: Characteristics of all adults with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (SpA) who had initiated golimumab after discontinuation of non-TNFi biologicals or tsDMARDs in the BIOBADASER database were analyzed. The probability of golimumab retention was assessed with the Kaplan-Meier method, and differences between groups with the log-rank test. Patients were right-censored if they were still treated with golimumab at the last observation for data analysis. We also compared the probability of retention of patients who initiated golimumab after discontinuation of non-TNFi biologicals or tsDMARDs with that of patients who initiated it after discontinuation of TNFis.

Results: A total of 125 patients (85 [68%] women) with RA (n=72), axSpA (n=23), or PsA (n=30) had initiated golimumab after discontinuation of non-TNFi biologicals or tsDMARD. Golimumab had been initiated as second line of therapy (i.e., after discontinuation of a first non-TNFi biological or tsDMARD) in 26 patients (21%), as third in 29 (23%) and as fourth/subsequent line of therapy in 70 patients (56%). Upon golimumab initiation, the median disease duration was 10.0 years. The most common previously discontinued therapies were secukinumab (n=34) and abatacept (n=23). The retention rates of golimumab were 61% (95% confidence interval [CI]: 51-69) at year 1 (number at risk: 66), 46% (95% CI: 36-55) at year 2 (number at risk: 39), 40% (95% CI: 30-50) at year 3 (number at risk: 23) and 33% (95% CI: 23-44) at year 4 (number at risk: 13). There were no differences in retention rates over 4 years when golimumab was used as the second, third, or fourth/subsequent line of therapy (p=0.462). Retention rate was lower in

RA patients (26% at year 3) than in axial SpA (68%) or PsA (49%) (p=0.002) (Figure 1). As second line therapy, the 3-year retention rate of golimumab was slightly lower when it was initiated after non-TNFi biologicals/tsDMARD than when the previously discontinued therapy was a TNFi (32% vs 55%, p=0.119), but the figures were similar when it was initiated as third (52% after non-TNFi biologicals/tsDMARD vs 50% after TNFi, p=0.838) or as fourth/subsequent line of therapy (37% vs 44% respectively, p=0.554).

Conclusion: We present, for the first time, 4-year retention rates for golimumab in patients who discontinued non-TNFi biologicals or tsDMARDs, most of them in third and fourth/subsequent line of therapy. In this difficult-to-treat rheumatic population, overall golimumab retention rates were favorable through 4 years of treatment, with higher rates in SpA and PsA compared to RA patients.

EFFICACY OF SECUKINUMAB IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: ANALYSIS BY SYMPTOM DURATION AND AGE

A. Deodhar[1], D. Poddubnyy[2], R. Blanco[3], S. Hall[4], M. Magrey[5], E. Quebe-Fehling[6], R. Calheiros[7], P. Pertel[6], H. Marzo-Ortega[8]. [1]*Oregon Health and Science University, Division of Arthritis and Rheumatic Diseases, Portland, United States of America;* [2]*Charité Universitätsmedizin, German Rheumatism Research Centre, Berlin, Germany;* [3]*Hospital University Marqués de Valdecilla, IDIVAL, Division of Rheumatology, Santander, Spain;* [4]*Monash University, Department of Medicine, Melbourne, Australia;* [5]*Case Western Reserve University School of Medicine, University Hospitals, Rheumatology Department, Cleveland, Ohio, United States of America;* [6]*Novartis Pharma AG, Immunology, Hepatology & Dermatology, Basel, Switzerland;* [7]*Novartis Pharmaceuticals, Immunology, Hepatology & Dermatology, East Hanover, New Jersey, United States of America;* [8]*NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust and LIRMM, University of Leeds, Leeds, United Kingdom*

Background: Patients (pts) with axial spondyloarthritis (axSpA) often experience delayed diagnosis, which can lead to treatment delay[1]. However, earlier diagnosis and treatment of axSpA pts can lead to a greater clinical response[2]. Secukinumab (SEC) 150 mg has demonstrated sustained improvement in signs and symptoms over 2 years in non-radiographic (nr)-axSpA pts[3].

Objectives: To assess the efficacy of SEC in pts with nr-axSpA [tumour necrosis factor (TNF) naïve] by subgroups of younger versus (vs) older pts and early vs late symptom duration of back pain.

Methods: PREVENT (NCT02696031) is a phase 3, randomised study in pts with nr-axSpA and detailed study design is reported previously4. In this post hoc analysis, efficacy outcomes including Assessment of SpondyloArthritis international Society 40 (ASAS40), ASAS partial remission (ASAS PR), Ankylosing Spondylitis Disease Activity Score-C-reactive protein (ASDAS-CRP) inactive disease (ID) and low disease activity (LDA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and the proportion of pts meeting the minimal clinically important difference criteria for total back pain (improvement of ≥50%) were assessed in the TNF naïve population. Age categories included 4 approximately equally distributed age groups (18 to 33, 34 to 42, 43 to 51 and ≥52 years). The categories for time since onset of back pain as a surrogate of disease symptoms and sign, was based on patients' distribution and the hypothesis that patients with shorter disease duration will present better results (≤2, >2 to 5, >5 to 10 and >10 years). Missing responses were imputed as non-response up to Week (Wk) 16 and reported as observed at Wks 52 and 104. Data is presented here for categories 18-33 vs ≥52 years and patients with symptom duration ≤2 vs >10 years.

Results: At Wk 104, greater improvements in ASAS40 scores were reported in younger (18-33 years) vs older age categories (>52 years) treated with SEC and also in patients with shorter disease duration (≤2 years) when compared to long term disease (Figure 1 and Table 1).

Conclusion: Efficacy responses were numerically higher with SEC in patients with nr-axSpA with shorter symptom duration and in younger age. These data suggest that earlier treatment improves patient outcomes in nr-axSpA.

FACTORS ASSOCIATED WITH THE RETENTION OF SECUKINUMAB (SEC) IN PATIENTS WITH PSORIATIC ARTHRITIS (PSA) IN REAL WORLD PRACTICE: RESULTS FROM THE RETROSPECTIVE FORSYA STUDY

A. Ruyssen-Witrand[1], J. Lucas[2], E. Desfleurs[3], P. Claudepierre[4], M. Dougados[5], P. Goupille[6], C. Lukas[7], A. Saraux[8], A. Tournadre[9], D. Wendling[10]. *[1]University Hospital of Toulouse, Department of Rheumatology, Toulouse, France; [2]RCTs Clinical Research Organisation, Biostatistics, Lyob, France; [3]Novartis Pharma SAS, Medical affairs, Rueil Malmaison, France; [4]Hôpital Henri Mondor, Assistance Publique - Hôpitaux de Paris, Department of Rheumatology, Créteil, France; [5]Hôpital Cochin. Assistance Publique - Hôpitaux de Paris, Department of Rheumatology, Paris, France; [6]University Hospital of Tours, Department of Rheumatology, Tours, France; [7]University Hopsital Montpellier, Department of Rheumatology, Montpellier, France; [8]CHU Brest, Department of Rheumatology, Brest, France; [9]CHU Clermont Ferrand, Department of Rheumatology, Clermont Ferrand, France; [10]CHRU de Besançon, Department of Rheumatology, Besançon, France*

Background: While data on real-life retention of SEC in patients (pts) with PsA is accumulating, there are no data on predictive factors for this retention.
Objectives: The primary objective of FORSYA study was to assess whether objective signs of inflammation (OSI) were predictive of SEC retention at 1 year.
Methods: French retrospective study collecting between October 2019 and September 2020 data from axSpA pts a) having initiated and received at least one dose of SEC between August 11th 2016 and August 31st 2018, b)with at least a one year follow-up period. Retention of SEC at 1 year was estimated by the Kaplan Meier (KM) method. OSI were defined by at least one of the following within the 3 months before initiation of SEC: CRP> N, confirmed clinical dactylitis, confirmed clinical synovitis or ultrasonography power-Doppler positive synovitis except on MTP of first toe. Preselected factors at initiation of SEC retention at 1 year (≥1 OSI, age, sex, BMI, smoking status, axial feature, past or present psoriasis / uveitis / Inflammatory Bowel Disease (IBD) / active arthritis or synovitis, diagnostic delay, disease duration, SEC line of biologic therapy, SEC maintenance dose, concomitant csDMARD, concomitant oral corticosteroids, ≥1 comorbidity) were analyzed by multivariate cox model regression. Only variables with <20% missing data were included in the model after imputation and stepwise selection (significance level for entering variables = 20%; for removing variables = 10%). OSI was forced into the model whatever its significance level or rate of missing data.
Results: In total, 475 pts (male: 40.2%, mean age: 51.9 ± 12.2 years, mean disease duration: 9.3 ± 8.6 years) from 48 centers were included in the analysis. At initiation of SEC, 62.2% of pts had ≥ 1 OSI and respectively 11.0%, 19.5% and 69.6% were in 1st, 2nd and ≥ 3rd line (L) of biologic/targeted synthetic DMARD. The overall 1 year KM survival rate for SEC was 63% [95%CI: 59%-68%] and was numerically greater in 1st L vs 2nd and ≥3rd L (82% [72%-93%], 62% [52-72%], 61% [56%-66%] respectively). The overall survival rates for PsA pts with or without OSI were 62% [56%-68%] and 71% [62%-80%]. In multivariate analysis, absence of OSI, longer disease duration and lack of prior exposure to anti-TNF inhibitors were associated with a better SEC retention at 1 year (Table 1).

Table 1. Predictive factors of SEC 1 year retention of SEC identified by multivariate cox regression analysis (multiple imputation + Stepwise selection)

Predictive factors (* reference)		HR [95% CI]	p vs refp type III	
At least one objective sign of inflammation	No (N=175)*			
	Yes (N=295)	1.46 [1.05; 2.02]	0.023	
Disease duration (years)	≤ 7.2 years (N=241)*			
	> 7.2 years (N=229)	0.69 [0.51; 0.94]	0.017	
Secukinumab treatment line	1st L (N=50)*			0.015
	2nd L (N=92)	2.43 [1.17; 5.05]	0.018	
	≥ 3rd L (N=328)	2.72 [1.38; 5.36]	0.004	

Interpretation for predictor: HR> 1: the hazard of discontinuation at 1 year is X times higher in category vs reference.

Conclusion: The overall retention of SEC at 1 year in daily practice at the time of its launch in France was 63% for PsA patients and OSI, disease duration and prior exposure to TNF inhibitors were identified as predictive factors of SEC retention.

Tam1on behalf of APLAR SpA registry. *[1]The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong (SAR); [2]Singapore General Hospital, Rheumatology & Immunology, Singapore, Singapore; [3]Siriraj Hospital, Mahidol University, Medicine, Bangkok, Thailand; [4]Sengkang General Hospital, Rheumatology, Singapore, Singapore; [5]Institute of Rheumatic Diseases, Central Park Medical College, Rheumatology, Lahore, Pakistan; [6]SMG-SNU Boramae Medical Center, Internal Medicine, Seoul, Korea, Rep. of (South Korea); [7]Goyal Hospital, CARE Pain & Arthritis Centre, Udaipur, India; [8]Fatima Memorial Hospital & FMH College of Medicine and Dentistry, Internal Medicine, Lahore, Pakistan; [9]Hamad Medical Corporation, Rheumatology, Doha, Qatar; [10]Velammal Medical College Hospital, Rheumatology and Medicine, Maduri, India; [11]The University of Hong Kong, Medicine, Hong Kong, Hong Kong (SAR); [12]Chung Shan Medical University, Department of Allergy, Immunology & Rheumatology, Tai Chung, Taiwan, Republic of China; [13]Keio University, School of Medicine, Tokyto, Japan*

Background: Data on the extent of treat-to-target (T2T) recommendations application in SpA patients across Asia Pacific region is lacking. APLAR SpA Registry aimed to assess the utility of T2T on long term clinical outcomes, and to improve disease management and inform health care policy.
Objectives: To provide a snapshot of the registry including demographics, disease activity and medication use.

Methods: Patients fulfill the CASPAR 2006 for psoriatic arthritis (PsA) and 2009 ASAS criteria for axial spondylitis (AxSpA) were recruited. This cross sectional analysis included the first 188 patients recruited across 7 Asia Pacific regions (Hong Kong, Singapore, Korea, Thailand, India, Qatar & Pakistan).

Results: 83 patients PsA and 115 AxSpA patients were included. They had moderate inflammation (DAPSA: 19.61±14.29, ASDAS: 2.32±1.07). Majority of PsA patients received conventional synthetic disease-modifying drug (csDMARDs, 81%) with relatively low prevalence of biologic DMARDs (bDMARDs) (24%). Most AxSpA patients used NSAIDs (79%) while nearly half of them received bDMARDs (49%). Other details listed in Table 1. Prevalence of bDMARDs use in our registry was lower than that from the USA (Corrona PsA Registry, 59%), Turkey & Canada (PsArt-ID, 40%) and the Netherlands AxSpA registry (56%) (1-3). Regarding T2T, 28% and 44% of PsA patient achieved minimal disease activity (MDA) and Disease Activity in Psoriatic Arthritis low disease activity (DAPSA LDA) respectively. The proportion of patients achieving target in other cohorts were 46% for MDA (PsArt-ID) and 46% for DAPSA LDA (Corrona) (1, 2). 37% and 47% of AxSpA patient achieved Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)<4 and Ankylosing Spondylitis Disease Activity Score (ASDAS) LDA. Proportion of patients achieving ASDAS LDA were similar to the Netherlands registry for patients with ASDAS LDA or BASDAI<4 (Figure 1A)(3). Patient on bDMARD were more likely to achieve treatment target (Figure 1B). There were no significant difference between socio-economic status and disease features between bDMARD user and non-user.

Table 1. Demographics, clinical features and disease activity of patients

	PsA (n=83)		AxSpA (n=115)	
Age	50.0	12.8	36.5	12.4
Male n, %	42	51%	85	83%
Asian n, %	83	100%	101	96%
Disease duration, years	7.1	7.3	5.2	7.6
Any sacroiliitis n, %			102	99%
HLA B27, positive n, %			91	89%
Duration of early morning stiffness, min	30	39	25	29
Tender joint count	7	9	0	1
Swollen joint count	3	4	0	0
No. of dactylitis digit	1	1	0	0
PASI	4.0	5.0		
SPRACC	1	2	0	1
BASDAI			2.8	2.0
ESR, mm/h	31	26	20	16
CRP, mg/L	10	15	11	27
HAQ-DI	0.61	0.61	0.39	0.51
DAPSA	19.61	14.29		
ASDAS CRP			2.32	1.07

Data given in mean SD unless stated. No. of case from Hong Kong 40; Singapore 46; Korea 24; Thailand 20, India 15; Qatar 10; Pakistan 33; HLA - human leucucyte antigen; PASI - psoriasis area and severity index; SPRACC - Spondyloarthritis Research Consortium of Canada Enthesitis Index; BASDAI - Bath Ankylosing Spondylitis Disease Activity Index; ESR - erythrocyte sedimentation rate; CRP - C-reactive protein; HAQ-DI - Health assessment questionnaire disability index; DAPSA - Disease activity in Psoriatic Arthritis; ASDAS - Ankylosing Spondylitis Disease Activity Score

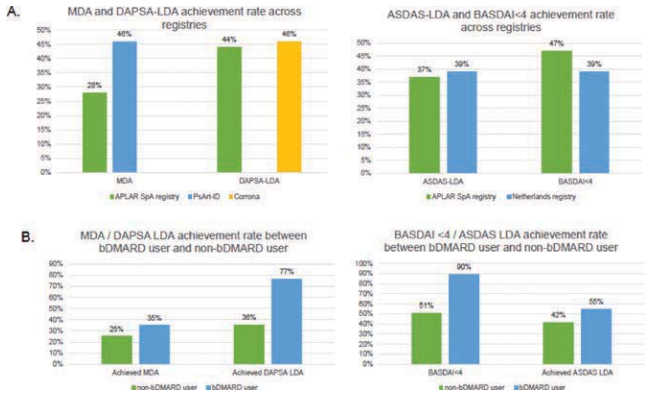

Figure 1. (A) Achievement of LDA in APLAR SpA registry and other registry and (B) use of bDMARDs among patients in APLAR SpA registry with or without achieving LDA

Conclusion: Patient using bDMARDs were more likely to achieve treatment target. We expect that when T2T is widely applied, better outcomes will be reported in future.

Background: Secukinumab (SEC), a human anti-IL-17A monoclonal antibody, has similar treatment response rates to tumor necrosis factor (TNF) inhibitors in patients with axial spondyloarthritis (SpA). However, the efficacy of SEC on anterior uveitis (AU) is unclear.

Objectives: This study aimed to evaluate the risk of new-onset or relapsing AU in axial SpA patients treated with SEC.

Methods: In this prospective cohort study, 130 axial SpA patients receiving SEC at the TURKBIO registry between 2019 and 2021 were evaluated. Demographic and clinical characteristics and data about the presence of AU pre or post-treatment were collected. The univariate and multivariate logistic regression analyses were performed to evaluate the predictors of AU development.

Results: The mean age of the patients (F/M: 59/71) was 47.4±10.9 years. The median follow-up time was 540 days (IQR: 330-630). SEC was the first biological agent in 50 (38.4%) patients and 35 (26.9%) patients were using at least one concomitant conventional synthetic DMARD (Table 1). While continued SEC therapy was in 93 (71.5%) patients, treatment withdrawal was in 37 cases (in 26 due to ineffectiveness, two adverse events and nine other reasons). Overall, 15(11.5%) patients had a history of AU before the SEC. During follow-up, AU attacks were seen in the 6 cases (4 were new-onset and 2 were flare) and 5 of these patients have a history of inadequate response to TNF inhibitors. The frequency of AU was

calculated as 3.42 per 100 patient-years during SEC treatment. The only significant predictor of AU development was the baseline high C-reactive protein (CRP) level on multivariate analysis (p=0.003, OR: 1.063 [95% CI 1.021-1.107]).

Table 1. Demographics and clinical characteristics of the patients

	Total (n:191)

AB0763 PERSONAL APPROACH IN AXIAL SPONDYLOARTHROPATHY MANAGEMENT

B. Bugaj[1], J. Wielinska[2], J. Swierkot[1], K. Bogunia-Kubik[2]. [1]*Wroclaw Medical University, Department of Rheumatology and Internal Medicine, Wroclaw, Poland;* [2]*Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Laboratory of Clinical Immunogenetics and Pharmacogenetics, Wroclaw, Poland*

Background: Spondyloarthropathies (SpAs) are a group of diseases characterized by arthritis in the spine (axialSpA - axSpA) and peripheral joints, and extra-articular symptoms like uveitis, psoriasis or inflammatory bowel diseases. The onset of the disease is difficult to observe. Due to the lack of a pathognomonic test, diagnosis is based on a combination of physical examination, laboratory test and imaging results. The pathogenesis of SpAs is not fully understood, and genetic, environmental and immunological factors are assumed to play a pivotal role.
Objectives: The study aimed to evaluate selected polymorphisms (ERAP1 rs2287987, ERAP2 rs2549782, TNF rs1800629, TNFRSF1B rs1061622, FCGR2A rs1801274) as prognostic factors of clinical presentations, and response predictors of anti-TNF treatment in axSpA patients.
Methods: The study enrolled 216 Caucasians: 106 axSpA patients and 110 healthy controls. AS patients were diagnosed according to modified New York criteria, while nr-axSpA patients were diagnosed according to ASAS criteria. Genotyping was performed using LightSNiP assays on the Real-Time PCR Instrument. Clinical data were assessed at baseline, as well as after three and six months of anti-TNF treatment. In addition, information's about extra-articular symptoms were collected.
Results: The statistical analysis revealed that TNFRSF1B rs1061622-GG was significantly associated with a higher VAS score at baseline (TT + TG vs GG, p = 0.001), and a higher BASDAI score corrected for the first therapy cycle (X1C BASDAI: TT + TG vs GG, p = 0.005). Moreover, homozygotes were more frequently observed with a lack of BASDAI improvement after six months (X1C BASDAI: TT+GG vs TG, p = 0.045, OR = 2.46, 95%CI 1.00-6.12). ERAP1 rs2287987- GG was more frequently observed with enthesitis (AA vs G+, p = 0.049, OR = 4.636, 95%CI 1.101-21.24). The GG genotype of TNFRSF1B rs1061622 was more common in patients with uveitis than TT variant (GG vs TT, p =0.042, OR = 5, 95%CI 1.08-20). Associations between genetic variants and clinical outcomes were evaluated using laboratory parameters. A lack of the ESR improvement after six months of treatment was more frequently observed within ERAP1 rs2287987-AG (AG vs AA + GG, p = 0.027, OR = 2.72, 95%CI 1.115-6.137) and TNFRSF1B rs1061622- TT (TT vs G+, p = 0.020, OR = 3, 95%CI 1.27-6.9) compared to other genotypes. After three months of therapy, the GG variant of ERAP2 rs2549782 polymorphism was more common among individuals with the lack of ESR improvement than T allele carriers (GG vs T+, p = 0.037, OR = 2.76, 95%CI 1.13-6.72). Differences were also detected between the FCGR2A rs1801274 polymorphism and X1CBASDAI score after six months. The low disease activity (BASDAI < 3) and BASDAI improvement was more frequently observed in patients carrying the A allele than the GG genotype (AA+AG vs GG, p = 0.028, OR = 4.545, 95%CI 1.337-16 and p = 0.012, OR = 6.212, 95%CI 1.683-20.47, respectively). The AG genotype was more common among patients with remission (BASDAI < 2) compared to homozygotes (AG vs AA+GG, p = 0.046, OR = 2.36, 95%CI 1.05-5.13).
Conclusion: Genetic profiling of patients will help to identify those at risk of high initial disease activity or the presence of extra-articular symptoms. Identifying patients less responsive to treatment may allow selecting a drug with an appropriate efficacy profile.

AB0764 FACTORS ASSOCIATED WITH REMISSION AFTER GRADUAL DECLINE OF TNFI IN SPONDYLOARTHRITIS

S. Abdellaoui[1], S. Lefkir[1]. [1]*Issad Hassani Beni messous hospital, Rheumatology, Algiers, Algeria*

Background: The natural history of axial spondyloarthritis (axSpA) includes periods of remission interspersed with flares. It is recommended to target remission during the disease management, the 2 most used definitions are ASAS partial remission and inactive disease (ASDAS <1.3 and / or BASDAI score <3.6). The factors associated with the gradual decline of biologics after achieving remission have been little explored.
Objectives: The objective of this work was to assess the proportion of patients with axSpA treated with TNFi in whom remission was maintained concomitantly with tapering at 3 years of follow-up and to identify the factors associated with this remission.
Methods: Single-center prospective descriptive study. A total of 44 patients included who attempted to space TNFi injections (etanercept, infliximab, adalimumab) among the 192 patients treated with bDMARDs, all of the patients fulfilled the ASAS criteria for SpA. Data collected: socio-demographic, clinical-biological and imaging data up to 3 years of follow-up.
Results: At the 3-year visit, a biologic decrease was achieved in 22.9% (86.4% maintenance of remission and 9.1% with relapse). That is a total of 19.8% (38/192) of patients (mean age 34.2 ± 8.1 years; 71% of men with HLAB27 positive 63.2% with low BMI in 68.4%) maintained clinical remission with TNFi tapering at the 3-year visit There was a significant association between ASDAS (p <0.001), BASDAI (p <0.001) and CRP (p = 0.004) per visit and maintenance of remission. Likewise, patients in remission more often presented strictly axial damage without enthesitic or peripheral damage and minimal structural on concomitant radiography (p = 0.03). They reported low smoking and stopping use of NSAIDs. Factors associated with successful 3-year TNFi spacing were a shorter delay between diagnosis and initiation of the biologic (0.9 [0.64-1.3]) and initial presentation of acute illness according to patient examination (2.37 [1.06-5.26]), a lower BASDAI and BASFI (respectively 1.3 [0.84-1.6] and 0, 9 [0.74-1.4]) and a lower NSAID score (0.715 [0.43-0.9]).
Conclusion: AxSpA patients in remission as defined by ASAS had significantly fewer objective signs of inflammation concomitantly but also over time. It is possible to maintain this remission after gradual decline in the biologics at 3 years in axSpA. Low activity and functional scores, as well as low consumption of NSAIDs are predictive of the success of tapering. Discontinuation treatment is not recommended due to the high risk of relapse.

ANALYSIS OF THERAPY IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS WHO ACHIEVED THE ASAS PARTIAL REMISSION AND THE CLINICAL-LABORATORY REMISSION AT THE 3RD YEAR OF FOLLOW-UP

D. Timokhina[1], T. Dubinina[1], A. Demina[1], O. Krichevskaya[1], S. Erdes[1].
[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation

Background: The main goal of "T2T" strategy for spondyloarthritis (SpA) is to achieve clinical remission or inactive disease. In 2001, the ASAS formulated criteria for partial remission [1], and the Russian Expert Group for Study of SpA (ExSpA) in 2018 identified clinical-laboratory remission (absence of clinical manifestations of the disease that persists for 6 months with normal values of CRP and ESR) [2].
Objectives: to analyze the therapy in patients with early axial spondyloarthritis who achieved the ASAS partial remission and the clinical-laboratory remission at the 3rd year of follow-up.
Methods: The study included patients with early axSpA (ASAS criteria 2009 with inflammation back pain duration less than 5 years) from the CORSAR cohort (Cohort of Early SpondyloArthritis), formed at the V.A. Nasonova Research Institute of Rheumatology. The cohort includes 175 patients with axSpA. The analysis included 66 patients followed for at least 3 years, of which 37 (56%) were men. The average age of patients was 31.5 (5.7) years, the average duration of the disease was 22.1 (17.0) months, 63 (95.4%) patients were HLA B27 positive. The criteria for clinical-laboratory remission include the following indicators (at least during 6 month): ASDAS≤1,3, BASDAI ≤1,0, morning stiffness<30 min., absence of swollen joints, absence of enthesitis, nocturnal pain ≤1,0 (NRS), spinal pain≤1,0 (NRS), no active extra-articular manifestations, normal levels of CRP and ESR [2]. The criteria for ASAS partial remission include a value not above 2 units in each of the 4 domains: patient global, pain, function, inflammation [1].
Results: Initially, no patients met the ASAS partial remission and the clinical-laboratory remission criteria. By the 3rd year of follow-up, the clinical-laboratory remission was achieved by 21 (31.8%) patients; the ASAS partial remission - 29 (44.0%) patients. When analyzing therapy at the 3rd year of follow-up of patients with early axSpA who achieved the clinical-laboratory and the ASAS partial remission, it was revealed that patients more often achieved remission when taking NSAIDs, a quarter of patients achieved remission on combined therapy with biologics and NSAIDs (Table 1). It is noting that a quarter of patients canceled therapy on their own.

Table 1. Therapy of patients with axSpA who achieved the clinical-laboratory and the ASAS partial remission at 3 years of follow-up.

	The ASAS partial remission (n=29)	The clinical-laboratory remission (n=21)	p
NSAIDs, n (%)	14 (48,2%)	9 (42,8%)	p>0,05
NSAIDs+sulfasalazine, n (%)	0	1 (4,7%)	p>0,05
Biologics, n (%)	2 (6,8%)	0	p>0,05
Biologics+NSAIDs, n (%)	6 (20,6%)	5 (23,8%)	p>0,05
Biologics+sulfasalazine, n (%)	0	1 (4,7%)	p>0,05
Biologics+sulfasalazine+NSAIDs, n (%)	1 (3,4%)	0	p>0,05
Without therapy, n (%)	6 (20,6%)	5 (23,8%)	p>0,05

Conclusion: 1. In the 3d year of follow-up 32% of patients with early axSpA achieved the clinical-laboratory remission and 44% - of the ASAS partial remission.
2. More than 40% of patients with early axSpA achieved remission while taking NSAIDs.

Background: Biological therapies are the main treatment options for patients with active spondyloarthropathy (SpA) who do not respond to nonsteroidal anti-inflammatory drugs or conventional synthetic disease-modifying drugs. Kidney diseases are not a contraindication to biologic therapies. However, there are some safety concerns for these drugs for patients with advanced chronic kidney disease. De novo infection or recurrence of infections are the main challenges in patients with multiple comorbidities during biologic treatments. Neverthless, physicans should initiate these treatments in active and resistant diseases.
Objectives: Here, we evaluated which biologic therapies clinicians' first option to initiate in SpA patients with advanced chronic kidney disease (CRD).
Methods: Total 140 patients of TREASURE database who fullfield axial and/or peripheral ASAS SpA criteria with glomerular filtration rate < 60 ml/dk (stage 3,4 or 5 CRD according to The National Kidney Foundation classification) were included to the study. Renal stages of the patients were evaluated when biologic therapy was initiated. Five anti-TNF (adalimumab, certolizumab, etanercept, golimumab, infliximab) and an interleukin-17A blocker (secukinumab) were on the market during the study. We evaluated physicans' first choice for biologic therapy for patients with stage 3,4 and 5 CRD respectively.
Results: More than two thirds of the patients had stage 3 CRD. Anti-TNF drugs were the first choice of biologic treatment in the patients with advanced CRD. Etanercept was started at most to the patients in general, in stage 3 and in stage 5 CRD groups. However, adalimumab was the first choise in stage 4 CRD. Both etanercept and adalimumab were the first drug of choise in three fourth of the stage 4 and stage 5 patients. All two patients on Il-17A blocker had stage 3 CRD (Table 1).

Table 1. Drug of choise in the SpA patients with advanced chronic renal diseases

	N	Total n (%)	N	Stage 3 n (%)	N	Stage 4 n (%)	N	Stage 5 n (%)
Adalimumab	140	44 (31.4)	108	30 (27.8)	20	9 (45.0)	12	5 (41.6)
Etanersept		52 (37.1)		41 (38.0)		5 (25.0)		6 (50.0)
Golimumab		9 (6.0)		7 (6.5)		2 (10.0)		0 (0)
Infliksimab		28 (20.0)		23 (21.3)		4 (20.0)		1 (8.4)
Secukinumab		3 (2.1)		3 (2.8)		0 (0)		0 (0)
Sertolizumab		4 (2.8)		4 (3.7)		0 (0)		0 (0)

Conclusion: We show that rheumatologists in the TREASURE group prefer to initiate anti-TNF drugs first in all advanced CRD stages. Etanercept was the first choice in these patients.

AB0767 COMPARISON OF THE CLINICAL-LABORATORY REMISSION AND THE ASAS PARTIAL REMISSION IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS

D. Timokhina[1], T. Dubinina[1], A. Demina[1], O. Krichevskaya[1], S. Erdes[1].
[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation

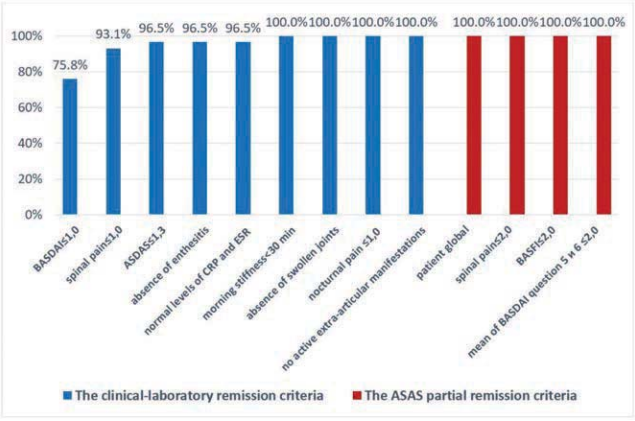
Background: The main goal of "T2T" strategy for spondyloarthritis (SpA) is to achieve clinical remission or inactive disease. In 2001, the ASAS formulated criteria for partial remission [1], and the Russian Expert Group for Study of SpA (ExSpA) in 2018 identified clinical-laboratory remission (absence of clinical manifestations of the disease that persists for 6 months with normal values of CRP and ESR), MRI remission and complete remission (a combination of clinical-laboratory and MRI remission) [2].

Objectives: to compare the ASAS criteria for partial remission and the clinical-laboratory remission in patients with early axial SpA (axSpA) at 3rd year of follow-up.

Methods: The study included patients with early axSpA (ASAS criteria 2009 with inflammation back pain duration less than 5 years) from the CORSAR cohort (Early SpondyloArthritis Cohort), formed at the V.A. Nasonova Research Institute of Rheumatology. The cohort includes 175 patients with axSpA. The analysis included 66 patients followed for at least 3 years, of which 37 (56%) were men and 29 (44%) - women. The average age of patients was 31.5 (5.7) years, the average duration of the disease was 22.1 (17.0) months, 63 (95.4%) patients were HLA B27 positive. The criteria for clinical-laboratory remission include the following indicators (at least during 6 month): ASDAS≤1,3, BASDAI ≤1,0, morning stiffness<30 min., absence of swollen joints, absence of enthesitis, nocturnal pain ≤1,0 (NRS), spinal pain≤1,0 (NRS), no active extra-articular manifestations, normal levels of CRP and ESR [2]. The criteria for ASAS partial remission include a value not above 2 units in each of the 4 domains: patient global, pain, function, inflammation [1].

Results: Initially, no patients met the ASAS partial remission clinical-laboratory criteria. At 3 year of follow-up, the clinical-laboratory remission was achieved by 21 (31.8%) patients; the ASAS partial remission - 29 (44.0%) patients.

We matched patients who achieved the ASAS partial remission (n=29) to criteria for clinical-laboratory remission and, conversely, patients who achieved the clinical-laboratory remission (n=21) to criteria for ASAS partial remission. When comparing the criteria for clinical-laboratory remission to the group of patients who achieved the ASAS partial remission, it turned out that the criteria were achievable (more than 93%), the fewest patients with ASAS partial remission achieved BASDAI≤1.0 (75.8%) (graph 1). All patients with early axSpA who achieved clinical-laboratory remission met the ASAS criteria for partial remission (graph 1).



Graph 1. Comparison of the clinical-laboratory remission and the ASAS partial remission in patients with axSpA at 3 y. of follow-up.

Conclusion: The criteria for clinical-laboratory remission are comparable to the ASAS criteria for partial remission in patients with early axSpA and can be used in a practice of rheumatologists. Further research is needed to analyze the various remission criteria for axSpA and their applicability in a practice.

AB0768 INFLUENCE OF CONTINUOUS NON-STEROIDAL ANTI-INFLAMMATORY DRUGS INTAKE ON BONE MARROW EDEMA IN NON-RADIOGRAPHIC SPONDYLOARTHRITIS

D. Ben Nessib[1], M. Yasmine[1], H. Ferjani[1], W. Triki[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. *[1]Kassab Institute of orthopedics, Rheumatology, Tunis, Tunisia*

Background: The concept of non-radiographic axial spondyloarthritis (nr-axSpA) has revolutionized the classical understanding of axSpA. Indeed, it facilitated the classification of patients with axSpA who did not present substantial structural damage as it was only detectable on magnetic resonance imaging of the sacroiliac joints (MRI-SIJ) [1]. Continuous non-steroidal anti-inflammatory (NSAIDs) intake has been reported as a potential factor reducing the sensitivity of MRI-SIJ to detect bone marrow edema (BME).

Objectives: The aim of the study was to investigate the effect of continuous NSAIDs intake on BME in nr-axSpA.

Methods: We undertook a cross-sectional study including nr-SpA according to the ASAS criteria and treated with NSAIDs at baseline. Socio demographic data as well disease characteristics were recorded. Disease activity parameters were also collected including the duration of morning stiffness, night awakenings, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). MRI-SIJ was performed for all the patients. All the images were screened for bone marrow edema with the corresponding sequence (short tau inversion). Patients were grouped according to NSAIDs intake: G1: continuous versus G2 occasional. The level of significance was fixed for $p<0.05$.

Results: The study included 43 nr-axSpA patients. There was a female predominance with a sex ratio of 0.43. The mean age of the patients was 42±12 years [20-71] and the mean disease duration was 17±9.7 years [4-38]. The mean morning stiffness duration was 47.3±45.6 [15-240] minutes. The mean spinal VAS was 5.9±2.6 [0-10]. Nearly 41% of the patients had an active disease with a mean BASDAI of 4.7± 2.1 [0-8.6]. The prescribed NSAIDs were as follows: Diclofenac (44 %), Indomethacin (8%), Ketoprofen (18%), Meloxicam (3%), Celecoxib (3%), Piroxicam (3%) and Naproxen (21%). Nearly half of the patients were continuously taking NSAIDs (52.6%) versus occasional intake (47.4%). Four patients failed two NSAIDs and were treated with a third one. Both groups were comparable for age (p=0.193), sex (p=0.386), and disease duration (p=0.4). Similarly, there were no statistically significant differences regarding disease activity parameters between both groups: numerical rating scale of pain (p=0.713), ESR (p=0.314), CRP (p=0.644), morning stiffness (p=0.428), night awakening (p=1), as well as BASDAI (p=0.514). Regarding MRI-SIJ findings, hyper signal in STIR sequence was comparable between both groups (G1: 35% vs G2:33%, p=0.914). Moreover, the increased signal with Gadolinium injection on T1-weighted images was similar between both groups (p=0.113).

Conclusion: Our study showed that continuous NSAIDs intake was not associated with significant changes in MRI-SIJ features. This study suggests that a NSAID-free period is not necessary before assessing bone marrow edema on MRI-SIJ.

AB0769

TREATMENT OUTCOMES OF PATIENTS WITH BIOLOGICAL THERAPY DURING PREGNANCY AND EFFECT OF PREGNANCY PLANNING ON TREATMENT PREFERANCE OF RHEUMATOLOGISTS

Y. Erez[1], S. B. Kocaer[1], G. Can[1], M. Birlik[1], F. Onen[1], İ. Sari[1]. [1]*Dokuz Eylul University School of Medicine, Division of Rheumatology, İzmir,Turkey*

Background: Rheumatic diseases occur mostly in adults at reproductive age. In addition to the impact of disease course on fetal and maternal health, safety concerns regarding the effects of biological drugs on the course of pregnancy have come to the fore with the introduction and widespread use of them. Unlike other biological treatments, all tumor necrosis factor (TNF) antagonists can be used during pregnancy.
Objectives: To investigate clinical features, treatment characteristics and pregnancy outcomes of patients with biological treatment and evaluate impact of planning pregnancy on treatment preferance.
Methods: The study was planned between January 2015 and December 2021. Patients who received biological treatment at conception were determined retrospectively. Demographycal data, clinical features, treatment characteristics and pregnancy outcomes were recorded.
Results: 15 patients (mean age 37.2±4) were included. Mean age at diagnosis was 25.6±5.4 and age at gestational was 33±3.9. Mean follow-up duration was 96±55 months. Median period of biological therapy was found 37 (1-156) months. Six (40%) patients were diagnosed with Axial Spondyloarthritis, 6 (40%) Psoriatic Arthritis, 1 (6.6%) Rheumatoid arthritis. While 12 (80%) patients had planned (wanted) pregnancies, 10 (66%) patients were evaluated as eligible for pregnancy in terms of rheumatological disease by rheumatologists. 13 (86.6%) patients were in remission/partial remission before pregnancy. 5 (33.3%) patients were using steroid and *disease modifying anti-rheumatic drugs (DMARDs)* were stopped before conception. 10 (66.6%) patients were receiving certolizumab, 4 (26.7%) patients were receiving adalimumab. It was found that the treatment of the patient who received rituximab was interrupted due to the pregnancy planning. While certolizumab treatment continued in 6 (60%) patients during pregnancy, the treatment of patients receiving adalimumab was discontinued within first trimester. Activation of disease was occurred in 2 patients whose therapy interrupted. Biological treatment was restarted during pregnancy in 3 of 9 patients whose biological treatment was discontinued. No perinatal complication was developed except premature rupture of membranes in one patient. It was observed that all infants were healthy at birth, but baby of the mother who received certolizumab was diagnosed mental retardation in early childhood.
Conclusion: In this study, it was established that the majority of patients using TNF antagonist during pregnancy;
1-Having wanted/planned pregnancy,
2-Being in remission or low disease activity before pregnancy,
3-Not experiencing disease activation during pregnancy.
In this study, it was concluded that having a pregnancy plan may be an important factor for rheumatologists to decide type of TNF antagonist, and physicians tend to prefer certolizumab in patients with pregnancy plan.

Table 1. Baseline clinical and treatment characteristics

Age, years	**37.2±4**

AB0770

TREATMENT OF ANKYLOSING SPONDYLITIS (AS) WITHIN 1 YEAR AFTER DELIVERY.

O. Krichevskaya[1], E. Ilinykh[1], T. Dubinina[1], S. Glukhova[1], A. Demina[1], I. Andrianova[1]. [1]*V.A.Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation*

Background: Prescribing therapy to women after childbirth is still a difficult task in Russia due to the well-established ideas among patients and pediatricians of the incompatibility of lactation and treatment. Monitoring AS activity in patients without lactation is also important: maintaining physical and mental health are necessary for full-fledged care of the newborn and the joy of motherhood.
Objectives: To describe the frequency of drug use in women with AS within 1 year after childbirth, to determine the relationship with AS activity, to compare the incidence of diseases in children under one year whose mothers received and did not receive AS therapy during breastfeeding.
Methods: 44 pts with confirmed AS (modified New York criteria, 1984) were followed within 1 year after childbirth. The average age of the pts was 32,5 ± 5,8 years. BASDAI at 1, 6 and 12 months after delivery was: 2,4 [1,4;4,2]; 2,6 [1,4; 4,4]; 2,7 [1,5; 4,1], respectively. ASDAS-CPR was: 2,0 [1,2; 2,7]; 1,9 [1,4; 2,5]; 1,7[1,3; 2,3], respectively. AS activity in pts with and without lactation did not differ. 41 pts (93,2%) had been continuing lactation during 1 month after delivery, 27 (61,4%) pts – during 1 month after delivery, 17 (38,6%) pts – during 1 month. Adherence to nonsteroidal anti-inflammatory drugs (NSAID) therapy was defined as the ratio of the actual dose taken to the prescribed dose. The total dose of NSAIDs was determined by the NSAID intake index (M. Dougados, 2001).
Results: NSAIDs. Ibuprofen was the drug of choice in pts with lactation, 51,2%, 74,1% and 88,2% of pts received it after 1, 6 and 12 months after delivery. Women without lactation received various NSAIDs in 100% of cases. The index of NSAID intake in pts with lactation increased during the first six months after delivery and after 1, 6 and 12 months after delivery and was 0 [0; 25], 33,3 [12; 42,1] and 33,3 [17; 50], respectively ($p < 0,05$ compared to 1 month after delivery). The index of NSAID intake at 1 and 12 months after delivery in pts without lactation was higher than in pts with lactation ($p < 0,05$). Adherence to NSAID therapy in pts with lactation increased during follow-up and after 1, 6 and 12 months after delivery was 10 [0; 100], 71 [30; 100] and 100 [50; 100], respectively ($p < 0,05$ compared to 1 month after delivery). There was no effect of NSAIDs intake on the AS activity.
Sulfasalazine (SSZ) because of arthritis in the 3rd trimester of pregnancy was received by 5 pts (11,4%); 2 of them independently canceled SSZ after childbirth due to fear of its negative effect on the baby during breastfeeding, both had recurrent arthritis within a year after childbirth. Against the background of lactation, only 1 woman received SSZ at a dose of 1,5 g per day.
bDMARD. During the year after childbirth, 17 (38,6%) pts had a need for bDMARD, however, for insufficient availability only 11 pts (25%) received bDMARD: 1 (certolizumab pegol, CZP) within 1 month after childbirth, 8 (CZP– 4, ADA – 4) within 2 – 6 months, 11 (CZP – 4, adalimumab – 4, infliximab – 1, golimumab – 1, etanercept – 1) within 7 – 12 months. Of these, 4 pts (all pf them intake CZP) received TNF inhibitors during lactation. AS activity in pts with and without lactation on the background of iTNF-alpha therapy did not differ. There was a clear trend of AS activity decreasing against the background of iTNF therapy: ASDACRP 6 and 12 months after delivery was 2,7 ± 0,6 and 2,4 ± 0,5, respectively. In pts with lactation, the same trend was noted: ASDACRP was 2,8 ± 0,5 and 2,1 ± 0,3, respectively.
There were no differences in the frequency of acute respiratory viral infections, atopic dermatitis, the need for antibiotics, and the frequency of hospitalizations in breastfed children whose mothers received and did not receive AS therapy during lactation.
Conclusion: NSAIDs in low doses do not affect AS activity. According to our data performed on a small group of patients with AS, the effectiveness of TNF-alpha therapy does not differ against the background of lactation and without it. It is necessary to increase the knowledge of patients and pediatricians about therapeutic possibilities during lactation to avoid unjustified drug cancellation.

AB0771

EVALUATION OF THE EFFICACY OF INHIBITORS OF TUMOR NECROSIS FACTOR ALPHA FOR PATIENTS WITH ANKYLOSING SPONDYLITIS IN REAL CLINICAL PRACTICE.

E. Rozochkina[1], E. Koltsova[1], D. Murtazalieva[1], E. Zhilyaev[2], E. Koshkarova[3], G. Lukina[1,4]. [1]*A.S. Loginov Moscow Clinical Scientific Center, Rheumatology, Moscow, Russian Federation;* [2]*European Medical Center, Rheumatology, Moscow, Russian Federation;* [3]*JSC «Aston Consulting», Rheumatology, Moscow, Russian Federation;* [4]*V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: The question of the comparative efficacy of tumor necrosis factor-alpha (TNF-α) inhibitors is topical today, because the research data that were distributed in random sequence mainly reflect the efficacy of the only specific drug, and the available data obtained in the ankylosing spondylitis (AS) treatment use of a network meta-analysis are limited.
Objectives: To make a comparative evaluation of the efficacy of various TNF-α inhibitors for patients with AS in real clinical practice.
Methods: The study involved patients with a reliable diagnosis of AS (according to the 1984 New York criteria) who received TNF-α inhibitor during the 12-month

course of therapy, from 2018 to 2022. The efficacy of the drugs was evaluated by the ASDAS (CRP) (Ankylosing Spondylitis Disease Activity Score) and BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) – disease activity indices obtained 6 and 12 months after the start of therapy. Comparison of indicators between drugs was carried out using a non-parametric Kruskal-Wallis test, designed to test the equality of the medians of several samples.

Results: The study involved 257 patients with AS who were treated with various TNF-α inhibitors, among which Adalimumab was taken by 77 patients (29.96%), Golimumab - 20 (7.78%), Infliximab - 15 (5.84%), Certolizumab pegol - 27 (10.51%) and Etanercept - 118 (45.91%). The mean age of the involved patients was 46.1 ± 11.4 years old, the mean age at the onset of the disease was 28.7 ± 11.7 years old. The majority of patients were males - 167 (64.98%), 143 (55.64%) had Higher education, 163 (63.42%) were married, 103 (40.08%) have been working and - 150 patients (58.37%) had never smoked before the study. Mean ASAS (CRP) and BASDAI, disease activity indices, values for each drug before therapy, 6 and 12 months after the start of therapy are presented in Table 1. «Head-to-head» comparison of medical preparations revealed no significant differences between TNF-α inhibitors in terms of the studied parameters (p > 0.05).

Table 1.

	Months since start of therapy	BASDAI	ASDAS (CRP)
Adalimumab	0	5,84	3,38
	6	3,52	1,91
	12	4,11	2,24
Golimumab	0	5,91	3,29
	6	5,17	2,91
	12	4,61	2,68
Infliximab	0	3,56	2,25
	6	2,59	1,08
	12	2,20	1,39
Certolizumab pegol	0	6,57	3,80
	6	3,38	2,17
	12	3,50	2,81
Etanercept	0	6,13	3,79
	6	3,75	2,20
	12	3,80	2,28

ASDAS - Ankylosing Spondylitis Disease Activity Score; BASDAI - Bath Ankylosing Spondylitis Disease Activity Index; CRP - C-reactive protein

Conclusion: The studied TNF-α inhibitors demonstrate similar clinical efficacy in real clinical practice. A direct comparison of drugs didn't reveal significant differences between TNF-α inhibitors.

AB0772 SAFETY AND SURVIVAL ANALYSIS OF SECUKINUMAB TREATMENT IN A COHORT OF RHEUMATIC PATIENTS NAÏVE TO BIOLOGICAL THERAPY

M. Gomez Vargas[1], M. Lisbona Muñoz[2]. *[1]Hospital Universitario Virgen del Rocio, Rheumatology, Sevilla, Spain; [2]Hospital Universitario Virgen del Rocio, Rheumatology, sevilla, Spain*

Background: Secukinumab is a fully human monoclonal antibody that selectively binds to IL-17A and inhibits the interaction with the IL-17 receptor. IL-17A plays a key role in the pathogenesis of plaque psoriasis, psoriatic arthritis (PsA), ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (SpA).

Objectives: To describe the safety and survival profile of treatment with Secukinumab in a cohort of patients (pac) with PsA, AS and non-radiographic SpA naïve to biological therapy.

Methods: Descriptive observational study. Patients: Cohort of patients with PsA, AS and non-radiographic SpA from the Rheumatology Service of the H.U.V. del Rocío of Seville who undergo treatment with Secukinumab 150mg sc/m as the first line of biological treatment. Main variable: Secukinumab suspension due to adverse event (AE) (mild: requires suspension, serious: hospital admission or death), inefficacy (primary or secondary failure), decision of the pac, clinical remission or other reasons.

Secondary variables: age, sex, type of disease (PsA, AS or non-radiographic SpA), clinical manifestations (axial, peripheral affectation and both) other clinical manifestations (cutaneous affectation, enthesis and/or dactylitis). Time from diagnosis to start of biological therapy (months) and exposure time to Secukinumab (months). Concomitant treatment with DMARDs. Statistical analysis: The statistical package SPSS v21 was used. Qualitative variables were analyzed using the Chi2 and Fisher tests, as required. It was considered statistically significant, p values <0.05. Survival analysis was performed using Kaplan-Meier survival curves, compared using the Log-Rank test.

Results: 171 patients who underwent treatment with Secukinumab during their disease were analyzed. A total of 61 patients naïve to biological therapy were included. The baseline characteristics of the sample are shown in Table 1. The patients received treatment with Secukinumab for a median of 35m (SD +/- 17.5m). The drug was suspended in 27 patients; In 19 patients (70%) due to inefficiency (11 due to primary failure and 8 due to secondary failure); in 5 patients due to mild AD (1 patient with mucocutaneous candidiasis); 3 patients due to loss of follow-up and 1 patient for their own decision. There were no serious AEs. The average exposure time of the drug was 32.7 months. Drug survival was 85%, 76%, 68%, and 56%, at 6 months, 1, 2, and 3 years, respectively, with an overall survival of 69%.

Table 1. Basal features

Gender, men	36 (59%)
Age, years (average, SD)	47,8 (+/- 13,3)
Disease:	
-Psoriatic arthritis	36 (59%)
-Ankylosing spondylitis	22 (36%)
-Non-radiographic axial spondyloarthritis	3 (5%)
Disease time of evolution, years (average, SD)	12,6 (+/- 8)
Time from diagnosis to start of biological therapy with Secukinumab, years (median)	6
Clinical manifestations (%):	
-Axial involvement	32 (52%)
-Peripherical involvement	43 (70%)
-Axial and peripherical involvement.	31 (50,8%)
Other manifestations:	
-Enthesis	18 (29%)
-Dactylitis	17 (27%)
Concomitant treatment with DMARDs after 6 months of treatment with Secukinumab (n, %):	
-Methotrexate	19 (31%)
-Leflunomide	7 (11,5%)
-Sulfasalazine	6 (9,8%)

There was no association between the different diagnoses and drug suspension, both variables were independent (p=0.702) with a 5% significance level. There was also no evidence of a significative relationship between the type of involvement (axial/peripheral/both), and the suspension of treatment (p=0.743).

Conclusion: The suspension of the drug due to AEs was small in our sample (8,2%) and the AEs detected were mild (including a mucocutaneous candidiasis). No serious AEs were observed. We found an overall drug survival of 70% in our study. These data are consistent with those published in the different clinical trials of the drug (FUTURE I, II and V, MEASURE I, II and III, PREVENT...). Therefore, we can conclude that Secukinumab constitutes a drug with a good security profile.

AB0773 SERUM VEGF LEVEL MAY BE HAVE A ROLE IN THE EVALUATION OF TREATMENT RESPONSE AND DISEASE ACTIVITY DURING TNFI THERAPY IN PATIENTS WITH AXSPA

M. Gulec Yazır[1], E. Durak Ediboglu[2], G. Alp[2], H. Cinakli[2], İ. Kurut Aysin[2], E. Erpek[2], E. Otman Akat[2], S. Gucenmez[2], M. Ozmen[2], S. Ketenci[2], O. Bayindir[2], D. Solmaz[2], S. Akar[2]. *[1]Izmir Katip Çelebi University, Department of Internal Medicine, Izmir,Turkey; [2]Izmir Katip Çelebi University, Department of Internal Medicine, Division of Rheumatology, Izmir,Turkey*

Background: Patient reported outcomes (BASDAI and BASFI) are used to evaluate disease activity in axial spondylarthritis (axSpA), however, apart from C-reactive protein (CRP) there are no widely used serum biomarkers to assess disease activity and treatment responce.

Table 1. The factors associated with serum VEGF levels longitudinally

	Univariate analiz		BASDAİ+CRP Model		ASDAS -CRP Model	
	B (%95 CI)	**p**	**B (%95 CI)**	**p**	**B (%95 CI)**	**p**

HLA-B27 positivity	-233.4 (-440.67 to -26.11)	**0.027**	-135.78(-326.08- 54.52)	0.16	-126.54(-309.2- 56.1)	0.17
BASDAI	4.12 (1.06- 7.18)	**0.008**	5.60 (2.16- 9.05)	**0.001**		
ASDAS-CRP	110.04 (58.18- 161.88)	**<0.001**			132.31(74.70- 189.92)	**<0.001**
Serum CRP level	5.86 (1.02- 10.7)	**0.018**	4.09 (-0.99- 9.183)	0.11		

Objectives: In this study, we aimed to evaluate the relationship between serum biomarkers (serum leptin, VEGF, MMP-3) and disease activity as well as the changes of those biomarker levels during TNFi treatment.

Methods: Patients with axSpA who put on their first TNFi and had serum samples at baseline and 6th month of therapy were included in the analysis The demographic, clinical and laboratory characteristics disease activity and function parameters (BASDAI, BASFI, ASDAS-CRP, serum CRP levels) at baseline and 6th months were recorded. Levels of serum leptin, VEGF and MMP-3 were studied by ELISA method. The relationship between serum biomarkers and disease activity scales in addition CRP levels were tested by correlation analysis. The factors affecting the change in seruml biomarkers level in 6th month were also analyzed by GEE which is a longitudanal analysis method.

Results: A total of 74 patients (mean age (SD) 48.7 (12.8) years, 54.1% male, 68.9% with AS) were included in this study. Baseline median BASDAI scores (IQR) were 5.8 (2.4), ASDAS scores (IQR) 3.7 (1.5) and median CRP levels (IQR) 12 (23). Disease activity parameters (BASDAI, BASFI, ASDAS-CRP) were significantly decreased at 6th month of therapy (p<0,001, p<0,001, p<0,001, respectively). The correlation between baseline serum biomarker levels (leptin, MMP3, VEGF) and between biomarkers level and disease activity were eveluated and only serum MMP-3 levels were found to be associated with baseline ASDAS-CRP (p=0.02). Serum VEGF level decreased significantly compared to the baseline at the 6 th month of TNFi treatment (p<0.001), however, serum leptin and MMP-3 levels were not associated with disease activity and affected by biologic treatment (p=0.89, p=0.50, respectively). In the longitudinal analysis, serum VEGF level were significantly associated with gender, hip involvement, delay in diagnosis in addition to disease activity (Table 1).

Conclusion: TNFi treatment is not only effectively control disease activity but also cause significant decrease in serum VEGF levels in patients with axSpA. Considering the role of VEGF in radiographic progression it could be a promising biomarker in axSpA

Kaşifoğlu[7], S. M. Türk[8], E. Gönüllü[8], A. Erden[9], C. Bes[10], H. Emmungil[11], U. Kalyoncu[2], Y. Pehlivan[1]on behalf of TReasure. *[1]Uludağ University, Rheumatology, Bursa, Turkey; [2]Hacettepe University, Rheumatology, Ankara, Turkey; [3]Ankara University, Rheumatology, Ankara, Turkey; [4]Gazi University, Rheumatology, Ankara, Turkey; [5]Namık Kemal University, Rheumatology, Tekirdağ, Turkey; [6]Katip Çelebi University, Rheumatology, İzmir, Turkey; [7]Osmangazi University, Rheumatology, Eskişehir, Turkey; [8]Sakarya University, Rheumatology, Sakarya, Turkey; [9]Ankara City Hospital, Rheumatology, Ankara, Turkey; [10]Başakşehir Çam and Sakura City Hospital, Rheumatology, İstanbul, Turkey; [11]Trakya University, Rheumatology, Edirne, Turkey*

Background: Biologic agents have altered our ability to treat chronic inflammatory diseases effectively. Although paradoxical reactions (PRs) were initially described with TNF-α inhibitors, they have been reported with newly developed biologic agents or classes too (1). Due to the potential consequences of PRs, it is critical to identify and treat these drug class side effects as soon as possible.

Objectives: The aim of this study was to characterize PRs, especially psoriasis, in a large cohort of patients treated with biologic agents and to investigate their clinical implications.

Methods: TReasure database, which was launched in 2017, is a web-based prospective observational cohort comprised of patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA) from 17 centers located throughout Turkey. Characteristics of patients with PRs and clinicians' treatment approaches and outcomes were evaluated using descriptive statistics.

Results: 3147 RA and 6071 SpA patients were evaluated. 139 (1.5%) patients (40 (28.8%) with RA and 99 (71.29%) with SpA) developed a PRs (Table 1). The rate of paradoxical psoriasis was 90.6% and 9.7% of the patients had a family history of psoriasis. Females constituted 64% of the patients. The mean age was 46±12 years and the disease duration were 146±92 months. Mean time interval between the PRs and diagnosis was 99,6±86 months, whereas median 12 (1-132) months between the PRs and the biological agent. Adalimumab (30.9 %), etanercept (20.1 %), and infliximab (18.7 %) were the three most frequently used agents during the PRs. However, 8.6% of the patients developed PRs with non-TNF agents. Only seven patients (5.1%) who had PRs discontinued the drug, while 28 patients (20.6%) continued to receive the agent that caused the PRs. Majority of patients were switched to other TNF-α inhibitors (48.5%) and non-TNF agents (25.7%). When we limited our analysis to paradoxical psoriasis patients, we observed complete remission in 43.5% of patients and progression in only six (4.7 %) of patients. (Figure 1).

Table 1. Characteristics of RA and SpA patients who developed paradoxical reactions

	N	Patients (N, %)
Paradoxical reactions (PRs)	139

Etanercept		31 (22.8%)
Adalimumab		15 (11%)
Secukinumab		12 (8.8%)
Other***		43 (57.5%)

PRs: Paradoxical reactions IBD: Inflammatory bowel disease. *Drug-induced lupus:3 Vasculitis:1. ** Adalimumab: 43 (30.9%), Etanercept: 28 (20.1%), Infliximab: 26 (18.7%), Certolizumab: 20 (14.4%), Golimumab: 10 (7.2%). *** Certolizumab: 9 (6.6%), Tofacitinib: 9 (6.6%), Infliximab: 7 (5.1%), Tocilizumab: 5 (3.7%), Golimumab: 4 (2.9%), Ustekinumab: 4 (2.9%), Rituximab:3 (2.2%), Abatacept: 1 (0.7%), Anakinra: 1 (0.7%). † mean ± standard deviation. †† median (min-max)

Conclusion: Clinicians should be aware that PRs may develop with biologic agents other than TNF-α inhibitors. Additionally, it is important to keep in mind that the development time of PRs could be variable. The mechanism(s) behind PRs remain unknown, and there is no currently available diagnostic or therapeutic protocol (2). The decision whether to continue or discontinue biologic agents should be individualized. We found that the majority of patients can be managed without discontinuing biologic agents. Finally, we believe that the experience of our large cohort can help physicians in clinical practice where sufficient protocol is lacking.

AB0775 EFFICACY, SAFETY AND SURVIVAL OF SECUKINUMAB IN SPONDYLOARTHRITIS.

M. López I Gómez[1], N. Del Val del Amo[1], L. Ibarrola[1], U. Astigarraga Urkia[1], J. Mendizabal[1], G. Sada[1], S. Garcia Perez[1], I. Paniagua Zudaire[1], L. Garrido Courel[1], L. Horcada[1], R. Gutierrez[1], C. Fito-Manteca[1]. [1]*Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain*

Background: Secukinumab (SCK) is a fully human monoclonal antibody that selectively inhibits IL-17A indicated for both axial and peripheral spondyloarthritis (SpA) and psoriatic arthritis (PsA). In this paper we present our experience with SCK since its approval, in a tertiary hospital.
Objectives: To describe the efficacy, survival and safety of SCK treatment in real clinical practice in patients with SpA and PsA.
Methods: We performed a descriptive, retrospective analysis of patients diagnosed with SpA according to ASAS criteria and PsA according to CASPAR criteria. For this purpose, data were collected from the medical records of 75 patients treated with SCK in the rheumatology service.
To evaluate efficacy in the Spa group, analytical variables (C-reactive protein (CRP)), the Ankylosing Spondylitis Disease Activity Score (ASDAS) scale and the patient's visual analog scale (VAS) were analyzed. In the PA group, VAS and CRP were assessed at baseline and at 12 months. Survival was evaluated with respect to the causes of drug discontinuation and its association with individual baseline characteristics, such as metabolic syndrome. Safety was evaluated by analyzing intercurrent infections or neoplasms requiring discontinuation.
Results: Seventy-five patients with spondyloarthritis included in treatment with SCK were analyzed, 40 had Spa and 34 had PAs. The mean age at diagnosis was 45.1 years (SD 11.3) and the median time from diagnosis to onset of SCK was 4.5 years (IQR 1-10) (Table 1).

Table 1. Baseline characteristics

	SpA	APs	Total
Age at diagnosis	45.1 (SD11.8)	44.9 (SD10.9)	45.1 (SD11.3)
Age at begging of SCK	53.5 (SD 9.3)	52.2 (SD 10)	52.9 (9.6DE)
Hypertension	10 (25.0%)	10 (29.4%)	20 (27.0%)
Dyslipidaemia	17 (42.5%)	17 (51.5%)	34 (46.6%)
Diabetes mellitus	5 (12.5%)	6 (17.6%)	11 (14.9%)
Body Mass Index	27.9 (SD4.4)	30.5 (SD8.4)	29.2 (SD6.7)
Tobacco	14 (35.0%)	10 (29.4%)	24 (32.4%)
Cardiovascular disease	5 (12.5%)	2 (5.9%)	7 (9.5%)
Previous sDMARD			
-Methotrexate	13 (32.5%)	24 (70.6%)	37 (50%)
-Leflunomide	1.7% (15%)	12 (35.3%)	18 (24.2%)
Initial corticosteroids	7 (18.4%)	15 (44.1%)	22 (30.6%)

Fifty-seven patients (76%) were on treatment with anti-TNF prior to SCK initiation. The mean number of anti-TNF prior to SCK was 1.8 (SD 1.2). Twenty-six patients (35.1%) received were on treatment with SCK at a dose of 150 mg and 48 (64.9%) with 300 mg every 4 wk. The mean CRP before starting SCK was 8.46 mg/L (SD 18.38) and VAS 4.83 (SD 2.99).
Statistically significant improvement was observed in both pathologies in VAS (-2.1 SD 3.1) (p 0.003). Despite the improvement in CRP, in both groups of -3.7 mg/L (SD 15) was not statistically significant. Regarding ASDAS, in the Spa group, 2 patients (5.3%) showed great improvement (>3.1), 9 patients (23.7%) clinical improvement (>1.1), 17 patients (42.5%) improvement (<1.1), 6 patients (15%) showed no improvement and 4 patients (10.5%) worsening.
The overall drug survival to date is 19.41 months (SD 13.76), 20.6 months (SD 14.8) in the Spa group and 18 (SD 12.6) in the AP group (Figure 1).

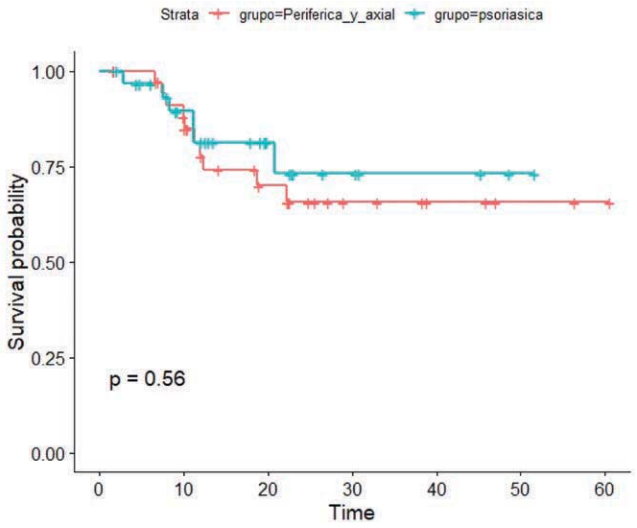

Figure 1. Secukinumab survival in both groups

17 patients (23%) discontinued treatment, with a median duration of 12 months (SD 4.66). 12 (70.6%) due to ineffectiveness, 1 (5.9%) by their own decision, 3 (17.6%) due to persistent mechanical pain and 1 (5.9%) due to neoplasia (gastric adenocarcinoma). The clinical variables of metabolic syndrome were evaluated (Table 1) none of these characteristics had a statistically significant association as a cause of drug discontinuation. No patient presented infections that required discontinuation of the drug. No association was detected between drug discontinuation or the development of metabolic syndrome.
Conclusion: In our cohort, SCK showed a statistically significant improvement in the VAS scale in both groups. A 23.7% of patients with Spa showed clinical improvement according to ASDAS values, 5.3% showed great improvement and 42.5% showed mild improvement. The overall drug survival to date is 19.41 months (SD 13.76) slightly longer in the SpA group than in APs. SCK seems to be a safe drug as none of our patients presented infections during its use.

AB0776 CLINICAL AND LABORATORY PECULIARITIES OF TREATMENT-REFRACTORY ANKYLOSING SPONDYLITIS.

K. Sakharova[1], S. Erdes[1], M. Cherkasova[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Axial spondyloarthritis, Moscow, Russian Federation*

Background: Despite the availability of newest guidelines for the treatment of ankylosing spondylitis and various groups of genetically engineered biological drugs, there are still patients with refractory, i.e., resistant to therapy (with two or more genetically engineered drugs), AS, maintaining high clinical and laboratory activity.
Objectives: To analyze the clinical peculiarities of patients with refractory AS and to identify markers for early detection of such cases.
Methods: Patients who received 2 or more GEBDs and demonstrated a primary or secondary failure were considered cases of refractory ankylosing spondylitis. Twenty-four (16 %) patients with refractory AS (mNYC 1984) were enrolled, including 14 males, 10 females. This group was selected from 150 successive AS patients admitted to the clinic of the Scientific Research Institute of Rheumatology in 2020–2021. Ninety-three per cent of patients had HLA B 27, the mean age was 39 [31.5;49] years, the age of onset of the disease was 21.7 [15.5;29] years, the duration of the disease was 17.3 [11;24]. They were treated with drugs of various groups (i-TNF-α, IL-17, 6 and Janus kinase inhibitors). The refractory AS patients were compared to a control group with the corresponding gender, age of onset and duration of the disease admitted successively to the Institute during the same period.
The examination followed the ASAS recommendations. All patients had additional nephelometric assay of SAA level using commercial reagent kits, reference value < 5 mg\L.

Results: Median SAA, CRP, ESR levels, BASDAI, ASDAS scores and correlation indicators are shown in Table 1.

Parameters	Refractory AS	Control	p
Median			
SAA, Me [25th; 75th percentiles]	53.6 [15.75;205.5]	10.7 [4.9;31.1]	p = 0.001
CRP, Me [25th; 75th percentiles]	16.35 [3.55;63.1]	11 [4.9;29.3]	p = 0.001
ESR, Me [25th; 75th percentiles]	35 [20.5;110]	29.1 [13.9;48.1]	p = 0.001
BASDAI, Me [25th; 75th percentiles]	5.95 [4.85;6.6]	5.2 [4.8;6.1]	p = 0.126
ASDAS-CRP, Me [25th; 75th percentiles]	3.8 [3.11;4.49]	2.8 [2.2;3.2]	p = 0.020
Peripheral arthritis, %	87.5	79.2	
Enthesitis, %	66.6	70	
Coxitis, %	75	71.5	
Knee and hip replacement, %	20.8	8.3	
The onset of the disease			
- urogenital infection, %	54	8.3	
- juvenile onset, %	30	30	
Correlation			
SAA and CRP	r = 0.82	r = 0.55	p < 0.001 and p < 0.001
SAA and ESR	r = 0.8	r = 0.5	p < 0.001 and p < 0.001
SAA and BASDAI	r = 0.2	r = 0.3	p = 0.330 and p = 0.421
SAA and ASDAS	r = 0.3	r = 0.4	p = 0.006 and p < 0.001
CRP and ESR	r = 0.8	r = 0.56	p < 0.001 and p < 0.001
CRP and ASDAS	r = 0.3	r = 0.4	p = 0.295 and p < 0.125

The refractory AS group had a higher SAA level compared to that of the control group (53.6 and 10.7, p = 0.001). There was no significant difference in the SAA, CRP levels, BASDAI and ASDAS scores. There was a strong association between SAA level and CRP level, ESR; correlation with BASDAI and ASDAS was non-significant and moderate.

The clinical presentation was dominated by peripheral arthritises 87.5% and coxitises 75%, followed by enthesopathies 66.6%. No significant differences from the control group were observed. At the onset of the disease, a urogenital infection was detected in 54% of patients with refractory AS.

Conclusion: Patients with refractory AS demonstrate higher levels of SAA in the clinical presentations. Patients with the onset of reactive arthritis prevail. A study of new markers, including genetic ones, is required to identify a refractory disease at an early stage.

AB0777 INFLUENCE OF TNF INHIBITORS ON SUBCLINICAL ATHEROSCLEROSIS IN SPONDYLOARTHRITIS PATIENTS

A. Ben Tekaya[1,2], T. Mehmli[1,2], F. Ahmed[2,3], S. Boukriba[2,3], O. Saidane[1,2], R. Leila[1,2], S. Bouden[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], H. Mizouni[2,3], L. Abdelmoula[1,2]. *[1]Charles Nicolle Hospital, Rheumatology Department,Tunis, Tunisia; [2]University Tunis El Manar, Faculty of medicine of Tunis,Tunis,Tunisia; [3]La Rabta Hospital, Radiology department,Tunis,Tunisia*

Background: Spondyloarthritis is a chronic inflammatory disease associated with increased cardiovascular morbidity and mortality due to accelerated atherosclerosis. Recent studies have reported the benefit of TNF inhibitors in reducing the risk of cardiovascular events and its association with changes in lipid profile. Nevertheless, it remains controversial.

Objectives: We aimed to investigate the effect of TNF inhibitors on subclinical atherosclerosis assessed with carotid intima-media thickness (CIMT) and flow mediated dilatation (FMD) in patients with spondyloarthritis (SpA).

Methods: We performed a cross sectional study including 47 patients meeting ASAS 2009 criteria for SpA. Patients with traditional cardiovascular risk factors were excluded. We collected clinical data, therapeutic modalities and biological tests including total cholesterol, HDL, LDL and triglyceride after 12 hours of fasting. FMD and mean CIMT (mean value of right and left carotid artery) were measured with a Mindray Resona 7 ZST+ ultrasound machine by an experienced radiologist.

Results: Among the 47 subjects, 18 patients (38%) were receiving TNF inhibitors for a median duration of 36 months (IQR 25-75%: 24-72) (9 were on Etanercept, 7 were on Adalimumab, one patient was on Infliximab and one was on Golimumab). The group treated with TNF inhibitors had a median age of 43 years (IQR 25-75%: 36-46.5) and a median duration of the disease of 12 years (IQR 25-75%: 9.5-22). Median ASDAS and BASDAI scores were 2.40 (IQR 25-75%: 1.48-3.1) and 2.60 (IQR 25-75%: 1.55-3.75) respectively. On the other hand, patients naïve to TNF inhibitors had a median age of 32 years (IQR 25-75%: 55-42), median disease duration of 7 years (IQR 25-75%: 3-12.5), median ASDAS of 2.13 (IQR 25-75%: 1.61-2.91), and median BASDAI of 2.40 (IQR 25-75%: 1.55-3.75). When comparing the two groups, there was no significant difference regarding disease activity scores ASDAS (p=0.431) and BASDAI (p=0.793) as well as biochemical variables; total cholesterol (p=0.483), HDL (p=0.395), LDL (p=0.263) and triglyceride (0.092). In contrast, patients on TNF inhibitors were significantly more aged (p=0.009) and had a significantly higher duration of the disease (p=0.004). Doppler ultrasound examination showed a median CIMT of 0.56 mm (0.48-0.64) in patients treated with TNF inhibitors versus 0.55 mm (0.48-0.60) in patients naïve to TNF inhibitors with no significant difference (p=0.238). Patients on TNF inhibitors had lower values of FMD (with a median of 12.5 (6.7-16) versus 15.5 (10-24.5)). However this difference was not significant (p=0.182).

Conclusion: In our study, biological treatment with TNF inhibitors did not affect endothelial function and subclinical atherosclerosis in patients with spondyloarthritis. Given the small size of our study population and its heterogeneity in terms of age and duration of the disease, no conclusions can be drawn. Further longitudinal studies that involve larger samples are necessary.

AB0778 BASELINE CRP LEVEL AND RESPONSE TO INFLIXIMAB TREATMENT IN SPONDYLOARTHRITIS

S. Sayouri[1], N. Akasbi[2], H. Bourkhime[3], I. El Mezouar[2], T. Harzy[2]. *[1]Hassan II University Hospital, Rheumatology Department, fez, Morocco; [2]Hassan II University Hospital, Department of Rheumatology, fez, Morocco; [3]Faculty of Medicine and Pharmacy of Fez, Sidi Mohammed Ben Abdellah University, Laboratory of epidemiology, clinical research and community health, fez, Morocco*

Background: The treatment of spondyloarthritis (SpA) is based on cDMARDS (Conventional disease-modifying anti-rheumatic drugs) and bDMARDS (Biologic disease-modifying anti-rheumatic drugs) and aims at remission or low disease activity. Elevated C-reactive protein (CRP) is a good marker of inflammation [1].

Objectives: Our goal was to find a link between the CRP level and the response to infliximab.

Methods: Retrospective study was conducted in the rheumatology department at the University Hospital of Fez from January 2011 to January 2021. The patients were recruited according to the ASAS 2009 criteria (Assessment of Spondyloarthritis International Society). A negative CRP is defined as less than or equal to 6mg / L and the ESR (Erythrocyte Sedimentation Rate) according to age. The main criteria for evaluating the response to the biological at 3, 6 and 12 months are: BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) and ASDASCRP (Ankylosing Spondylitis Disease Activity Score). The secondary criteria are: global evaluation (EVA) and ESR. They were divided into 2 groups according to the CRP while seeking its link with the response to infliximab and with the other epidemiological, clinical and biological parameters.

Results: 375 SpA patients including 65 on infliximab: 50.8% men and 49.2% women. Mean age was 43.40(±1.86) years. Average duration of evolution was 7.71(±6.33) years. Mean baseline CRP was 35.1(±42.7) mg/L. Mean baseline ASDASCRP was 4.04(±1.49). 77.4% had a good ASDAS CRP response to treatment and 22.6% had no response. 59.7% had a good answer according to BASDAI. The bivariate analysis did not find a significant relationship between the initial CRP and the main treatment response criteria: ASDASCRP (p=1) BASDAI (p=0.14), nor with ESR (p= 0.09) and overall EVA (p=0.1).

Conclusion: No relationship was found between baseline CRP and disease remission. Further studies with a larger sample would be needed to discuss these results.

COMPARISON OF TNF-α INHIBITORS EFFICACY BETWEEN RHEUMATIC DISEASES AND INFLAMMATORY BOWEL DISEASES

T. Nuriakhmetova[1], D. Abdulganieva[2], I. K. Valeeva[3], J. Shevnina[4]. [1]*Kazan State Medical University, Hospital therapy, Kazan, Russian Federation;* [2]*Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation;* [3]*Kazan State Medical University, Central Scientific Research Laboratory, Kazan, Russian Federation;* [4]*Republican clinicl hospital n.a. N.A. Semashko, Outpatient clinic, Simferopol, Russian Federation*

Background: The features of the underlying immune-mediated disease can affect the efficacy of TNF-α inhibitors (TNFi). No previous studies compared head-to-head the efficacy of TNFi between rheumatic diseases (RD) and inflammatory bowel diseases (IBD).
Objectives: To compare the efficacy of TNFi in the treatment of RD (ankylosing spondylitis (AS) and rheumatoid arthritis (RA)) and IBD (Crohn's disease (CD) and ulcerative colitis (UC)).
Methods: 123 patients were included into the study. 70 of them had RD (50 (40.7%) patients with AS, 20 (16.3%) with RA) and 53 patients had IBD (38 (30.9%) with CD and 15 (12.2%) with UC). The patients received infliximab (INX, 13 (18.6%) with RD and 23 (43.4%) with IBD), adalimumab (ADM, 36 (51.4%) with RD and 13 (24.5%) with IBD) or certolizumab pegol (CZP, 21 (30%) with RD, 17 (32.1%) with IBD). The response to the treatment was evaluated by ASAS20 for AS, EULAR criteria for RA, decrease in CDAI of ≥100 points for CD and Mayo Score decrease for UC. Statistical analysis was performed using the standard methods of descriptive statistics, Chi-squared test and Fisher's exact test for categorical variables, incidence rate and incidence rate ratio calculation, Student t test for continuous variables. Survival analysis was performed using Kaplan–Meier method and Cox proportional hazards regression. Log rank test was used to statistically compare the curves and p value was calculated.
Results: 95 (77.2%) patients were still responding to TNFα inhibitor after 23 [8; 24] months of observation. 10 (14.3%) patients in RD group and 18 (33.96%) patients in IBD group had loss of response to the treatment. Thus, the response rate of TNF inhibitor in RD patients was 1.3 times higher than among IBD patients (OR 1.298, 95%CI 1.046 to 1.61, p=0.016). Similarly, patients with AS responded to the treatment 1.3 times more often than patients with CD (86% vs 65.79%, OR=1.307, 95%CI 1.013 to 1.687, p=0.025). The efficacy rate of INX and ADM was comparable between the RD and IBD groups (23.1% vs 34.8%, for INX and 16.7% vs 30.8% for ADM, p>0.05) while loss of response to CZP developed more frequently among patients with IBD that with RD (35.3% vs 4.8%, OR 1.472, 95%CI 1.023 to 2.0, p=0.031). Incidence rate (number of cases of inefficacy per 100 patient-years) of TNFα inhibitor inefficacy was much higher in IBD than in RD (5.43 vs 17.02 cases per 100 patient-years, IRR 3.13, 95%CI 1.37 to 7.59, p=0.0033). The same ratio was observed between CD and AS patients (16.92 vs 5.29 cases per 100 patient-years, IRR 3.19, 95%ДИ 1.19 to 9.46, p=0.012). Median time to loss of response was 28.00±8.08 months in RD patients and 21.11±2.63 months in IBD patients (p>0.05). Only among patients taking INX the duration of therapy at the time of loss of response was significantly shorter in IBD group than in RD group (26.0±4.62 vs 53.67±13.37 months, p=0.03, Student t test 2.575). Event-free survival of the treatment (maintenance of efficacy during the whole period of observation) was significantly higher among RD patients than IBD patients (Log-rank test=8.1, plog-rank=0.0044). Cox proportional hazards regression was used to analyze the time to inefficacy, and a hazard ratio of 2.999 (95%CI 1.35 to 6.61, p=0.0052) was reported for IBD patients. This means that at any random time point patients with IBD have 74.9% probability of developing loss of response ealier than patients with RD.
Conclusion: TNFi are more efficient for the treatment of AS and RA than for IBD (CD and UC).

AB0780

ASSOCIATION OF LOW TROUGH LEVEL OF TNFI AND THEIR IMMUNOGENICITY WITH EFFICACY IN RHEUMATIC DISEASES AND INFLAMMATORY BOWEL DISEASES

T. Nuriakhmetova[1], D. Abdulganieva[1], A. Odincova[2], E. Sukhorukova[3], J. Shevnina[4]. [1]*Kazan State Medical University, Hospital therapy, Kazan, Russian Federation;* [2]*Republican clinical hospital, Gastroenterology, Kazan, Russian Federation;* [3]*Republican clinical hospital, Rheumatology, Kazan, Russian Federation;* [4]*Republican clinical hospital n.a. N.A. Semashko, Outpatient clinic, Simferopol, Russian Federation*

Background: The immunogenicity of TNF-α inhibitors (TNFi) is known to affect the efficacy of these biologic drugs. No previous studies compared this effect head-to-head between different groups of immune-mediated diseases.
Objectives: To compare the effect of immunogenicity of TNFi and their trough level on their efficacy in rheumatic diseases (RD) (ankylosing spondylitis (AS) and rheumatoid arthritis (RA)) and inflammatory bowel diseases (IBD) (Crohn's disease (CD) and ulcerative colitis (UC)).
Methods: 123 patients receiving infliximab (INX) (n=36, 29.3%), adalimumab (ADM) (n=49, 39.8%) and certolizumab pegol (CZP) (n=38, 30.9%) were included into the study. 70 (56.9%) of them had RD (50 (40.7%) with AS and 20 (16.3%) with RA) and 53 (43.1%) of them had IBD (38 (30.9%) with CD and 15 (12.2%) with UC). The specific criteria were used to assess the response to the treatment (ASAS20 for AS, EULAR for RA, CDAI for CD and Mayo Score for UC). Measurement of trough level of TNFi and the level of anti-drug antibodies (ADAb) was performed with the use of commercially available ELISA kits. The threshold of low trough level depended on the diseases based on the guidelines: 1 μg/mL for INX[1] in RD group and 5 μg/mL for INX[2] in IBD group, 5 μg/ml for ADM[3], and 20 μg/l for CZP[4].
Results: Efficacy of TNFi was 1.3 times more prevalent among patients with RD than among IBD patients (n=60, 85.7% vs n=35, 66%, OR 1.3, 95%CI 1.0 to 1.6, p=0.01). Rate of response to INX and ADM was comparable between the diseases while CZP was more efficient in RD (4.8% vs 35.3%, OR 1.5, 95%CI 1.0 to 2.0, p=0.031). Median trough levels of TNFi did not differ between the groups (p>0.05). Low level was determined in 26 (40.6%) patients with RD and 27 (45.8%) patients with IBD. Low level of TNFi most often was found in patients with UC (n=12, 80%, OR 5.6, 95%CI 1.493 to 20.999, p=0.006). Only INX low level was more prevalent in IBD patients than in RD (87% vs 46.2%, OR 5.7, 95%CI 1.1 to 29.2, p=0.046). The rate of low level of other TNFi was comparable between the groups (p>0.05). In RD group low level was associated with loss of response (80%, OR 6.0, 95%CI 1.2 to 30.7, p=0.036) while in IBD group no relation was found (51.4% vs 50%, p>0.05). Positive ADAb were determined in 22 (17.9%) patients: 14 (20%) in RD group and 8 (15.1%) in IBD group. TNFi did not differ significantly by the rate of ADAb-positivity (p>0.05). Association of loss of response with ADAb was observed in 4 (40%) patients with RD and 2 (11.1%) patients with IBD. Inefficacy of TNFi due to immunogenicity was 6 times more frequent in RA than in IBD (p>0.05). ADAb to INX (a chimeric antibody) were found only in patients with inefficacy (n=2, 66.7%, p=0.067). After exclusion of patients receiving ADM (a humanized antibody) 3 (75%) non-responders to INX or CZP with RD had positive ADAb while significantly less non-responders among IBD patients were ADAb-positive (n=2, 14.3%; OR 0.06, 95%CI 0.004 to 0.84, p=0.044).
Conclusion: Most of non-responders with RD had either low trough level of TNFi or ADAb, while in IBD group only half of cases of non-response could be attributed to the effect of ADAb or low trough level of TNFi.

Spondyloarthritis - clinical aspects (other than treatment)

AB0781 MALAYSIA SPONDYLARTHRITIS ACCELERATED MANAGEMENT (SAM) MODEL: EXPEDITING AXSPA PATIENT JOURNEY FROM EARLY REFERRAL, DIAGNOSIS AND ACCESS TO OPTIMAL CARE

F. Yahya[1], H. Mohd Yusoof[2], A. Mohd[3], S. Ch'ng Suyin[2], S. C. Gun[3], M. Mohd Zain[2], S. Sockalingam[1], S. L. Lai[4], C. Bao Jing[4], J. Tiong[4], I. S. Lau[2], R. Sengupta[5]. *[1]University of Malaya, Rheumatology, Kaula Lumpur, Malaysia; [2]Hospital Selayang, Rheumatology, Selangor, Malaysia; [3]Hospital Tuanku Ja'afar, Rheumatology, Seremban, Malaysia; [4]Novartis, Rheumatology, Petaling Jaya, Malaysia; [5]Royal National Hospital for Rheumatic Diseases, Rheumatology, Bath, United Kingdom*

Background: Axial spondyloarthritis (axSpA) is an important cause of inflammatory back pain (IBP). It is under-recognized, leading to significant delays in diagnosis. Early recognition and diagnosis are crucial to achieve the best outcomes for patients and in Malaysia, significant gaps in the clinical management of axSpA remain. Therefore, we sought to implement a strategy to improve the time to diagnosis and management of axSpA in Malaysia by collaborating and adopting guidance from an international axSpA expert.
Objectives: The objectives were to improve disease recognition among healthcare practitioners (HCPs), reducing time to specialist referral and diagnosis whilst improving disease management by developing and implementing a new patient care model called the Spondyloarthritis Accelerated Management (SAM) and measure its effectiveness in 3 Rheumatology centers in Malaysia.
Methods: The SAM initiative was developed by the Malaysian SpA Consortium Working Group involving 8 Malaysian rheumatologists from 3 local centers and 1 international axSpA expert from the UK as part of the steering committee. Selections were based on clinical expertise. The first local alignment meeting on model structure was held in July 2020 with subsequent meetings held to address key barriers to early axSpA diagnosis and timely access to quality care. A care model with feasible key performance indicators (KPIs) was established, adapted and tracked monthly in the 3 rheumatology centers (Figure 1). Referral tools were developed to facilitate early referrals to rheumatologists. These included a QR-coded '3-R' referral guide[1] and a patient self-screening tool with a patient self-referral letter all hosted on the Malaysian Society of Rheumatology (MSR) website, educational talks to HCPs and public awareness forums on IBP and axSpA. Data were collected on referral source, duration of referrals, knowledge on IBP in HCPs by surveys and imaging accessibility at baseline and at 1 year after the initiative was launched. Baseline data collected were from August to October 2020 and 1 year data were from November 2020 to November 2021.

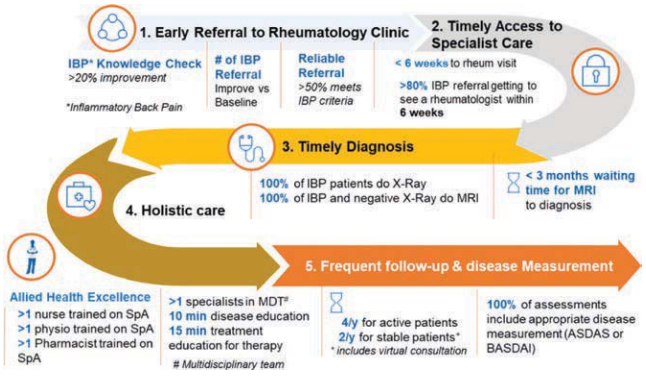

Figure 1. Summary of optimal Key performance indicators (KPIs) for Malaysia SAM

Results: At 1 year, the SAM initiative showed a 44.4% (Median: 1.33 [IQR 1-1.7] vs 1.92 [IQR 1.6-2.1]) increase in IBP referrals, a reducing trend from 9.5 (IQR 8-11.1) to 5.9 (IQR 5.1-6.8) weeks of waiting time to a first Rheumatology visit and an increase of 37.2% (34% vs 71%) in IBP patients who were seen at the rheumatology clinic within 6 weeks. All patients with IBP had x-rays (sacroiliac joints or pelvis). MRI requests in x-ray negative patients suspected of axSpA was increased by 13.9% (77.8% vs 91.7%) and waiting time for MRI was reduced by 3.1 weeks (12 vs 8.9 weeks). The IBP knowledge among 224 HCPs improved by 40.6% (45.7% vs 86.3%). The number of patients newly diagnosed with axSpA increased by 40% (Median: 5 [IQR 4-9.5] vs 7 [IQR 6.5-7]) despite the COVID-19 pandemic.
Conclusion: The SAM initiative has shown promising initial results in improving referrals of patients with IBP, promoting earlier diagnosis and establishing the importance of having timely access to optimal care. A nationwide implementation is being planned to improve the recognition of the axSpA in Malaysia.

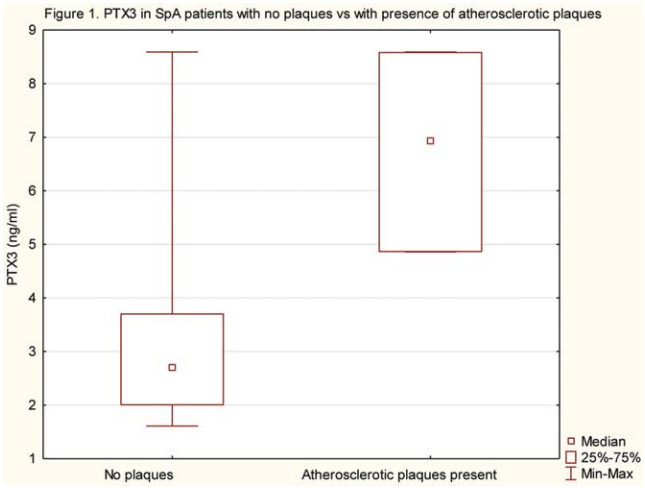
AB0782 SERUM PENTRAXIN 3 AS A BIOMARKER IN PATIENTS WITH SPONDYLOARTHRITIS.

B. Targonska-Stepniak[1], A. Drelich-Zbroja[2], K. Grzechnik[3]. *[1]Medical University of Lublin, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland; [2]Medical University of Lublin, Department of Interventional Radiology and Neuroradiology, Lublin, Poland; [3]Independent Public Teaching Hospital No 4, Department of Rheumatology and Connective Tissue Diseases, Lublin, Poland*

Background: A proper evaluation and management of patients with spondyloarthritis (SpA) requires the use of biomarkers, facilitating early diagnosis, reflecting disease activity and clinical response to therapies. The chronic, systemic inflammatory process is responsible for increased CV risk in SpA patients. Pentraxin 3 (PTX3) is an inflammatory marker, a member of long pentraxin superfamily, argued to be involved in pathogenesis of both inflammation and atherosclerosis. PTX3 is produced locally in the inflamed tissue, by different cell types including macrophages, endothelial cells, synoviocytes, but not hepatocytes. PTX3 is produced in walls of blood vessels, in atherosclerotic plaques, as a response to pro-inflammatory cytokines.
Objectives: The aim of the study was to assess the role of PTX3 as a biomarker in patients with SpA and to evaluate the relationship between PTX3 and CV risk markers (carotid intima-media thickness (cIMT), lipid profile).
Methods: The study group consisted of 40 consecutive patients with SpA: 29 patients with psoriatic arthritis (PsA) and 11 patients with ankylosing spondylitis (AS). The group consisted of 16 (40%) women and 24 (60%) men, with the mean (SD) age 43.9 (12.0) (range 25–68) and disease duration 7,8 (7,6) years (range 1–32). An assessment of the disease activity included: laboratory inflammatory parameters (erythrocyte sedimentation rate (ESR), C-reactive protein, CRP) and clinical assessment (in patients with peripheral SpA (pSpA) joints counts and disease activity score in 28 joints (DAS28); in patients with axial SpA (axSpA) Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and pain of the spine according to the patient in visual analogue scale (VAS). A measurement of carotid intima-media thickness (cIMT) was performed using high-resolution B-mode ultrasonography to estimate features of atherosclerosis (cIMT> 0.9 mm and/or presence of atherosclerotic plaques).
Results: The median (IQR) PTX3 concentration in SpA patients was 3.39 (2.22-3.88) ng/ml. The mean (SD) value of ESR was 27.7 (28.3) mm/h and CRP concentration 13.6 (19.9) mg/l. The mean values of clinical indices were as follows: DAS28 3.8 (1.1), BASDAI 4.02 (2.1), BASFI 4.22 (2.2), VAS spine pain 41.4 (24.0). The mean (SD) cIMT value was 0.77 (0.23) mm (range 0.48-1.33). The features of atherosclerosis were detected in 7 (17.5%) patients. No significant correlations were found between PTX3 and other inflammatory markers (ESR, CRP). There were no correlations between PTX3 concentration the clinical indices of the disease activity (DAS28, BASDAI, BASFI, VAS spine pain). No differences of PTX3 concentrations were detected between pSpA and axSpA patients. The PTX3 concentrations were significantly higher in patients with definite atherosclerosis (cIMT > 0.9 mm) than in patients with subclinical or no atherosclerosis (cIMT=< 0.9) (5.79 (3.84-8.59) vs 3.06 (2.0-3.52) ng/ml, p=0.01), as well as in patients with atherosclerotic plaques in comparison with no plaques (6.79 (4.86-8.59) vs 3.26 (2.0-3.71) ng/ml, p=0.02) (Figure 1).



Conclusion: The results of our study suggest that in patients with SpA, PTX3 could be regarded as a biomarker indicating intensity of atherosclerosis. However PTX3 was not associated with parameters of disease activity in patients with SpA.

AB0783 BARRIERS DELAYING THE EARLY DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS: DOES SEX MAKE A DIFFERENCE?

C. Fernández-Carballido[1], R. Almodovar González[2], X. Juanola[3]. *[1]Hospital Universitario San Juan de Alicante, Rheumatology, Alicante, Spain; [2]Hospital Universitario Fundación Alcorcón, Rheumatology, Madrid, Spain; [3]Hospital Univesritario de Bellvitge. IDIBELL., Rheumatology, Barcelona, Spain*

Background: The diagnostic delay in patients with axial spondyloarthritis (axSpA) in Spain is almost 9 years, being about 2 years longer in women (1). MIRADDAS is an educational project focused on raising awareness among different specialties involved in the diagnostic journey of patients with axSpA (e.g. Primary Care, Rehabilitation, Orthopedic Surgery, etc.), with the objective of achieving an earlier referral and diagnosis, especially in women.

Objectives: To identify the present barriers hindering a correct and earlier diagnosis of patients with axSpA in Spain.

Methods: Rheumatologists with a broad experience in axSpA prepared a survey addressed to rheumatologists participating in an educational project (MIRADDAS). First, the participants answered a survey, then they received training that was disseminated locally afterwards.

Results: A total of 80 rheumatologists from different Spanish regions answered the survey. Almost all rheumatologists (94%) recognized that there is a diagnostic delay and that this is higher in women (85%). Participants stated that the most significant factors are: 1. the presence of generalized pain in women (83%) and 2. the historical assumption of a higher prevalence of axSpA in men. Most of the rheumatologists (65%) do not have referral protocols for axSpA, though more than half participate in multidisciplinary clinics with Ophthalmology and Dermatology. Of the patients referred due to suspected axSpA from other specialties, from 20% to 50% were finally diagnosed with axSpA, the majority coming from Primary Care. Regarding the diagnostic delay of axSpA, the barriers most frequently identified by rheumatologists are: lack of knowledge about the disease and sex and gender differences by other specialties and hence a tendency not to refer women with suspected axSpA. Other important barriers are the delayed referral to rheumatologist, lack of communication between different specialties, lack of time during the visits and the delay to perform the imaging tests.

Conclusion: Sex and gender differences of patients with axSpA seem to contribute significantly to the diagnostic delay. The lack of knowledge by other specialties about sex and gender differences in axSpA presentation was identified as one of the most important barriers for an early diagnosis of these patients. Targeted educational projects such as MIRADDAS could contribute to reducing and improving the diagnostic journey of women with axSpA, ensuring equal access to health care for men and women.

AB0784 SYMPTOMS COMPATIBLE WITH ROME IV FUNCTIONAL BOWEL DISORDER IN PATIENTS WITH ANKYLOSING SPONDYLITIS

L. Wang[1], C. Song[1], Y. Wang[1], L. Hu[1], X. Liu[1], J. Zhang[1], X. Ji[1], S. Man[2], Y. Yang[3], L. Peng[3], Z. Wei[4], F. Huang[1]. *[1]The First Medical Center of Chinese PLA General Hospital, Department of Rheumatology and Immunology, Beijing, China; [2]Beijing JiShuiTan Hospital, Department of Rheumatology and Immunology, Beijing, China; [3]The First Medical Center of Chinese PLA General Hospital, Department of Gastroenterology and Hepatology, Beijing, China; [4]The Guard Bureau of the Joint Staff Department, Department of Health Service, Beijing, China*

Background: Clinical manifestations of gut problems except for inflammatory bowel disease (IBD) have not been well-established in patients with ankylosing spondylitis (AS). One study investigated that 30% patients with axial spondyloarthritis (axSpA) had irritable bowel syndrome (IBS) symptoms meeting Rome III criteria.[1]

Objectives: To determine the frequency of symptoms meeting Rome IV functional bowel disorder (FBD) in patients with AS, investigate factors associated with FBD symptoms, and assess whether having FBD symptoms might influence AS disease activity.

Methods: In this cross-sectional study, we consecutively enrolled 153 AS patients without known colonic ulcer and 56 sex- and age-matched controls to evaluate FBD (or its subtypes) symptoms.[2] In AS group, logistic regression models were used to explore whether demographic data, disease activity, level of gut inflammation, drug use, and fibromyalgia [3] were associated with presence of gut symptoms. Finally, potential impacts of gut symptoms on AS disease status were assessed in linear regression models.

Results: Sixty (39.2%) of 153 AS patients had FBD symptoms, which was more prevalent than controls (23.2%). Besides, symptoms compatible with IBS and chronic diarrhea were detected in 18 and 43 AS patients respectively. For AS group, multivariable logistic regression analyses showed that symptoms of FBD, IBS, and chronic diarrhea were negatively associated with using non-steroidal anti-inflammatory drug (NSAID), and positively associated with comorbid fibromyalgia, respectively. In exploration about effects of FBD (or its subtypes) symptoms on AS disease activity by multivariable linear regression analyses, FBD symptoms and chronic diarrhea had positive associations with assessments of AS respectively.

Conclusion: Patients with AS had frequent symptoms compatible with FBD, IBS, and chronic diarrhea, proportions of which were lower in those with NSAID-use. The improvement of FBD symptoms, especially chronic diarrhea, might be conducive to disease status of AS patients.

ROLE OF PATIENT ORGANIZATIONS IN IMPLEMENTATION OF RECOMMENDED NON-PHARMACOLOGICAL TREATMENT MODALITIES IN SPONDYLOARTHRITIS: EVIDENCE FOR THE EFFECTIVENESS OF SELF-MANAGEMENT STRATEGIES

D. Meyer-Olson[1,2], K. Hoeper[3,4], L. Hammel[5], S. Lieb[6], A. Haehle[6], U. Kiltz[7,8].
[1]Medizinische Hochschule Hannover, Department of Rheumatology and Immunology, Hanover, Germany; [2]m&i Fachklinik Bad Pyrmont/MVZ Weserbergland, Department of Rheumatology and Immunology, Bad Pyrmont, Germany; [3]Medizinische Hochschule Hannover, Department of Rheumatology and Immunology, Hannover, Germany; [4]Regionales Kooperatives Rheumazentrum Niedersachsen e.V, Rheumatology, Hanover, Germany; [5]Deutsche Vereinigung Morbus Bechterew e.V, Rheumatology, Schweinfurt, Germany; [6]Novartis Pharma GmbH,, Immunology, Hepatology and Dermatology, Nürnberg, Germany; [7]Rheumazentrum Ruhrgebiet,, Rheumatology, Herne, Germany; [8]Ruhr Universität, Rheumatology, Bochum, Germany

Background: EULAR recommends participation in patient (pt) organizations to improve pt self-management of axial spondyloarthritis (axSpA)[1]. Non-pharmacological treatment modalities (NPTM)[2] are recommended in axSpA treatment guidelines.[3]

Objectives: To characterize the impact of pt advocacy group membership and its association with NPTM frequency and clinical parameters in axSpA.

Methods: Pts with a confirmed axSpA diagnosis were enrolled in the multicenter, observational ATTENTUS-axSpA survey conducted across Germany (11/2019–07/2020). Demographics, clinical and pt-related data were collected electronically.

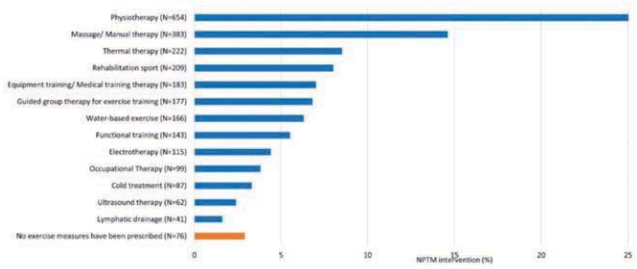
Results: Of the 787 enrolled axSpA pts, this analysis was conducted on the working population (n=695)[4]. Overall, 12.2% (n=85) pts were members of a pt advocacy group and 87.8% (n=610) were not. Pt advocacy group members had higher Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores, increased functional impairment (BASFI, Bath Ankylosing Spondylitis Functional Index) and higher impact of axSpA on health (ASAS-HI, Assessment of SpondyloArthritis International Society-Health Index; Table 1). Despite worse prognostic factors, there was no significant difference in Work Productivity and Activity Impairment (WPAI) score [40.6 (27.0) for pt advocacy group members vs 36.8 (29.9) for non-members; p=0.380]. Membership in a pt advocacy group was associated with increased prescribed, supervised NPTM (57.6% [n=49] vs 34.4% [n=210]). Pts reported to have ever received 2.6 rehabilitation measures, and ≥3.0 different rehabilitation NPTM measures. Cumulatively, 25.0% (N=654) of rehabilitation measures were physiotherapy (Figure 1).

Table 1. Descriptive characteristics and impact of membership in pt advocacy group

Characteristic	Patient advocacy group member (n=85)	Not patient advocacy group member (n=610)	Total (n=695)	p-value
Age (yrs), mean (SD)	50.2 (7.7)	44.6 (11.1)	45.3 (10.9)	**<0.001**
BMI (kg/m2) mean (SD)	27.5 (5.0)	28.0 (12.7)	28.0 (12.0)	0.713
Male, n (%)	45 (52.9)	378 (62.0)	423 (60.9)	0.128
Disease duration (yrs) mean (SD)	13.7 (10.3)	12.5 (11.1)	12.6 (11.0)	0.303
ASAS-HI, 0-17	7.3 (3.4)	6.4 (3.9)	6.5 (3.8)	**0.045**
BASDAI, 0-10	4.3 (1.9)	3.8 (2.2)	3.9 (2.2)	**0.044**
BASDAI ≥4, n (%)	49 (57.6)	275 (45.1)	324 (46.6)	**0.025**
BASFI, 0-10	3.9 (2.3)	3.2 (2.5)	3.3 (2.4)	**0.015**
Biologic treatment, n (%)	52 (61.2)	312 (51.1)	364 (52.4)	0.072
Full time employment, n (%)	48 (56.5)	410 (67.2)	458 (65.9)	0.06
Absenteeism*, mean (SD)	8.4 (21.2)	10.9 (26.8)	10.6 (26.2)	-
Presenteeism*, mean (SD)	38.4 (24.6)	31.8 (25.7)	32.6 (25.6)	-
Overall work impairment score*, mean (SD)	40.6 (27.0)	36.8 (29.9)	37.2 (29.6)	0.380
Activity impairment, mean (SD)	46.7 (21.7)	40.5 (26.8)	41.3 (26.4)	0.058
Pts having ever received medicinal rehabilitation measures, mean (SD)	67 (78.8)	328 (53.8)	395 (56.8)	**<0.001**
Prescribed supervised group NPTM[#], mean (SD)	49 (57.6)	210 (34.4)	259 (37.3)	**<0.001**
Regular physical training[†], mean (SD)	76 (89.4)	515 (84.4)	591 (85.0)	0.231

*Work-related questions of WPAI-score have been calculated for pts in employment (N=340); [†]regular physical training in the context of axSpA; [#]rehabilitation sport and/or functional training. ASAS-HI, Assessment of SpondyloArthritis International Society-Health Index; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BMI, Body Mass Index; n, number of pts; pts, patients; SD, Standard Deviation; WPAI, Work Productivity and Activity Impairment; yrs, years.

Figure 1. NPTM measures ever received in patients with axSpA (2617 answers from 770 pts)



Multiple answers were permitted. A total of 2617 answers were submitted from 770 patients. N, total number of pts. NPTM, non-pharmacological treatment modalities.

Conclusion: Pt advocacy group membership was associated with increased prescribed NPTM in axSpA. Pt organizations may support the implementation of guidelines and improvement of self-management strategies in pts with axSpA, which may influence work participation.

AB0786

SELF-REPORTED DISEASE BURDEN IS GREATER IN SPONDYLOARTHRITIS THAN IN RHEUMATOID ARTHRITIS PATIENTS ACCORDING TO MULTIDIMENSIONAL QUESTIONNAIRE (MDHAQ / RAPID3) SCORES, DESPITE FEWER FEMALES, WHO GENERALLY HAVE HIGHER SCORES ON PATIENT QUESTIONNAIRES

R. Morlà[1], T. Ll[2], G. Luta[3], T. Pincus[4]. [1]*Hospital Clinic de Barcelona, Rhematology, Barcelona, Spain;* [2]*Georgetown University, Department of Biostatistics, Bioinformatics and Biomathematics, Washington DC, United States of America;* [3]*Georgetown University, Department of Biostatistics, Bioinformatics and Biomathematics, Washington DC, United States of America;* [4]*Rush University Medical Center, Rhematology, Chicago, United States of America*

Background: Female patients generally have higher scores than males on most items on self-report questionnaires, including MDHAQ/RAPID3 (multi-dimensional health assessment questionnaire/routine assessment of patient index data)[1]. MDHAQ/RAPID3 was validated in patients with rheumatoid arthritis (RA), but is informative in all diseases studied, including spondyloarthritis (SpA)[2]. More SpA patients are men than RA patients, suggesting lower scores, but MDHAQ scores are higher in SpA than RA.

Objectives: We compared self-report MDHAQ/RAPID3 scores in RA vs SpA patients according to gender.

Methods: Patients who met classification criteria for RA or SpA (axial SpA and psoriatic arthritis) completed MDHAQ at a routine rheumatology visit. The MDHAQ includes 10 activities for physical function (FN) (8 identical to HAQ), scored 0-3, total 0-30, divided by 3 for a 0-10 score, 3 0-10 visual numeric scales (VNS) for pain (PN), patient global assessment (PATGL), and fatigue (FT), a 60-symptom checklist (ROS60) and a RADAI self-report of painful joints (0-48). RAPID3 is a 0-30 index of FN + PN + PATGL. Means and standard deviations (SDs) of age, education, and 7 MDHAQ scores were computed in patients with RA versus SpA, and in subsets of female versus male patients with either RA or SpA. Unadjusted differences were evaluated using Student's t and chi-square tests; mean differences were adjusted for age, gender and education using analysis of covariance.

Results: 170 patients were studied, 102 with RA and 68 with SpA. 82% of patients with RA and 47% of patients with SpA were female (p<0.001); age and education did not differ between the 2 groups (Table 1). All 7 mean MDHAQ scores analyzed were higher in patients with SpA than in those with RA, although only differences for FN were statistically significant (Table 1). Within both the RA and SpA groups, however, all 7 scores were higher in women than in men, statistically significant for PN, PATGL, RAPID3 and fatigue in RA, and only for fatigue in SpA. In analyses adjusted for gender, FN, PATGL, FT, and RAPID3 were statistically significantly higher in SpA than in RA (Table 1).

Conclusion: The self-reported disease burden measured by MDHAQ / RAPID3 was higher in patients with SpA than in those with RA, despite having a lower proportion of women, who generally have higher scores on all patient self-report questionnaires, including MDHAQ/RAPID3, within both the RA and SpA groups. Gender differences may lead to underestimation of the greater disease burden in SpA compared to RA.

AB0787

EXPLORATION OF PAIN SYNDROME IN PATIENTS WITH ANKYLOSING SPONDYLITIS WITH ANXIETY-DEPRESSIVE SPECTRUM DISORDERS

I. Blaginina[1], E. Komarova[1], O. Rebrova[1], P. Bakhtoyarov[2], N. Bludova[1]. [1]*Lugansk State Medical University, Internal medcine, Lugansk, Ukraine;* [2]*Lugansk State Medical University, neurology, Lugansk, Ukraine*

Background: To date, it has been established that anxiety-depressive spectrum disorders (ADSD) increase the perception of chronic pain. ADSD, as well as immuno-inflammatory diseases, in particular ankylosing spondylitis (AS), are caused by increased production of pro-inflammatory cytokines. Cytokines activate the hypothalamic-pituitary-adrenal system, and chronic stress factors provide a new release of cytokines with its subsequent sensitization, impairing the adaptive capabilities of the body, thereby exacerbating endocrine dysfunction that regulates stress and immune response in the body, which increases the level of proinflammatory cytokines, and is clinically manifested by a decrease in mood, chronic pain, fatigue, sleep disorders.

Objectives: To study the features of pain syndrome in patients with ankylosing spondylitis with anxiety-depressive spectrum disorders.

Methods: The exploration involved 112 patients with AS, aged 25 to 58 years (43.7±7.9 years), the average duration of the disease was 9.5±4.4 years. 67 of them (group 1) showed signs of ADSD, established by the Spielberger anxiety and Hamilton depression scales. The remaining 45 patients without ADSD were included in the 2nd observation group. The patients in the groups did not differ in age (p=0.67), however, they differed in the duration of the disease (p=0.035) - in the 1st group 10.2±4.5, in the 2nd group 8.4±4.0 years. In addition, patients of the 1st and 2nd groups did not differ in the frequency of occurrence of chronic fatigue (p=0.2) and decreased mood (p=0.08). However, sleep disorders (difficulty falling asleep, shallow sleep, early awakening) were significantly more frequent in-group 1 (p=0.046). Quantitative indicators of pain syndrome (PS) were studied using the McGill Pain Questionnaire (MGPQ). The severity of pain in the spine, morning stiffness, the patient's state of health (PSH) were studied using visual analog scales (VAS); BASDAI and BASFI indices, ESR and CRP indices were also recorded.

Results: Patients in the groups did not differ in BASDAI indices - in group 1, 4.04±1.24, in group 2, 3.83±0.98 and BASFI - 4.21±0.99 and 4.24±0.84, respectively; there were also no differences in the level of CRP and ESR. Spinal pain in group 1 (67.8±17.5 mm) was significantly stronger (p=0.02) than in group 2 (60.2±15.9 mm), morning stiffness was also significantly (p=0.028) more pronounced in group 1 (67.4±15.9 mm) than in group 2 (60.3±17.2 mm). According to the indicator of SPP, a more negative tendency to its increase should be noted in the 1st group (68.7±15.2 mm) than in the 2nd (63.7±14.4 mm), but without significant differences (p=0.084). All quantitative indicators of BS according to the ICD in the groups had significant differences (p<0.05), reaching maximum significance for the sensory and affective components of pain, the index of the number of selected descriptors (INSD). Namely: in group 1, the number of sensory and affective class descriptors was 5.9±0.8 and 4.5±0.7, the evaluative component of pain was 2.9±0.5, INSD was 11.9±1.4 points, the pain rank index (PRI) was 26.3±5.5 points; in group 2, the number of sensory and affective descriptors was 5.0±0.9 and 3.75±0.6, evaluative - 2.6±0.6, INSD - 10.3±1.5, RIB - 21.2±5.1 points. A higher number of affective class descriptors and ICPD in group 1 indicates the emotional lability of patients with ADSD and to a certain extent explains the significantly more significant negative indicators of BS recorded during the survey using VAS.

Conclusion: Significantly higher quantitative indicators of BS in patients with AS with ADSD confirm the presence in this category of patients of a pronounced emotional-affective component of pain, which has a central origin, and contributes to the growth of its somatic perception.

THE INTERNATIONAL MAP OF AXIAL SPONDYLOARTHRITIS (IMAS): A US PATIENT PERSPECTIVE ON DIAGNOSIS AND BURDEN OF DISEASE

M. Magrey[1], J. A. Walsh[2], S. Flierl[3], R. Calheiros[4], D. Wei[5], M. A. Khan[6].
[1]Case Western Reserve University School of Medicine, University Hospitals, Rheumatology, Cleveland, United States of America; [2]University of Utah School of Medicine and Salt Lake City Veterans Affair Medical Center, Rheumatology, Salt Lake City, United States of America; [3]Ipsos, Ipsos, Basel, Switzerland; [4]Novartis Pharmaceuticals Corporation, Rheumatology, East Hanover, United States of America; [5]Novartis Pharmaceuticals Corporation, Rheumatology, East Hanover, United States of America; [6]Case Western Reserve University School of Medicine, Rheumatology, Cleveland, United States of America

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease encompassing radiographic (traditionally known as ankylosing spondylitis) and non-radiographic forms that lead to chronic pain, structural damage, and disability.[1] The International Map of Axial Spondyloarthritis (IMAS) survey is an initiative developed to generate insights into the real-life experiences of people living with axSpA to ultimately improve quality of life.[2]
Objectives: To assess the burden and daily experience of patients with axSpA in the United States.
Methods: The IMAS survey generates a report on patient-reported aspects of disease burden and experience with axSpA using adaptations of the original Atlas of axSpA questionnaire developed in collaboration with patients, the Axial Spondyloarthritis International Federation, and clinical academic experts. In this US adaptation of the IMAS survey, a 30-minute quantitative online survey was administered to US patients aged ≥18 years who completed screening questions, self-reported having been diagnosed with axSpA by a healthcare provider, and were under the care of a healthcare provider between July 22, 2021, and November 10, 2021. Survey questions were tailored to reflect differences in the US healthcare systems and the availability of treatments. This analysis presents a portion of the US data describing patient demographics, clinical characteristics, journey to axSpA diagnosis, and the emotional impact and overall burden of disease on quality of life using the General Health Questionnaire 12 (GHQ-12), the Assessment of SpondyloArthritis international Society – Health Index (ASAS-HI), and a global limitation index of 18 activities of daily living. All results were reported descriptively using summary statistics.
Results: Survey data from 228 US patients with axSpA were collected in this analysis. The mean age was 45 years, 60% of patients were female, and the mean BMI was 27.7 kg/m2 (Table 1). Participating patients had an average of 5.6 comorbidities, with anxiety (43%), depression (41%), and hypertension (32%) as the most commonly reported comorbidities. Among all patients, the mean age at onset of first symptoms was 26 years and the mean age at diagnosis was 35 years; overall, mean diagnostic delay was greater in female than in male patients (11.2 vs 5.2 years; Figure 1**A**). According to the validated GHQ-12, over half of the patients (57%) were at risk for psychological distress (GHQ-12 score ≥3; Figure 1**B**). Patients who were older (>40 years old), physically inactive, or who had active disease (BASDAI ≥4) were at risk for psychological distress. Most patients (82%) suffered from a high degree of impairment (ASAS-HI ≥6), 47% had a medium or high limitation in activities of daily living, and 46% of patients were not employed at the time of the survey.

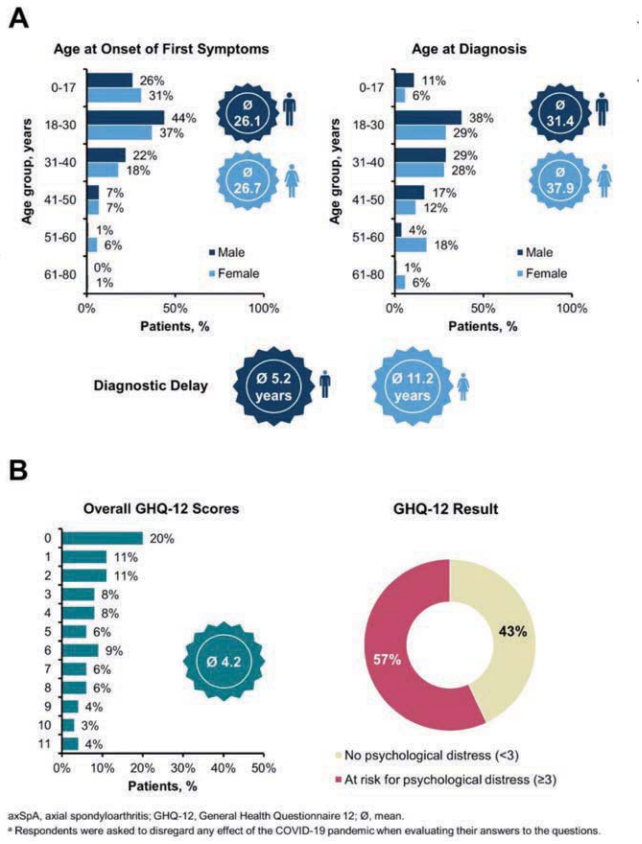
Table 1. Patient Demographic and Clinical Characteristics

Characteristic	Patients with axSpA (N=228)
Mean age, years	45
Female, %	60
White, %	86
Mean body mass index, kg/m^2	27.7
Nonsmoker, %	62
Alcohol consumption behavior, %	
Never	19
Every day	9
Mean number of comorbidities	5.6
Common comorbidities (≥20% of patients), %[a]	
Anxiety	43
Depression	41
Hypertension	32
Obesity/overweight	31
Sleep disorders	30
Hypercholesterolemia	29
Uveitis	24
Psoriatic arthritis	23
Fibromyalgia	20
Spinal or other fractures	20
Psoriasis	20
Employed, %	54

axSpA, axial spondyloarthritis. [a]Respondents could have selected ≥1 answer.

Conclusion: This study showed that a high proportion of US patients with axSpA report impaired function and are at risk for psychological distress. Patients also experienced a substantial delay in the time to axSpA diagnosis, with longer delays than those reported in the European Union. Delays were twice as long in women compared to men. These findings highlight the large impact of disease on daily activities and mental distress in US patients with axSpA.

Figure 1. (A) Age of First Symptom Onset and Diagnosis By Sex and **(B)** Burden of Disease on Psychological Distress Among Patients With AxSpA[a] (N=228)



axSpA, axial spondyloarthritis; GHQ-12, General Health Questionnaire 12; Ø, mean.
[a] Respondents were asked to disregard any effect of the COVID-19 pandemic when evaluating their answers to the questions.

WHAT DRIVES THE BASDAI IN PREGNANT PATIENTS WITH AXIAL SPONDYLOARTHRITIS? A POOLED ANALYSIS OF FOUR EUROPEAN PREGNANCY REGISTRIES.

Y. Meissner[1], A. Moltó[2,3], N. Costedoat-Chalumeau[4,5], R. Fischer-Betz[6], F. Förger[7,8], M. Wallenius[9,10], A. Strangfeld[1]. *[1]German Reumatism Research Centre Berlin, Epidemiology and Health Services Research, Berlin, Germany; [2]Assistance Publique – Hôpitaux de Paris, Rheumatology Department, Paris, France; [3]Inserm, U-1153, Paris, France; [4]Assistance Publique – Hôpitaux de Paris, Internal Medicine Department, Referral center for rare autoimmune and systemic diseases, Paris, France; [5]Inserm, INRA, Paris, France; [6]University Clinic Duesseldorf, Department for Rheumatology, Düsseldorf, Germany;*

[7]Inselspital, Department of Rheumatology and Immunology, Bern, Switzerland; [8]University of Bern, Rheumatology, Bern, Switzerland; [9]Norwegian University of Science and Technology, Unit for Orthopedics and Rheumatology, Trondheim, Norway; [10]St. Olav's University Hospital, Department of Rheumatology, Trondheim, Norway

Background: The patient reported Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) includes the six components fatigue, neck, back or hip pain, pain or swelling in other joints, tenderness, morning stiffness severity and duration on a 0-10 scale.
Objectives: To explore the driving factors for the BASDAI in pregnant patients with axial spondyloarthritis (axSpA).
Methods: Anonymized pooled data of the European Network of Pregnancy Registries in Rheumatology (EuNeP) were used. The four participating registries are located in France, Germany, Norway and Switzerland, and collect data of women with child wish, during and after pregnancy prospectively and nationwide on regular time points. For the analysis, women who fulfilled ASAS classification criteria for axSpA and for whom a pregnancy outcome was reported until 12/2019 or 07/2020, depending on the registry, were selected. Mean BASDAI and its components were analysed descriptively.
Results: A total of 332 pregnancies from 304 women with axSpA were eligible. The Norwegian registry contributed half of the pregnancies (50.3%), followed by Germany (26.2%), France (15.4%) and Switzerland (8.1%). Mean maternal age was 31 years, the average disease duration 5 years. Mean BASDAI was 3.0 before conception, 3.4, 3.4 and 3.5 in the 1st, 2nd and 3rd trimester, and 3.4 within 6 months postpartum. The figure shows mean values of the BASDAI and its individual components in the different time periods. Fatigue was higher than the mean score during all phases, and especially elevated in the 1st and 3rd trimester. Furthermore, values for neck, back or hip pain were higher than the mean score, especially from 2nd trimester on. All other components were lower than the mean score. Data were not reported for all pregnancies and all time periods. Availability was highest in the 2nd and 3rd trimester with reported BASDAI in 60% and 62% of the pregnancies, respectively. Lowest reporting was 24% in the preconception period because only a part of the women was also observed before pregnancy.
Conclusion: The BASDAI is a validated instrument for assessing disease activity in patients with axSpA. Since the calculation of the score also includes factors that can be influenced by pregnancy, it may only be of limited value for measuring disease activity in pregnancy. This analysis shows that mainly fatigue and back pain in particular have an impact on the mean BASDAI. A limitation of this analysis is that data were not available for all measured time points of the individual pregnancies. Therefore, the results should be confirmed by other studies.

	Fatigue	Neck, back or hip pain	Pain/swelling in other joints	Tenderness	Level of morning stiffness	Duration of morning stiffness	BASDAI
Preconception	4.3 ± 3.2	3.5 ± 2.6	2.2 ± 2.6	2.5 ± 2.7	2.7 ± 2.6	2.9 ± 2.9	**3.0 ± 2.1**
1st trimester	5.6 ± 2.8	3.7 ± 2.9	1.9 ± 2.3	2.9 ± 3.0	3.1 ± 3.1	2.9 ± 2.6	**3.4 ± 2.2**
2nd trimester	5.0 ± 2.6	4.1 ± 2.6	1.9 ± 2.4	2.9 ± 2.8	3.2 ± 3.0	2.9 ± 2.8	**3.4 ± 2.2**
3rd trimester	**5.6 ± 2.7**	**4.1 ± 3.0**	**2.1 ± 2.5**	**3.0 ± 2.9**	**3.4 ± 3.2**	**3.2 ± 2.9**	**3.5 ± 2.3**
6 months postpartum	4.4 ± 2.8	4.1 ± 2.8	2.6 ± 2.7	3.0 ± 2.9	3.5 ± 3.0	3.1 ± 2.9	**3.4 ± 2.3**

Figure 1. Means of BASDAI components before, during and after pregnancy (the table presents means ± standard deviation).

AB0790 EFFECTS OF PHYSICAL ACTIVITY ON DISEASE ACTIVITY AND CLINICAL ENTHESITIS SCORES IN PATIENTS WITH SPONDYLOARTHRITIS

M. Slouma[1], S. Ben Dhia[1], C. S. Bellagha[1], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[2]. [1]The Military Hospital of Tunis, Department of Rheumatology, Tunis, Tunisia; [2]The Military Hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia

Background: Regular physical activity (PA) highly recommended for patients with inflammatory diseases [1]. It was shown to significantly improve disease activity [1]. However, data regarding the effects of physical activity on disease activity and clinical enthesitis scores in patients with SA are scarce.
Objectives: We aim to assess the effects of performing PA on disease activity and clinical enthesitis scores in patients with SA.
Methods: We performed a cross-sectional study including patients with axial spondyloarthritis. Each patient was asked if he performed regular physical activity. Clinical disease activity scores were calculated: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score using C-Reactive Protein (ASDAS-CRP). Clinical enthesitis scores were calculated: Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) [2], Spondyloarthritis Research Consortium of Canada Enthesitis Index (SPARCC) [3] and Leeds Enthesitis Index (LEI) [4].
Results: Thirty-seven patients were included: 29 males and 8 females. The mean age was 44.51±12.08 years. The mean disease duration of 9±7.8 years. Regular PA was reported by 51% patients (19). Aerobic exercise was performed by 48.6% of patients (walking: 27%, jogging: 8.1%, football: 5.4%, biking: 2.7%, handball: 2.7% and fitness exercise: 2.7%). Anaerobic exercise was performed by only one patient (2.7%) and consists of weightlifting. The mean weekly duration of PA was of 4.32±3.4 hours. Means BASDAI, ASDAS-CRP, and ASDAS-ESR were of 4.74±2.2, 3.02±1.2 and 3.26±1.3, respectively. Mean MASES was of 2.95±2.86, LEI of 1.51±1.72 and SPARCC of 2.97±3.42. Patients who performed regular PA had significantly lower disease activity evaluated with BASDAI (3.53 vs 5.45, p=0.007), ASDAS-CRP (2.64 vs 3.44, p=0.045) and ASDAS-ESR (2.84 vs 3.7, p=0.44). Clinical enthesitis scores were also significantly lower in physically active patients (MASES: 1.74 vs 4.22, p=0.007, LEI: 0.95 vs 2.11, p=0.038, SPARCC: 1.79 vs 4.22, p=0.029). However, no significative difference was found between the two groups regarding CRP (16.11 mg/L vs 39.67 mg/L, p=0.107). No correlation was found between the weekly number of hours of PA and the evaluated scores.
Conclusion: Physical activity was associated with lower disease activity scores and lower clinical enthesitis score. This highlights the importance of physical activity as a non-pharmacologic treatment in SA for the management of disease activity and entheseal involvement.

AB0791 MADRID SONOGRAPHIC ENTHESIS INDEX: USEFUL OUTCOME IN THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS

C. S. Bellagha[1], M. Slouma[1], S. Ben Dhia[1], J. Ben Katib[1], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[2]. [1]The Military Hospital of Tunis, Department of Rheumatology, Tunis, Tunisia; [2]The Military Hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia

Background: Madrid Sonographic Enthesis Index (MASEI) is an ultrasound (US) score for the evaluation of enthesis including inflammatory abnormalities and chronic damage in spondyloarthritis (SpA) [1]. This score includes bilaterally: plantar aponeurosis, Achilles tendon, distal and proximal patellar ligament, distal quadriceps, and brachial triceps tendons.
Objectives: We aimed to study the diagnosis value of MASEI score in axial spondyloarthritis.

Methods: We conducted a case-control study including 74 subjects divided into 2 groups: -G1: 37 patients fulfilling the Assessment of SpondyloArthritis international Society (ASAS) criteria for axial SA. -G0: 37 healthy controls matched for age and sex. Eight hundred eighty-eight entheses were assessed by a musculoskeletal experienced sonographer who was blinded to the clinical data concerning patients and controls. The MASEI was calculated for the 2 groups. For G1, we collected the following parameters: disease activity using Bath Ankylosing Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS-ESR). Statistical analysis was performed using "IBM SPASS Statistics" software version 21. A Receiver Operator Curve (ROC) analysis was performed to determine the cutoff of MASEI able to discriminate G0 from G1.

Results: The study included 29 men (78%) and 8 women (22%) in each group. The mean age was 44.51 ± 12.08 years. The mean age of onset was 38.06 ± 11.36 years. The mean disease evolution of 9.02 ± 7.83 years. The mean BASDAI and ASDAS-ESR were 4.47 ± 2.21 and 3.26 ± 1.31. MASEI score was significantly higher in patients compared to healthy controls (25.76 ± 9.8 versus 8.32 ± 6.65, p <0.0001). A cutoff of 18 of the MASEI was able to distinguish G1 from G0 with a sensitivity of 81.1% and specificity of 91.9%. The air under curve (AUC) value was 0.920 (p<0.0001). No correlation was found between MASEI and BASDAI, and ASDAS-ESR.

Conclusion: Our study showed that MASEI score is significantly higher in SpA patients and seems to have a diagnostic accuracy. Besides, MASEI was able to distinguish between SpA patients and healthy controls with a cut-off of 18. Those results agree with the findings of other researchers in the field [2].

AB0792 HIP INVOLVEMENT IN SPONDYLOARTHRITIS: ANALYSIS OF ASSOCIATED FACTORS

H. Tbini[1], M. Slouma[1], S. Rahmouni[1], A. Abdennadher[2], K. Amri[2], Y. Mallat[2], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[3]. *[1]Tunis, Department of Rheumatology, Military Hospital, Tunis, Tunisia., Tunis, Tunisia; [2]Tunis, Department of Orthopaedic Surgery, Military Hospital, Tunis, Tunisia., Tunis, Tunisia; [3]Tunis, Department of Internal Medicine, Military Hospital, Tunis, Tunisia., Tunis, Tunisia*

Background: Hip involvement occurs in about one-third of patients with spondyloarthritis (SA) [1]. It can be responsible for significant disability and functional impairment.

Objectives: This study aimed to assess the associated factors with hip involvement in SA.

Methods: We conducted a cross-sectional study, including 165 patients with SA diagnosed according to Assessment of SpondyloArthritis international Society (ASAS) criteria over a period from 2017 to 2021. Demographic, clinical, biological and radiographic data were collected. We compared following parameters assessed at the time of diagnosis of coxitis: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP), modified Stoke Ankylosing Spondylitis Spine Score (mSASSS), Bath Ankylosing Spondylitis Radiology Index (BASRI), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). We used logistic regression analysis to identify factors associated with hip involvement in SA.

Results: A total of 165 Patients were enrolled (121 men and 44 women), the mean age was 46.13 ± 13.07 years. The mean age of disease onset was 35.01 ± 12.55 years. The average diagnostic delay was 37.54 ± 50.51 months. The average disease duration was 10.91 ± 6.94 years. Eighty seven percent of patients had axial spondyloarthritis, 72% had extra-articular manifestations. Mean ESR and CRP values were 37.49 ± 28.1 mm and 30.14 ± 43.55 mg/L, respectively. Mean BASDAI and ASDAS-CRP values were 4 ± 1.8 and 3.09 ± 1.13, respectively. Hip involvement was noted in 60 patients (36.4%). It was bilateral in 75% of cases (n=45). A total number of affected hips was 105. Following parameters were significantly higher in patients with hip involvement: age over 40 years old (73.3 vs 56.3%, p=0.030), symptoms duration over 10 years (60% vs 40.2%, p=0.015), elevated CRP (87.9% vs 73.7%, p=0.036), radiographic sacroiliitis (95% vs 82.7%, p=0.023), frequency of pulmonary involvement (25.0% vs 11.4%, p:0.023), frequency of osteoporosis (20.0% vs 8.6%, p:0.034), BASMI (3.71 vs 1.65, p<0.001), BASRI spine (5.97 vs 2.91, p<0.001), and mSASSS (16.24 vs 5.80, p:0.001). However, no association was found between HLA-B27 and hip involvement (50% vs 28.6%, p=0.099). A multivariable logistic regression model showed that age over 40 years (OR=2.688 [1.020 - 7.083], p=0.045), radiographic sacroiliitis (OR=5.656 [1.007 - 31.769], p=0.049), and very high disease activity (ASDAS-CRP≥3.5) (OR=5.328 [1.774 - 16.002], p=0.003) were independently associated with hip involvement in SA.

Conclusion: Our study showed that age, symptoms duration, radiographic sacroiliitis, extra-articular manifestations, axial structural damage, elevated CRP, and very high disease activity were associated with hip involvement. These finding suggest that the control of disease activity and inflammation may prevent the onset of hip involvement. There are controversial findings regarding the association between HLA B27 gene and hip involvement [2].

AB0793 FACET JOINT DISEASE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A RETROSPECTIVE CONVENTIONAL COMPUTED TOMOGRAPHY STUDY

G. Slobodin[1], M. Sagiv[2], T. Khreish[3], A. Shouval[1], S. Croitoru[4], I. Eshed[5]. *[1]Bnai Zion Medical Center, Rheumatology, Haifa, Israel; [2]Sheba Medical Center, Internal Medicine, Ramat Gan, Israel; [3]Bnai Zion Medical Center, Internal Medicine, Haifa, Israel; [4]Bnai Zion Medical Center, Radiology, Haifa, Israel; [5]Sheba Medical Center, Radiology, Ramat Gan, Israel*

Background: Facet joints' (FJ) ankylosis was reported to occur frequently in patients with ankylosing spondylitis (AS). However, a detailed FJ evaluation was not reported in patients over the spectrum of axial spondyloarthritis (AxSpA).

Objectives: To analyze structural lesions in the FJ of patients with different forms of AxSpA, using computed tomography (CT).

Methods: All available conventional CT studies of the cervical, thoracic, lumbar spine, or studies of the chest or abdomen of patients with AS or non-radiographic AxSpA (nrAxSpA) from a single medical center cohort were analyzed for the presence of erosions, ankylosis, joint-space narrowing, osteophytes, subchondral sclerosis, subchondral cysts and vacuum phenomenon by 2 experienced readers. All patients, as well as age and gender matched control group, who performed conventional CT of the spine for any cause, but did not have a known rheumatic disease, had to be at the age of 50 years or less at the time of the study. The findings were binarically scored as present/absent. Several types of changes could be noted in the same FJ. All FJ findings were compared between groups of AxSpA patients and controls, separately for the cervical, thoracic and lumbar spine. Further, AxSpA patients were subdivided into three groups of which FJ findings were compared: AS patients with (AS+) or without (AS-) syndesmophytes on the cervical or lumbar radiographs, and patients with nrAxSpA as per pelvic radiograph. Fisher's exact test or Chi-Square test at < http://vassarstats.net >, were used to compare between groups.

Results: 959/666 FJs (49/44 patients) were assessed in the AxSpA/control group patients, respectively. The study group consisted of 16 AS+ patients, 22 AS- patients, and 11 nrAxSpA patients. FJ ankylosis was significantly more prevalent in all spinal segments of the AS + group compared to the two other groups. Erosions were seen almost exclusively in patients with AS. Joint-space narrowing and osteophytes were noted in all segments and all subgroups of AxSpA patients, including those with nrAxSpA.

Conclusion: FJ involvement is prevalent in all forms of AxSpA, including its non-radiographic form. Facet joints of all spinal segments are involved in AxSpA patients

AB0794 **HOPELESSNESS IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

A. Komac[1], N. Gokcen[1], A. Yazici[1], A. Cefle[1]. [1]*Kocaeli University Faculty of Medicine, Rheumatology department, Kocaeli,Turkey*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease leading to loss of function that is strongly related to impaired psychological status. Therefore, depression and anxiety are frequently investigated in these patients (1). However, hopelessness, regarded as a valuable psychological factor characterized by negative expectations and negative emotional states, was not well studied in AS patients(2).
Objectives: The aim of the study is to investigate the frequency of hopelessness in patients with AS and its relationship with clinical parameters and disease activity indices.
Methods: The study was designed as a prospective cross-sectional study. 113 AS patients were included in the study. Demographic data, clinical variables, laboratory results were recorded. Disease activity (ASDAS-CRP and ASDAS-ESR), patients' functionality (BASFI, BASMI), enthesitis (Leeds enthesitis index) and quality of life (SF-36) were assessed. Hopelessness was evaluated by Beck hopelessness scale (BHS). The relation of BHS scores with the clinical variables was assessed. The strength of the correlations were regarded as very weak(0–0.19), weak(0.2–0.39), moderate(0.40–0.59), strong(0.6–0.79) and very strong(0.8-1). Multiple linear regression analysis was performed to find the association between BHS scores and other clinical variables.
Results: Minimal, mild, moderate, and severe hopelessness were observed in 46 (40.7%), 36 (31.9%), 22 (19.5%), and 9 (8.0%) patients, respectively. Disease duration (p=0.025), ASDAS-CRP (p=0.033), ASDAS-ESR (p=0.015), visual analogue scale (p=0.030), all SF-36 subscales (all p<0.025), BASFI (p=0.024), and BASMI (p=0.009) were statistically different among the groups. BHS scores were higher in patients with high and very high disease activity (p=0.027) (in pairwise comparison, inactive disease vs. high disease activity, p=0.035) (Figure 1). BHS scores showed weak correlation with ASDAS-CRP, ASDAS-ESR, visual analogue scale, BASMI, Leeds enthesitis index, and BASFI. Moreover, negative moderate correlations were detected between BHS scores and SF-36 subscales except social functioning and body pain, which were found weak correlation. In multiple linear regression analysis, BASMI-maximal intermalleolar distance, SF-36 energy, SF-36 mental health, and SF-36 general health were found associated with BHS scores (Table 1).

Table 1. Multiple linear regression analysis to find predictors related to the Beck hopelessness scale scores

		B	95% CI	p
ASDAS-CRP		-0.063	(-1.939) to 1.282	0.687
VAS		-0.085	(-0.722) to 0.396	0.564
BASMI	Lateral spinal flexion	0.311	(-0.299) to 1.479	0.191
	Tragus to wall distance	0.157	(-0.404) to 1.602	0.239
	Modified Schober	0.298	(-0.114) to 1.368	0.096
	Maximal intermalleolar distance	0.228	0.076 to 0.557	0.010
	Cervical rotation	0.092	(-0.665) to 1.085	0.635
	Total	-0.730	(-5.572) to 1.042	0.177
SF-36	Physical function	-0.024	(-0.056) to 0.046	0.840
	Role physical	-0.114	(-0.046) to 0.017	0.364
	Role emotional	-0.019	(-0.029) to 0.024	0.870
	Energy/fatigue	-0.283	(-0.125) to (-0.005)	0.035
	Mental health	-0.306	(-0.142) to (-0.022)	0.008
	Social functioning	0.022	(-0.033) to 0.041	0.822
	Body pain	0.182	(-0.018) to 0.086	0.192
	General health	-0.344	(-0.125) to (-0.030)	0.002
BASFI		-0.085	(-0.606) to 0.248	0.408

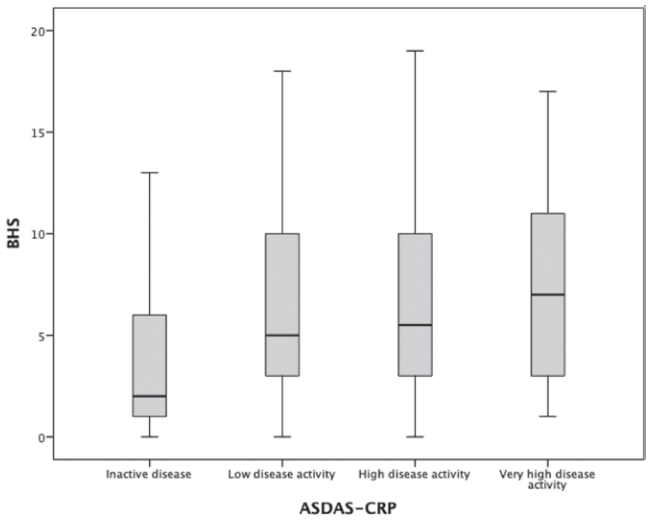

Figure 1. Beck hopelessness scale scores according to disease activity subgroups

Conclusion: Higher level of hopelessness is strongly related to higher disease activity in AS patients. Furthermore, higher BHS scores are negatively correlated with SF-36 subscales. Especially, lower energy and impaired mental health are associated with higher level of hopelessness.

AB0795 **ARE PATIENTS WITH ANKYLOSING SPONDYLITIS AFRAID OF FALLING COMPARED TO HEALTHY CONTROLS?: THE ROLE OF BALANCE AND POSTURE**

H. Bulbul[1], Y. Ulus[2], A. Bilgici[2]. [1]*Terme, Physical Medicine and Rehabilitation, Terme,Turkey;* [2]*Ondokuz Mayıs University - Faculty of Medicine, Physical Medicine and Rehabilitation, Samsun,Turkey*

Background: Fear of falling is a low perception of self-efficacy in avoiding falling during basic, non-hazardous activities of daily life, and concern about falling. It is a risk factor for falls and individuals without a history of falls may have fear of falling. Although it has been shown that the risk of falls is increased in patients with ankylosing spondylitis (AS), there is a lack of sufficient data on the fear of falling in AS patients and the relation of falls with spinal mobility and balance in these patients is controversial.
Objectives: The aims of this study were to compare the fear of falling and balance parameters of AS patients with healthy controls and to evaluate the relation of fear of falling with spinal mobility, balance parameters, pain, disease activity, and functional capacity in patients with AS.
Methods: Forty patients diagnosed with AS and 50 gender-age matched healthy controls were included. Demographic data and the number of falls within the last one year were questioned for all participants. Fear of falling by Falls Efficacy

Scale-International (FES-I), balance with the Berg Balance Scale (BBS) and Short Physical Performance Battery (SPPB) were assessed in all participants. In patients; spinal mobility by Bath AS Metrology Index (BASMI), pain by visual analog scale (VAS), disease activity by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional capacity by Bath Ankylosing Spondylitis Functional Index (BASFI) were evaluated. Kolmogorov Smirnov test, chi-square test, Student t test, Pearson correlation analysis, and Multivariate linear regression analysis were used for statistical analyses.

Results: The mean ages of the patient and control groups were 45.73 ± 9.5 (18-63) and 42.28 ± 8.1 (26-56), respectively. Patients' fear of falling scores were significantly higher, and BBS and SPPB scores were significantly lower compared to the controls (p<0.001). In the patients FES-I scores were positively correlated with VAS pain, BASFI and BASDAI scores, and negatively correlated with BBS and SPPB scores (SPPB p<0.05, others p<0.001). BASMI scores were only correlated with BBS scores negatively (p<0.05). In the regression analysis, positive correlation with FES-I was BASFI scores (p<0.05).

Conclusion: In this study, patients with AS had more fear of falling than healthy individuals. Patients' balance parameters were worse than controls and fear of falling was associated with poor balance in AS patients. Functional limitation, increased pain and disease activity were also associated with fear of falling in AS patients. Since AS sample in this study had a good mobility, no correlation might not have been found between fear of falling and spinal mobility. According the results of this study AS patients may have fear of falling even if there is no history of falls; and balance exercises, reducing disease activity, preserving functions may help to reduce fear of falling in these patients. Future studies including patients with mobility restriction may clarify the relationship between fear of falling and mobility in AS patients.

QUANTITATIVE BONE MARROW LESION CHARACTERIZATION AT THE SACROILIAC JOINT WITH T1-MAPPING

T. Diekhoff[1], D. Deppe[1], D. Poddubnyy[2], K. Ziegeler[1], F. Proft[2], K. G. Hermann[1], M. Protopopov[2], F. Radny[1], M. Makowski[3]. *[1]Charité Universitaetsmedizin Berlin, Clinic for Radiology, Institut für Radiologie, CCM, Germany; [2]Charité Universitaetsmedizin Berlin, Department of Gastroenterology, Infectiology and Rheumatology, Berlin, Germany; [3]Technische Universität München, Devision of Radiology, München, Germany*

Background: Conventional magnetic resonance imaging (MRI) uses T1-weighted and short-tau inversion recovery (STIR) sequences to characterize bone marrow lesions in axial spondyloarthritis. However, quantification is restricted to the extent of marrow lesions because signal intensities are highly variable within and across patients and scanners. Furthermore, some marrow lesions are less visible in MRI and need further characterization with computed tomography (CT), e.g. sclerosis. Quantitative MRI in form of mapping sequences might help to better characterize bone marrow lesions.

Objectives: To evaluate the performance of T1-mapping for differentiating different bone marrow lesions at the sacroiliac joints in patients with suspected axial spondyloarthritis.

Methods: Sixty-two patients (mean age 41±12.5; thirty-two were finally diagnosed with axial spondyloarthritis and 30 with another condition) underwent CT and MRI of the sacroiliac joints. Besides standard oblique coronal T1 and STIR sequences a T1-mapping sequence (Modified Look-Locker Inversion Recovery) was added to the protocol. Bone marrow lesions (maximum 4 lesions per patient, 1 lesion of the same type per joint) were characterized by an expert radiologist into four groups, namely sclerosis (lesion type (LT) 1), osteitis (LT2), fat lesion (LT3) and mixed marrow lesions (LTm). Relaxation times on T1-maps were compared using Kruskal-Wallis test correcting for multiple comparisons and correlated to quantitative measures from conventional MRI sequences and CT.

Results: 119 lesions were selected (LT1: 38, LT2: 27, LT3: 40; LTm: 14). T1-map showed highly significant differences between LT1-3 with the lowest values for sclerosis (1522±227 ms), followed by osteitis (1906±82 ms) and fat lesions (2391±200 ms); p<0.0005. However, mixed lesions showed a broad distribution of values (1869±670), irrespective of their characteristics. T1-map correlated to a high degree with conventional T1-values (r = 0.74) and Hounsfield units in CT (r = -0.69) with p < 0.0001, respectively, but not with STIR (p = 0.8).

Conclusion: T1-Mapping allows for accurately characterizing lesions at the sacroiliac joint in patients with suspected axial spondyloarthritis and, thus, may combine information from two conventional sequences and CT into one in the future while providing superior capacity for quantification. However, in our study mixed lesions and inhomogeneous bone marrow remained problematic. Thus, further sequence development is needed before its implementation in clinical routine.

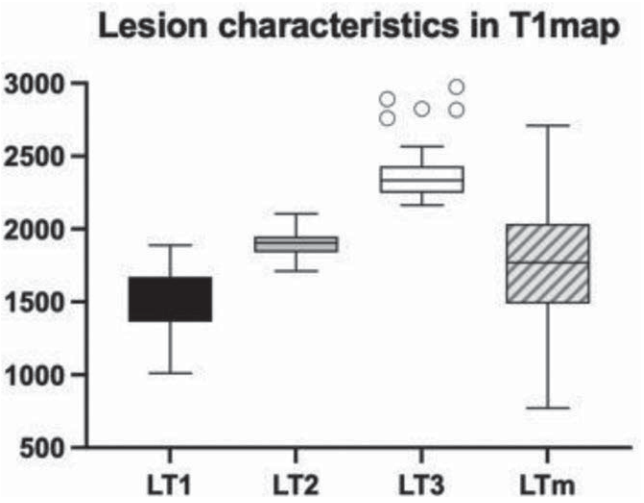

Figure 1. T1-mapping values of the different lesions, LT1: Sclerosis, LT2: Osteitis, LT3: Fat lesion, LTm: Mixed lesion. Differences are highly significant, which allows T1-mapping to characterize those different lesions in one sequence.

FACTORS ASSOCIATED WITH ADVERSE OUTCOMES IN UVEITIS RELATED TO SPONDYLARTHRITIS (SPA-U)- DEVELOPMENT OF A PROGNOSTIC OUTCOME SCORE IN PATIENTS WITH SPA-U

C. Sieiro Santos[1], C. Álvarez Castro[1], I. Sendino Tenorio[2], M. Cordero-Coma[2], C. Moriano[1], I. González Fernández[1], E. Diez Alvarez[1]. *[1]Complejo Asistencial Universitario de León, Rheumatology, León, Spain; [2]Complejo Asistencial Universitario de León, Ophtalmology, León, Spain*

Background: Uveitis is the most frequent extra-articular manifestation of spondylarthritis (SpA), characterized by a sudden onset, often unilateral, anterior and recurrent and may be the first clinical manifestation of the disease. The lack of standardized and validated outcome measures in uveitis makes it difficult to evaluate the efficacy and refractoriness to treatment and determine factors associated with adverse outcomes.

Objectives: To develop a prognostic outcome score for patients with uveitis associated with spondylarthritis (SpA-U) and determine factors associated with adverse outcomes in uveitis associated to SpA-U in patients under systemic treatment.

Methods: Clinical records of patients with SpA-U from 1990 to 2020 were retrospectively reviewed, including sociodemographic features, factors related to articular involvement, therapeutic choices and data related to uveitis outbreaks. The prognostic outcome score was defined by visual acuity, inflammation in anterior chamber (anterior chamber cells, hypopyon, presence of fibrin, active posterior keratic precipitates), presence of synechia, pupilar membrane, epiretinal membrane or any complications (macular oedema, vitritis, panuveitis, peripheral ulcerative keratitis), and refractoriness to 2 or more d/csDMARDs (conventional synthetical disease-modifying anti-rheumatic drug) or 1 or more bDMARD (biological disease-modifying anti-rheumatic drug) treatment. The prognostic outcome score ranked from 0 (good) to 5 (bad). Factors associated with adverse outcomes in uveitis were studied using linear regression. For categorical factors, marginal averages and their standard errors are displayed together with linear regression coefficients with 95% confidence intervals (CI). For continuous factors, averages and standard deviations are reported in addition to linear regression coefficients with 95% CI. For each variable, two regression coefficients are reported: unadjusted and adjusted for age at diagnosis and sex.

Results: 42 patients were included, 59.5% were male, with a mean age at diagnosis of 36.6±11.9 years and with a total of 190 uveitis outbreaks. Time since diagnosis was 12.5±7.9 years. 64.4% of patients had uveitis as disease onset. 52.4% were overweight (BMI≥30 kg/m2), 16.7% were former/active smokers.

28.6% of patients had a family history of SpA. 14.3% had 1-2 uveitis outbreaks, 47.6% had 3-5 uveitis outbreaks and 38.1% had 6-11 uveitis outbreaks. 102 (53.7%) uveitis outbreaks fulfilled 1 criterion, 38 (20%) uveitis outbreaks fulfilled 2 criteria, 19 (10%) uveitis outbreaks fulfilled 3 criteria and 5 (2.6%) uveitis outbreaks fulfilled 4 or more. The results of the linear regression model revealed that the uveitis was more severe in patients with smoking history (β=0.34), axial and peripheral involvement (β=0.43), a BASDAI (Bath Ankylosing Spondylitis Disease Activity Index)>4 (β=0.32), positive HLA-B27 (β=0.29), female sex (β=0.19), patients with CRP (C-reactive protein) elevation (β=0.002) and a history of bilateral ocular involvement (β=0.32) while shorter disease evolution (β=-0.02) and normal vitamin D levels (β= -0.03) were associated with a better outcome.

Conclusion: We identified factors associated with adverse outcomes in SpA-U by developing a prognostic outcome score that integrates ocular inflammatory activity, ocular complications and refractoriness to treatment.

AB0798 THE PRESENCE OF HEEL ENTHESITIS DURING PHYSICAL EXPLORATION IN PATIENTS WITH RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IS ASSOCIATED WITH POORER OUTCOMES AFTER 2 YEARS OF FOLLOW-UP. DATA FROM REGISPONSER-AS

C. López-Medina[1], M. Á. Puche Larrubia[1], M. L. Ladehesa Pineda[1], R. E. M. Granados[1], F. U. Pilar[1], E. Collantes Estevez[1]. [1]*Reina Sofia University Hospital, Rheumatology, Cordoba, Spain*

Background: Enthesitis represents one of the most important peripheral musculoskeletal manifestation in patients with axial Spondyloarthritis (axSpA). The prevalence and the burden of the disease associated with this symptom have been widely studied in axSpA and Psoriatic Arthritis (PsA). However, studies evaluating specifically the heel enthesitis and its impact over time are scarce.

Objectives: A) to evaluate the prevalence of patients with heel enthesitis during physical exploration in patients with radiographic axSpA (r-axSpA); b) to evaluate the association of heel enthesitis with higher Patient Reported Outcomes (PROs); c) to assess the impact of the heel enthesitis on the outcome measures after two years of follow-up in these patients.

Methods: Observational and prospective study during 2 years of follow-up that included patients with r-axSpA from the REGISPONSER-AS study (Spanish Rheumatology Spondyloarthritis Registry). The patients were divided into two groups according to the presence on heel enthesitis on physical exploration during the study visit. The PROs evaluated were the Global VAS, BASDAI, ASDAS, BASFI and the mental and physical components from the SF12 questionnaire. Linear regression models were performed using the PROs as the dependent variable and the presence of heel enthesitis as the explanatory variable, adjusting for bDMARDs intake and age. The impact of the heel enthesitis on PROs over two years of follow-up was evaluated using mixed models for repeated measures adjusting for confounders. Finally, the achievement of ASDAS Low Disease Activity (ASDAS-LDA) and ASDAS Inactive Disease (ASDAS-ID) after 2 years of follow-up between the two groups were evaluated.

Results: 749 patients were included (mean age 48.4 years; 75.3% men). 46 (6.1%) patients suffered from heel enthesitis on the study visit. Patients with heel enthesitis showed an increase (β coefficient, 95%CI) in Global VAS (1.32, 0.52-2.12), BASDAI (1.49, 0.81-2.18), ASDAS (0.45, 0.12-0.77) and BASFI (9.54, 1.78-17.30) compared with patients without heel enthesitis after adjusting for confounders. The impact of the presence of enthesitis on the PROs after two years of follow-up is shown in [Table 1]. Patients with heel enthesitis showed higher scores during the two years of follow-up in Global VAS, BASDAI, ASDAS and BASFI. In addition, the percentage of patients who achieved ASDAS-LDA after 2 years of follow up was lower in patients with heel enthesitis (15.9% vs. 31.5%, p=0.030) in comparison with patients without enthesitis. No differences were found regarding ASDAS-ID.

Table 1. Impact of the presence of heel enthesitis on PROs over two years of follow-up: mixed models for repeated measures.

	Current heel enthesitis N = 46 Mean (SD)	No current heel enthesitis N = 703 Mean (SD)	p-value	p-value age and bDMARDs adjusted
Global VAS	5.1 (2.8)	4.3 (2.6)	0.015	0.010
BASDAI	4.8 (2.7)	3.9 (2.7)	<0.001	<0.001
ASDAS	2.9 (1.1)	2.6 (1.0)	0.007	0.005
BASFI	43.8 (29.7)	40.0 (27.4)	0.245	0.161
PC-SF12	33.3 (11.4)	35.3 (10.7)	0.128	0.110
MC-SF12	47.4 (14.2)	48.2 (12.2)	0.547	0.281

Conclusion: In patients with r-axSpA, the presence of heel enthesitis on physical exploration was associated with poorer scores on the outcome measures after two years of follow-up, in comparison with patients without heel enthesitis. The achievement of a low disease activity is less likely in patients with this manifestation.

AB0799 ANATOMICAL ABNORMALITIES OF THE LOWER LUMBAR SPINE DO NOT CHANGE THE COURSE OF NON-RADIOLOGICAL AXIAL SPONDYLOARTHRITIS

D. Becker-Capeller[1], S. Kapsimalakou[2]. [1]*Rheumatologic Practice, Clinic Dr. Hancken, Stade, Germany;* [2]*Klinik Dr. Hancken GmbH / MVZ Radiologie und Nuklearmedizin, Radiology Department MRI Spine Center, Stade, Germany*

Background: Diagnosing early spondyloarthritis (SpA) is crucial for effective therapeutic intervention. Magnetic resonance imaging (MRI) helps us to diagnose non-radiographic SpA (nr-ax SpA) in an early stage according to the criteria of the imaging arm of the Assessment of Spondyloarthritis International Society (ASAS) classification. Diagnosis of sacroiliitis using MRI has limitations because of the lack of specificity and sensitivity. Several differential diagnoses are well known and should be considered[1]. In our daily practice, anomalies of the lower lumbar spine and the sacrum, such as spondylolysis, dysraphia, or assimilation joints, are often found to be accompanied by changes in the sacroiliac joints (SIG) corresponding to sacroiliitis.

Objectives: To investigate the presence of anatomical anomalies of the lower lumbar spine in our cohort of early diagnosed nr-ax SpA patients fulfilling the criteria of ax SpA and show if they cause a difference in the outcome.

Methods: Patients (n = 56, age < 45 years, symptom duration 3– 24 months) recently diagnosed with sacroiliitis using MRI and meeting the ASAS criteria for axial SpA were followed-up for 2 years[2]. We retrospectively analyzed the anatomic anomalies of the lower lumbar spine on MRI and, if available, on radiograph images.

Results: MRI on t0 revealed that 15 (26.7%, one female and 14 males) of 56 patients had anatomical anomalies of the lower lumbar spine, indicating bone marrow edema with clinical ax SpA according to the ASAS classification criteria. Spondylolysis, assimilation joints, and dysraphia were found in 4 (7.1%), 7 (12,5%), and 7 (12.5%) patients, respectively. The presence of HLA-B-27 and assessment results (CRP-ASDAS and BASDAI, BASMI) were similar to patients without the mentioned anatomical anomalies. Patients with spondylolysis and dysraphia of the lower spine and those without anomalies displayed similar progression of MRI findings between t0 and t2.

Conclusion: In addition to the well-known noninflammatory causes of sacroiliitis, such as pregnancies or intensive sporting activity, anatomical peculiarities could not be considered noninflammatory reasons. Contrary to the latest literature[3], they are not responsible for non-specific sacroiliitis. No difference in the development to axial SpA was observed when patients with and without anatomical changes were compared.

AB0800 ULTRASONOGRAPHY OF SUPRASPINATUS ENTHESES IN AXIAL SPONDYLOARTHRITIS

C. S. Bellagha[1], M. Slouma[1], S. Ben Dhia[1], J. Ben Katib[1], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[2]. [1]*The Military Hospital of Tunis, Department of Rheumatology, Tunis, Tunisia;* [2]*The Military Hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia*

Background: Several scoring systems have been developed to quantify ultrasound (US) abnormalities of the entheses in patients with spondyloarthritis (SpA). These scores included entheses of the lower limb, triceps tendon, and lateral epicondylar tendon [1] [2].

Studies regarding the involvement of supraspinatus enthesis in patients with SpA are scarce.

Objectives: This study aimed to assess the supraspinatus enthesis in patients with axial SpA using ultrasonography.

Methods: We performed a cross-sectional case-control study including 74 subjects (148 entheses):

- G1: 37 patients with axial radiographic SpA diagnosed according to Assessment of SpondyloArthritis International Society (ASAS) criteria.
- G0: 37 age and sex-matched healthy controls.

All subjects underwent the US by a qualified-US rheumatologist. The long axis of the supraspinatus was assessed with the patient's hand placed near the ipsilateral hip and the elbow directed posteriorly. Following parameters were evaluated at the bone attachment supraspinatus tendon: thickness, echogenicity, loss of normal fibrillar structure, calcifications, enthesophytes, erosions, cortical irregularities, bursitis, and vascularity at power Doppler. Statistical analysis was performed using SPSS Statistics software version 21.

Results: The mean age was 44.62 + 12.31 years. There were 29 men and 8 women for each group. In G1, the mean disease activity using ASDAS-CRP was 3.03 with levels ranging from 0.10 to 5.66. The mean thickness of supraspinatus tendon at its bone attachment was 4.54 ± 0.84 mm in G1 versus 4.02 ± 0.57 mm in G0 (p=0.03). Receiver Operator Curve (ROC) analysis showed the cutoff point with the best accuracy in distinguishing patients of controls to be 4.65 mm, with a sensitivity of 45.9% and specificity of 86.5% (air under the curve (AUC) value: 0.666 (p=0.014). Hypo-echogenicity and loss of normal fibrillar structure were noted in 27% (n =10 patients) and 5% (n = 2), respectively, in G1. Structural damage lesions were found in 3 % in G0 (n= 1) and 51 % in G1 (n=19), p< 0.0001. In G1, structural damage lesions included: calcifications (38%, n=14), erosions (30%, n = 11), cortical irregularities (16%, n=6), and enthesophytes (8%, n=3). In G0, structural damage lesions comprised: calcifications (3%, n=1) and cortical irregularities (3%, n=1). Vascularity at power Doppler was found in 11% in G1 (n= 4) and 0 % in G0. Subacromial-subdeltoid bursitis was noted in 3% in G1 (n=1) and in 0% in G0.

Conclusion: Our study showed that structural damage lesions of supraspinatus enthesis were frequent in patients with SpA compared to healthy controls. A cut-off of 4.65mm supraspinatus's thickness was able to discriminate patients with SpA from healthy controls. This finding suggests that supraspinatus enthesis evaluation can be added in entheses US scores.

AB0801 THE ASAS HEALTH INDEX (HI): CONSTRUCT VALIDITY AND RESPONSIVENESS IN RELATION TO TNF INHIBITOR (TNFI) TREATMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS (AXSPA).

S. Juhl Pedersen[1], I. J. Sørensen[2], B. Jensen[2], O. Madsen[2], M. Klarlund[2], J. Møllenbach Møller[3], M. P. Johansson[2], K. K. Gosvig[3], M. Østergaard[2]. *[1]Rigshospitalet, Department of rheumatology and spine diseases, Copenhagen, Denmark; [1]Rigshospitalet, Department of rheumatology and spine diseases, Copenhagen, Denmark; [3]Herlev Hospital, Department of radiology, Copenhagen, Denmark*

Background: The Assessment of Spondyloarthritis International Society (ASAS) has developed the ASAS HI aiming to capture the full range of functioning and disability in patients with axSpA.

Objectives: To examine the construct validity and responsiveness of ASAS HI in relation to TNFi treatment.

Methods: In this investigator-initiated 52-week prospective observational study (MANGO study; NCT02011386)(3) axSpA patients initiated sc. Golimumab 50 mg every month. Key inclusion criteria were BASDAI >4.0 and sacroiliitis on radiography and/or MRI.

Results: 45 of 53 TNFi naïve patients completed ASAS HI at weeks 0, 4, 16 and 52. 55.6% were male, 75.6% HLA-B27 positive, median age 34.6 yrs (IQR 28.3;46.1) and symptom duration 5.1 yrs. (2;13)(Table 1A). ASAS HI decreased from week 0 to weeks 4, 16 and 52, from median 10.0 (IQR 8;11)) to 7.0 (2.3;10), 5.5 (1.3;8) and 4.0 (1;7.5)(Wilcoxon-Pratt; all p<0.001). Patients with low ASAS HI (score 0-5, good heath state(4)) at week 16 and 52 had significantly lower ASDAS, BASDAI, BASFI, pain, pt. global and CRP than patients with moderate to high ASAS HI (6-17) (Table 1B). Patients with a decrease of >3 (clinically meaningful change(3)) or >30%(5) in ASAS HI from week 0-16 had significantly larger reductions in ASDAS, BASDAI, BASFI, pain, pt. global and SPARCC MRI spine inflammation score (Table 1C). At baseline, ASAS HI correlated with BASFI and SPARCC SIJ inflammation score (rho: 0.37-0.38, p<0.05), and changes in ASAS HI from week 0-16 correlated with changes in ASDAS, BASDAI, BASFI, pain, pt. global (0.51-0.67, p<0.001) and change in MRI SIJ inflammation score (0.30, p<0.05). ASAS HI had high responsiveness (Table 1D).

Conclusion: ASAS HI showed good construct validity and responsiveness.

Median (IQR). Mann-Whitney test. * p<0.05. ** p<0.01. *** p<0.001. Standardized response mean (SRM) and effect size (ES) ≥0.50 to <0.80 and ≥0.80 represents moderate and high responsiveness.

It increases mortality and comorbidity in patients with immune-mediated inflammatory diseases.
Objectives: The main objective is to estimate the prevalence of NAFLD in three of the most common rheumatologic pathologies: rheumatoid arthritis (RA), axial spondyloarthritis (SpA-ax) and psoriatic arthritis (PsA). As a secondary objective, the possibility of finding associated risk factors in this group of subjects that may imply a higher risk of developing NAFLD is proposed.
Methods: We conducted a prospective single center observational study which included patients diagnosed with RA, EspA-ax, and PsA attended in the Rheumatology department of a tertiary hospital from January to April 2021. Anthropometric parameters, history related to cardiovascular risk factors and disease activity at the time of the visit were collected. Additionally, blood tests and transitional elastography were performed in all patients and the presence of NAFLD was assessed by the fatty liver index (FLI) scale. Different variables were considered to study their association with NAFLD.
Results: 90 patients were included: 28 diagnosed with RA, 36 with EspA-ax and 26 with PAs. 41.1% were male (age range: 27-79 years). Patients with previous liver disease were excluded from the study. 22 (27.2%) patients had NAFLD measured by FLI ≥ 60. No significant differences in prevalence of hepatic steatosis were found between the 3 groups, although values were higher in patients with PsA.
The variables that were significantly associated with the development of NAFLD in our cohort were: body mass index (BMI), abdominal perimeter, blood glucose level, HOMA-IR (Homeostatic Model Assessment for Insulin Resistance), HDL, TG, GGT, ferritin and uric acid levels. The rest of the variables studied did not show statistically significant differences (Table 1).

Table 1.

	NO STEATOSIS (FLI<60) n=59		STEATOSIS (FLI>60) n=22		
	Mean	Standard deviation	Mean	Standard deviation	p
BMI	24,52	3,00	30,29	2,77	< 0,001
Abdominal perimeter	86,34	10,01	106,82	8,55	< 0,001
Age	52,93	12,87	57,59	8,24	0,1185
Glucose	78,64	8,37	90,64	19,69	0,0002
Insulin	8,83	10,12	12,40	6,66	0,1302
HOMA	1,75	2,02	2,76	1,70	0,0500
HbA1c	5,35	0,45	5,69	0,64	0,0096
Total cholesterol	190,98	29,46	201,41	38,53	0,1977
HDL	64,88	17,66	55,59	11,55	0,0249
LDL	110,44	28,45	120,00	36,21	0,2163
TG	81,12	32,42	128,50	55,52	< 0,001
GPT	25,83	30,73	37,18	19,82	0,1116
GOT	27,20	23,49	26,82	10,69	0,9413
GGT	20,80	17,66	49,95	38,46	< 0,001
Creatinin	0,75	0,19	0,84	0,18	0,0583
Uric acid	4,78	1,30	5,91	1,14	0,0007
Ferritina	121,75	111,30	208,00	140,17	0,0050
PCR	2,89	4,55	2,67	2,33	0,8307

Conclusion: Hepatic steatosis was present in 27.2% of patients vs 25% estimated prevalence in the general population. Identification of risk factors involved would allow better control of the comorbidities associated with NAFLD.
The fact that the prevalence found in our sample population is so close to that of the general population, may be related to a good inflammatory control of the underlying disease.
Further prospective studies with larger sample sizes are needed to find additional predictive factors for the development of NAFLD in this group of diseases.

ACCURACY OF "HOSPITAL MILITAR CENTRAL" ADMINISTRATIVE DATA BASE FOR PSORIATIC ARTHRITIS DIAGNOSIS IN PATIENTS AT A HIGH COMPLEXITY CENTER.

A. Beltrán[1], S. Puentes[2], S. M. Moreno Lopez[3], C. A. Camargo Rodríguez[1], M. Laguna[3], J. Amador[4], M. Botero Varon[2], L. A. Castro[4]. [1]*Hospital Militar Central, Research Department, Bogota, Colombia;* [2]*Universidad Militar Nueva Granada, Dermatology, Bogota, Colombia;* [3]*Hospital Militar Central, Biomedical Research Department, Bogota, Colombia;* [4]*Hospital Militar Central, Dermatology, Bogota, Colombia*

Background: Psoriatic Arthritis (PsA) is a chronic inflammatory musculoeskeletal disease highly associated with Psoriasis (Pso), with a substantial morbidity and disability. (1,2) Initially considered as a type of Rheumatoid arthritis but afterwards was defined as a distinct entity (3). PsA can cause damage to joints which lead patients to great impairment.(4)The estimated prevalence is variable according to the geographical zone, but it has been established in general population between 0,2-1%, meanwhile in Pso patients could be as frequent as 6-42% (5,6). Patients with PsA present pain and stiffness in the affected joints, they even can have axial skeleton compromise, peripheral arthritis, several nail changes, enthesitis and dactylitis (5,6). A delay in diagnosis as much as 6 months is associated with a much lower treatment response, meanwhile early treatment with anti-inflamatory or immune-modulating drugs improves clinical and radiological outcomes (7). There are several useful tools which allow us to establish easily prevalence, incidence or even chronic associations or acute diseases in public healthcare, these tools are known as administrative databases. (8) In the last few years, there has been developed multiple algorithms for the diagnosis of different pathologies using the information gathered from diagnostic codes, pharmacy reports and surgical procedures in order to identify relevant information for example a disease prevalence of an specific population.(9)
Objectives: Determine the accuracy of the 10th International Classification of diseases (CIE-10) for Psoriatic Arthritis (PsA) diagnosis in the hospital Militar of Bogotá administrative database and to examine the effects of adding specific pharmacy data to CIE 10 on accuracy of PsA diagnosis.
Methods: We drew a random sample of patients from all ambulatory patients who had at least 1 clinic visit to the hospital between January 1 2015 and February 1 2020 who are 18 years or older. Charts of 972 patients were reviewed. The gold standard for PsA diagnosis was chart documentation of PsA diagnosis by a Rheumatologist. The data definitions of PsA diagnosis included presence of CIE-10 alone or various combinations of CIE-10 an the addition of specific pharmacy data to the algorithm. Accuracy of data definitions of PsA was assessed by calculating sensitivity, specificity, positive and negative predictive values, plausibility reasons and area under the receiver operator characteristics curve (ROC). We used Python and R studio software for the database analysis.
Results: From the administrative database we had a prevalence of 5.2% patients with PsA, and was determined the diagnosis algorithm using CIE-10 code L40.5 had a correct classification rate by the algorithm of 97.9%, with 84.3% sensitivity CI 95% (71.4-93), and a higher specificity of 99.3% CI 95% (98.7-99,8). Evaluating positive predictive value of the test was 89.6% CI 95% (77.3 -96.5), while the negative predictive value was 99.1% CI 95% (98.3-99.6). In these results the number of false negatives are higher than the number of false positives, when compared with the gold standard (physician diagnosis in clinical chart). Through a statistical analysis we calculate the ROC curve and the area under the curve which was 0.92 CI 95% (0.868-0.969) when used the CIE-10 code L40.5 for PsA diagnosis. Indicating that the test, taking into account the CIE-10 code L40.5, has a very good performance classifying correctly the PsA patients.
Conclusion: CIE-10 code L40.5 in the administrative database is a very sensitive and specific screening tool for identifying patients with PsA in the general clinic population. This can be used to evaluate large population samples and classified them for public health research using this kind of databases.

ASSOCIATIONS BETWEEN ULTRASOUND CHRONIC LESIONS IN PERIPHERAL ENTHESES AND RADIOGRAPHIC STRUCTURAL SPINAL CHANGES IN MEN AND WOMEN WITH ANKYLOSING SPONDYLITIS

A. Deminger[1,2], M. Geijer[3,4], N. Nilsson[5], M. Hedberg[6], L. T. H. Jacobsson[1], H. Forsblad-D'elia[1,2]. [1]*Institute of Medicine, Department of Rheumatology and Inflammation Research, Göteborg, Sweden;* [2]*Region Västra Götaland, Sahlgrenska University Hospital, Department of Rheumatology, Göteborg, Sweden;* [3]*Institute of Clinical Sciences, Department of Radiology, Göteborg, Sweden;* [4]*Region Västra Götaland, Sahlgrenska University Hospital, Department of Radiology, Göteborg, Sweden;* [5]*Region Västra Götaland, Alingsås Hospital, Section of Internal Medicine, Alingsås, Sweden;* [6]*Region Västra Götaland, Södra Älvsborg Hospital, Section of Rheumatology, Borås, Sweden*

Background: Ankylosing spondylitis (AS) is characterised by spinal bone formation and enthesitis. Whether patients with spinal bone formation have a

generalised bone formation phenotype also involving the peripheral entheses is not fully known.

Objectives: To assess in cross-sectional analyses the association between chronic ultrasound (US) lesions in peripheral entheses with spinal bone formation and factors associated with spinal bone formation, overall and by sex.

Methods: The entheses at 14 sites at the extremities were examined in 173 patients (54 % men, mean age (SD) 55 (13) years and symptom duration 29 (13) years) with AS (modified NY criteria) using US. Entheses were assessed for structural components (enthesophytes, calcifications and erosions) according to the OMERACT definition [1]. Each lesion was evaluated 0 or 1 and summarised to a damage score (0-42). Spinal radiographs from the same time point were graded according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) and presence of syndesmophytes were determined. The associations between US damage score and mSASSS and factors associated with spinal bone formation were analysed with Spearman´s correlation analysis overall and by sex. Also, Mann Whitney´s test and multivariable logistic regression analysis with presence of ≥ 1 syndesmophyte as dependent variable and age, sex, BMI, smoking status, CRP, and US damage score as independent variables were used.

Results: Presence of any US structural component was found in 158 (91 %) of the patients with no significant difference between men and women (95 % vs 87 % respectively, p = 0.15). The US damage score was median (IQR) 4 (2 to 6) in the total group with a higher score in men compared to women, 4.5 (2 to 7) vs 3 (2 to 5), p = 0.002. In analogy, more men had presence of syndesmophytes in the spine compared to women, 63 % vs 35 %, p <0.001 and men had higher mSASSS compared to women; median (IQR) mSASSS in men 14 (3 to 43) compared to 2 (0 to 11.5), p<0.001. Men had higher body mass index (BMI), but there were no sex differences for age, symptom duration, CRP, and smoking status.

The results from correlation analyses for US damage score and mSASSS, age, symptom duration, CRP, smoking status, and BMI are presented in the Table 1. Spinal bone formation (mSASSS) was positively correlated with the US damage score in the total group and in men. In both men and women, higher age was associated with higher US damage score. A comparison between patients with and without syndesmophytes showed that patients with syndesmophytes had higher US damage score than patients without syndesmophytes, median (IQR) 5 (3 to 7) and 3 (1 to 5) respectively, p<0.001. In the multivariable logistic regression analyses the US damage score was not independently associated with presence of syndesmophyte in the total group or in men. If age was excluded from the analyses though, the US damage score was significantly associated with presence of syndesmophyte, odds ratio (95 % CI) for total group 1.20 (1.05 to 1.37) and for men 1.26 (1.05 to 1.51).

Table 1.

	Ultrasound damage score					
	Total group (n=173)		Men (n = 94)		Women (n = 79)	
	rs	p-value	rs	p-value	rs	p-value
Age, years	**0.44**	**<0.001**	**0.43**	**<0.001**	**0.51**	**<0.001**
Symptom duration, years	**0.28**	**<0.001**	**0.34**	**<0.001**	**0.27**	**0.015**
BMI, kg/m^2	**0.21**	**0.006**	0.11	0.28	0.19	0.10
Current or past smoking	0.039	0.61	0.18	0.090	-0.10	0.37
CRP, mg/L	0.12	0.13	0.028	0.79	0.20	0.073
mSASSS, score	**0.31**	**<0.001**	**0.27**	**0.010**	0.20	0.084

r_s: Spearman´s correlations coefficient

Conclusion: Structural lesions were common in the entheses in patients with long-standing AS. Men had more severe bone formation in the spine and the peripheral entheses compared to women. Chronic lesions at the entheses accumulate with increasing age and US damage score could not independently identify patients with syndesmophytes in this cohort with long-standing AS. However, if age was not considered, there was an association between bone formation in the peripheral entheses and the spine in men with AS.

LEVELS OF NATURAL KILLER CELLS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A META-ANALYSIS

H. Zhou[1,2], L. Xie[1,2], Q. Y. Su[1,2,3], G. M. Xia[1,2], J. Wang[1,2], S. X. Zhang[1,2,3], C. Wang[1,2,3]. [1]*Shanxi Medical University, Key laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, China, Taiyuan, Shanxi Province, China;* [2]*Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, Shanxi Province, China;* [3]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China*

Background: Ankylosing Spondylitis(AS) is a complex chronic inflammatory autoimmune disease that mainly affects the spine. Natural Killer (NK) cells are classified among the recently discovered innate lymphoid cell subsets and have capacity to influence both innate and adaptive immune responses. However, the status of NK cells remains debated in AS.

Objectives: This study aims to clarify the level of peripheral NK cells in AS patient.

Methods: We used CNKI, CBM, Wanfang data and Chinese science, scientific and technological journal data, PubMed, Embase, Web of science, Cochrane library and Medline to collect relevant literature data, and sorted out the proportion of NK cells in AS patients. Random effects were selected to assess pooled data, inconsistency was assessed using I-squared index (I^2), and Egger's test was used to assess potential publication bias (STATA v.12.0).

Results: A total of 11 case-control studies involving 561 AS patients and 592 healthy controls (HC) were included in this study. AS patients had a significantly lower proportion of $CD16^+CD19^+$NK cells compared with HCs [SMD=-0.41, 95%CI (-0.71,-0.11), P<0.05,] (Figure 1), with no publication bias according to Egg's test[t=0.50, P=0.63].

Conclusion: The proportion of of $CD16^+CD19^+$ NK cells in AS patients was significantly reduced, suggesting disturbance of NK closely involved in the pathogenesis of AS.

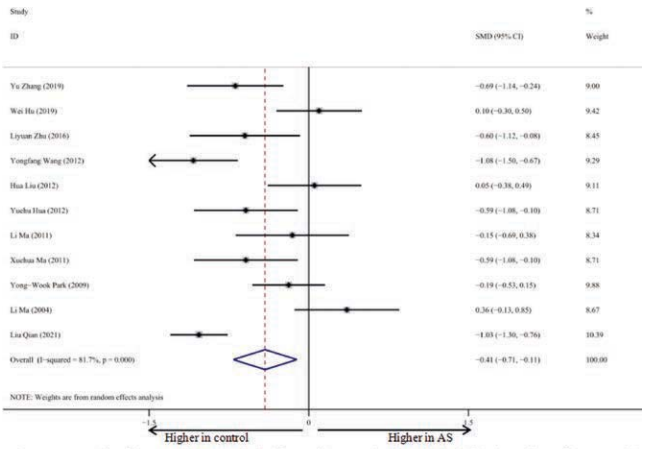

Figure1: Forest plot of the overall meta-analysis of NK cells proportions in peripheral blood,regardless of the NK cells definitions used, between AS patients and healthy controls.

GENDER AND IMAGING PROGRESSION IN EARLY AXIAL SPONDYLOARTHRITIS: RESULTS FROM A 48-MONTH FOLLOW-UP (ITALIAN ARM OF SPACE STUDY).

M. Lorenzin[1], A. Ortolan[2], S. Vio[3], G. Cozzi[1], V. Scapin[3], G. De Conti[3], A. Doria[1], R. Ramonda[1]. *[1]University of Padova, Department of Medicine DIMED, Rheumatology Unit, Padova, Italy; [2]University of Padova, Department of Medicine DIMED, Rheumatology Unit, Padova, Italy; [3]University of Padova, Radiology Unit, Padova, Italy*

Background: Gender differences in disease presentation and imaging features of early axial-spondyloarthritis (axSpA) have not been thoroughly investigated.
Objectives: To assess the influence of gender on spinal/pelvic radiographic progression and magnetic-resonance-imaging (MRI) features in early-stage axSpA.
Methods: Baseline data from the Italian arm of SPondyloArthritis-Caught-Early-cohort, including patients with chronic-back-pain (CBP;duration≥3 months and ≤2 years;onset<45 years) were analyzed.Patients underwent a diagnostic work-up, including MRI and X-rays of the sacroiliac joints (SIJ), to establish a diagnosis of axSpA (according ASAS criteria). Clinical features, disease-activity and functional indices, imaging were collected at baseline (T0) and yearly during 48-months.Spinal and SIJ X-rays and MRIs were performed every 2-years and scored independently by 2 readers following *Stoke Ankylosing Spondylitis Spinal Score System modified by Creemers* (mSASSS) (score 0-72),*modified New York criteria grading system* (mNY-criteria) (score 0-4 per each joint) and *Spondyloarthritis Research Consortium of Canada* (SPARCC) (score of 0–40 for SIJ and of 0-92 for the spine). Characteristics of axSpA patients according the gender (male/female) were compared over-time with descriptive-statistics; multivariate-logistic-regression model was constructed to assess predictors of spinal and SIJ radiographic progression at 48-months.
Results: Out of 98 CBP patients, 91 had axSpA (83.5% non-radiographic;16.5% radiographic);47.3% were male. At T0 males were younger with less axial symptoms duration (p=0.04);had more frequently human-leukocyte-antigen (HLA)-B27+ (p=0.02),radiographic sacroiliitis with bilateral/symmetric pattern (p<0.02) and more signs of spondylitis (p=0.03).Females presented more frequently an associated peripheral/entheseal involvement (p=0.04) and a non-radiographic form (p=0.03). Functional and disease-activity indices decreased with slightly higher *Maastricht Ankylosing Spondylitis Enthesitis Score* (MASES),*Visual Analogue Scale of pain* (VAS),*Bath Ankylosing Spondylitis Disease Activity Index* (BASDAI) and *Bath Ankylosing Spondylitis Functional Index* (BASFI) values in females (p<0.04). Males showed a slight increased for both pelvic and spinal radiographic progression than females (Figure 1 **A-E**).At T0, 62 (68.1%) axSpA patients presented inflammatory lesions on MRI-SIJ, with more signs of active sacroiliitis in males (83.7% vs. 54.2%;p<0.05).Fifty-seven (62.6%) patients showed inflammatory-corner-lesions on MRI-spine: the frequency of these lesions no differed between males and females, while the localization varied:prevalently cervical/thoracic lesions were observed in females, instead lumbar lesions in males (p<0.05).We also found a higher prevalence of signs of active anterior spondylitis without active sacroiliitis on MRI in females (29.2% vs. 14.0%;p=0.03).Signs of enthesitis were found in 68.1% patients, with slightly higher prevalence of these lesions in thoracic area in females (p=0.04).Significant downtrend of SPARCC SIJ/spine scores was found, regardless the gender. More fat lesions were observed on MRI-spine in females, while more fat lesions were observed on MRI-SIJ in males (Figure 1**F-G**).Skin psoriasis was a predictor of spinal progression in all patients (OR=0.18; 95%CI:0.04-0.78).
Conclusion: The gender was associated with distinct axSpA features.Males had an increased pelvic and spinal radiographic progression and more frequently active sacroiliitis on MRI.Female axSpA showed a higher prevalence of cervical and thoracic spine-MRI signs (inflammatory-corner-lesions and fat lesions).

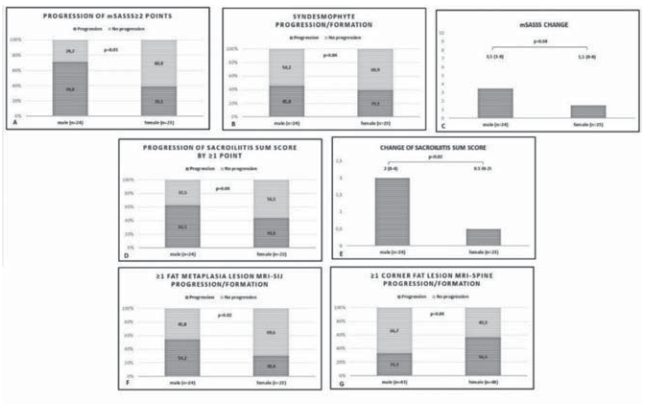

Figure 1 A-G: Association of gender with spinal and SIJ radiographic progression and fat lesions on MRI in axSpA after 48-months of follow-up.

RELAPSE INCIDENCE ACCORDING TO HLA-B*27 IN PATIENTS WITH SPONDYLOARTHRITIS IN A SPECIALIZED CENTER IN COLOMBIA

O. J. Felipe Díaz[1], W. G. Rojas Zuleta[1], C. Orozco-González[2], A. E. Pantoja Marquez[1], C. Ceron[1], C. L. Giraldo Herrera[3], M. M. Barbosa-Rengifo[4], C. Becerra-Arias[5], J. H. Donado Gómez[2], N. Duque Zapata[2]. *[1]Medicarte, Rheumatologist, Medellín, Colombia; [2]Medicarte, Epidemiologist, Medicarte Research Group (GIM), Medellín, Colombia; [3]Medicarte, Rheumatologist, Cali, Colombia; [4]Medicarte, Epidemiologist, Medicarte Research Group (GIM), Cali, Colombia; [5]Medicarte, Epidemiologist, Medicarte Research Group (GIM), Bucaramanga, Colombia*

Background: Spondyloarthritis (SpA) is a group of inflamatory diseases with multiple clinical manifestations (axial, peripheral, skin, eye, and intestine) including ankylosing spondylitis (AS), reactive arthritis, psoriatic arthritis (PsA), arthritis associated with inflammatory bowel disease, and non-radiographic axial spondyloarthritis. SpA is genetically related to HLA-B*27 as more tan 95% of the cases have it, while in general population its frequency is below 10%. The etiology and pathogenesis of this disease are unknown. Notwithstanding, the misfolding hypothesis suggests that it may be triggered by the formation of HLA-B*27 homodimers. The risk of developing SpA is 5-7% in positive HLA-B*27 individuals (1,2).
Objectives: Explore the relapse incidence and its associations with HLA-B*27 in SpA patients.
Methods: SpA patient cohort in a specialized multicentric health institution in Colombia (November 2011 to June 2021). Relapse was defined as the BASDAI increment ≥1+2≤ final BASDAI ≤4. A stratified analysis was performed for HLA-B*27 between diagnosis, current medication, and relapse. For group comparisons χ^2 and Wilcoxon tests were used, according to variable distribution. A logistic regression model was run in order to explain relapse incidence.
Results: 515 patients were included, among whom 60.9% were HLA-B*27 positive. 87.0% had an AS diagnosis (53.3% of men), 11.4% (64.4% of women) non-radiographic axial spondyloarthritis and 1.55% PsA (62.5% of women). Table 1 shows demographic and clinical characteristics. The relapse incidence was associated with positive HLA (Odss Ratio-OR 2.14 CI95% 0.982-4.674, p=0.055) and with time of disease evolution (OR 1.05 IC95% 1.02-1.091, p= 0.001) adjusting for sex.

Table 1. Demographic and clinical characteristics

Yes	10	4.98	31	9.87	0.045

* p value for the difference between HLA-B*27 positive and negative groups. IQR: interquartile range

Conclusion: In SpA patients, HLA-B*27 frequency is higher in AS patients compared to other SpA forms. Furthermore, this is associated with a higher relapse risk and longer time of disease evolution.

AB0808 COSTOVERTEBRAL, COSTOTRANSVERSE, STERNOCLAVICULAR AND MANUBRIOSTERNAL JOINT INVOLVEMENT IN SPONDYLOARTHRITIS: PRELIMINARY RESULTS OF SINGLE CENTRE EXPERIENCE

E. B. Ata[1], E. Bilgin[1], G. Durhan[2], G. Ayan[1], M. Arıyürek[2], U. Kalyoncu[1].
[1]Hacettepe University, Rheumatology, Ankara, Turkey; [2]Hacettepe University, Radiology, Ankara, Turkey

Background: Costovertebral (CV), costotransverse (CTr), sternoclavicular (SC) and manubriosternal (MS) joint involvements may be in spondyloarthritis (SpA). However, the radiological and clinical characteristics of these involvements need further assessment.
Objectives: In this study, we aimed to determine the characteristics of CV, CTr, SC, and MS joint involvements in SpA patients.
Methods: SpA patients (searched from the hospital data-processing system according to ICD-10 system to determine the patients having M07 (enteropathic arthropathies), M45 (ankylosing spondylitis (AS)), M46 (other inflammatory spondylopathies) and/or M48 (other spondylopathies) codes) who have been requested a chest computed tomography (CT) for any reason between January 2010 and December 2020 included in this retrospective cross-sectional analysis. Chest CT reports were reviewed, and any CV, CTr, SC or MS joint involvement attributed to SpA accepted as positive CT for SpA involvement. Demographic/clinic data including smoking status, disease characteristics (duration, drug history, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI) and other related parameters) at the time of CT scan were collected and analyzed.
Results: After the confirmation of the diagnoses among 1700 patients, total of 339 SpA patients were included in the study. 244 were diagnosed with ankylosing spondylitis (AS), 66 with psoriatic arthritis (PsA), 14 with enteropathic arthritis, 13 with peripheral SpA, and 2 with non-radiographic axial SpA. According to CT reports, the number of patients with inflammatory changes in any of the CV, CTr, SC or MS joints on thoracic CT were 44. Of these patients, 42 were diagnosed with AS (95,5%), 1 with PsA (2,3%), and 1 (2,3%) with peripheral SpA. 39 CV, 9 SC, 5 MS joints, and 3 CTr joints were affected. Joint involvements (17%) were higher in patients with AS than in other patient groups (p<0.001). In the chest CT positive group, Schober's test, and chest expansion were significantly lower than chest CT negative group. Smoking history, C-reactive protein (CRP) value at diagnosis and at CT evaluation, and disease duration were associated with joint involvement. Demographic and clinical characteristics of patients with and without chest CT involvement were shown in Table 1.

Table 1. Demographic and clinical characteristics of patients with and without involvement on chest CT

	n	Without involvement	n	With involvement	P value	Odds Ratio

Morning stiffness (min)	178	20 (10-30)	26	22.5 (10-30)	0.84	

Data are presented as median (25-75 percentile) or number (%) CT; computerized tomography, BMI; body mass index, ESR; erythrocyte sedimentation rate, CRP; C-reactive protein, BASDAI; Bath Ankylosing Spondylitis. Disease Activity Index, BASMI; Bath Ankylosing Spondylitis Metrology Index, BASFI; Bath Ankylosing Spondylitis Functional Index
Conclusion: In this study, we have found that CV, CTr, SC, and MS joint involvement on thorax CT were more common in men and smokers and were associated with disease duration and appears to affect chest expansion and Schober's tests. In previous studies, CV and CTr joint involvement in AS patients with chest pain were 80-82% and 60%, respectively [1,2]. Our study showed that 17% of AS patients had involvement regardless of pain symptoms. As this is the preliminary data and the CTs will be re-evaluated by our radiologist, we will be capable to report more unbiased results.

AB0809 ASSESSMENT OF THE IMPACT OF AXIAL SPONDYLOARTHRITIS ON PATIENT'S SOCIAL LIFE. RESULTS FROM THE EUROPEAN MAP OF AXIAL SPONDYLOARTHRITIS (EMAS)

M. Garrido-Cumbrera[1,2], V. Navarro-Compán[3], C. Bundy[4], R. Mahapatra[5], S. Makri[6], J. Correa-Fernández[1], L. Christen[7], C. J. Delgado-Domínguez[1], D. Poddubnyy[8,9]on behalf of EMAS working group. *[1]Health & Territory Research (HTR), Universidad de Sevilla, Seville, Spain; [2]Spanish Federation of Spondyloarthritis Patient Associations (CEADE), Patient Advocacy, Madrid, Spain; [3]Hospital Universitario La Paz, IdiPaz, Madrid, Spain; [4]Cardiff University, School of Healthcare Sciences, Cardiff, United Kingdom; [5]Axial Spondyloarthritis International Federation (ASIF), Patient Advocacy, London, United Kingdom; [6]Cyprus League for People with Rheumatism (CYLPER), Patient Advocacy, Nicosia, Cyprus; [7]Novartis Pharma AG, Patient Engagement, Basel, Switzerland; [8]Charité-Universitätsmedizin Berlin, Rheumatology Department, Berlin, Germany; [9]German Rheumatism Research Centre, Rheumatology Department, Berlin, Germany*

Background: As spinal mobility becomes progressively impaired and pain levels escalate, difficulty in performing simple physical routines places a huge burden on axial spondyloarthritis (axSpA).
Objectives: The aim is to evaluate the impact of axSpA on patients' social life and to identify the factors associated with this.
Methods: Data from 2,846 unselected patients participating in EMAS, an online survey (2017-2018) across 13 European countries, were analysed. Impact of axSpA on social life was assessed by: "Score your relationships since you have been affected by Spondylitis / Spondyloarthritis" [Much worse to much better relationships with spouse, family, friend, and neighbours], and "Please indicate the frequency with which you do the following activities since you became affected by Spondylitis/ Spondyloarthritis?" [Much less frequent to much more frequent engagement in restaurants, cultural outings, travel, and sports]. Patients who rated at least one relationship as "worse/much worse" and at least one of social activity as "less/much less frequent" were considered to have a negatively impacted social life. BASDAI (0-10), spinal stiffness (3-12), functional limitation (0-54), and mental health via the General Health Questionnaire GHQ-12 (0-12) were assessed. Univariable and multivariable binary logistic regression were used to identify variables possibly explaining negative impact on social life (n= 2,120).
Results: Mean age was 43.8±12.3 years, 61.5% female, 49.2% had a university degree, and 68.2% married. 44.9% (n= 1,205) patients had their social life negatively impacted since the onset of axSpA. Those experiencing a negative impact on their social life were more frequently females (49.5% vs. 37.5% males, p<0.001), divorced/separated (59.5% vs. 34.4% widowed, p<0.001), and on sick leave (temporary and permanent) or unemployed (63.9%, 60.9% and 57.0% vs. 36.8% employed, p<0.001). Furthermore, those whose social life was negatively impacted reported greater BASDAI (6.2 vs. 5.0), functional limitation (24.4 vs. 17.4), spinal stiffness (8.4 vs. 7.3), longer diagnostic delay (9.7 vs. 7.4), poorer mental health (6.7 vs. 3.6), anxiety (62.6% vs. 37.1% no anxiety), depression (61.9% vs. 38.5% no depression), or sleep disorders (55.7% vs. 37.5% no sleep disorders), all p<0.001. The variables associated with negative impact on social life in the multivariable logistic regression were higher disease activity (OR=1.15),

poor mental health (OR=1.14), being on a sick leave/unemployed (OR=1.49), divorced/separated (OR=1.46), anxiety (OR= 1.41) and female gender (OR= 1.30; Table 1).

Table 1. Factors associated with a worsening social life (n= 2,120)

	Univariable logistic analysis		Multivariable logistic analysis	
	OR	CI 95%	OR	CI 95%
Age	0.99	**0.98, 0.99**	1.00	0.99, 1.01
Gender. Female[1]	1.63	**1.39, 1.91**	1.30	**1.06, 1.60**
Marital status. Divorced/separated[2]	1.93	**1.48, 2.50**	1.46	1.05, 2.04
Employment status. Sick Leave/Unemployed[3]	2.66	**2.24, 3.17**	1.49	**1.20, 1.85**
BASDAI (0-10)	1.41	**1.35, 1.48**	1.15	**1.08, 1.22**
Functional Limitation (0-54)	1.03	**1.02, 1.03**	1.02	**1.09, 1.02**
Spinal Stiffness (3-12)	1.20	**1.16, 1.24**	1.06	**1.01, 1.11**
Diagnostic delay	1.02	**1.01, 1.03**	1.01	0.99, 1.02
GHQ-12 (0-12)	1.22	**1.19, 1.24**	1.14	**1.11, 1.17**
Anxiety	2.84	**2.39, 3.37**	1.41	**1.08, 1.83**
Depression	2.59	**2.17, 3.10**	1.14	0.87, 1.49
Sleep disorders	2.10	**1.79, 2.46**	1.02	0.81, 1.27

[1]Female vs. male; [2]Divorced/separated vs. single/married/widow; [3]Sick leave/unemployed vs. other employment status.

Conclusion: Almost half of the axSpA patients reported to have negatively impacted their social life. Being female, divorced/separated, on sick leave/unemployed, with higher disease activity, poor mental health, and anxiety increase the likelihood of worsening social life. As relationships with others and engagement in social or community activities influence quality of life, greater attention to enabling individuals to participate socially through controlling disease activity and addressing mental health comorbidity in the management of axSpA.

ASSESSING HEALTHCARE UTILIZATION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS. RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbrera[1,2], E. Collantes-Estévez[3,4], V. Navarro-Compán[5], P. Zarco-Montejo[6], C. Sastré[7], J. Correa-Fernández[1], J. Gratacos-Masmitja[8,9]on behalf of Atlas working group. *[1]Health & Territory Research (HTR), Universidad de Sevilla, Seville, Spain; [2]Spanish Federation of Spondyloarthritis Patient Associations (CEADE), Patient Advocacy, Madrid, Spain; [3]Reina Sofia University Hospital, Rheumatology Department, Cordova, Spain; [4]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), University of Cordoba, Cordova, Spain; [5]Hospital Universitario La Paz, IdiPaz, Madrid, Spain; [6]Hospital Fundación Alarcón, Rheumatology Department, Madrid, Spain; [7]Novartis Farmacéutica Spain, Inmunology, Hepatology and Dermatology, Barcelona, Spain; [8]Hospital Universitari Parc Taulí, Rheumatology Department, Sabadell, Spain; [9]I3PT, UAB, Barcelona, Spain*

Background: Healthcare utilization by patients with axial spondyloarthritis (axSpA) is substantial, leading to a considerable social and economic burden[1]. Understanding patients' characteristics and the main determinants of healthcare utilization is essential to reduce this burden.

Objectives: The aim of the present study is to assess healthcare utilization in patients with axSpA in Spain.

Methods: Data from an online survey of 680 unselected axSpA patients pertaining to the Spanish Atlas of Axial Spondyloarthritis were analysed. Total healthcare utilization was assessed as the sum of number of healthcare visits, medical tests, hospital admissions, and emergency visits, all relying on the last 12 months prior to the survey. Mann-Whitney and Pearson's $\chi 2$ tests were used to analyse possible associations between sociodemographic (age, gender, educational level, marital status, and patient organizations membership) and patient-reported outcomes (disease activity measured by BASDAI [0-10], mental health measured by GHQ-12 [0-12], functional limitation index (0-54), spinal stiffness index (3-12), and diagnostic delay) with respect to total healthcare utilization. Simple and multiple linear regression was used to analyse its possible associated factors.

Results: A total of 530 axSpA patients participated in this study: the mean age was 45.3 years, 51.1% were female, 39.6% had a university degree, and 70.6% were married. In the previous 12 months, 77.9% (n= 530) used at least one healthcare source, of which 75.3% visited at least once a rheumatologist (n= 512, mean= 4.4), 55.6% GP (n= 378, mean= 9.4) and 33.5% physiotherapist (n= 228, mean= 20.1). With respect to medical tests performed in the last 12 months, 75.3% performed at least one x-rays test (n= 512, mean= 4.4) and 71.2% blood test (n= 484, mean= 4.5). Furthermore, 7.9% of patients were hospitalised (n= 54, mean= 2.2 and 23.1% of patients visited outpatient centre (n= 157, mean= 5.5).

Younger patients (r= -0.195) and females (52.0 vs 32.2 of males) showed higher healthcare utilization (p<0.001). In addition, a low positive correlation was found between healthcare utilization and disease activity (r= 0.290), mental health (r= 0.257), functional limitation (r= 0.283) and diagnostic delay (r= 0.151), all p-values <0.001.

In the multiple linear regression, the qualitative factors associated with higher healthcare utilization was female gender (B= 12.854), while the quantitative factors associated with high healthcare utilization were younger age (B= -0.737), higher disease activity (B= 3.378), greater functional limitation (B= 0.576), and longer diagnostic delay (B= 0.959; Table 1).

Table 1. Linear regression analysis of socio-demographic and patient-reported outcomes according to healthcare utilization (N= 402)

	Simple linear regression		Multiple linear regression	
	Beta	95% CI	Beta	95% CI
Age	-0.884	**-1,266, -0.503**	-0.737	**-1.190, -0.283**
Gender. Female	19.792	**11.600, 27.984**	12.854	**3.502, 22.207**
BASDAI (0-10)	7.260	**4.934, 9.586**	3.378	**0,571, 6.185**
GHQ-12 (0-12)	2.724	**1.786, 3.663**	1.126	-0.048, 2.300
Functional Limitation (0-54)	1.418	**1.007, 1.828**	0.576	**0.007, 1.145**
Diagnostic Delay	0.966	**0.419, 1.512**	0.959	**0.374, 1.544**

Conclusion: Higher healthcare utilization was associated with higher disease activity, greater functional limitation, and longer diagnostic delay, in younger and females axSpA patients. Optimal monitoring of axSpA patients may help to minimise healthcare utilisation in patients with axSpA.

AB0811

RESPIRATORY TRACT INFECTIONS AND RISK FACTORS FOR INFECTION IN A SPONDYLOARTHRITIS COHORT: IS THERE A DIFFERENCE BETWEEN PSORIATIC ARTHRITIS AND AXIAL SPONDYLOARTHRITIS?

N. Frede[1], E. Rieger[1], R. Lorenzetti[1], A. Venhoff[1], A. M. Kanne[1], M. Von Deimling[1], N. Bartholomä[1], J. Thiel[1], R. Voll[1], N. Venhoff[1]. [1]*Medical Center - University of Freiburg, Faculty of Medicine, University of Freiburg, Department of Rheumatology, Freiburg, Germany*

Background: Respiratory tract infections (RTIs) are the most common infections in patients with rheumatic diseases under immunosuppressive treatment. RTIs may cause significant morbidity with reduced quality of life (QOL), increased healthcare costs and may lead to interruption of DMARD therapy. However, to date only limited data on infection risk in spondyloarthritis (SpA) patients are available.

Objectives: To assess the occurrence of respiratory tract infections in a real-world SpA cohort and determine associated factors.

Methods: Questionnaire-based screening and retrospective medical chart analysis of a monocentric cohort of 314 SpA patients comprising 168 psoriatic arthritis (PsA) and 146 axial spondyloarthritis (axSpA) patients.

Results: Out of 314 SpA patients, 89% had a history of upper respiratory tract infections (URTI) and 31.1% of lower respiratory tract infections (LRTI) within the last two years (Table 1). In a linear regression model LRTIs were associated with glucocorticoid (GC) therapy (p=0.015), CRP level (p=0.018), previous history of severe respiratory infections (p=0.007) as well as absence of HLA B27 (p=0.024). In general, patients with LRTIs were significantly older (p=0.007), had increased functional impairment (p<0.001), a reduced health-related QOL (p<0.001), poorer sleep quality (p=0.001) and more depression (p=0.001). 46% of patients had required antibiotics for RTIs within the last two years. Antibiotic therapy was associated with smoking (p=0.006), biologic therapy (p=0.005) and poor sleep quality (p=0.005). Smoking was associated with LRTI (p=0.009), but not URTI. Female patients reported a significantly higher frequency of LRTI (p=0.003), sinusitis (p=0.001), pharyngitis/laryngitis (p=0.009) and had received more courses of antibiotics than male patients (p=0.032).

Table 1. ***Patient characteristics and infections***

	axSpA (n=146)	PsA (n=168)	Total (n=314)
Age, years, mean (SD)	49.6 (14.2)	57.4 (12.4)	53.8 (13.9)
Male / Female, %	56.8 / 43.2	53.0 / 47.0	54.8 / 45.2
BMI, kg/m^2, mean (SD)	27.1 (7.2)	27.4 (5.4)	27.3 (6.2)
Smokers, n (%)	41 (31.8)	27 (16.3)	68 (23.1)
HLA B27, n (%) (n=230)	97 (71.9)	23 (24)	120 (52.2)
Therapy:			
n (%)			
csDMARD	29 (19.6)	84 (50.6)	113 (36.2)
bDMARD	109 (75.2)	102 (60.7)	211 (67.4)
Glucocorticoids	14 (9.9)	15 (8.9)	29 (9.4)
Hypogammaglobulinemia (IgG<7g/l), n (%)	5 (3.5)	6 (3.6)	11 (3.6)
Polyclonal IgA (>4g/l) elevation, n (%)	15 (10.9)	29 (17.8)	44 (14.7)
URTI: n (%)	114 (88.4)	148 (90.2)	262 (89.4)
Rhinitis, %	87.1	87.5	87.3
Laryngitis/pharyngitis, %	37	36.9	36.9
Sinusitis, %	40.5	30.2	34.7
Otitis media, %	14.3	6.8	10.1
LRTI: n (%)	39 (30.5)	52 (32.1)	91 (31.1)
Bronchitis, %	28.0	30.6	29.6
Pneumonia, %	3.9	3.1	3.4
Pleuritis, %	2.4	1.2	1.7

There were no significant differences between PsA and axSpA regarding frequency of URTI or LRTI, though PsA patients had tendentially more overall RTIs. Biological therapy did not lead to a significantly increased occurrence of infections, but was associated with increased antibiotic therapy (p=0.039). Patients with a history of pneumonia had received anti-IL17 therapy more frequently (p=0.002), while there was no significant association with anti-TNF therapy (p=0.156). Patients on GC had a relative risk for LRTIs of 2.04.

Hypogammaglobulinemia was rare in SpA patients (3.6%) despite continuous immunosuppressive treatment, occurred with equal frequency in axSpa and PsA patients and was associated with pneumonia (p=0.007) and increased antibiotic use (p=0.016). Polyclonal IgA elevation was observed in 14.7% of patients (mean 4.98g/l) and was associated with fewer episodes of rhinitis (p=0.027), whereas LRTIs and antibiotic use did not differ significantly.

Conclusion: This study quantifies the incidence and effects of RTIs in a real-world SpA cohort. While infections constitute significant adverse events of biologicals, and URTI were common, severe respiratory tract infections were rare. Differences in infection risk between SpA and PsA need to be studied more closely.

EFFECT OF PRO-INFLAMMATORY CYTOKINE-INTERLEUKIN 6 ON THE COURSE OF ANKYLOSING SPONDYLITIS IN PATIENTS AFTER COVID-19

N. Abdurakhmanova[1], K. Akhmedov[2]. [1]*Tashkent Medical Academy, Department of internal diseases #3, Ташкент, Uzbekistan;* [2]*Tashkent Medical Academy, Department of internal diseases #3, Tashkent, Uzbekistan*

Background: Everyone knows that COVID-19 not only has a severe effect on the pulmonary system, but also triggers a whole cascade of autoimmune reactions. The study of the effect of the pro-inflammatory cytokine - interleukin 6 (IL6) on the clinical course of patients with ankylosing spondylitis (AS) undergoing COVID-19 is an important problem in rheumatology..

Objectives: To study the significance of the pro-inflammatory cytokine-IL-6 on the clinical features of the course of AS in patients who have undergone COVID-19.

Methods: In the period from 2020-2021, 44 patients with a diagnosis (AS) were hospitalized in the City Clinical Hospital # 3 of Tashkent city. The patients were divided into two groups: Group I - 20 patients with AS who underwent COVID-19 and Group II of 24 patients with no history of AS who had COVID-19 infection. The average age of patients in group I was 32 ± 4.1 years and in group II - 36.5 ± 5.2 years. All patients underwent clinical and laboratory studies, including studies of serum IL-6 levels. Disease activity was assessed using the BASDAI and ASDAS scales, pain was assessed using a numerical rating scale (NRS), and peripheral joint damage was assessed by the presence of pain and swelling in 44 joints. All patients underwent PCR, as well as ELISA-IHLA tests for the presence of antibodies to COVID-19.

Results: Clinical examination of the patients revealed the presence of pain in the spine, which was assessed using the numerical rating scale – (NRS) in group I it was 8.5 ± 1.2 points and 5.9 ± 2.3 points in patients of group II. Examination of peripheral joints showed an average number of painful joints (PJ) of 16.9 ± 3.2 in group I and 8.6 ± 2.7 in group II, the number of swollen joints (NSJ) 8.8 ± 2.1 in group I and 4.2 ± 1.7 in group II. group. The study of AS activity using the BASDAI scale showed an average level of 5.1 ± 1.7 points in group I and 4.4 ± 2.1 points in group II. And the study of activity on the ASDAS scale showed an average level of 4.0 ± 1.7 points in group I and 2.5 ± 0.8 points in group II, which indicates a very high activity of the pathological process in group I and medium-high activity in group II. The IL-6 level in group I was 10.2 ± pg / mL, 4.2 pg / mL in group II and 1.39 pg / mL in the control group.

Conclusion: 1. The clinical course of AS in patients who have undergone COVID-19 is characterized by a more pronounced disease activity according to the BASDAI and ASDAS scales, a high intensity of pain syndrome according to a NRS, as well as a high level of IL-6.

2. A high level of IL-6 in group I indicates the impact of COVID-19 on the course, activity and severity of the autoimmune process in patients with AS, which is many times higher than in patients of group II, which allows us to consider it as a biomarker of damage to the articular and connective tissue in this infection.

AB0813

CORRESPONDENCE BETWEEN PATIENT-REPORTED FLARE AND DISEASE ACTIVITY SCORE VARIATION IN AXIAL SPONDYLOARTHRITIS

F. Costantino[1,2], A. Leboime[2], L. Bessalah[3], M. Breban[1,2]. [1]*Université Paris-Saclay / INSERM, UMR1173, Montigny le Bretonneux, France;* [2]*APHP Ambroise Paré Hospital, Rheumatology, Boulogne-Billancourt, France;* [3]*BE PATIENT,, Paris, France*

Background: There is currently no consensual definition of flare in axial spondyloarthritis (axSpA).
Objectives: The aims of this study were to determine thresholds of variations of BASDAI associated with patient-reported flare and to test performance of ASAS preliminary definitions of flare[1].
Methods: This prospective study was proposed to all patients registered on the Spondy+ platform, a secure e-health platform for SpA patients. Every week during one year, patients were invited to connect to the platform to fill a BASDAI questionnaire, a 0-10 pain visual analogic scale and to answer to the following question: "has your disease flared up since last week?". Variations of BASDAI and pain between connections were assessed and associated to the change of perception of flare. ROC curves were built to assess performances of BASDAI and VAS to identify patient-reported occurrence and resolution of flare. Performance of ASAS preliminary definitions of flare was also assessed.
Results: 99 patients participated to this study for an average duration of 309 ± 148 days. 92% of them reported at least one episode of flare over follow-up. Area under the ROC curve (AUC) was significantly higher for ΔBASDAI than for Δpain, to predict outbreak of flare (0.81 vs 0.77, p=0.02). In contrast, ΔBASDAI and Δpain were comparably accurate to predict flare resolution with no significant difference of AUC (0.78 vs 0.80, p=0.4). Best performance was obtained for an increase of 0.2 points of BASDAI (sensitivity=70%; specificity=79%) and 0.5 of pain VAS to predict outbreak of flare and a decrease of 0.4 points of BASDAI and 0.5 of pain VAS to predict flare resolution (Figure 1). None of the ASAS definitions yielded sensitivity values higher than 37% whereas specificity was higher than 95% for all of them.

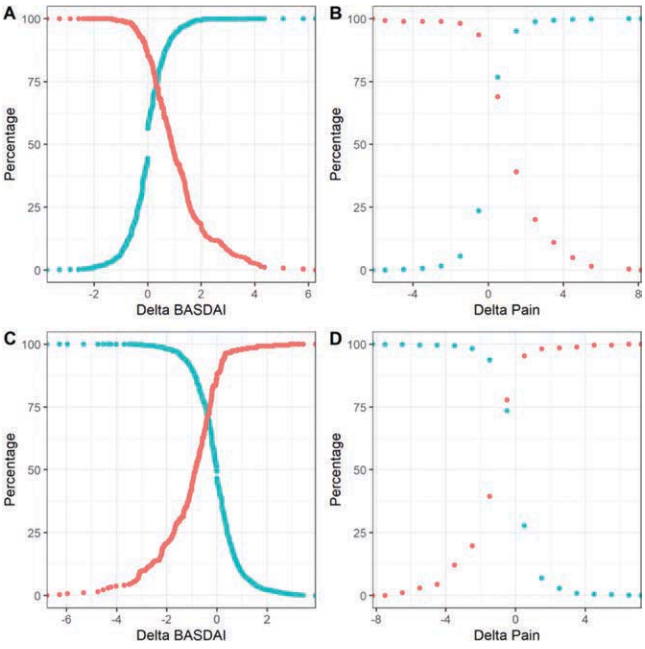

Figure 1. Sensitivity (red dots) and specificity (blue dots) according to ΔBASDAI (panels A,C) and Δpain (panels B,D) threshold as predictors of outbreak (panels A,B) or resolution (panels C,D) of flare.

Conclusion: ΔBASDAI appeared as a suitable variable to monitor both occurrence and resolution of SpA flare, as reported by patient.

ASSOCIATION BETWEEN UVEITIS AND OTHER CLINICAL MANIFESTATIONS OF ANKYLOSING SPONDYLITIS

A. Godzenko[1,2], I. Razumova[3], M. Godzenko[4]. [1]*Federal State Budgetary Educational Institution of Additional Professional EducationRussian Medical Academy of Continuous Professional Education, Rheumatology, Moscow, Russian Federation;* [2]*Federal State Budgetary Scientific Institution "V.A. Nasonova Research Institute of Rheumatology", Educational department, Moscow, Russian Federation;* [3]*Federal State Budgetary Scientific Institution Research Institute of Eye Diseases, Retinal and optic nerve pathologies, Moscow, Russian Federation;* [4]*Federal state budgetary institution «National Medical Research Center for Surgery named after A.V. Vishnevsky, Department of radiological methods of diagnostics, Moscow, Russian Federation*

Background: Uveitis is a frequent extra-skeletal manifestation of ankylosing spondylitis (AS).
Data on the association of uveitis with other clinical manifestations of AS are contradictory and require further study.
Objectives: To assess the association of uveitis in AS with demographics and genetics, spine lesions, peripheral disease, coxitis, enthesitis.
Methods: 402 AS pts (New York criteria, 1984), were observed in V.A. Nasonova Research Institute of Rheumatology. 168 pts had at least 1 episode of uveitis (group 1), 234 pts did not have uveitis (group 2). The patients underwent standard clinical, laboratory and instrumental examination, including HLA-27- testing, X-ray examinaiton of joints and spine, ultrasonography of joints and entheses. Two groups were compared by gender, onset age and AS duration, presence of HLA-B27, damage of the spine, hip and peripheral joints and enthesitis.
Results: Both groups were dominated by men: 117 of 168 in group 1 and 189 of 234 in group 2. However, among patients with uveitis, the proportion of women was significantly higher: 51/168 (30.3%) and 45/234 (19.2%), p=0.01. The average duration of the disease was comparable in both groups – 14.9±10.2 and 12.8±9.9 years, respectively. The number of patients with AS onset before the age of 16 also did not significantly differ: 22/168 (13.1%) in the group with uveitis, 35/234 (14.9%) in the group without uveitis, p=0.6. HLA-B27 in the group with uveitis was in 166/168 patients (98.8%) and in 221/234 (94.4%) in the group without uveitis, p=0.04. Syndesmophytes were observed in both groups with similar frequency: in the cervical spine - in 49/168 (29.1%) in group 1 and in 78/234 (33.3%) in group 2, p>0.05; in the lumbar spine – in 87 /168 (51.8%) and in 139/234 (59.4%), respectively, p>0.05. Hip joint lesion (coxitis) was present in 75/168 (44.6%) and in 112/234 (53.8%) respectively, p=0.52; enthesitis – in 114/168 (67,9%) and in 168/234(71,8%), p>0.05. Peripheral arthritis was observed significantly more often in the group with uveitis: in 113/168 (67.2%) and in 70/234 (33.2%) respectively, p<0.001; its predominant localization was knee - 71/113 (62.8%) and ankle - 54/113 (47.8%).
Conclusion: AS with uveitis is characterized by a greater proportion of women and stronger association with HLA-B27, compared with patients without uveitis. Peripheral arthritis with predominant involvement of the knee and ankle joints is significantly more common in AS pts with uveitis compared with pts without uveitis.

SLEEP DISORDERS ARE FREQUENT IN SPONDYLOARTHRITIS, ASSOCIATED WITH REDUCED QUALITY OF LIFE AND DEPRESSION AND MORE PREVALENT IN FEMALE PATIENTS

N. Frede[1], E. Rieger[1], R. Lorenzetti[1], A. Venhoff[1], C. Hentze[1], I. Jandova[1], C. Glaser[1], J. Thiel[1], R. Voll[1], N. Venhoff[1]. [1]*Medical Center - University of Freiburg, Faculty of Medicine, University of Freiburg, Department of Rheumatology, Freiburg im Breisgau, Germany*

Background: Axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) may have a profound impact on health-related quality of life (HRQoL) and sleep despite effective treatment.
Objectives: To assess sleep and HRQoL in SpA and determine associated factors.
Methods: Monocentric questionnaire-based assessment of HRQoL, function, sleep and depression in 314 SpA patients (n=168 PsA, n=146 axSpA).
Results: Under effective treatment 138 SpA patients (46.5%) demonstrated abnormal sleep behaviour. 49.3% reported not being able to sleep through the night, with 6.1 % needing sleeping pills. 11.9% indicated feeling unrefreshed most mornings. Abnormal sleep behaviour was associated with female sex (p=0.005),

HLAB27 (p=0.034), functional impairment (p=0.001) and depression (p<0.001). Patients reporting unrestful sleep had significantly more depressive symptoms (p<0.001) and highly reduced physical and mental HRQoL (p<0.001). Satisfaction with health was rated significantly lower (p<0.001). Patients with axial involvement (axSpA/axPsA) reported worse sleep quality (p=0.002) and waking too early (p=0.038) despite 73.7% receiving biologics. Sleep quality and early awakening correlated with BASDAI (p<0.001). Smokers had a reduced HRQoL (p=0.018) despite younger age (p=0.008). Female patients had worse sleep quality (p<0.001), needing more time to fall asleep (p=0.022), not being able to sleep through the night (p=0.026) and feeling unrefreshed in the morning (p<0.001). They had a reduced physical (p=0.019) and mental HRQoL (p=0.003), more depressive symptoms (p=0.040) and lower functional capacity (p=0.002). Functional capacity was associated with younger age (p<0.001), sex (p=0.042), smoking (p=0.008), sleep quality (p<0.001) and depression (p<0.001). 66.2% of patients have been assessed longitudinally, before and 3y later during COVID19 pandemic. Physical and mental HRQoL were stable over time. Functional capacity had decreased slightly. Subjective QoL during the COVID19 pandemic was not reduced compared to before. Regarding depressive symptoms, there was a mild but significant improvement over time (p=0.019). Furthermore, we observed an improvement of environmental QoL (p=0.034) during COVID pandemic. Overall subjective QoL as well as satisfaction with health did not change significantly. Patients who had changed therapy (37% of the cohort) still had a reduced physical HRQoL (p=0.022) as well as significantly more depressive symptoms (p=0.010) and perceived their overall QoL as being worse (p=0.016).

Conclusion: Despite treatment many SpA patients have a reduced HRQoL and impaired sleep quality with significant differences between male and female patients. Impact of COVID19 pandemic was low.

AB0816 COMORBIDITY AND THE USE OF BIOLOGICAL THERAPY IN AXIAL SPONDYLOARTHRITIS, IS THERE ANY IMPACT?

K. Tahir[1], N. Akasbi[1], I. El Mezouar[1], T. Harzy[1]. [1]*University Hospital Center Hassan II, Rheumatology, Fez, Morocco*

Background: Spondyloarthritis (SpA) is a chronic inflammatory rheumatism that can be associated with a lot of comorbidities. Comorbidity seems to be a factor that is can influence the treatment tactics.

Objectives: The aims of our study were to describe the prevalence of commonly reported comorbidities in spondyloarthritis and to study the influence of comorbidity on the prescription of biological therapies in patients with SpA.

Methods: A retrospective study was conducted in a single rheumatology hospital in Morocco, including patients diagnosed as having SpA according to ASAS criteria 2010, during a period of 9 years. Comorbidity data were obtained through careful examination of the history and medical records. The Charlson comorbidity index [1] calculated for every patient.

Results: 375 patients were included in the study. 206 (54,9%) women, mean age 46.8±14,0 years. 105 patients were treated with biologic therapy (28%), in majority with TNF alpha inhibitors (99 patients). 188 (50,1%) patients had Charlson comorbidity index =1. The most common comorbidities were type 2 diabetes (12% patients), cancer (4,5%), chronic liver disease (2,9%), chronic kidney disease (2,1%), peptic ulcer (1,6%), ischemic heart disease (1,3%). Mean Charlson index was 1,14 ± 1,56 in total group; it was significantly lower in patients who were treated with biological therapy (0,6 ± 1,03) than in biologic naïve SpA (1,35 ± 1,68), p=0,0001. Biologics were prescribed in 66,7% of patients without comorbidities, in comparison with 17,1% of patients with Charlson comorbidity index = 1, 8,6% with Charlson comorbidity index = 2 and 6,8% of patients with Charlson index = 3 or more.

Conclusion: Comorbidities are common in SpA and have a direct impact on the use of biological therapy. The development of therapeutic strategy for treating comorbid conditions is a must to achieve therapeutic goals in SpA.

AB0817 COMORBIDITIES IN ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: ARE THERE ANY DIFFERENCES?

K. Tahir[1], N. Akasbi[1], I. El Mezouar[1], T. Harzy[1]. [1]*University Hospital Center Hassan II, Rheumatology, Fez, Morocco*

Background: While comorbidity is increasingly being recognized and examined within patients with Axial spondyloarthritis (axSpA), few studies have investigated the occurrence of comorbidities in patients with non-radiographic axial spondyloarthritis (nr-axSpA) in relation to ankylosing spondylitis (AS).

Objectives: The aims of our study were to compare characteristics, comorbidities and medications between AS and nr-axSpA patients and to compare comorbidities between the two groups.

Methods: A cross-sectional study was conducted in a single rheumatology hospital in Morocco, including patients diagnosed as having axSpA according to ASAS criteria 2010, during a period of 9 years. The comorbidities studied were hypertension, diabetes, dyslipidemia, cardiac, digestive and pulmonary disorders, osteoporosis, renal insufficiency and neoplastic pathologies. Demographic, clinical, laboratory, comorbidities and treatment data were compared between AS and the nr-axSpA subgroups.

Results: 375 patients were included in the study. The cohort was predominantly female (54,9%) with a mean age of 46,83 years (± 14,00). 129 (50,2%) had at least one comorbidity. The mean number of comorbidities was 0,8 (± 1,05). We compared 257 AS to 118 with nr-axSpA.

AS patients were significantly young (45 vs 50 years; p=0,0001), more frequently male (55% vs 22%; p=0001) and had higher serum inflammatory markers than those with nr-axSpA. The mean number of comorbidities was similar between AS and nr-axSpA groups. 31,1% of patients SA have a history of biologics

DMARD-use (p=0,046) and less use NSAID (89,5 % vs 96,6 %; p=0,02). There were no statistically significant differences in prevalence of comorbidities between AS and nr-axSpA groups except hypertension which was higher in nr-SpA patients (24,6% vs. 14,4%, p=0,016) and digestive disorders which was most frequently detected in patients with AS (12,5 % vs 5,9%, p=0,05). The prevalence of cardiac disorders (p =0,068) and diabetes (p = 0,09) was nearly statistically significant. The multivariate analysis showed that hypertension is associated to AS form (OR: 1,976; IC [1,088-3,589])

Conclusion: Comorbidities were common in both axSpA populations with small differences between AS and nr-axSpA. These results highlight the importance of identifying and managing comorbidities.

AB0818 PREDICTORS OF REMISSION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

A. S. Pinto[1], B. Farisogullari[2], P. Machado[3]. [1]*Unidade Local de Saúde da Guarda, Rheumatology, Guarda, Portugal;* [2]*Faculty of Medicine, Hacettepe University, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey;* [3]*University College London, Centre for Rheumatology & Department of Neuromuscular Diseases, London, United Kingdom*

Background: Achievement of remission is a desirable outcome in axSpA, and the identification of remission predictors may further aid in the clinical and personalised management of the disease.

Objectives: To systematically review and summarize the predictors of remission in patients with axSpA.

Methods: A comprehensive search was performed in MEDLINE, EMBASE, Cochrane CENTRAL, and 2020-2021 abstracts of ACR and the EULAR annual meetings. To identify the relevant studies, medical subject headings and keywords related to "axial spondyloarthritis", "remission," and "prognostic study" were used. Studies were included if: patients were diagnosed with axSpA by a physician; age ≥18 years; the study assessed the potential predictive or prognostic factors related to remission, according to any definition; and the statistical analysis included multivariable analysis. The methodological quality of the included studies was assessed using the *Quality* of *Prognosis Studies* in Systematic Reviews tool.

Results: The systematic literature review (SLR) comprised 22 articles from 4245 citations identified in our search (Figure 1). Two studies investigated "sustained remission" (at least in 3 consecutive follow-up visits), while the others assessed "point remission" (at single points in time). The most commonly used remission criteria were Ankylosing Spondylitis Disease Activity Score (ASDAS) inactive disease (14 studies) and Assessment of SpondyloArthritis international Society partial remission (ASAS-PR; 11 studies) criteria. However, other non-validated definitions, most of them including Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) cut-offs, were also used. In 19 studies, subjects were treated with biological disease-modifying antirheumatic drugs (bDMARDs) with or without concomitant conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) or non-steroidal anti-inflammatory drugs (NSAIDs), while in one study patients were treated with a Janus kinase inhibitor, upadacitinib. Study duration ranged from 12 weeks to 8 years. Younger age, HLA-B27 positivity, male gender, lower baseline BASDAI, lower baseline Bath Ankylosing Spondylitis Functional Index (BASFI) and treatment with tumour necrosis factor inhibitor (TNFi), were the most consistent predictors of remission. Additionally, lower baseline ASDAS-CRP, lower body mass index (BMI), shorter disease duration, TNFi naivety, and concomitant use of csDMARDs were found to be predictors of remission in two studies each. Other predictors were only found to be associated with remission in single studies, namely: higher education level, more intense morning stiffness, lower baseline total back pain score, history of peripheral arthritis, no smoking, higher pain catastrophizing, lower modified Rheumatic Disease Comorbidity Index, fulfilment of ASAS clinical arm criteria, fulfilment of European Spondyloarthropathy Study Group criteria, lower erythrocyte sedimentation rate, higher Spondyloarthritis Research Consortium of Canada magnetic resonance imaging (MRI) sacroiliac joint (SIJ) and spinal inflammation score, positive MRI of the SIJ, lower Bath Ankylosing Spondylitis Metrology Index, lower Health Assessment Questionnaire for the Spondyloarthropaties, lower global pain, lower back pain score and lower enthesitis index. Of note, contradictory data were found regarding CRP and NSAIDs usage.

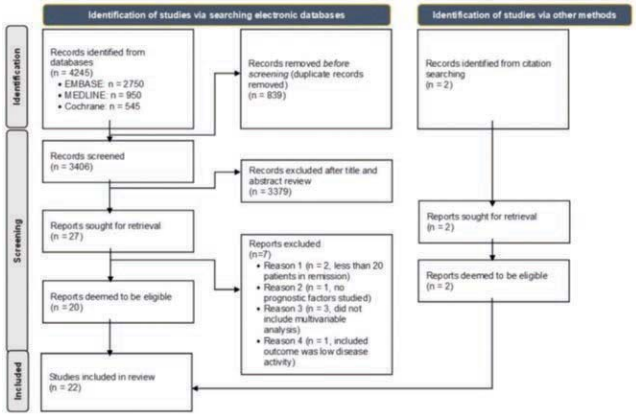

Figure 1. Flow chart of study selection

Conclusion: Thirty-four predictors of remission in axSpA were identified. However, many of these predictors were only identified in one or two studies. Considering the differences in study design, particularly characteristics of the population, duration of remission and remission criteria, further well-designed studies are needed to allow generalisation of the identified predictors to the general axSpA population.

AB0819 IMPACT OF CHILDBIRTH ON THE SACROILIAC JOINTS IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

M. Yasmine[1], D. Ben Nessib[1], H. Ferjani[1], W. Triki[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of orthopedics, Rheumatology, Tunis, Tunisia*

Background: The era of magnetic resonance imaging (MRI) has contributed to a better assessment of patients with early disease stages of axial spondyloarhtis (ax-SpA), to the extent that a new entity has emerged. Indeed, the spectrum of SpA has broaden to include non-radiographic axial spondyloarthritis (nr-axSpA). Childbirth has been found to be associated with bone marrow edema (BME) in the sacroiliac joints (SIJ) [1], yet the extent of these lesions is inadequately described, which complicates the distinction with nr-axSpA.

Objectives: This study aimed to explore the impact of childbirth on MRI findings and BME in nr-axSpA.

Methods: We conducted a cross-sectional study including women diagnosed with nr-axSpA according to the ASAS (Assessment of SpondyloArthritis international Society) criteria. Socio-demographic data as well as childbirth history were recorded. The sacroiliac joints manoeuvers' examination were also transcribed. Ultrasound of the SIJ as well MRI-SIJ was performed in all the women. The sequence protocol included the following: T1-weighted, T2-weighted and axial STIR and were scored for BMO. We investigated an association between the number of children and MRI abnormalities mainly the presence of BME. The level of significance was fixed for $p<0.05$.

Results: The study included 30 women. The mean age at diagnosis was 40±9.8 years old [21-59] and the mean age at inclusion was 49±11 years old [26-74]. The median number of children was 2 [0-7]. Half of the patients were multiparous. Doppler ultrasound of the SIJ was found in 59.1% of cases. Overall, 36.7% of the women fulfilled the ASAS definition of a positive MRI. BME was displayed on STIR MRI sequence in 26.5% of cases and was equally present at the right SIJ compared with the left (26.7% vs 23.3%). Gadolinium enhancement was found in 16.7% of cases and subchondral erosions were found in 36.7% of cases.

There was no association between the different sacroiliac maneuvers on physical examination and the number of children: distraction test (p=0. 145), compression test (p=0.088), Gaenslen test (p=0.475), and Mennel test (p=0.088). BME was more frequent among multiparous women (33% vs 29%) without reaching a statistically significant difference (p=0.635). There was no association between the number of children and Hyper T1 (p=0.608), T1 gadolinium (p=0.55) as well as sclerosis (p=0.55). Similarly, there was no association between the presence of Doppler signal on ultrasound and multiparity (p=0.5).

Conclusion: Our study showed that MRI-SIJ findings were similar in nr-axSpA women regardless of the number of children, mainly BME. More trials are needed to evaluate the discriminatory capacity of MRI abnormalities and to palliate to the lack of specificities of the ASAS MRI criteria.

AB0820 REMISSION CRITERIA IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: DON'T MISS SUBCLINICAL INFLAMMATION

D. Ben Nessib[1], M. Yasmine[1], H. Ferjani[1], W. Triki[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]. [1]*Kassab Institute of orthopedics, Rheumatology, Tunis, Tunisia*

Background: With the advent of the treat-to-target strategy (T2T), clinical remission has become the main objective to achieve in patients with rheumatic diseases. Contrary to rheumatoid arthritis, the T2T strategy is less codified in axial spondyloarthritis, even more in non-radiographic SpA (nr-axSpA) [1]. More importantly, T2T based on imaging remission and guidance for tapering medication has not been extensively studied.

Objectives: The objective of this study was to investigate the prevalence of bone marrow edema in the sacroiliac joint of nr-axSpA patients in remission.

Methods: We undertook a cross-sectional study including nr-axSpA patients according to the ASAS criteria, treated with NSAIDs. Socio demographic data as well disease characteristics were recorded. Disease activity parameters were also collected including the duration of morning stiffness, the number night awakening, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). MRI-SIJ was performed for all the patients. All the images were screened for bone marrow edema with the corresponding sequence (short tau inversion). To define remission, we used in addition to BASDAI<4, more stringent criteria: BASDAI<4 and CRP<6 mg/l and ESR<20 mm/h and EGM<4 [2]. The level of significance was fixed for p<0.05.

Results: The study included 43 nr-axSpA patients. There was a female predominance with a sex ratio of 0.43. The mean age of the patients was 42±12 years [20-71] and the mean disease duration was 17±9.7 years [4-38]. The mean ESR and CRP were 2.2 mg/L [2-65] and 6.4mm/h [1-47], respectively. A higher level of acute phase reactants was found in 40.5% of cases (ESR: 35.7%, CRP: 11.9%). Forty percent of the patients had high CRP or ESR despite BASDAI<4. According to BADSAI<4, of the 15 patients in remission, BME was displayed in 43.5% of the cases. According to the used criteria, 25.6% of the patients were in remission, of which 45.4% exhibited BME in the sacroiliac joint. There was no statistically significant association between disease activity according to the used definition and the presence of BME (p=0.473). Nr-axSpa patients in remission without BME had more durable morning stiffness and articular involvement without reaching a statistically significant difference (p=0.361, p=0.08 respectively). Similarly, we did not find an association between this subgroup and sex, age, night awakenings, the presence of HLAB27 (p>0.05).

Conclusion: Our study showed that even when using stringent criteria, subclinical remission evidenced by BME was not achieved in nr-ax SpA. Nevertheless, imaging remains one important parameter to consider in therapeutic decision making. More studies are needed to identify the best criteria for an optimal remission in this population.

AB0821 THE FREQUENCY OF LUMBOSACRAL TRANSITIONAL VERTEBRAS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

N. Gokcen[1], O. Ozdemir Isik[1], A. Yazici[1], A. Cefle[1]. [1]*Kocaeli University Faculty of Medicine, Internal Medicine, Division of Rheumatology, Kocaeli, Turkey*

Background: Lumbosacral transitional vertebras (LSTVs) are anatomic variations observed at L5-S1 junction (1). The prevalence of LSVT ranges from 3.9% to 35.6%, indicating that this congenital anomaly is common in general population. LSVTs are well-defined anatomical differences causing low back pain and pelvic trauma (2). However, the studies assessing the influence of abnormal lumbosacral anatomy on low back pain and sacroiliac joints in patients with ankylosing spondylitis (AS) are scarce (3).

Objectives: The current study aimed to investigate the frequency of LSVTs and the their effects on clinical variables in AS patients.

Methods: The study was designed as a prospective cross-sectional study. 113 patients were included in the study. Demographic data, clinical variables, laboratory results were recorded. Disease activity (ASDAS-CRP and ASDAS-ESR), patients' functionality (BASFI, BASMI), enthesitis (Leeds enthesitis index) and quality of life (SF-36, visual analogue scale) were evaluated. The baseline pelvic conventional radiographs and the sacroiliac magnetic resonance imaginings at the diagnosis were screened and assessed by two independent physicians. LSTVs were classified via Castellvi classification. Kappa coefficient was used to find the interobserver reliability.

Results: LSVTs were observed in 38 (33.6%) patients. Castellvi type Ia, Ib, IIa, IIb, IIIa, IIIb, and IV were found in 10 (8.8%), 7 (6.2%), 7 (6.2%), 6 (5.3%), 4 (3.5%), 1 (0.9%), and 3 (2.7%) patients, respectively. The kappa value for interobserver reliability was 0.69. There were not any differences between AS patients with and without LSVTs in terms of disease activity, functionality, and quality of life (Table 1). No statistically significant correlation was found between LSVTs identified by conventional radiography and sacroiliitis determined by MRI. When compared the patients according to Castellvi classification, visual analogue scale was higher in patients with IIIa than in patients with IV (p=0.013). Disease duration was longer in patients with Ib than in patients with Ia (p=0.029). ASDAS-CRP and ASDAS-ESR were higher in patients with IIIa than in patients with IV (p=0.008 and p=0.007).

Table 1. The comparison of clinical characteristics between patients with and without LSVTs

	Patients without LSVTs (n=75)	Patients with LSVTs (n=38)	p
VAS	3.0 (2.0–5.0)	3.4 (1.0–6.0)	0.734
Disease duration (month)	122.0 (60.0–180.0)	120.0 (57.0–183.0)	0.834
ASDAS-CRP	1.8 (1.2–2.5)	1.8 (1.2–2.9)	0.855
ASDAS-ESR	1.6 (1.2–2.5)	1.6 (1.0–2.7)	0.976
CRP	1.8 (0.8–5.3)	2.5 (1.0–6.1)	0.471
BASMI	2.9 (2.0–4.4)	3.0 (2.1–4.0)	0.796
BASFI	1.8 (0.7–4.6)	2.1 (0.7–3.0)	0.768
SF-36 Physical function	80.0 (55.0–95.0)	80.0 (63.8–95.0)	0.765
Role physical	45.6 (0–100.0)	50.0 (25.0–100.0)	0.280
Role emotional	66.7 (0–100.0)	33.0 (0–100.0)	0.267
Energy/fatigue	50.0 (35.0–70.0)	60.0 (38.8–71.3)	0.201
Mental health	64.0 (48.0–76.0)	68.0 (52.0–80.0)	0.330
Social functioning	62.5 (50.0–87.5)	75.0 (50.0–100.0)	0.252
Body pain	67.5 (45.0–80.0)	67.5 (45.0–90.0)	0.751
General health	45.0 (35.0–65.0)	50.0 (40.0–71.3)	0.411

Values are given as median (interquartile range)

Conclusion: In AS patients, the frequency of LSVT is 33.6%, which is consistent with the general population. Type I, also known as a dysplastic transverse process, is the most observed type of LSVT. The presence of LSVTs is associated neither with clinical variables nor with sacroiliitis.

AB0822 **FACTORS ASSOCIATED WITH A DELAYED DIAGNOSIS OF SPONDYLOARTHRITIS IN A POPULATION OF THE SOUTH OF MOROCCO**

P. C. Mouele Mboussi[1], Z. Baba[1], F. E. Chekkouri[1], A. Rafi[1], A. Mougui[1], I. El Bouchti[1]. [1]*CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, RHEUMATOLOGY, Marrakech, Morocco*

Background: Spondyloarthropathies are chronic inflammatory diseases with predominant axial involvement. Early diagnosis is a major challenge for physicians. Misdiagnosis and diagnostic delays lead to unnecessary paraclinical investigations, inadequate treatment and to poor outcomes including functional impairment and quality of life.
Objectives: We assess the diagnostic delay in spondyloarthritis and identify factors associated with it.
Methods: A retrospective study including patients diagnosed with spondyloarthritis between 2004 and 2020 according to ASAS 2010 criteria.Diagnostic delay was defined as period between the first symptom and diagnosis establishment. The potential factors predicting the diagnostic delay were explored through univariable and multivariable linear regression analysis, included epidemiological characteristics (age, gender, educational level, socio-economic level), clinical and biological presentation and sacroiliitis (radiographic or in MRI). Events occurring before the diagnostic were also analyzed.
Results: The study included 276 patients: 146 males (53%) and 130 females (47%) with a sex ratio of 1.1 and the mean age at the diagnostic was 38.87 years. Comorbidities included smoking (33 patients), cardiopathy (3 patients), hypertension (19 patients), diabetes (14 patients) and peptic ulcer (5 patients). The mean duration of symptoms was 2.6 years, and average diagnostic delay was 6.5 years with a median of 2.1 years. In univariable and multivariable linear regression analysis, low socio-economic level (p =0.023) and low educational level (p=0.042) were statistically significant parameters associated with a delayed diagnosis. There was no statistically significant association between the delay of diagnosis and age, clinical presentation or sacroiliitis (radiographic or in MRI). The use of traditional and herbal treatments before consulting a rheumatologist was also associated with a longer delayed diagnosis.
Conclusion: Spondyloarthropathies have a delayed diagnosis. This delay, also found in other studies, is responsible for persistent disease activity and important functional consequences. In our context, low socio-economic level, low educational level, and the use of traditional unconventional treatment are factors associated with a delayed diagnosis.

AB0823 **DUAL ENERGY X-RAY ABSORPTIOMETRY IN PATIENTS WITH SPONDYLOARTHRITIS. CORRELATION WITH DISEASE DURATION, ACTIVITY AND CHANGES IN SACROILIAC JOINTS ON MAGNETIC RESONANCE IMAGING**

O. Iaremenko[1], D. Fedkov[1], K. Mazanko[1]. [1]*Bogomolets National Medical University, Department of internal medicine #3, Kyiv, Ukraine*

Background: Bone loss (osteopenia or osteoporosis) and osteoporotic vertebral fractures are well-known complications of spondyloarthritis (SpA), and their prevalence in SpA patients (pts) is higher than in patients with mechanical low back pain [1, 2]. Osteopenia and osteoporosis can develop in both the late and early stages of SpA. The presence of bone marrow edema at the lumbar spine and sacroiliac joints (SIJ) on magnetic resonance imaging (MRI) was more common among pts with low BMD (bone mineral density) than normal BMD [3, 4]. At the same time, the dynamics of osteoporotic and osteosclerotic changes in the spine during the progression of SpA makes the assessment of DEXA results ambiguous.
Objectives: To determine the presence of osteopenia/osteoporosis in pts with SpA and to establish its correlations with disease duration, disease activity, active changes in SIJ on MRI.
Methods: 40 patients with SpA (55% – male, mean age 39.87±9.79, mean disease duration – 6.75±7.43 years) underwent DEXA. Spondyloarthritis Research Consortium of Canada (SPARCC) MRI SIJ score (0-72) was utilized for evaluation of the active inflammatory lesions in SIJ, Danish MRI scoring method (0-48) – for chronic changes. Disease activity was measured by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI, cm), Ankylosing Spondylitis Disease Activity Score (ASDAS), C-reactive protein (CRP, mg/l), and erythrocyte sedimentation rate (ESR, mm/hr). For correlation, the Spearman correlation coefficient was calculated.
Results: The mean value of DEXA parameters were: BMD – 0.72±0.15, T-score – -0.16±0.88, Z-score – 0.17±0.89 (forearm); BMD – 0.96±0.17, T-score – -1.13±1.35, Z-score – -0.88±1.31 (spine); BMD – 0.85±0.14, T-score – -0.85±0.93, Z-score – -0.56±0.97 (hip). Mean value (M±σ) of indices and laboratory parameters were: BASDAI – 4.44±1.76, ESR – 30.2±24.1, CRP – 17.9±19.7, ASDAS-CRP – 3.07±1.13, ASDAS-ESR – 3.14±1.14. SPARCC score was 12.3±11.8, Danish score – 15.2±7.77. Osteoporosis was present in 7 (17.5%), osteopenia - in 24 (60%) SpA pts. There was positive correlation between BMD at forearm and Danish MRI score (r=0.331, p=0.02). The CRP level showed negative correlation with BMD at hip (r=-0.322, p=0.02), BMD at spine (r=-0,288, p=0,038) and T-score at spine (r=-0.301, p=0.031). Patient's age showed negative correlation with BMD at hip (r=-0.268, p=0.05). Disease duration negatively correlated with BMD (r=-0.343, p=0.016) and T-score (r=-0.310, p=0.027) at hip. All correlations were weak. No other correlations were found.
Conclusion: Among disease activity parameters, only high CRP was associated with a decrease in BMD for both the back and hip. A decrease in hip BMD was also associated with the patient's age and disease duration. Regarding MRI indicators, only chronic changes in SIJ, measured by MRI, positively correlated with BMD at forearm only.

AB0824 **BREASTFEEDING IN WOMEN WITH ANKYLOSING SPONDYLITIS (AS)**

O. Krichevskaya[1], E. Ilinykh[1], T. Dubinina[1], S. Glukhova[1], A. Demina[1], I. Andrianova[1]. [1]*V.A.Nasonova Research Institute of Rheumatology, Laboratory of axial spondyloarthritis, Moscow, Russian Federation*

Background: Breast milk is the natural and most physiological nutrition for a child from the first days of life. The benefits of breastfeeding are numerous, including psychological aspects. However, some women with rheumatic diseases are afraid that their disease or therapy is not compatible with breastfeeding.
Objectives: To describe frequency, duration and reasons for stopping lactation in women with AS, to compare the activity of AS in women with and without lactation.
Methods: 44 women with confirmed AS (modified New York criteria, 1984) were followed within 1 year after childbirth. Visits were carried out in 1, 6 and 12 months after delivery. The average age of patients was 32,5 ± 5,8 years, the duration of the disease was 149,0 ± 96,3 months. BASDAI at 1, 6 and 12 months after giving birth was: 2,4 [1,4; 4,2]; 2,6 [1,4; 4,4]; 2,7 [1,5; 4,1], respectively. ASDAS-CPR was: 2,0 [1,2; 2,7]; 1,9 [1,4; 2,5]; 1,7[1,3; 2,3], respectively.
Results: Lactation was established in 41 women (93,2%), duration – 10 [4; 12] months; in 17 patients (41,5%) lactation persisted for 12 months. Lactation was unreasonably medically suppressed in 3 women in an obstetric unit due to therapy of AS (sulfasalazine – 2, certolizumab pegol – 1); in 1 woman lactation was not established for organizational reasons. Lactation lasted less than 6 months in 16 patients (39%), 13 of them had a natural attenuation of lactation, and in 3 cases, drug-induced suppression of lactation was carried out on the recommendation of pediatricians in connection with onset of AS therapy (adalimumab).
During lactation, 51,2%, 74,1% and 88,2% of women received nonsteroidal anti-inflammatory drugs for 1, 6 and 12 months after delivery, respectively; adherence to NSAID therapy did not differ in women with and without lactation. TNF-α

inhibitors (certolizumab pegol) were received by 4 women (7,3%), while the need for iTNF-α was in 13 patients (not received due to medicine unavailability).
In women who retained lactation, the severity of back pain was: 3,0 [2,0; 6,0], 3,0 [2,0; 5,0] and 3,0 [2,0; 4,5] according to NRS (numerical rating scale) after 1, 6 and 12 months since delivery, respectively; severity of night pain - 3,0 [2,0; 5,0], 3,0 [2,0; 5,0] and 2,0 [2,0; 4,0] according to NRS, respectively. BASDAI activity at 1, 6 and 12 months after delivery was 2,3 [1,0; 4,2], 2,1 [1,4; 4,1] and 2,2 [1,6; 2,8], respectively. Activity on ASDAScrp was 1,9 [1,2; 2,7], 1,6 [1,4; 2,6] and 1,6 [1,3; 1,7], respectively. CRP level was 3,4 [1,9; 8,2], 4,5 [2,0; 12,5] and 2,0 [0,8; 5,6] mg/l, respectively. The severity of back pain, BASDAI and ASDAS values of CRP did not differ in women with and without lactation.
Women with high AS activity (BASDAI≥4) maintained lactation at 1, 6 and 12 months after delivery in 84,6%, 50% and 8,3%, respectively; while patients with low activity did it in 93,6%, 66,7% and 51,6%, respectively ($p < 0,05$ 12 months after delivery).
Conclusion: The vast majority of women with AS are set up for lactation. High AS activity becomes a risk factor for termination of lactation more than 6 months after delivery. It is necessary to conduct training for obstetricians-gynecologists and pediatricians on issues related to medicine capabilities during lactation, in order to exclude unjustified cancellation of medicines compatible with breastfeeding.

AB0825 A SOLUTION PROPOSAL TO THE INTRAOBSERVER DISAGREEMENT PROBLEM IN THE EVALUATION OF SACROILIAC JOINT RADIOGRAPHY: "IMAGE PROCESSING METHOD"

A. C. Genç[1,2], F. Turkoglu Genc[3], D. Karatas[4], Z. N. Kaya[5], L. Rada[6], E. Gönüllü[4]. *[1]Bahcesehir University, Artificial Intelligence Graduate Education Institute, Istanbul, Turkey; [2]Hendek State Hospital, Internal Medicine, Sakarya, Turkey; [3]Akyazı State Hospital, Internal Medicine, Sakarya, Turkey; [4]Sakarya University, Internal Medicine, Rheumatology, Sakarya, Turkey; [5]Saratoga High School, Student, CA, United States of America; [6]Bahcesehir University, Faculty of engineering and natural sciences, Istanbul, Turkey*

Background: Ankylosing spondylitis (AS) is a rheumatological disease that causes low back pain. The diagnosis of ankylosing spondylitis is delayed for an average of 8 years due to the insidious course of the disease. Late diagnosis of AS can cause functional and physical disabilities. Radiographic sacroiliitis can be graded in the range of 0-4 and these classes may not be sharply separated from each other. Interpretation of the sacroiliac joint radiography may differ from physician to physician. In fact, the same physician may interpret it differently at different times (1). The reason for such confusion is the presence of blur or illumination and contrast problems leading to difficulties to detect pathological areas. This paper has developed a simple image processing technique that adjusts the contrast of such images by modifying their intensity distribution using the histogram information. This transformation gives a linear trend to the cumulative probability function associated with the image and makes the images better for human vision. The common characteristic of low contrast images is the concentration of the histogram values of the image intensity near a narrow range (2).
Objectives: Changing the contrast range into a wider range changes the image value distribution that leads to better image vision.
Methods: Rheumatologist scored 260 x-ray scans grade 0 to 4. One day later, the same rheumatologist scored again the same scans randomly. It has been noticed that most of the answers were closed to the first-day decision but not all of them. We processed all the x-ray images with histogram equalization. Then the rheumatologist scored the scans randomly and answered two times in two consecutive days. To compare the agreement in radiography interpretation Kappa test was used. We use IBM SPSS 21 for the statistical analysis (kappa test) and Matlab R2021a for the image processing part.
Results: Severe improvement before and after the image processing application by increasing the Kappa value from 0.55 ($p<0.001$) [moderate agreement] to 0.71($p<0.001$) [substantial agreement] which is a substantial agreement.
Conclusion: Multidisciplinary approach can be helpful in solving the intraobserver disagreement problem. The use of image processing techniques can be used for the benefit of the patient in radiographs whose standardization is difficult due to multifactorial reasons. The histogram equalization method was found to be statistically significant in finding the optimum contrast for interpreting the sacroiliac joint radiography. The output of this work indicates and motivates our team into deeper research and more analyses on how to further improve our results.

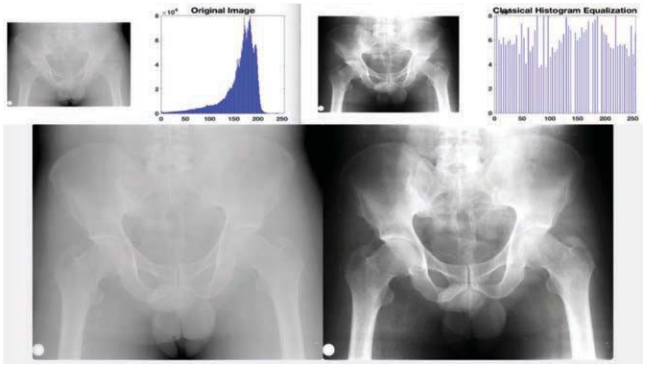

Figure 1. The original graph on the left, the classical histogram equalization method on the right and their histogram tables.

AB0826 KEEP AN EYE ON THE BACK: SPONDYLOARTHRITIS IN PATIENTS WITH ACUTE ANTERIOR UVEITIS

J. Rademacher[1,2], H. Müllner[1], T. Diekhoff[3], H. Haibel[1], S. Igel[1], D. Pohlmann[2,4], F. Proft[1], M. Protopopov[1], V. Rios Rodriguez[1], M. Torgutalp[1], U. Pleyer[4], D. Poddubnyy[1]. *[1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany; [2]Berlin Institute of Health at Charité – Universitätsmedizin Berlin, BIH Biomedical Innovation Academy, BIH Charité (Junior) (Digital) Clinician Scientist Program, Berlin, Germany; [3]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Radiology, Berlin, Germany; [4]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Ophthalmology, Berlin, Germany*

Background: Patients with acute anterior uveitis (AAU) have an increased risk for concomitant spondyloarthritis (SpA). Different referral strategies have been proposed to identify AAU patients with high probability of SpA, among them an Assessment of SpondyloArthritis international Society(ASAS)-based referral strategy focusing on patients with chronic back pain starting before the age of 45 years and the Dublin Uveitis Evaluation Tool (DUET) also including psoriasis, HLA-B27 and arthralgia (*Poddubnyy et al., Haroon et al., both ARD 2015*).
Objectives: To analyse the prevalence of SpA in patients with AAU, to identify parameters associated with SpA presence, and to evaluate referral algorithms.
Methods: Patients with non-infectious AAU underwent structured rheumatologic assessment including magnetic resonance imaging of sacroiliac joints allowing a definitive diagnosis/exclusion of concomitant SpA. Fisher's exact test and Mann–Whitney U test were used to compare AAU patients with and without SpA. Furthermore, logistic regression analyses were performed. Sensitivity, specificity, positive predictive value, positive and negative likelihood ratios were analysed for referral strategies.
Results: The 189 AAU patients with complete rheumatologic assessment and SIJ imaging were 40.8 years old, and 55% were males. SpA was diagnosed in 106 AAU patients (56%). The majority (93%) had predominantly axial SpA, 7 patients peripheral SpA. In 74 patients (70%), the SpA diagnosis was established for the first time. Pelvic X-rays were available for 88 (89%) of the axSpA patients, 66% of whom were classified as having radiographic axSpA.
SpA was equally frequent in patients experiencing the first episode of AAU and in patients with recurrent disease. In our cohort, AAU patients with and without underlying SpA showed no differences in their ophthalmologic examination. In multivariable logistic regression analysis, psoriasis (OR 12.5 [95%CI 1.3-120.2]), HLA-B27 positivity (OR 6.3 [95%CI 2.4-16.4]), elevated CRP (OR 4.8 [95%CI 1.9-12.4]) and male sex (OR 2.1 [95%CI 1.1-4.2]) were associated with SpA presence.

Table 1. Parameters associated with the presence of spondyloarthritis in patients with acute anterior uveitis.

	univariable		multivariable	
	OR	95%CI	OR	95%CI
Psoriasis (ever)	14.6	(1.9; 112.4)	12.5	(1.3; 120.2)
HLA-B27 positivity	6.2	(2.7; 14.6)	6.3	(2.4; 16.4)
Elevated CRP (≥ 5 mg/l)	4.1	(1.8; 9.0)	4.8	(1.9; 12.4)
Male sex	2.2	(1.2; 4.0)	2.1	(1.1; 4.2)
Inflammatory back pain (ASAS definition)	2.1	(1.2; 3.9)	1.9	(0.9; 4.0)
Any peripheral manifestation (ever)	1.9	(1.1; 3.5)	1.9	(0.9; 3.8)
Age in years	1.0	(1.0; 1.0)	1.0	(1.0; 1.0)

Univariable and multivariable logistic regression analyses. ASAS Assessment of SpondyloArthritis international Society; CRP C-reactive protein; OR odds ratio; CI confidence interval.

The Dublin Uveitis Evaluation Tool showed higher specificity for SpA recognition than the ASAS referral tool (42% vs. 28%), which had slightly higher sensitivity (78% vs. 80%). However, both referral strategies would have missed more than 20% of SpA patients.

Conclusion: We revealed a high prevalence of overall and previously undiagnosed SpA in AAU patients. Therefore, we propose rheumatologic evaluation for all AAU patients with musculoskeletal symptoms. Rheumatologists should consider that SpA in AAU patients might present "atypically" with back pain starting after 45 years and lasting shorter than 3 months.

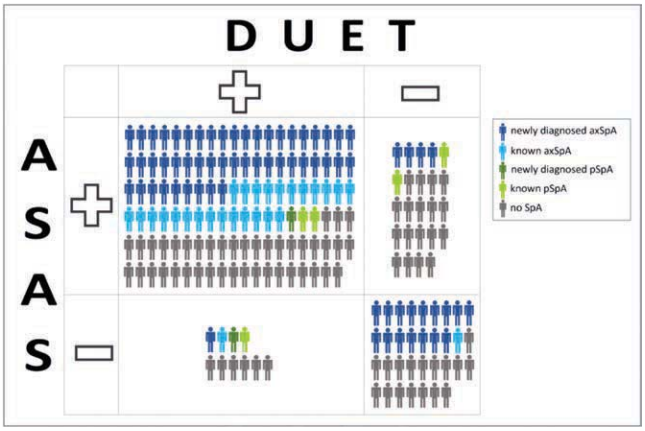

Figure 1. Performance of Referral Strategies in Patients with Acute Anterior Uveitis. Dublin Uveitis Evaluation Tool (DUET) and an ASAS-based referral tool (ASAS). + respective tool fulfilled, - not fulfilled. ASAS Assessment of SpondyloArthritis international Society; AxSpA axial spondyloarthritis, pSpA peripheral spondyloarthritis.

Acknowledgements: The authors would like to thank the rheumatologists S. Lüders, B. Muche and A.-K. Weber for participating in the clinical data acquisition; and A. Langdon and L. Meinke for their support monitoring and coordinating this study. Furthermore, we are grateful to all participating ophthalmologists who included their patients in this study and to all patients. AB0827 FREQUENCY OF SEXUAL DYSFUNCTION AXIAL SPONDYLOARTHRITIS, SANTO DOMINGO, DOMINICAN REPUBLIC

A. Cornelio[1], T. Polanco Mora[1], J. Santana Peralta[1], R. A. Alvarez Santana[1], D. Garcia[1], E. Rodriguez Bautista[1], I. Paulino[1], L. Concepción Sanchez[1], I. Mercedes[1], T. Valdez[1], A. Feriz[1], R. Muñoz Louis[1]. [1]*Hospital Docente Padre Billini, Reumatología, Santo Domingo, Dominican Republic*

Background: Axial spondyloarthritis (SpAa) is a chronic inflammatory disease of unknown etiology that affects the axial skeleton, affecting peripheral joints, entheses and extra-articular structures, with a prevalence of 0.5-1% associated with HLA-B27+.[1] The impact of Chronic disease is often multifactorial that affects physical, hormonal and psychological alterations, leading to problems of sexuality.[2] The CSFQ-14 (Changes in Sexual Functioning Questionnaire), evaluates changes in sexual functioning due to disease and/or or treatment in 5 domains with a score range of 14-70; cut-off point indicating sexual dysfunction <41 men and <47 women.[3,4]

Objectives: To evaluate the frequency and degree of sexual dysfunction in patients with axial spondyloarthritis.

Methods: Prospective, observational, cross-sectional study. of the SpAa cohort of the Hospital Docente Padre Billini rheumatology service Patients were interviewed in July 2021. Inclusion criteria: > 18 years, diagnosis of SpAa according to the ASAS 2009 classification criteria, at least 1 sexual. Exclusion criteria: previous diagnosis of another autoimmune disease, depression, diabetes mellitus (DM), treatment with antidepressants, antiepileptics, narcotics. Measurement of: CSFQ-14, BASDAI. Statistical analysis was performed with the Pearson correlation (r_P) with p>0.05. The data was analyzed by SPSS V23.

Results: Of the SpAa cohort, 87 met the inclusion criteria. Male 67.8% (59), female 32.2% (28), mean age 45.7±8 years, mean diagnosis 7, married 67.8%(59), single 24.1%(21), widowed 8%(7), HLA-B27+51.1 %, hypertension 8% (7), diabetes 6.8% (6), dyslipidemia 10.3%(9), smokers 4.5%(4), 100% (87) bDMARD´s, 13.6% (12) combined with csDMARD´s, Frequency of sexual dysfunction 24.1%(21). Sexual dysfunction in women 6.9% (6) and men 17.2% (15) by CSFQ-14. Global domains: Desire/Interest 2.3% (2), Desire/Frequency 2.3% (2), Pleasure 5.7% (5), Arousal 2.3% (2), Orgasm/Completion 2.3% (2). Female: Desire/interest 6.8% (4), desire/Frequency 3.4% (2), pleasure 8.5% (5). Male: Desire/interest 3.4% (2), desire/Frequency 3.4% (2), pleasure 8.5% (5), arousal 6.8% (4), orgasm/completion 3.4% (2). Correlation CSFQ-14 domains with BASDAI: r_p =. -0.088 p>0.05: Desire/interest dysfunction: inactive BASDAI 71.4% (15). Desire/frequency: inactive BASDAI 90.5% (20). Pleasure: inactive BASDAI 23.8% (5), active 23.8% (5). Excitation: inactive BASDAI 14.3% (3). Orgasm/completion> inactive BASDAI 90.5% (20)

Conclusion: The study showed a low frequency of sexual dysfunction, being more frequent in males. The greatest dysfunction was found in the pleasure domain in both sexes. A statistically significant inverse linear association was found between sexual dysfunction and disease activity.

AB0828 DIFFERENCES IN EARLY-ONSET VS. LATE-ONSET PSORIATIC ARTHRITIS: DATA FROM THE RESPONDIA AND REGISPONSER STUDIES.

M. Á. Puche Larrubia[1], M. L. Ladehesa Pineda[1], M. D. López Montilla[1], E. Collantes Estevez[1], C. López-Medina[1,2]. [1]*Reina Sofía University Hospital, Rheumatology, Cordoba, Spain;* [2]*Cochin Hospital, Rheumatology, Paris, France*

Background: The prevalence of late-onset psoriatic arthritis (PsA) is increasing in parallel with the progressive aging of the population. The elderly population presents a greater functional deterioration and a greater number of comorbidities than the young people. With this study we aim to find clinically relevant differences to predict the evolution and prognosis of the disease depending on the onset of the symptoms to carry out a more exhaustive follow-up.

Objectives: To evaluate the association of the age at onset of PsA symptoms with the characteristics and burden of the disease.
Methods: Observational study that includes a subgroup of 231 patients with Psoriatic Arthritis (PsA) from the REGISPONSER study (Registry of Spondyloarthritis of Spanish Rheumatology) and the RESPONDIA study (Ibero-American Registry of Spondyloarthropathies). Patients with less than 10 years of disease duration (since the first symptom) were selected so that the sample was homogeneous. Patients were divided into two groups according to the age of PsA onset (early-onset: ≤40 years old and late-onset: ≥60 years old). The characteristics and burden of the disease were compared using the Student's t-test/ Mann-Whitney U test for quantitative variables or using the chi-square/Fisher test for qualitative variables.
Results: 411 patients were included [early-onset 179 (77.5%); late-onset 52 (22.5%)]. There was a higher percentage of men in the late-onset group compared to the early-onset group [94 (62.3%) vs. 38 (86.4%), p = 0.003]. The diagnostic delay was shorter in those whose onset of the disease was late [1.5 (2.7) vs 4 (7.7), p=0.036], as well as the duration of the disease [2.9 (2.4) vs 4.2 (2.7), p= 0.012]. A lower presence of sacroiliitis was found in patients with late-onset PsA [6 (12.2%) vs 58 (32.6%), p=0.005] as well as enthesitis [5 (9.8%) vs 44 (24.6%), p =0.023]. Regarding the comorbidities, there was a higher frequency of heart disease among patients with late-onset PsA [4 (7.8) vs 0 (0), p=0.000]. No statistically significant differences were found between kidney and lung disease. Regarding the outcome measures, the BASFI score was higher in the late-onset group [3.3 (2.5) vs. 2.2 (2.2), p=0.002]. The late-onset group had a lower FSF12 component [34.6 (8.7) vs. 38.7 (10.5), p = 0.001]. The radiographic indices measured by BASRI showed worse results in those patients with late-onset disease both in the spine [2.9 (3) vs 1.6 (2), p=0.020] and in the total BASRI [3.4 (3 .4) vs 1.9 (2.4), p=0.012].
Conclusion: Our study suggests that the age of onset of PsA was associated with the different characteristics of the disease. Patients with late-onset PsA were more frequently males, showed worse functionality and more structural damage in comparison with early-onset PsA. Sacroiliitis and enthesitis were found less frequently in the late-onset group. Quality of life, disease activity and treatments taken were not associated significantly with age of onset.

Table 1. Description of different characteristics across two groups: early and late onset

	Early-onset N=179 n (%)=77.5	Late-onset N=52 n (%)=22.5	p-value
Sex (male)	94 (62.3)	38 (86.4)	0.003
Age (SD)	38.7 (9.3)	71.3 (7.5)	0.000
Enthesitis	44 (24.6)	5 (9.8)	0.023
Dactilytis	36 (20.1)	9 (17.6)	0.695
Sacroiliitis	58 (32.6)	6 (12.2)	0.005
Diagnostic Delay, mean (SD)	4 (7.7)	1.5 (2.7)	0.036
Disease Duration, mean (SD)	4.2 (2.7)	2.9 (2.4)	0.012
Arthritis (lower limbs)	118 (65.9)	33 (64.7)	0.872
Arthritis (upper limbs)	82 (45.8)	31 (60.8)	0.059
BASDAI, mean (SD)	3.9 (2.5)	3.8 (2.4)	0.932
BASFI, mean (SD)	2.2 (2.2)	3.3 (2.5)	0.002
ASDAS, mean (SD)	2.3 (1.1)	2.3 (0.9)	0.894
FSF12, mean (SD)	38.7 (10.5)	34.6 (8.7)	0.001
MSF12, mean (SD)	47.7 (10.6)	49.3 (9.2)	0.341

AB0829 BODY COMPOSITION IN SPONDYLOARTHRITIS: IS THERE ANY IMPACT ON DISEASE ACTIVITY?

F. Chennouf[1], H. Azzouzi[1], H. Boutaibi[1], I. Linda[1]. [1]*Mohamed I University, Rheumatology department, Oujda, Morocco*

Background: The relationship between obesity and inflammation is bidirectional. Thus, obesity may influence clinical response to biological treatment.
Objectives: To investigate the association of obesity and body composition with disease activity in patients with spondyloarthritis (SA).
Methods: This is a cross-sectional study designed on spondyloarthritis patients diagnosed according to ASAS 2009 classification. Bath ankylosing spondylitis disease activity index (BASDAI), ankylosing spondylitis disease activity score (ASDAS), Bath ankylosing spondylitis functional index (BASFI), and Bath ankylosing spondylitis metrology index (BASMI) were assessed. Obesity was evaluated clinically by body mass index (BMI) and waist circumference (WC). Total body composition, total and regional fat and lean mass, android/gynoid ratio (A/G), fat mass index (FMI), fat-free mass index (FFMI) were measured by dual-energy X-ray absorptiometry (DXA) and reported as absolute values. Blood samples were collected to determine C-reactive protein serum (CRP) levels for each patient. Socio-demographic data, comorbidities, physical activity, disease-related variables (duration, characteristics, and drugs) were also collected. Correlations and regressions were made by SPSS.20.
Results: Forty-four SA participants (65.9% male) were enrolled. Their mean age was 39.82 ± 14.20 years and the mean ASDAS CRP was 1.42 ± 0.86. Patients under biologic disease-modifying antirheumatic drugs (bDMARDs) showed lower FMI (p = 0.011), percentage of fat mass (p = 0.008), and gynoid fat mass (p = 0.01). Correlations between ASDAS using CRP, total body fat mass, FMI, FFMI, visceral adipose tissue (VAT), appendicular lean height, and the A/G ratio were not statistically significant. Nevertheless, ASDAS CRP was positively correlated to total body mass (r = 0.352; p = 0.019), gynoid fat mass (r = 0.329, p = 0.029), and android fat mass (r = 0.323, p = 0.032). The association of disease activity and gynoid fat mass persisted after adjustment on disease duration and age (ß = 0.355, 95%IC [0.00003; 0.0003], p = 0.021).
Conclusion: Gynoid and android fat mass affected disease activity in our SA patients. However, FMI, visceral fat, and skeletal muscle mass showed no significant association with disease activity.

AB0830 TURKISH TRANSLATION AND CROSS-CULTURAL ADAPTATION OF THE MODIFIED SHORT QUESTIONNAIRE TO ASSESS HEALTH-ENHANCING PHYSICAL ACTIVITY (MSQUASH).

G. Ayan[1], S. Ramiro[2,3], F. M. Pimentel-Santos[4], A. Spoorenberg[5], S. Arends[5], L. Kılıç[1]. [1]*Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey;* [2]*Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands;* [3]*Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands;* [4]*NOVA Medical School, Universidade Nova De Lisboa, Department of Rheumatology, LISBOA, Portugal;* [5]*University Medical Center Groningen, University of Groningen, Department of Rheumatology & Clinical Immunology, Groningen, Netherlands*

Background: The Short Questionnaire to Assess Health-enhancing physical activity (SQUASH) is a validated tool measuring the duration, frequency, and intensity of physical activity. The modified version of the SQUASH (mSQUASH) has been developed, in collaboration between spondyloarthritis (SpA) experts and axial (ax)SpA patients, to better address the needs of these patients in the assessment physical activity (1).
Objectives: To translate and cross-cultural adapt the mSQUASH into Turkish as well as its cognitive debriefing to test the conceptual equivalence of the translated version among patients with axSpA.
Methods: The mSQUASH was translated into Turkish by 2 bilingual translators, native speakers of Turkish one from medical (informed) and the other is without medical background (uninformed). The consensus on forward-translation was reached by the team included two rheumatologist (GA and LK) and the translators. Backward-translation into Dutch was performed by 2 bilingual translators, native speakers of Dutch and who were blinded to the original mSQUASH version. After the review of the Turkish version by an expert committee that included translators, two patients and the research team a pre-final version was prepared. This version was used in a field-test with cognitive debriefing and involved a sample of 10 axSpA patients (7 radiographic- and 3 non-radiographic axSpA patients) with variation in gender, age, disease duration, and educational background. The final Turkish mSQUASH version was reached after the patients were interviewed to check understandability, interpretation and cultural relevance of the translation. The whole process was performed according to the Beaton method (Figure 1) (2).

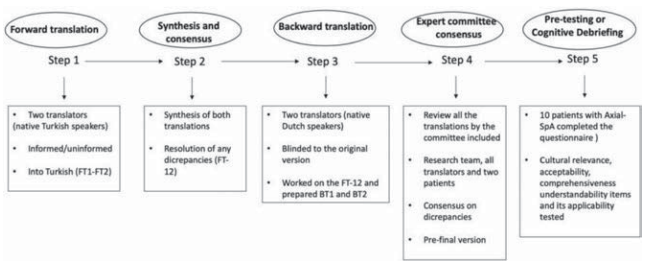

Figure 1. Flow-chart of the translation and cross-cultural adaptation process

Results: After the forward-backward translation process, small incompatibilities were resolved during the expert committee meeting. For example: `Ander transport (heen en terug)` was translated as `Diğer hedeflere (gidip gelmek)`. The meaning in English is `Other transport (round trip)'. This item questions the way of going to other places and the discrepancy raised whether to use `transportation` or the `target` as the title. To make it culturally adaptable consensus reached to use a word equivalent to `the target` which is semantically equal to the Dutch version. A total of 10 patients with axSpA [7 females, mean (SD) age of 38 (10)] participated in the field test. Mean (SD) time to complete the mSQUASH was 6.1 (2.4) minutes. Cognitive debriefing showed that items of the mSQUASH are clear, relevant, understandable, and easy to complete. None of the patients indicate any important aspect of physical activity that is missing from the questionnaire items. During the cognitive debriefing, 2 patients suggested a change in the wording of one item to make it more suitable to the Turkish culture. This item inquires after sport activities and patients raised the concern that the example activities, ice-skating, tennis, handball are not culturally suitable. According to their comments these items were replaced by other examples such as football.

Conclusion: The final Turkish version of the mSQUASH showed acceptable linguistic validity and can be used in both clinical practice and for research purposes. However, to implement the Turkish version of the mSQUASH, further assessment of its psychometric properties (validity and reliability) is needed.

AB0831 THE QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS EVALUATED UNDER SF-36 QUESTIONNAIRE, ITS CONNECTION WITH THE DISORDER OF BONE MINERAL DENSITY

O. Pavliuk[1], S. Shevchuk[1], O. Zviahina[1], T. Smaha[1]. [1]*National Pirogov Memorial Medical University, Vinnytsya, Internal Medicine Chair # 2, Vinnytsia, Ukraine*

Background: In recent time, the peculiarities of the quality of life in patients with many chronic diseases, which progress unaffectedly and lead to the restriction of all components of normal life, are being actively studied. Ankylosing spondylitis (AS) is no exception, it is the second most common inflammatory rheumatic disease, characterized by predominant lesions of the spine and sacroiliac joints. Rapid progression of the disease, constant pain in the joints, as well as in the periarticular tissues and muscles lead to significant functional limitations, gradual loss of mobility of the spine and deterioration of the quality of life. However, impaired quality of life can be caused not only by the manifestations of the underlying disease, but also by the presence of complications observed in the early stages of the disease. Thus, it is the decrease in bone mineral density and the development of osteoporosis that cause pathological fractures and, as a result, lead to early disability, reduced duration and quality of life. However, clear data on the peculiarities of the quality of life in patients with AS suffering from impaired bone mineral density have not been found to date.

Objectives: To investigate quality of life indicators using the SF-36 questionnaire in men with AS and to assess their relationship with the structural and functional state of bone tissue.

Methods: 105 patients with AS aged 40,7 ± 0,8 years were examined, the average duration of the disease was 8,7 ± 0,5 years. The control group included 25 healthy individuals of appropriate age and sex. All patients were diagnosed with AS according to ASAS criteria (2009). The SF-36 questionnaire was used to characterize the quality of life. Bone mineral density was measured by dual-energy X-ray absorptiometry on a Hologic Discovery Wi apparatus (S/N 87227).

Results: The analysis of quality of life according to the SF-36 questionnaire showed that patients with AS had significantly lower indicators of both physical (37,3 ± 1,5 points) and mental (44,2 ± 1,7 points) components of health in comparison with the control group (99,1 ± 0,3; 97,4 ± 0,7 points, respectively). Among the subscales that form the total physical component, the lowest indicators were recorded in role physical functioning (RP) (14,0 ± 3,1 vs. 99,0 ± 0,6 points) and pain (P) (37,2 ± 1,6 vs. 100,0 ± 0,0 points). And according to the subscales assessing the mental component of health, the most significant differences were found for the indicator of role emotional functioning (RE), which was 4,5 times lower than in the control group (22,2 ± 3,9 vs. 98,2 ± 0,7 points respectively).

The study did not reveal significant differences in quality of life in case of low bone mineral density (BMD). The average levels of total physical and mental components of health in patients with BMD (35,2 ± 2,4; 42,2 ± 3,2 points) were only 12,2 – 7,1% lower than in patients with preserved BMD (40,8 ± 2,7; 46,4 ± 2,8 points, respectively). In the group of patients with osteoporosis (Z-score -2,7 ± 0,1) there was a tendency to reduce the physical component due to the indicator of general health (GH), which was significantly lower (35,8 ± 2,1 points) than in patients with preserved BMD (43,4 ± 2,7 points).

Conclusion: In men with AS, there is a significant decrease in the total physical and mental components of health according to the SF-36 questionnaire which do not have a clear relationship with structural and functional state of bone tissue.

AB0832 NONINFECTIOUS UVEITIS FROM THE RHEUMATOLOGIST'S PERSPECTIVE: PATTERNS FROM A SINGLE TERTIARY REFERRAL RHEUMATOLOGIC CLINIC IN ITALY

P. Triggianese[1], M. Fatica[1], A. D'antonio[1], E. Cela[1], C. Minerba[1], G. Raffone[1], S. Modica[1], B. Kroegler[1], P. Conigliaro[1], E. Greco[1], A. Bergamini[1], M. S. Chimenti[1]. [1]*Rheumatology, Allergology and Clinical Immunology, Department of "Medicina dei Sistemi", University of Rome Tor Vergata, Rome, Italy*

Background: The noninfectious uveitis (NIU) is the intraocular inflammation that can be the first or one of extra-articular manifestations of systemic inflammatory rheumatic diseases mainly including spondyloarthritis (SpA), Behcet's disease (BD) and juvenile idiopathic arthritis (JIA)[1]. Rheumatologists are often asked to help in diagnostic assessment and relatively targeted treatment of particular subsets of NIU[2].

Objectives: To explore patterns and treatments of NIU from a population-based single-center study carried out in a Tertiary Referral Rheumatologic Clinic.

Methods: Selection criteria of this cross-sectional descriptive study consisted of having a diagnosis of NIU in an age of onset ≥16 years old regardless of its etiology among patients who were admitted (February 2018-December 2021) to Rheumatologic Clinic of Tor Vergata University Hospital (Rome, Italy). Clinical data were collected from medical records: gender, age of onset and admission, recurrence and anatomic patterns, HLA-B27 susceptibility, associated rheumatologic diagnosis and treatments were investigated.

Results: We included 100 patients with 58% women. Median age at NIU onset was 39.6±15 years whereas patients were 44±14 years old at the first referral, without gender-difference. NIU represented the main reason of referral in 22% of cases. Anterior uveitis occurred in 73% of patients and posterior in 25%; intermediate (IU) and panuveitis (PanU) were isolated cases. The prevalent course was acute (57%) followed by recurrent (31%) and chronic (12%); both eyes were involved in 39 patients. Almost half of NIU was associated with SpA including IBD-SpA (20%), ankylosing spondylitis (AS, 18%), and Psoriatic Arthritis (12%). A diagnosis of BD was reported in 14% of NIU while Rheumatoid Arthritis and other systemic autoimmune diseases occurred in 11% and 12%, respectively. Idiopathic NIU and JIA-NIU constituted the lowest prevalence (8% and 5%, respectively). A higher prevalence of BD-NIU and AS-NIU resulted in males than females ($p<0.01$ and $p<0.05$, respectively). One-third of the NIU cohort (34.3%) showed $B27^+$: a higher percentage of unilateral ($p=0.09$) and acute course ($p=0.02$) occurred in $B27^+$ than $B27^-$. AS was prevalent in $B27^+$ NIU than $B27^-$ ($p<0.00001$) while IBD-SpA and BD were mainly present in $B27^-$ NIU than $B27^+$ ($p=0.09$ and $p=0.04$ respectively). The only two cases of IU and PanU were both idiopathic $B27^-$ NIU. At the onset of NIU, most patients were not on systemic treatment (68%): remaining cases were on cDMARDs (22%) and bDMARDs (10%). During rheumatologic follow-up, 80% of patients changed therapies: cDMARDs were added in 43.7% patients while bDMARDs were started in 40%. Systemic steroids were added in the remaining 16.3% of patients. At the latest follow-up (follow-up-time 33±28 months), 86% of patients had achieved remission of NIU while 14% had recurrence of active uveitis.

Conclusion: Findings from this population-based study describe a representative estimate of extent and patterns of NIU in an Italian adult cohort from a single Rheumatologic Clinic and document that Rheumatologic referral might dramatically impact treatment strategies in NIU.

AB0833 **EPICARDIAL FAT THICKNESS: A NOVEL MARKER OF SUBCLINICAL ATHEROSCLEROSIS IN SPONDYLOARTHRITIS PATIENTS**

A. Ben Tekaya[1,2], T. Mehmli[1,2], I. Ben Mrad[2,3], K. Mzoughi[2,3], O. Saidane[1,2], S. Bouden[1,2], R. Leila[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], L. Abdelmoula[1,2]. *[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; [2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; [3]Habib Thameur Hospital, Cardiology Department, Tunis, Tunisia*

Background: Chronic inflammatory process seems to be the underlying cause contributing to atherosclerosis in spondyloarthritis. Epicardial adipose tissue (EAT) which is the accumulation of visceral fat between the myocardium and the visceral layer of pericardium, is actually considered a novel cardiometabolic risk predictor (1). Recent studies have shown its association with the development of coronary atherosclerosis.
Objectives: The aim of our study was to assess the epicardial fat thickness (EFT) in patients with spondyloarthritis (SpA) in comparaison with healthy subjects.
Methods: We performed a prospective study including 47 patients meeting ASAS 2009 criteria for SpA compared to 47 healthy controls matched for age, gender and body mass index (BMI). Patients with history of cardiovascular risk factors or diseases were not included. Sociodemographic, clinical, biological and radiographic features related to the disease were recorded. All subjects underwent transthoracic echocardiography with measurement of EFT.
Results: SpA group included 33 men and 14 women, with a median age of 36 years (IQR: 28-46). Median BMI was 24.5 kg/m^2 (IQR: 20.7-26.8). Median systolic (SBP) and diastolic (DBP) blood pressure were respectively 121 mmHg (IQR: 110-130) and 71 mmHg (IQR: 67-78). Median disease duration was 11 years (IQR: 5-16). Median disease activity scores BASDAI and ASDAS-CRP were 2.6 (IQR: 1.8-3.8) and 2.18 (IQR: 1.62-2.91) respectively. Median CRP level was 6.45 mg/l (IQR: 1.5-19.9). Median BASFI and BASMI were 3 (IQR: 1.5-5.1) and 1.5 (IQR: 0-4) respectively. Coxitis was found in 53% of patients. SpA patients received: NSAIDs (92%), csDMARDs (51%) and TNF inhibitors (38 %). EFT was significantly increased in SpA patients compared with healthy controls; median EFT value was 3.1 mm (IQR: 2.5-4) versus 2.4 mm (IQR: 2-3) (p=0.001).
Conclusion: As an early marker of atherosclerosis, EFT was significantly higher in SpA patients, supporting clinical evidence of increased cardiovascular risk in SpA. Thus, more studies that involve larger samples should be conducted, using EFT to cardiovascular risk stratification in SpA.

AB0834 **EPICARDIAL FAT THICKNESS IS ASSOCIATED WITH PATIENT-REPORTED OUTCOMES IN SPONDYLOARTHRITIS**

T. Mehmli[1,2], A. Ben Tekaya[1,2], I. Ben Mrad[2,3], O. Saidane[1,2], R. Leila[1,2], S. Bouden[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], L. Abdelmoula[1,2]. *[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; [2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; [3]Habib Thameur Hospital, Cardiology Department, Tunis, Tunisia*

Background: Epicardial adipose tissue (EAT) is a metabolically active visceral fat located between the myocardium and the visceral pericardium. Increased epicardial fat thickness (EFT) has been shown as a novel cardiovascular risk factor in some recent studies (1), (2) and have been suggested as a marker for cardiovascular risk stratification. Few studies have studied EFT in patients with SpA.
Objectives: The aim of our study was to assess the relationship between EFT and Patient-Reported Outcomes (PROs) in SpA patients.
Methods: We conducted a case control study over a 12 months period. Patients diagnosed with SpA according to ASAS 2009 criteria and age and sex matched controls were included. All subjects were aged less than 50 years old and without cardiovascular risk factors. Clinical data related to the disease were collected. Patient-Reported Outcomes (PROs): morning stiffness duration, nocturnal awakenings, pain visual analog scale (VAS) and patient global assessment (PGA) were recorded. BASG-s (Bath Ankylosing Spondylitis-Global score) was also raised. All patients underwent echocardiographic examination with measurement of EFT.
Results: We included 94 subjects (47 patients and 47 controls), sex ratio was 2.35, and median age was 36 years (IQR: 18-32). Median disease duration was 11 years (IQR: 5-16). Median disease activity scores BASDAI and ASDAS-CRP were 2.6 (IQR: 1.8-3.8) and 2.18 (IQR: 1.62-2.91) respectively. Regarding Patient-Reported Outcomes (PROs); median duration of morning stiffness was 5 minutes (IQR: 0-180) and median number of nocturnal awakenings was 0 (IQR: 0-2). Median VAS pain and median PGA were 50 (IQR: 30-60) and 40 (IQR: 30-60), respectively. Median EFT was significantly increased in SpA patients 3.1 mm (IQR: 2.5-4) compared with healthy controls 2.4 mm (IQR: 2-3) (p=0.001). EFT was positively correlated with VAS pain (p=0.012; r=0.363) and BASG-s (p=0.025; r=0.327). No significant association was found between EFT and Morning stiffness duration (p=0.164; r=0.206), Nocturnal awakenings (p=0.463; r=0.11) and PGA (p=0.07; r=0.267). In multivariate linear regression analysis, pain visual analog scale was found to be independently associated with EFT (B=0.126; 95% Confidence Interval: 0.017-0.236; p=0.025).
Conclusion: EFT measurement as an early marker of atherosclerosis was associated with pain and BASG score.

AB0835 **INFLUENCE OF SOCIODEMOGRAPHIC PARAMETERS ON ATHEROSCLEROSIS IN SPONDYLOARTHRITIS PATIENTS**

A. Ben Tekaya[1,2], E. Hannech[1,2], A. Fendri[2,3], S. Boukriba[2,3], O. Saidane[1,2], R. Leila[1,2], S. Bouden[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], H. Mizouni[2,3], L. Abdelmoula[1,2]. *[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; [2]Faculty of medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; [3]Radiology Department, La Rabta Hospital, Tunis, Tunisia*

Background: The increased risk of atherosclerosis is most likely multifactorial in patients with Spondyloarthritis (SpA). Ultrasound measurements of Intima Media Thickness and (IMT) Flow Mediated Dilation (FMD) can be used to investigate infra-clinical atherosclerosis [1].
Objectives: We aimed to investigate the relationship between socio-demographic parameters in SpA patients with the IMT and FMD.
Methods: It was a case control study conducted over a period of 12 months and including patients with SpA, aged less than 50 years old and without cardiovascular disease, and age and sex matched healthy controls. Sociodemographic and clinical features were recorded in our patients. All subjects had Doppler ultrasound with measurement of carotid IMT and FMD.
Results: There were 47 SpA patients and 47 controls. The median age was 36 years for patients group (18-50) and 32 years for controls (18-50). For the patients group: there were 14 female (28.8%) and 33 male (70.2%). The median duration of the disease was 11 years (1-32). For the marital status, 55.32% were single, 40.43% were married, and 4.26% were divorced. Thirty seven patients (79%) were living in an urban area. For the education level, 17% had a primary education, 64% a secondary education, and 19% were university graduates. Occupational status was recorded as follows: 17% unemployed, 11% students, and 72% employed. The median IMT was 0.55 millimeters (mm)(0.32 -0.83). We found a higher mean, right and left IMT (p<0.0001) in SpA patients compared with controls. Carotid IMT was positively correlated with age (p<0.0001; r=**0,578**). The analysis by 10-year age group showed a statistically significant difference in the IMT between patients (p=0.004). Median IMT increased significantly with age (every 10 years). IMT was significantly associated with occupational status (p=0.036); unemployed patients had the higher IMT (0.58 mm). The median FMD was 14.6% (2-32%). A significantly lower FMD (p=0.008) was noted in SpA patients compared with controls. FMD were negatively correlated with age (p=0.017; r=**-0,347**). FMD was also associated with sex (p=0.036), and with the marital status (p=0.013). The median FMD was significantly lower in male 13.8% (IQR;8-17.5) vs 22.5% (IQR; 10-25), and married patients (10%; 6-18). There was no significant difference with the other sociodemographic variables (living environment, educational level, occupation). In multiple regression analysis, age was an independent predictor of increased carotid IMT (B=0.004; T=3.146; p=0.003; CI 95% 0.001-0.006].
Conclusion: Our study showed that subclinical atherosclerosis in patients with SpA was strongly associated with age, although we included young patients with a limit age at 50 years.

MICRONUTRIENTS DEFICIENCIES IN ENTEROPATHIC SPONDYLOARTHRITIS: THE INTERPLAY WITH METABOLISM AND HLA-B27 IN DISEASE PHENOTYPE

P. Triggianese[1], A. D'Antonio[1], E. Manna[1], M. Fatica[1], G. Raffone[1], P. Conigliaro[1], E. Lolli[2], E. Calabrese[2], L. Biancone[2], A. Bergamini[1], M. S. Chimenti[1]. *[1]Rheumatology, Allergology and Clinical Immunology, Department of "Medicina dei Sistemi", University of Rome Tor Vergata, Rome, Italy; [2]Gastroenterology Unit, Department of "Medicina dei Sistemi", University of Rome "Tor Vergata", Rome, Italy*

Background: Micronutrients play immunomodulatory roles through interactions with innate and adaptive immunity influencing the pro/anti-inflammatory balance. Serum levels depend on multiple factors such as gender, nutrition, and gut microbiome. Micronutrient deficiencies (MNDs) are associated with a pro-inflammatory status and co-morbidities in patients with chronic inflammatory diseases. No studies focused on potential interplay between MNDs and disease phenotype in Enteropathic Spondyloarthritis (ESpA) in which the combination of SpA with inflammatory bowel diseases (IBD) might dramatically affect micronutrients status.
Objectives: We analysed the occurrence of anemia (Hb ≤12 g/dl) and deficiencies of ferritin (Fe, ≤15 ng/dL), vitamin D [25(OH)D, ≤20 ng/ml], vitamin B12 (VB12, ≤200 pg/ml), and folic acid (FA, ≤ 4ng/mL) in ESpA patients. The interplay of MNDs with gender, metabolic parameters, HLA-B27 susceptibility, type of SpA and IBD, disease activity, and treatments was also explored.
Methods: Selection criteria of this cross-sectional descriptive study consisted of having a diagnosis of ESpA, regardless of its type, in an age of ESpA onset ≥18 and ≤80 years, among patients who were admitted to a combined Gastro-Intestinal and RHEumatologic "GI–Rhe" clinic (Tor Vergata University Hospital, Rome, Italy). Exclusion criteria were represented by active IBD, pregnancy or lactation, kidney and/or liver failure, alcohol abuse, neoplasia, ongoing supplementations. SpA disease activity was assessed by ASDAS-CRP and functional status by HAQ-S. All the enrolled patients underwent blood chemistry analysis to determine parameters including CRP, uric acid (SUA), Fe, 25(OH)D, VB12, FA, and HLA-B27 typing.
Results: We included 164 patients comprising 109 females and 55 age-matched males. A diagnosis of Crohn's Disease (CD) occurred in 70% of patients while Ulcerative Colitis (UC) represented a third of the cohort. Peripheral (per) and axial (ax) SpA were equally distributed (50%*vs*50%). Patients with ax-SpA displayed a greater prevalence of CD than UC (p=0.02) while UC was prevalent in per-SpA (p=0.02). $B27^+$ was revealed in 19% of our cohort: $B27^+$ patients had a higher prevalence of ax-SpA (p=0.016) and a more severe disease activity (p=0.02) than $B27^-$. Moreover, B27 positivity and uveitis were prevalent in ax-SpA compared to per-SpA (p=0.009 and p=0.01, respectively). According to univariate analysis, males showed higher SUA (P=0.004) and BMI (p=0.03) than females. Conversely, females showed a higher prevalence of anemia than males (p=0.002). A third of ESpA cohort showed FA (31.6%) and 25(OH)D (27.8%) deficiency while VB12 defect was less frequent (18.2%) and was registered almost entirely in $B27^-$ ESpA (p=0.02). CD-ESpA showed a lower mean VB12 (p=0.04) and a higher prevalence of ocular/skin co-morbidities (p=0.02) and ax-SpA (p=0.04) than UC-ESpA. Accordingly, CD-ESpA were on bDMARDs more than UC-ESpA (p=0.04).
Conclusion: Our findings document that FA and 25(OH)D deficiencies represent the main MNDs among ESpA patients while VB12 seems to be deficient mostly in patients with CD and almost exclusively in $B27^-$ patients. Otherwise, $B27^+$ in ESpA results to be associated mainly with disease phenotype and treatments. In ESpA, the gender of patients appears to impact principally on dysmetabolism highlighting the role for nutritional interventions particularly in males. The interplay of MNDs with B27 and dysmetabolism in ESpA deserves further investigations also taking into account CD/UC localization and behavior.

AB0837

NEUROPATHIC PAIN COMPONENT AND ITS RELATIONSHIP WITH QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

I. Kedyk[1], M. Stanislavchuk[1]. *[1]National Pirogov Memorial Medical University, Vinnytsya, Department of Internal medicine №1, Vinnytsya, Ukraine*

Background: Ankylosing spondylitis (AS) is a chronic systemic inflammatory disease of the connective tissue[1]. AS often affects men aged 20-40 years and characterized by a progressive affect with rapid loss of work ability, deteriorating quality of life and reducing its duration. Quality of life is one of the markers of disease progression and evaluation of the treatment efficacy. The leading clinical symptom of AS is chronic pain, which may have not only nociceptive but also neuropathic component, which is not taken into account in the treatment of this category of patients, while pain is one of the main factors in reducing quality of life.
Objectives: To investigate the prevalence of the neuropathic pain component (NPC) and its relationship with the quality of life in patients with AS.
Methods: AS patients was diagnosed according to the New York 1984 classification criteria. The NPC was assessed by the Leeds Assessment of Neuropathic Symptoms and Signs (LANSS) and The Douleur Neuropathique 4 (DN4). Quality of life was assessed by the Ankylosing Spondylitis Quality of Life (ASQoL). We examined 142 patients with AS (79.5% of men) in the rheumatology center from 2016 to 2021. The mean age was (M±SD) 41.9 ± 9.7 years, the disease duration was 5.7 ± 4.6. Statistical analysis performed by the Microsoft Excel and IBM Statistics SPSS 20.
Results: NPC assessed by the LANSS (≥ 12) was found in 31% of patients, by the DN4 (> 4) in 38%. ASQoL in patients with AS with NPC by the LANSS was 12.27 ± 4.27, by the DN4 - 11.64 ± 4.19, which was significantly higher than in patients with AS without NPC: LANSS (7.97 ± 3.76), DN4 (7.86 ± 3.88). ASQoL had a strong direct correlation with LANSS (0.561; p <0.01) and DN4 (0.478; p <0.01) that means - presence of neuropathic pain substantially effects quality of life in patients with AS.
Conclusion: NPC is found in 31% - 38% of patients with AS. It is established that the presence of the neuropathic pain component significantly reduces the quality of life in patients with AS, which should be taken into account during the treatment.

THE IMPACT OF COMORBIDITIES ON PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A CLUSTER ANALYSIS

S. Lee[1], S. Kang[1], Y. Eun[1], H. Kim[1], H. S. Cha[1], E. M. Koh[1], J. Lee[1]. *[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Previous study using cluster analysis technique analyzed the association between comorbidities and various outcome measures in patients with axial spondyloarthritis (axSpA). Due to the cross-sectional nature of the study, however, prognostic information about each group were not provided.
Objectives: This study aims to perform cluster analysis to differentiate axSpA patients in terms of comorbidities and to examine the differential treatment outcomes of these groups using the data retrieved from Korean College of Rheumatology Biologics (KOBIO) registry which includes longitudinal data of axSpA patients using anti-TNF agents.
Methods: Clinical characteristics and demographic data of axSpA patients in KOBIO registry were analyzed using an agglomerative hierarchical cluster analysis. The optimum number of clusters was determined by the pseudo-F statistic. After clustering, baseline clinical characteristics and treatment outcomes were compared between isolated axSpA and classified comorbidity groups using multivariable linear models and mixed linear models, respectively.
Results: 1,207 patients were included in the study. At least one comorbidity was seen in 464 (38%) axSpA patients. Compared with those with isolated axSpA, patients with comorbidity were older, longer disease duration, and reported higher PtGA (p = 0.019), and BASFI (p <0.001), but did not have significantly different BASDAI, ESR, and CRP levels. The most common comorbidities were hypertension (14.4%), hyperlipidemia (13.0%), and obesity (4.5%). The hierarchical cluster analysis classified patients in 21 groups. We combined clusters 17-21 for further evaluation due to the small size of clusters (<5 patients). In multivariable linear models for baseline clinical characteristics, we found that patients in the hypothyroidism, asthma, and headache clusters reported poorer PtGA, BASDAI, or BASFI, and the weight loss cluster had higher level of CRP, compared with patients with isolated axSpA even after adjustment of patient demographic data. After 1-year treatment of anti-TNF agents, the patients in the hypothyroidism and weight loss clusters decreased greater amounts of BASDAI and BASFI scores and ESR/CRP levels, respectively, compared with patients with isolated axSpA (Table 1). However, the degree of improvement in asthma and headache clusters, which had higher disease activities at baseline, was similar with isolated axSpA. Therefore, they still had higher disease activity scores at the 1-year follow-up.

Table 1. Comparing each cluster to patients with isolated axSpA (i.e. no comorbidity) using multivariable linear mixed models for each treatment outcome measure at 1-year follow-up as the dependent variable.

Cluster/description	PtGA	BASDAI	BASFI	ESR	CRP
2 isolated axSpA	-	-	-	-	-
3 Obesity	0.233 (-0.57 - 1.036)	0.098 (-0.648 - 0.844)	-0.078 (-0.811 - 0.656)	**9.005 (0.481 - 17.529)†**	0.358 (-0.553 - 1.269)
10 Hypothyroidism	-1.243 (-3.139 - 0.653)	**-2.147 (-3.908 - -0.385)†**	**-2.38 (-4.076 - -0.684)†**	2.234 (-18.11 - 22.578)	-0.087 (-2.123 - 1.95)
11 Weight loss	-0.618 (-2.804 - 1.568)	-0.901 (-2.932 - 1.131)	-1.93 (-3.886 - 0.026)	**-26.891 (-50.351 - -3.431)†**	**-4.197 (-6.544 - -1.849)†**
15 Asthma	0.049 (-2.138 - 2.235)	0.833 (-1.199 - 2.864)	0.254 (-1.702 - 2.209)	-1.058 (-24.517 - 22.402)	2.018 (-0.552 - 4.589)
16 Headache	-0.103 (-1.052 - 0.846)	0.169 (-0.713 - 1.051)	0.463 (-0.387 - 1.312)	0.344 (-9.693 - 10.382)	-0.046 (-1.132 - 1.04)

† p-value < 0.05. Only clusters including significant results were shown due to the limitation oft he number of characters.

Conclusion: Comorbidity could affect the treatment outcomes in patients with axSpA in certain subgroups. Thus, we should also pay attention to the comorbidities when treating axSpA.

AB0839 EXTRA-ARTICULAR MANIFESTATIONS IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

K. Tahir[1], N. Akasbi[1], I. El Mezouar[1], T. Harzy[1]. [1]*University Hospital Center Hassan II, Rheumatology, Fez, Morocco*

Background: Spondyloarthritis (SpA) is a chronic inflammatory arthritis that combines joint involvement and extra-articular manifestations such as inflammatory bowel disease (IBD), uveitis and psoriasis.

Objectives: The aim of our study was to compare extra-articular manifestations in patients with ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA).

Methods: A retrospective study was conducted in a single rheumatology hospital in Morocco, including patients diagnosed as having SpA according to ASAS criteria 2010, during a period of 9 years. The patients were classified as AS by the presence of radiographic sacroiliitis according to the modified New York criteria and nr-axSpA defined by the presence of sacroiliitis on MRI. Extra-articular manifestations are compared between the two groups

Results: 375 patients were analyzed. 206 were female (54,9%). The mean age were 46,8 ± 14 years [16-84]. The mean duration of disease progression were 13.38 ± 8.44 years. The mean BASDAI were 4.20 ± 1.60 and the mean BASFI were 4.40 ± 2.24. 68,5% of patients had AS and 31.5% patients had nr-axSpA. Extra-articular manifestations were found in 109 (29,1%) of the patients, 72 (19,2 %) had IBD, 49 (13,1%) had uveitis and 9 (2,4%) had psoriasis. In bivariate analysis, IBD was noted in 23 % of patients with AS versus 11 % of patients with nr-axSpA (p= 0.006), psoriasis was present in 3.5% of patients with AS (p = 0.040), uveitis was present in 15.6% of AS (p = 0.034).

Conclusion: Extra articular manifestations are frequent in SpA. They are more frequent in patient with AS. Physicians need to screen carefully for extra articular manifestations at diagnosis and over follow-up.

AB0840 COMPARATIVE ANALYSIS OF MACROSCOPIC CHANGES IN BONE TISSUE OF HEADS AND ACETABULUMS OF THE HIP JOINTS (HJ) IN PATIENTS WITH ANKYLOSING SPONDYLITIS (AS): DATA FROM A RETROSPECTIVE ANALYSIS

A. Dubinin[1], A. Khramov[1], T. Dubinina[2], E. Ilinykh[2], S. Maglevaniy[1], E. Bialik[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, traumatological and orthopedic, Moscow, Russian Federation;* [2]*V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, axial spondyloarthritis, Moscow, Russian Federation*

Background: According to the results of Russian studies, coxitis occurs in 56% of patients (pts) with AS. At the same time, the need for total hip arthroplasty (THA) is only 8%, which is associated with the use of biologic disease-modifying anti-rheumatic drugs (bDMARDs).

Objectives: The aim of the study was to compare macroscopic changes in bone tissue of femoral heads (FH) and acetabulums in pts with AS who received and did not receive bDMARDs.

Methods: The retrospective study included 170 pts with a verified diagnosis of AS, who met the modified New York criteria of 1984, who were treated in the traumatological and orthopedic department in the period from 1998 to 2020, THA was routinely performed to all pts. Most of them were male (80.6%). The average age was 38.1±11.3 yrs. 82.9% of pts had low activity of the disease according to the BASDAI index at the time of surgical treatment and 17.1% of them had high activity. Nonsteroidal anti-inflammatory drugs were received by 61.7% of pts, sulfasalazine - 20.6%, methotrexate - 7.7%, systemic glucocorticoids - 8.8%, bDMARDs -53 (31.1%).

Results:

Parameter	All patients (n=170)	bDMARDs (+) n=53	bDMARDs (-) n=117
Average duration of the disease, years, M±σ	17,0±8,5	16,2±8,0	17,5±8,7
Age at the time of diagnosis, years, M±σ	27,6±9,1	27,6±10,0	27,6±8,9
Necessity of THA, years, M±σ	7,4±4,8	6,0±2,8	8,0±5,4
Osteophytes (Yes/No),%	90/10	96/4	88/12
Protrusion (Yes/No),%	75/25	68/32	78/12
Granulation (Yes/No),%	91/9	95/5	89/11
Ankylosis (Yes/No),%	47/53	48/52	37/53
Ankylosis (Fibrous/Osseous),%	77/23	80/20	75/25
Cysts of femoral heads (Yes/No),%	39/61	36/64	39/61
Cysts of femoral heads (Single/multiple),%	78/22	70/30	71/29
Erosion of femoral heads,%	47	39	50
Osteonecrosis of femoral heads,%	75,5	75*	45

***p<0,05**

The vast majority (85.9%) of pts had III grade of secondary coxarthrosis and 14.1% - had IV grade before THA. Complete absence of cartilage on the surface of acetabulum was revealed in 71.7% of cases, and there were either partial abrasions of the cartilage in the places of maximal load (6.5%), or chondromalacia (21.8%) in rest of the pts. Deformity of the FH was detected in 98.2% of pts, while as a result of osteonecrosis of FH (ONFH) in 75.5%. Complete absence of cartilage on FH was in 130 (76.5%) pts, and there were either partial abrasions of the cartilage in the places of maximal load (11.2%), or chondromalacia (12.3%) in rest of the pts. There were no significant differences in the macroscopic picture of the lesion of FH and acetabulums of HJ in pts with and without intake of bDMARDs, except for a higher frequency of ONFH in pts receiving bDMARDs.

Conclusion: The need for THA arose on average after 7.4±4.8 yrs from the appearance of pain in the hip joint (HJ). Macroscopic picture of HJ lesion in pts with AS was characterized as ONFH in 75.5% of cases, in almost half of cases - ankylosis of HJ, mainly fibrous (77.2%) with complete or partial absence of cartilage in acetabular surface and FH. According to the majority of macroscopic changes in the bone tissue of HF and acetabulums of HJ, pts with and without bDAMRDs did not differ, but the frequency of ONFH was significantly higher in the group of pts who was receiving bDAMRDs.

Disclosure of Interests: None declared.

AB0841

ANALYSIS OF THE FUNCTIONAL STATE OF HIP JOINTS (HJ) BEFORE TOTAL HIP ARTHROPLASTY (THA) IN PATIENTS WITH ANKYLOSING SPONDYLITIS (AS): DATA OF A RETROSPECTIVE ANALYSIS

A. Dubinin[1], A. Khramov[1], T. Dubinina[2], E. Ilinykh[2], S. Maglevaniy[1], E. Bialik[1].
[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, traumatological and orthopedic, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, axial spondyloarthritis, Moscow, Russian Federation

Background: Injury of hip joint (HJ) in patients (pts) with ankylosing spondylitis (AS) is considered as a factor of unfavorable prognosis, which can lead to rapid disability of pts.
Objectives: To assess the functional state of HJ before performing THA in patients with AS.
Methods: This retrospective study included 170 pts with a verified diagnosis of AS, who met the modified New York criteria of 1984, who were treated in the traumatological and orthopedic department in the period from 1998 to 2020, THA was routinely performed to all pts. Most of the pts were male (80.6%). 64% of them did not work due to the disease. Functional insufficiency of the joints at the time of surgical treatment in 64.1% of all the cases corresponded to III grade, in 26.5% - to IV grade, in 9.4% - to II grade. 82.9% of pts had low activity of the disease according to the BASDAI index at the time of surgical treatment and 17.1% of them had high activity. 53 (31.1%) pts were receiving bDMARDs and 87% of them were TNF-alpha inhibitors. The Harris quantitative scale was used to assess the functional state of HJ.
Results:

Parameter	All patients (n=170)	bDMARDs (+) n=53	bDMARDs (-) n=117
Age, years, Me±δ	38,1±11,3	37,5±12,3	38,3±10,8
Age of AS debut, years, Me± δ	20,7±8,4	21,2±8,4	20,5±8,4
Age at the time of diagnosis, years, Me± δ	27,6±9,1	27,6±9,9	27,6±8,9
Average delay in diagnosis, years, Me± δ	6,8±5,8	6,4±4,3	7,1±6,4
Average duration of the disease, years, Me± δ	17,0±8,5	16,2±8,0	17,5±8,7
Average duration of pain in HJ, years, Me± δ	7,4±4,8	6,1±2,2*	8,0±5,4
Average level of pain in HJ, VAS, Me± δ	72,3±14,0	69,9±12,9	73,4±14,5
Average overall score on the Harris scale before surgery	38,0±15,4	42,1±15,0	36,1±15,3*
The average level of pain on the Harris scale, VAS,, Me± δ	15,6±8,4	17,5±8,3	14,7±5,5
Antalgic Gait (absent/mild/moderate/severe), %	42,9/42,9/11,8/2,4	41,5/35,8/18,9/3,8	43,6/46,2/8,5/1,7
Walking a distance (unlimited /1500 meters /500 meters/in the apartment/unable to walk), %	2,4/21,2/0,6/44, 7/27,1/4,1	2,4/21,7/44, 7/27,1/4,1	3,4/21,6/45, 2/26,4/3,4
Additional support (missing/ walking stick for long distances/ walking stick permanently/one crutch/two walking sticks/two crutches), %	30,6/5,3/4,1/29, 5/4,1/26,4	22,6/7,5/3,8/24,5/ 7,5/34,0	34,2/4,3/4,3/31, 6/2,6/23,0
Putting on shoes (without difficulty/ with difficulty/ impossible)	4,2/65,8/30,0	7,4/67,9/24,5	3,4/64,9/33,3
Fixed adduction (<10°/>10°), %	30,0/70,0	26,4/73,6	31,6/68,4
Fixed internal rotation (<10°/>10°)	22,9/77,1	26,4/73,6	21,4/78,6
Flexion contracture (<15°/>15°), %	39,4/60,6	41,5/58,5	38,5/61,5

***p<0,05**

Conclusion: The vast majority of pts with AS had pronounced severe disorders of HJ before THA - the average score on the Harris scale was 38.0±15.4. Most of the patients (85.9%) had severe and moderate lameness, with the need for additional support in 69.4% of cases. Objective signs of functional disorders (fixed inward rotation and reduction, flexion contracture) of HJ were detected in more than half of the cases. According to the assessment of most parameters of the Harris scale, there were no significant differences between pts with AS on bDMARDs and without bDMARDs, except for the average duration of pain in HJ and the overall value of the scale (6.1±2.2 vs 8.0±5.4 and 42 vs 36, respectively, p<0.05 in both cases).

FOOT ENTHESES ULTRASOUND IN SPONDYLOARTHRITIS: A CASE CONTROL STUDY

M. Slouma[1], M. Abbes[1], C. S. Bellagha[1], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1].
[1]Military hospital of Tunis, Rheumatology, Tunis, Tunisia

Background: Foot entheses involvement is a common manifestation of spondyloarthritis (SpA). It can be responsible for functional impairment. The superiority of ultrasound (US) examination in foot entheses damages detection has been reported [1].
Objectives: We aimed to compare the US findings of foot entheses between SpA patients and asymptomatic healthy control subjects.
Methods: We conducted a cross-sectional study including 37 SpA patients (G1) fulfilling ASAS criteria for Axial SpA and 37 healthy subjects (G0) matched by age and gender. Demographic and clinical characteristics were collected. A blind US of foot entheses was performed by Mindray DC-70 equipment with a 6-16 MHz linear probe. Calcaneal enthesis (CT) and plantar fascia (PF) were examined bilaterally. A total of 296 entheses were assessed. In G1, disease activity was evaluated using the Bath Ankylosing Spondylitis Activity Index (BASDAI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS). Statistical Package for Social Sciences (SPSS) was used for analysis.
Results: The study included 58 men and 16 women. The mean age was 44.6 ± 12.3 years. In G1, the mean disease duration was 108.2±94 months. The average BASDAI was 4.5±2.2. The average $ASDAS_{CRP}$ was 3.2±1.3. In G1, clinical examination showed tenderness at the posterior insertion of the CT or inferior insertion of PF in 16.2% of patients. However, US lesions of the CT were found in 97% of cases in G1 and 67.6% in G0, p:0.001. US lesions are presented in Table 1.

Table 1. Elementary US lesions in SpA and healthy control groups

Enthesis		G1 (n (%))	G0 (n (%))	p
Calcaneal tendon	Thickness	15 (40.5)	6 (16.2)	0.02
	Erosion	9 (24.3)	1 (2.7)	0.007
	Enthesophyte	29 (78.4)	20 (54)	0.03
	Calcification	14 (37.8)	10 (27)	0.32
	Bursitis	4 (10.8)	3 (8.1)	1
	PD signal	10 (27)	0	0.001
Plantar fascia	Thickness	30 (81.1)	27 (73)	0.4
	Erosion	11 (30)	1 (3)	0.002
	Enthesophyte	12 (32.4)	2 (5.4)	0.003
	Calcification	18 (48.6)	6 (16.2)	0.003
	PD signal	11 (30)	0	<0.001

G0: control group, G1: Spondyloarthritis group, PD: power doppler

Calcaneal tendon thickness was noted in 40.5% in G1 and 16.2% in G2 (p=0.02). Hypo-echogenicity and loss of normal fibrillar structure were more frequent in G1 (86.5% versus 29.7%, p<0.001). Structural damage lesions were found in 89.6 % in G0 (n= 33) and 64.9% in G1 (n=24), p=0.01. In the PF, US structural damage lesions were significantly more frequent in the SpA patients (70% versus 21.6%, p<0.001). Vascularity at power Doppler was significantly more frequent in G1 (p=0.001 in CT and p<0.001 in PF). In G1, the disease activity was higher in patients with structural damage lesions of the CT ($ASDAS_{CRP}$: 3.2 versus 1.9; p=0.01). However, there was no associations between vascularity at power Doppler and high disease activity (p=0.47).
Conclusion: Our study showed that the US lesions of the heel entheses were frequent in SpA patients compared to healthy control. Moreover, US can reveal enthesitis even in asymptomatic patients.
The disease activity was higher in patients with US structural damage lesions of the CT.

OSTEOPOROSIS IN PATIENTS WITH SPONDYLOARTHRITIS: DO WE NEED TO DO MORE?

Z. Özsoy[1], K. Moral[2], F. Yeşil[2], E. Bilgin[1], E. C. Bolek[1], G. K. Yardımcı[1], B. Farisogullari[1], E. Duran[1], G. Ayan[1], G. Sandal Uzun[1], M. Ekici[1,2], E. Unaldi[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], A. İ. Ertenli[1], U. Kalyoncu[1]. *[1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; [2]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*

Background: Data regarding the prevalence and especially incidence of osteoporosis in Spondylarthritis (SPA) is scarce and very divergent among studies from different patient populations (1).
Objectives: In this study, we aimed to compare demographic, disease and laboratory characteristics of SpA patients regarding their bone mineral densitometry (BMD) categories and find out incidence of osteoporosis in the follow-up BMD of patients who were not found to have osteoporosis at baseline.
Methods: Between 2010-2021, patients with a SPA diagnosis in the HUR-BIO database were searched. HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a single center biological disease modifying anti-rheumatic drug (DMARD) registry since 2010. Patients with BMD measurement were included in the study. Follow-up BMD scores were also documented. The patients were divided into 3 groups as normal, osteopenia and osteoporosis in accordance with the WHO criteria (2). Demographic characteristics, comorbidities, laboratory data and drugs in each group were documented.
Results: 3245 patients were reviewed. BMD was measured at least once in 118 patients out of 3245 (3.6%) patients. When the groups classified, 34 patients (28.8%) were included in the normal, 49 (41.5%) osteopenia and 35 (29.7%) osteoporosis groups. Patients with normal BMD was younger than both groups. Diabetes and hypertension were more prevalent in patients with osteopenia. The BMI was significantly lower in the osteoporosis group. 25 patients with normal and osteopenia in baseline BMD measurement had at least 1 follow-up BMD measurement. During the total follow-up of 91 patient-years, 3 patients had osteoporosis, revealing a the incidence of 3.3% in 100 patient-years.
Conclusion: In our study, the incidence of OP development in SPA patients was found to be 3.3%. Frequency of osteoporosis was 29.7% among SpA patients with BMD measurement (118/3245; 3.6%), however; only 40% of them had appropriate treatment. Osteoporosis seems as an overlooked and undertreated comorbidity of SpA.

Table 1. Comparison of spondyloarthritis patients according to BMD scores (normal, osteopenia and osteoporosis) according to baseline BMD assessment

	NORMAL Number, (%)	OSTEOPENIA Number, (%)	OSTEOPOROSIS Number, (%)	P VALUE
Number of Patients	34 (28.8)	49 (41.5)	35(29.7)

CHARACTERIZING GUT MICROBIAL ENTEROTYPES IN UNDIFFERENTIATED SPONDYLOARTHRITIS

Y. Zhang[1,2,3], S. X. Zhang[1,2,4], J. Qiao[1,2,4], S. Song[1,2,4], R. Zhao[1,2,4], X. Li[1,2,4]. *[1]Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Shanxi Medical University, first clinical medical school, Taiyuan, China; [4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: The presence of dysbiosis in the gut microbiome is responsible for the initiation of autoinflammatory and autoimmune diseases. However, such dysbiosis is difficult to characterize in sweeping generalization owing to the high dimensional complexity of the gut microbiota.
Objectives: This study designed to characterize the gut microbial enterotype in patients with undifferentiated spondyloarthritis (USpA) from lower dimensionality and describe the dysbiosis.
Methods: The Fecal samples of 105 patients were diagnosed with USpA and gender- and age- matched 105 healthy controls (HC) were included in the intestinal microbiota composition analyses via Illumina sequencing of bacterial 16S rRNA genes. Microbiota-derived clustering was performed using Dirichlet multinomial mixtures (DMM) modeling. To identify discriminative features in abundance between enterotypes, the Linear Discriminant Analysis Effect Size (LEfSe) algorithm was used with the online interface Galaxy (Log10 LDA score > 4.0). The phyloseq R package to compute alpha diversity (ACE, Chao1, Shannon and Simpson indices), beta diversity (Bray-Curtis dissimilarity) and the microbial composition (at the genus level) to describe the richness and diversity of the microbiota between two enterotypes.
Results: As showed in Figure 1A and C, by evaluating the Laplace approximation to the negative log mode, 2 distinctly enterotypes were identified in the USpA and HC microbiota dataset. LEfSe Analysis indicated the distinctive abundant microbial clades between the 2 enterotypes (LDA score >4) in both the USpA and HC group respectively. At the genus level, Faecalibacterium and Prevotella

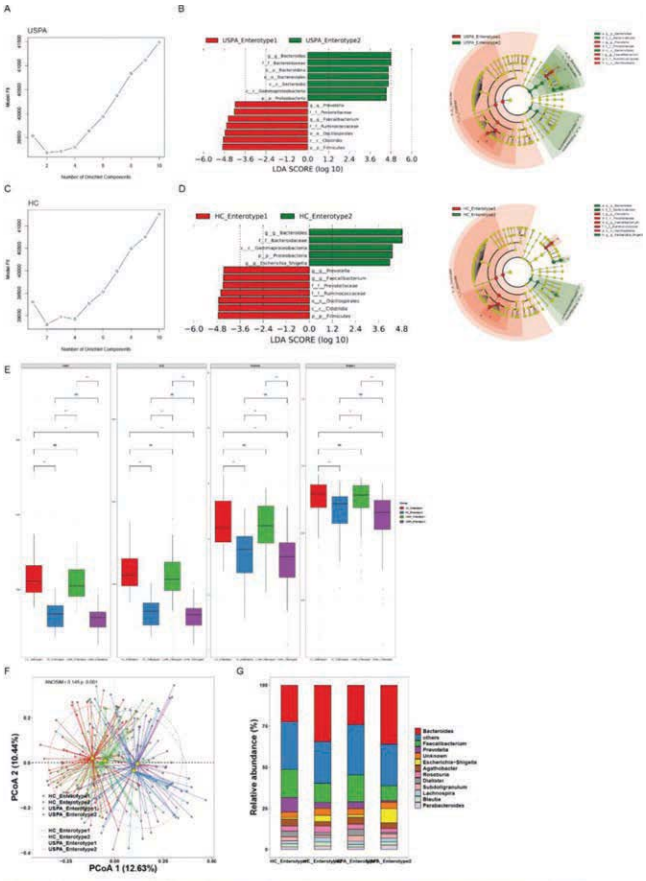

Figure 1 (A, C) Evaluates model fit for increasing number of K using the Laplace approximation to the negative log model evidence. (B, D) LEfSe-derived taxonomic cladogram; LDA score of enriched bacterial taxa (LDA >4 of LEfSe). Significantly enriched bacterial taxa in fecal samples in distinct enterotypes are indicated by different colors. Red bars indicate taxa enriched enterotype 1, and green bars indicate taxa enriched enterotype 2. (E) Comparison of alpha diversity indices between enterotype 1 and enterotype 1. (F) Comparison of beta diversity indices between enterotype 1 and enterotype 1, Principal coordinate analysis plot generated from the bray distance analyses. (G)The composition of gut microbiota between enterotype 1 and enterotype 2 in USpA and HC.

was the driving genus of enterotype 1 and Bacteroides contributed to enterotype 2 (Figure 1B, D). The alpha-diversity and beta diversity between the distinctive enterotypes was highly significantly different (P < 0.01, Figure 1E, F). Distinct bacterial profiles were also observed in enterotype 1 and 2 (Figure 1G). Interestingly, no significant differences were found between USpA patients and HC for the corresponding same intestinal type. This may be because USpA was at a comparatively early stage of spondyloarthritis (SpA).

Conclusion: Two significantly distinct bacterial microbiota structures existed in the USpA patients which was consistent with the general healthy population.

AB0845 IMPORTANCE OF WEIGHT MANAGEMENT ON ENDOTHELIAL FUNCTION IN SPONDYLOARTHRITIS

A. Ben Tekaya[1,2], E. Hannech[1,2], A. Fendri[2,3], S. Boukriba[2,3], O. Saidane[1,2], S. Bouden[1,2], R. Leila[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], H. Mizouni[2,3], L. Abdelmoula[1,2]. *[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; [2]Faculty of medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; [3]Radiology Department, La Rabta Hospital, Tunis, Tunisia*

Background: Subclinical atherosclerosis is not rare in spndyloarthritis (SpA) patients. Endothelial dysfunction is the first step of atherosclerosis process. Obesity is a major traditional cardiovascular risk factor.

Objectives: The purpose of our study was to determine the association of anthropometric measures with endothelial dysfunction in non-obese SpA patients.

Methods: This was a prospective study conducted over 12 months and including 47 SpA free cardiovascular disease patients and aged less than 50 years. The following anthropometric parameters were collected for each patient: weight, height, Body Mass Index (BMI), hip and waist circumferences. Endothelial dysfunction was assessed by the ultrasound evaluation of the Flow Mediated Dilatation (FMD).

Results: There were 14 female (28.8%) and 33 male (70.2%). The median age was 36 years (IQR; 18-50). The median disease duration was 11 years (IQR; 1-32). The median weight, height and BMI were 69 (IQR; 43-95), 170 cm (IQR; 144-193) and 24.5 kg/m^2 (IQR; 16.33 - 29.41), respectively. Overweight (BMI: 25-29 kg/m^2) was noted in 40% of patients. The median hip and waist circumferences were respectively 100 cm (IQR; 84-116) and 88 cm (IQR; 70-114). Median FMD was 18.18% (IQR; 12.8-23.1). We didn't found correlation between anthropometric parameters and FMD: weight (p=0.225; r=-0.180); height (p=0.273; r=-0.163), BMI (p=0.437; r=-0.116); waist circumference (p=0.22; r=-0.182) and hip circumferences (p=0.142; r=-0.217).

Conclusion: Our study showed that anthropometric parameters do not influence endothelial function in non-obese and young SpA patients. This highlights the importance of weight management and maintaining a healthy weight in SpA patients.

AB0846 HLA-B51 PREVALENCE IN PATIENTS WITH SPONDYLOARTHRITIS AND IMPACT ON DISEASE PHENOTYPE: A CASE-CONTROL STUDY

N. Ziade[1,2], R. Nacouzi[3], K. Mroue'[4], G. Merheb[5,6], P. Ghorra[3,7]. *[1]Saint-Joseph University, Rheumatology, Beirut, Lebanon; [2]Hotel-Dieu de France Hospital, Rheumatology, Beirut, Lebanon; [3]Saint-Joseph University, Medicine, Beirut, Lebanon; [4]Al Zahraa University Medical center, Rheumatology, Beirut, Lebanon; [5]Holy-Spirit University, Rheumatology, Kaslik, Lebanon; [6]ND Secours Hospital, Rheumatology, Byblos, Lebanon; [7]Hotel-Dieu de France, Immunlogy, Beirut, Lebanon*

Background: Spondyloarthritis (SpA) is a group of rheumatic diseases with a heritable component associated with Human Leucocyte Antigen B27 (HLA-B27). Although many studies have reported an overlap between the clinical features of SpA and Behcet's disease (BD), as well as an increased prevalence of HLA-B27 in BD, the prevalence of HLA-B5 (namely B51 and B52, the split antigens of B5) in SpA, have been scarcely examined, particularly in countries with a low HLA-B27 prevalence.

Objectives: To estimate the prevalence of HLA-B51 and HLA-B52 in patients with SpA compared to healthy controls (HC), to identify the alleles found in HLA-B locus in patients with SpA compared to HC, and to evaluate the impact of HLA-B51 on SpA disease phenotype.

Methods: A case-control study included consecutive patients with a diagnosis of SpA (axial SpA (axSpA), peripheral SpA (pSpA), and psoriatic arthritis (PsA)) from three rheumatology clinics. HC were recruited among blood donors and medical students. Demographic data, as well as SpA and BD disease features, were collected through an interview with a trained medical student and file review (low back pain, peripheral joint disease, enthesitis, dactylitis, psoriasis, uveitis, inflammatory bowel disease, family history, oral and genital ulcerations, skin, vascular and neurologic manifestations, CRP, BASDAI, imaging of the spine and sacroiliac joints). The entire B locus was tested using molecular biology technique on Luminex with the possibility of precise B51/B52 differentiation. The prevalence of HLA-B51/B52 was calculated in patients and compared to HC using the Chi-square test. A complete HLA-B mapping was performed for patients and HC. A binary logistic regression identified factors associated with HLA-B51 in patients with axSpA.

Results: Data from 119 HC and 89 patients with SpA were available (66 axSpA, 16 pSpA, and 7 PsA). Mean age of the patients was 44.8 years [SD 13.5], 66.3% were males, disease duration was 12 years [SD 12.7], 72.4% had a history of elevated CRP, 30.3% were positive for HLA-B27, 53.9% had sacroiliitis on MRI, 47.2% had radiographic sacroiliitis, and 23.6% had syndesmophytes. Oral ulcerations were reported in 38.2% of patients, genital ulcerations in 3.4%, uveitis in 5.6%, skin lesions in 18%, and vascular lesions in 3.4%. Patients with SpA fulfilled the classification criteria for BD in 2.9% (International Study Group criteria for BD) and 38.2% (International Criteria for BD). HLA-B51/B52 were found more frequently in patients with SpA (20.2%/ 7.9%) compared to HC (11.8%/4.2%), although the difference was not statistically significant. The difference was mainly driven by ant association between HLA-B51 and axSpA (27.2% versus 11.8%, OR 2.8 [95%CI 1.3-6.1], p=0.008) (Table 1). The most frequent allele in SpA and HC was HLA-B35; complete HLA-B mapping is shown in Figure 1. In patients with axSpA, HLA-B51 was associated with radiographic damage in peripheral joints, while it was negatively associated with sacroiliitis. Uveitis was numerically associated with HLA-B51, but the association did not reach statistical significance.

Table 1. Prevalence of HLA-B5 genes in patients with spondyloarthritis (SpA) and healthy controls

	Controls	SpA	Axial SpA	Peripheral SpA	Psoriatic Arthritis	p-value (SpA vs. Controls)	p-value (axSpA vs controls)
N	119	89	66	16	7		
HLA-B51+, N (%)	14 (11.8)	18 (20.2)	18 (27.3)	0 (0.0)	0 (0.0)	0.094	**0.008**
HLA-B52+, N (%)	5 (4.2)	7 (7.9)	5 (7.6)	2 (12.5)	0 (0.0)	0.262	0.331
HLA-B51 or HLA-B52+, N (%)	19 (16)	21 (23.6)	19 (28.8)	2 (12.5)	0 (0.0)	0.167	**0.039**

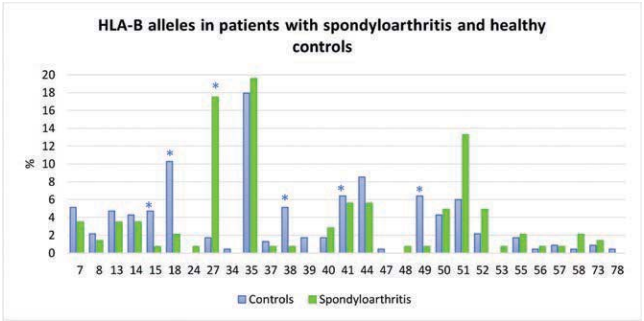

Figure 1. Distribution of the HLA-B alleles in patients with spondyloarthritis and healthy controls (Statistically significant differences between patients and controls indicated with*)

Conclusion: HLA-B51/B52 were more numerically more prevalent in patients with SpA compared to HC. A statistically significant association was found between HLA-B51 and axSpA and correlated with more peripheral and less axial radiographic involvement.

AB0847

PROFILE OF SPONDYLOARTHRITIS IN THE MOROCCAN POPULATION: RESULTS OF A MULTICENTER STUDY

H. Arabi[1], A. Mougui[1], H. Sahimi[2], N. Takhrifa[3], S. Mouhcine[4], I. Bentaleb[5], H. Taoufik[6], T. Harzy[2], F. Abourazzak[3], S. Janani[4], R. Bahiri[5], A. Bezza[6], I. Ghozlani[7], R. Niamane[8], I. El Bouchti[1]. *[1]Mohammed VI University Hospital Marrakech, Rheumatology, Marrakech, Morocco; [2]Hassan II University Hospital Fes, Rheumatology, Fes, Morocco; [3]Mohammed V Hospital Tanger, Rheumatology, Tanger, Morocco; [4]Ibn Rochd University Hospital Casablanca, Rheumatology, Casablanca, Morocco; [5]El Ayachi Hospital, Ibn Sina University Hosiptal Salé-Rabat, Rheumatology, Salé-Rabat, Morocco; [6]Military Hospital Mohammed V Rabat, Rheumatology, Rabat, Morocco; [7]Military Hospital Agadir, Rheumatology, Marrakech, Morocco; [8]Military Hospital Avicenne Marrakech, Rheumatology, Marrakech, Morocco*

Background: Spondyloarthritis (SpA) is a frequent group of chronic inflammatory rheumatic diseases, their epidemiology varies considerably in different regions of the world.
Objectives: The aim of our study was to describe the epidemiological, clinical, paraclinical and therapeutic profile of SpA in the Moroccan population.
Methods: This is a multicenter descriptive study, including patients followed for SpA. 8 hospital centers participated in this study. All data were measured by standard instruments.
Results: Seven hundred patients were included, 54% were men, the mean age was 40.42±14.19 years at the time of diagnosis [14 years-90 years]. The patients lived in urban and rural areas in 83.5% and 13.8% of cases, respectively. 38.4% were without occupation. A history of tuberculosis was noted in 5.9% of cases. Associated pathologies were autoimmune in 2.3% and neoplasia in 1.5% of cases. 15.6% of patients were smokers. A family history of SpA was noted in 11.7%, psoriasis in 1% and Inflammatory bowel disease (IBD) in 0.6% of cases. The average diagnostic delay was 59.76 months [0-444 months]. The revealing symptomatology was axial in 19%, peripheral in 10.1%, enthesitis in 0.4%, and a combination of the 3 forms in 22.1% of cases. Dactylitis was noted in 2.3% of cases. SpA was non-radiographic in 14% of cases. The forms of SpA were: ankylosing spondylitis (80.1%), IBD associated with SpA (9.4%), psoriatic arthritis (6%), and undifferentiated SpA (4%). Juvenile SpA accounted for 15.5% of cases. The prevalence of HLA-B27 was 65.51%. The mean BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) was 4.42 ± 1.67 and the mean ASDAS (Ankylosing Spondylitis Disease Activity Score) was 3.19 ± 1.24. Systemic involvement was dominated by uveitis (11.3%), followed by IBD (9.4%), restrictive syndrome (2.7%), renal involvement (0.6%) including amyloidosis (0.1%), IgA nephropathy (0.4%), interstitial nephropathy (0.1%), and aortic insufficiency in 0.2% of cases. The most commonly used treatments were non-steroidal anti-inflammatory drugs (81.7%), sulfasalazine (24.2%), methotrexate (22.9%) and 31.8% of patients were on biotherapy. Surgery for arthroplasty was necessary in 5.6% of patients.
Conclusion: This is a study of the clinical and demographic characteristics of Spondyloarthritis in a population in Morocco, on which a large scale data base could be initiated, in order to better determine the role of genetic and environmental factors in the pathogenesis of the disease.

AB0848

ATHEROGENIC INDEX IS THE BEST DETERMINANT OF SUBCLINICAL ATHEROSCLEROSIS IN SPONDYLOARTHRITIS PATIENTS

A. Ben Tekaya[1,2], E. Hannech[1,2], A. Fendri[2,3], S. Boukriba[2,3], O. Saidane[1,2], S. Bouden[1,2], R. Leila[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], H. Mizouni[2,3], L. Abdelmoula[1,2]. *[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia; [2]Faculty of medicine of Tunis, University Tunis El Manar, Tunis, Tunisia; [3]Radiology Department, La Rabta Hospital, Tunis, Tunisia*

Background: Blood lipid levels particularly total cholesterol (CT), low-density lipoprotein cholesterol (C-LDL), high-density lipoprotein cholesterol (C-HDL), and triglycerides (TG), are commonly used to predict cardiovascular risk. However, it has been demonstrated that atherogenic index (CT/HDL, C-LDL/C-HDL) are prognostic indicators of atherosclerosis [1].
Objectives: The purpose of our study was to determine the role of lipid indicators in predicting subclinical atherosclerosis among SpA patients.
Methods: It was a cross sectional study over a period of 12 months including patients with established SpA (ASAS Criteria). They were cardiovascular disease free. Lipid analyses were performed for all patients including the determination of: C-LDL, C-HDL, CT, and TG. The ratios CT/C-HDL, C-LDL/C-HDL were calculated. Atherosclerosis was assessed by Doppler ultrasound with measurement of the carotid Intima-Media Thickness (cIMT).
Results: There were 47 SpA patients: 14 female (28.8%) and 33 male (70.2%). The median age was 36 years (18-50). The median disease duration was 11 years (1-32). The median lipid factors levels were respectively 3.66 mmol/l (2.27-6.34) for CT, 0.84 mmol/l (0.43-2.88) for TG, 2.17 mmol/l (0.93-3.9) for C-LDL, and 1.08 mmol/l (0.63-1.49) for C-HDL. The median CT/C-HDL, C-LDL/C-HDL ratios were respectively 3.48 (2.21-6.79) and 1.99 (0.86-3.77). There were 17% of patients with a high ratio CT/C-HDL (>4.5) and 9.3% of patients with high ratio C-LDL/C-HDL (>3.22).
The median cIMT was 0.55 millimeters (0.32-0.83). cIMT was positively correlated with low linearity with CT (p=0.007; r=0.404) and with the CT/C-HDL ratio (p=0,028; r=0.34).
Conclusion: In our study, CT/HDL ratio and CT were the best determinant of subclinical atherosclerosis in SpA patients.

ASSESSMENT OF CAROTID INTIMA-MEDIA THICKNESS IN SPONDYLOARTHRITIS PATIENTS

A. Ben Tekaya[1,2], T. Mehmli[1,2], F. Ahmed[2,3], S. Boukriba[2,3], O. Saidane[1,2], R. Leila[1,2], S. Bouden[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], H. Mizouni[2,3], L. Abdelmoula[1,2]. *[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; [2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; [3]La Rabta Hospital, Radiology department, Tunis, Tunisia*

Background: Cardiovascular morbidity and mortality are increased in spondyloarthritis (SpA) (1), which is attributed to accelerated atherosclerosis. Recognition of subclinical atherosclerosis in asymptomatic population is important for risk stratification and optimal management. Due to its simplicity and non-invasive nature, carotid intima-media thickness (cIMT) is actually widely used for identifying subclinical atherosclerosis.
Objectives: The aim of our study was to investigate the presence of subclinical atherosclerosis in SpA patients compared with healthy controls, by evaluating cIMT.
Methods: We performed a case control study including 47 patients and 47 age and gender matched healthy controls. All subjects were included without history of cardiovascular disease or cardiovascular risk factors. Sociodemographic features, disease characteristics, radiographic structural damage and therapeutics were recorded. cIMT was measured with Mindray Resona 7 ZST+ ultrasound machine, from the right and the left carotid artery; than mean cIMT was calculated. We considered that cIMT was increased if the measurements were between 0.7 mm and 1.5 mm. Measurements higher than 1.5 were defined as an atherosclerotic plaque.
Results: Fourty seven patients with a sex ratio of 2.35 were included in our study. Median age was 36 years (IQR: 28-46) and median duration of the disease was 11 years (IQR: 5-16). Median BASDAI and ASDAS-CRP scores were 2.6 (IQR: 1.8-3.8) and 2.18 (IQR: 1.62-2.91) respectively. Of the 47 patients, 10 (21%) had an active disease according to BASDAI and 19 (40%) had an active disease according to ASDAS. Median BASFI score for functional impairment was 3 (IQR: 1.5-5.1). Median BASRI and mSASSS scores were 3 (IQR: 2-4) and 10 (IQR: 4-15) respectively. Regarding treatment, 92% of patients were using non-steroidal anti-inflammatory drugs (NSAIDs), 51% were on csDMARDs and 38% were on anti-TNF alpha drugs. Median right, left and mean cIMT were respectively 0.54 mm (IQR: 0.50-0.63), 0.55 mm (IQR: 0.49-0.61) and 0.55 mm (IQR: 0.48-0.62) respectively. Increased cIMT values were found in 8 patients (17%). No patient had atherosclerotic plaque. Median values of cIMT were significantly higher in patients with spondyloarthritis than the control subjects (p<0.0001) as shown in Table 1.

Table 1. Comparaison of carotid intima-media thickness values between spondyloarthritis patients and control subjects.

	Spondyloarthritis Patients	Control group	p
Right cIMT (mm)*	0,54 (0,50-0,63)	0,45 (0,42-0,50)	< 0.0001**
Left cIMT (mm)*	0,55 (0,49-0,61)	0,47 (0,45-0,50)	<0.0001**
Mean cIMT (mm)*	0,55 (0,48-0,62)	0,46 (0,43-0,50)	<0.0001**

cIMT: carotid intima-media thickness; mm: millimeters; *: median value (IQR 25-75%); **: p < 0.05 denotes statistical significance.

Conclusion: Our study demonstrated increased cIMT in patients with SpA compared with healthy population; which attests higher risk for subclinical atherosclerosis and cardiovascular atherosclerotic events.

AB0850 ENTHESITIS, FEMALE GENDER AND VITALITY PERCEPTION AS FATIGUE DETERMINANTS IN SPONDYLOARTHRITIS PATIENTS UNDER BDMARD

F. R. Martins[1], A. Martins[2], B. Samões[3], D. Santos Oliveira[2,4], R. Nicolau[5], F. Oliveira Pinheiro[2], M. Rato[2], M. Bernardes[2,6], L. Costa[2]. *[1]University Hospital Center of Algarve, Faro, Rheumatology, Faro, Portugal; [2]São João Universitary Hospital Center, Rheumatology, Porto, Portugal; [3]Centro Hospitalar Vila Nova de Gaia / Espinho, Rheumatology, Vila Nova de Gaia, Portugal; [4]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal; [5]Centro Hospitalar Tondela - Viseu, Epe, Rheumatology, Viseu, Portugal; [6]Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal*

Background: Fatigue is an important domain in quality of life of spondyloarthritis patients, not always directly associated with disease course. The explanatory factors of fatigue in these patients are still not clearly understood.

Objectives: To assess the determinants of fatigue in patients with SpA under biologic disease modifying anti-rheumatic drugs (bDMARDs).

Methods: A retrospective observational study was performed using registry data of patients with SpA under bDMARD therapy followed at a tertiary level hospital. Data regarding disease activity, response criteria measures, analytic markers, function, metrology, pain, general health and fatigue (using FACIT score) was gathered at baseline, 6 months (t6) and 12 months (t12) after introduction of bDMARD. Statistical analysis (significance at p < 0.05) was performed using paired T-test, Wilcoxon test and McNemar tests for paired samples, Mann Whitney-U, Kruskall-Walis and One Way ANOVA for independent samples. Linear and logistic regression models were performed to assess direction and strength of association.

Results: A total of 46 SpA patients were analysed; most were male (24, 52.2%) with a predominantly axial involvement (31, 68.9%) and 74.4% of them were positive for HLA-B27. Most patients had high school or lower education (29, 69.1%), never smoked (26, 61.9%), never drank (34, 79.1%) and had a full-time job (38, 88.4%). All patients were under TNF inhibitors, mostly adalimumab (23, 50%). There was a significant decrease in inflammatory markers (p<0.001), disease activity scores (ASDAS-CRP and BASDAI) (p<0.001), function index BASFI (p< 0.001), metrology indexes (p<0.05) and MASES enthesitis score (p< 0.01). Patient, physician and night pain VAS were significantly lower (p< 0.001) at t6 and t12, but spine VAS only varied significantly between t0 - t6 (p = 0.021) and not t0 - t12 (p= 0.405). FACIT didn't vary significantly after bDMARD initiation, and among the domains of SF36 questionnaire, only SF36 vitality score varied significantly (p<0.05). No significant changes in EQ5D, HADs anxiety or depression scores were observed.

At baseline, there was a strong negative correlation between fatigue, expressed by FACIT score, and pain VAS (R = 0.9, p=0.037), without other significant associations. Several positive correlations with fatigue at t6 were observed, the strongest with anxiety and depression HADs (p < 0.001), BASFI (p < 0.001) and ASDAS-CRP (p< 0.001). Other positive associations were seen with 66 TJC (p <0.01), patient VAS (p<0.001, pain VAS (p = 0.001), nocturnal pain VAS (p <0.001), BASDAI (p <0.001) and MASES (p <0.001). Fatigue at t6 had a negative correlation with increased ASAS response measures mean value (p = 0.014), all domains of SF36 (p < 0.001), the strongest correlation of which was with the general health domain (R=-0.811), and EQ5D (p<0.001). When comparing subgroups at t6, there was more fatigue in the female group (p=0.01) and in patient with higher ASDAS disease activity score (p < 0.05), with no differences according to work status, alcohol consumption or tobacco use, educational level, TNF inhibitor exposure or ASAS response.

Prediction analysis showed univariable association between several baseline variables and fatigue (lower FACIT scoring) at t6: age at bDMARD introduction (B = - 0,405, p = 0.02), age at diagnosis (B = -0.43, p = 0.02), physician VAS (B = 0.149, p < 0.05), MASES (B = -1.732, p <0.001), SPARCC (p < 0.05) and female gender (B = -7.95, p = 0.01). Multivariate linear regression analysis allowed for creation of a predictive model for FACIT scoring at t6 (R2 = 0.900, p = 0.019): (-3.426) x MASES t0 + (-24.074) x female gender + 0.949 x SF36 vitality score.

Conclusion: Enthesitis, female gender and subjective assessment of vitality seem to be determinants of fatigue in SpA patients under bDMARD. Fatigue in this population is associated with diverse factors that should be optimized in a holistic approach to the patient.

AB0851 APPLICABILITY OF THE MASEI INDEX IN ENTHESIS AND ITS ASSOCIATION WITH OTHER INDICES / SEROLOGICAL MARKERS OF ACTIVITY IN PATIENTS WITH SPONDYLOARTHRITIS

D. Castro-Corredor[1], L. Á. Calvo Pascual[2], E. C. Garrido Merchán[2], M. A. Ramírez Huaranga[1], M. Paulino Huertas[1]. *[1]Hospital General Universitario Ciudad Real, Rheumatology Department, Ciudad Real, Spain; [2]Universidad Pontificia de Comillas, Quantitative Methods Department, Madrid, Spain*

Background: Spondyloarthritis (SpA) are a group of chronic inflammatory diseases with affectation, mainly of the axial skeleton and, also, of peripheral joints. The enthesis is one of the target organs, since an inflammation of it, known as enthesitis, can be observed, which in many patients with spondyloarthritis could be unnoticed.

Objectives: Find the relation between the MASEI index (Madrid Sonographic Enthesitis Index) in entheses and other indices/serological activity markers (such as BASDAI, DAPSA or ASDAS and ESR, CRP) in spondyloarthritis patients.

Methods: Observational, descriptive and cross-sectional study. Data were collected from patients with SpA who underwent musculoskeletal ultrasound using the Madrid Sonographic Enthesitis Index (MASEI) and who were treated in our clinics from May 2021 to September 2021 and under the approval of the CEICm of our center. The variables evaluated were described using measures of frequency and measures of central tendency/dispersion, as appropriate. First, we tested the normality of all the variables, using a Shapiro-Wilk test. We studied the correlation of parametric numerical variables (such as MASEI-Vitamin D, MASEI-ASDAS), using the Pearson coefficient. On the other hand, for non-parametric numerical variables (such as MASEI-BASDAI) we use Spearman's coefficient. For parametric numeric and categorical variables (such as MASEI-VITAMINA D, ASDAS-VITAMINA D) we constrast the mean of differences using the T-Student test, while for non-parametric numerical and categorical variables, we contast the difference of means with the Mann-Whitney U test (MASEI-PCR, MASEI_VSG). Finally, to find out the correlation between categorical variables (such as VITAMIN D-PCR), we used a chi-square test. Finally, we have done a curve-fitting study with Matlab, obtaining the functions that better adjust the data avoiding overfitting. We have done this parametric optimization with the following pairings: MASEI-ASDAS, MASEI-BASDAI and MASEI DAPSA.

Results: We analyze twenty four patients with SpA (with mean age 50.50 ± 10.63 years) 8 women and 16 men. They present: radiographic axial spondyloarthritis (5 patients), non-radiographic axial spondyloarthritis (4 patients), psoriatic arthritis (10 patients), spondyloarthritis associated with inflammatory bowel disease (2 patients), reactive arthritis (2 patients), and, finally, one patient has undifferentiated peripheral spondyloarthritis. The variables have the following average levels: ASDAS, 2.35 (±1.09); BASDAI (for those with axial involvement) 4.54 (±2.93); DAPSA (for psoriatic arthritis) 10.98 (± 6.85) and total MASEI 19.88 (± 14.77). We have found a correlation between the total MASEI and the following variables: ASDAS (Pearson coefficient=0.696), BASDAI (Spearman coefficient=0.823) and DAPSA (Pearson coefficient=0.823). The mean vitamin D levels were 25.98 (±12.05), and it has a negative correlation with the MASEI equal to -0.317. As far as curve fitting is concern, a couple of sinusoidal functions were obtained for the MASEI-ASDAS and MASEI DAPSA pairings (see Figure 1 and Figure 3) and a linear regression for MASEI-BASDAI (see Figure 2). These three curves have an R-squared fit of 0.77, 0.87 and 0.52, respectively.

Conclusion: Patients with spondyloarthritis who present greater activity of the disease measured by ASDAS, BASDAI/DAPSA and by the serological markers of inflammation CRP and ESR, present a higher total MASEI than patients who are controlled. In addition, it has been observed that patients with low levels of vitamin D have higher disease activity and a higher total MASEI.

AB0852 ASSESSMENT OF ENDOTHELIAL DYSFUNCTION IN SPONDYLOARTHRITIS

A. Ben Tekaya[1,2], T. Mehmli[1,2], S. Boukriba[2,3], F. Ahmed[2,3], O. Saidane[1,2], R. Leila[1,2], S. Bouden[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], H. Mizouni[2,3], L. Abdelmoula[1,2]. *[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; [2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; [3]La Rabta Hospital, Radiology department, Tunis, Tunisia*

Background: Endothelial dysfunction is the earliest step in the pathogenesis of atherosclerosis, preceding structural vascular alterations. Few studies have focused on the endothelial dysfunction in spondyloarthritis.
Objectives: The aim of our study was to assess endothelial dysfunction using Flow-Mediated dilatation (FMD) in patients with spondyloarthritis.
Methods: Forty-seven consecutive patients meeting ASAS 2009 criteria for spondyloarthritis and 47 matched healthy subjects were included in the study. Subjects with traditional cardiovascular risk factors were excluded. Sociodemographic, clinical, biological and radiological features related to the disease as well as therapeutics were recorded. FMD was assessed ultrasonographically according to guidelines of American college of cardiology (ACC) (1).
Results: Spondyloarthritis group included 47 patients with a sex ratio of 2.35 and a median age of 36 years (IQR: 28-46). Median body mass index (BMI) was 24.5 kg/m2 (IQR 25-75%: 20.7-26.8) with no significant difference compared with the control group (p=0.238). Physical examination showed normal values of blood pressure (BP) with a median systolic BP of 121 mmHg (IQR 25-75%: 110-130) and a median diastolic BP of 71 mmHg (IQR 25-75%: 67-78). In laboratory findings, total cholesterol and triglyceride levels were increased in 2 and 3 patients respectively.
Median age at onset of SpA was 20 years (IQR 25-75%; 18-32). For disease activity, median CRP level was 6.45 mg (IQR 25-75%: 1.45-19.9) and median ASDAS-CRP and BASDAI were respectively 2.18 (IQR 25-75%: 1.62-2.91) and 2.6 (IQR 25-75%: 1.8-3.8). Median MASES score was 0 (IQR 25-75%; 0-0). Median BASFI and BASMI were 3 (IQR 25-75%; 1.5-5.1) and 1.5 (IQR 25-75%: 0-4). Regarding treatment, 92% of patients were using NSAIDs, csDMARDs (51%) and 38% were on TNF inhibitors.
Patients with spondyloarthritis exhibited significantly lower FMD values than healthy age and gender matched controls with a median value of FMD 14.6% (IQR; 9-24) versus 18.8% (IQR; 12.8-23.1%); p=0.008.
Conclusion: Our study demonstrates impairment of endothelial function in patients with spondyloarthritis compared with healthy population, confirming the accelerated atherosclerosis in spondyloarthritis.

AB0853 THE ROLE OF IL-17, IL-23 SERUM LEVELS IN PATIENTS WITH ANKYLOSING SPONDYLITIS WITH INFLAMMATORY BOWEL DISEASES

G. Lukina[1,2], P. Kulakova[1], E. Alexandrova[3], A. Novikov[3], N. Savenkova[1], A. Klimets[1], I. Kartushina[3], A. Kovshik[1], E. Volnukhin[1]. *[1]The Loginov Moscow Clinical Scientific Center of Moscow Healthcare Department" (The Loginov MCSC MHD), Rheumatology, Moscow, Russian Federation; [2]I.V. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; [3]The Loginov Moscow Clinical Scientific Center of Moscow Healthcare Department" (The Loginov MCSC MHD), Immunology, Moscow, Russian Federation*

Background: Currently, there is a lot of interest in the frequency and risks of developing of inflammatory bowel diseases (IBD) in patients with ankylosing spondylitis (AS) [1]. IL-17 and IL-23 are one of the key pathogenetic markers of AS [2]. A lot of studies also showed that the average number of IL-17 cells was significantly increased in active Ulcerative colitis (UC) and Crohn disease (CD) patients [3]. According to some studies cytokines, such as IL-17 and IL-23, play crucial role in intestinal protection and homeostasis [4].
Objectives: The aim of this study was to evaluate IL-17 and IL-23 serum levels in patients with AS without IBD and with AS and IBD.
Methods: In the analysis were included 50 patients with AS, fulfilling the modified New York criteria, among them man-36 (72%), woman-14 (28%), mean age of patients was 42.5±9.9, mean disease duration – 13.4±8.7 years. All patients were examined with ESR, CRP, esophagogastroduodenoscopy, colonoscopy, IL-17 and IL-23, using enzyme-linked immunosorbent assay for the quantitative measurement of IL-17 and IL-23 in serum ELISA kit. IL-17 and IL-23 levels were also studied in control group (13 healthy donors), mean IL-17 was 1.16±1.02 pg/mL, mean IL-23 was 33.03±18.02 pg/mL.
Results: All patients had a high disease activity, mean BASDAI was 5.3± 1.8, mean ASDAS CRP 3.7±1.01, mean ASDAS ESR 3.6±1.01. IBD were diagnosed in 11 cases: 6 patients (12%) with CD and 5 patients (10%) - UC, in the remaining cases (78%-39 patients) was no intestinal pathology. Patiens with AS had higher levels of IL-17(10.4±9.1 pg/ml) and IL-23(188±156 pg/ml), than the group of healthy donors. Patients with AS and IBD had slightly lower IL-17(6.7±4.5 pg/ml) and IL-23(155.5±97 pg/ml) levels than patients with AS without IBD(p=0.03). IL-23 was positively correlated with ESR (r=0.5) and CRP (r=0.5) (p <0.001) levels, however IL-17 level had negative correlation with ESR and CRP level (r=-0.2) (p<0.001).
Conclusion: IL-23 and IL 17 serum levels in patients with AS and IBD was lower than in patients with AS without IBD. There is a significant association between the CRP, ESR and IL-23 level, but not with IL-17.

AB0854 DESCRIPTIVE AND RETROSPECTIVE STUDY OF DIFFERENT TYPES OF SPONDYLOARTHRITIS AND REFERRAL AND DIAGNOSIS TIMES

U. Astigarraga Urkia[1], N. Del Val del Amo[1], L. Ibarrola Paino[1], M. Lopez Gomez[1], J. Mendizábal Mateos[1], G. Sada Urmeneta[1], S. García Pérez[1], L. Garrido Courel[1], I. Paniagua Zudaire[1], R. Gutierrez[1], L. Horcada[1], M. C. Fito Manteca[1]. *[1]Hospital Universitario de Navarra, Rheumatology, Pamplona, Spain*

Background: Spondyloarthritis (SpA) is a group of inflammatory arthropathies of unknown aetiology that share several clinical, pathophysiological, serological and radiological features. In many cases the initial symptoms are insidious, leading to a delay in diagnosis and initiation of treatment. The time between the onset of symptoms and treatment is of vital importance for the prognosis of the disease.
Objectives: To describe the clinical characteristics of the SpA cohort, to analyse the number of months from symptom onset to referral to the rheumatology department and diagnosis of SpA, as well as differences according to the referring department.
Methods: Retrospective descriptive study of patients with a diagnosis of PsA according to the ASAS criteria and CASPAR criteria for the psoriatic arthritis subgroup (PsA), in a single hospital centre.
We collected demographic variables separated by subgroups of peripheral and axial SpA and PsA, age at diagnosis, time from symptom onset to referral to the rheumatology department and to diagnosis, as well as differences according to the department making the referral.
Results: Seventy-five patients with SpA were analysed, 40 had peripheral and axial SpA and 35 (46.66%) PsA. Thirty-six patients (49.3%) were female (Table 1). Patients with peripheral and axial SpA had a higher mean age at diagnosis than patients with PsA. 45.1 years (SD 11.3) was the mean age at diagnosis. 73.6% of patients were referred from primary care (PC), 9.4% from traumatology, 9.4% from rehabilitation (RH), 3.8% from dermatology and 3.8% from the emergency department. The median time from first symptom to referral to rheumatology was 31.4 (SD 57.2), 7.1 (SD 38.5), 21.7 (SD 51.4) months in peripheral and axial SpA, PsA and total respectively (Table 2). The service with the longest time between symptom onset and referral to rheumatology is PC and rehabilitation for all groups. The median time from first symptom to diagnosis was 43.1 (SD 55.1), 34.4 (SD 65.8) and 39.2 (SD 59.7) months for peripheral and axial SpA, PsA and total respectively (Table 2). The time from referral to rheumatology to diagnosis of peripheral and axial SpA was 12.2 (SD 19.4), PsA 17 (SD 39.3) and total 14.3(SD 29.5) months.

Table 1. Demographic characteristics and time in months according to type of SpA.

	Peripheral and axial SpA	PsA	Total
Age at diagnosis	45.1 (SD11.8)	44.9 (SD10.9)	45.1 (SD11.3)
Female	20 (51.3%)	16 (47.1%)	36 (49.3%)
Hypertension	10 (25.0%)	10 (29.4%)	20 (27.0%)
Dyslipidaemia	17 (42.5%)	17 (51.5%)	34 (46.6%)
Diabetes mellitus	5 (12.5%)	6 (17.6%)	11 (14.9%)
Body Mass Index	27.9 (SD4.4)	30.5 (SD8.4)	29.2 (SD6.7)
Cardiovascular disease	5 (12.5%)	2 (5.9%)	7 (9.5%)
Cerebrovascular disease	2 (5.0%)	2 (5.9%)	4 (5.4%)
Depression	1 (2.5%)	1 (2.9%)	2 (2.7%)
Renal insufficiency	1 (2.5%)	1 (3.0%)	2 (2.7%)
Liver failure	3 (7.5%)	5 (14.7%)	8 (10.8%)
Time in months from 1st symptom to referral	31.4 (SD57.2)	7.1 (SD38.5)	21.7 (SD51.4)
1Primary care	30.9(SD10.9)	7.01(SD34.1)	21.07(SD35.2)
1Traumatology	5 (SD1.25)	5 (SD2.82)	5 (SD1.48)
Rehabilitation	36 (SD29.14)	19	27.5 (SD24.75)
7Dermatology		13 (SD1.41)	13 (SD1.41)
3Emergency service	1	1	1
Time from referral to diagnosis	12.2 (SD19.4)	17.0 (SD39.3)	14.3 (SD29.5)
Time from 1st symptom to diagnosis	43.1 (SD55.1)	34.4 (SD65.8)	39.2 (SD59.7)

Conclusion: In our cohort, patients are referred to rheumatology mainly from PC, which in turn is the service with the longest delay, especially in the peripheral and axial SpA group. Patients with PsA take less time to be referred than patients with peripheral and axial SpA. Once referred to rheumatology, peripheral and axial SpA patients take less time to be diagnosed than those in the PsA group.

AB0855 COMPARISON OF CARDIAC INVOLVEMENT BETWEEN ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLITIS

I. El Mezouar[1], N. Akasbi[1], T. Harzy[1]. *[1]CHU HASSAN II, Rheumatology, Fez, Morocco*

Background: While cardiac involvement is increasingly recognized and investigated in patients with axial spondyloarthritis (axSpA), few studies have investigated the occurrence of cardiac involvement in patients with non-radiographic axial spondyloarthritis (nr- axSpA) in relation to ankylosing spondylitis (AS).
Objectives: The objectives of the present study are to describe and compare the characteristics of cardiac involvement between AS and axSpA nr patients.
Methods: A cross-sectional study was conducted in the rheumatology department of the University Hospital of Fes in Morocco, including patients diagnosed as having axial spondyloarthritis according to the ASAS 2010 criteria, for a period of 9 years. Patients were classified as r-axSpA by the presence of radiographic sacroiliitis according to the modified New York criteria and nr-axSpA defined by the presence of sacroiliitis on MRI.
Results: 375 patients were included in the study. We compared 257 AS to 118 with nr-axSpA. The cohort was predominantly female (54.9%) with a mean age of 46.83 years (S.D. 14.00). AS patients were significantly young (45 vs 50 years), more frequently male (55% vs 22%) and had higher serum inflammatory markers than those with nr-axSpA. Between AS and nr-axSpA groups, arterial hypertension was higher in nr-SpA patients (24.6% versus 14.4%, p = 0.016). While valvulopathy, myocardial infarction, pericarditis and heart failure were higher in AS patients with respectively (8.6% vs 3.4%, p=0.067) (1.6% vs 0.8%, p=0.578) (1.2% versus 0.8%, p = 0.779) (0.4% versus 0%, p = 0.497). However, arrhythmias were similar in AS patients and nr-SpA patients (0.8% versus 0.8%, p = 0.571).
Conclusion: Cardiac involvement was common in both axSpA populations and similar between AS and nraxSpA except in hypertension where there is a significant difference between the two groups. These results highlight the importance of identifying and managing cardiac involvement in these patients

AB0856 PREVALENCE OF HLAB27 ANTIGEN IN MOROCCAN PATIENTS WITH SPONDYLOARTHRITIS (SPA): A MULTICENTER STUDY

I. Bentaleb[1], S. Rostom[1], B. Amine[1], I. El Binoune[1], I. El Bouchti[2], I. Ghozlani[3], R. Bahiri[1]. *[1]ALAYACHI HOSPITAL, Rheumatology, Salé, Morocco; [2]AR-RAZI HOSPITAL, Rheumatology, Marrakesh, Morocco; [3]Military Hospital AGADIR, Rheumatology, AGADIR, Morocco*

Background: Spondyloarthritis includes an heterogeneous group of rheumatisms characterized by their strong association with HLA-B27 (1). The association between SpA and HLA-B 27 is one of the strongest known associations between an HLA allele and disease (2). Several studies have highlighted the importance of this association for diagnosis, predicting disease phenotype and prognosis of spondyloarthritis (SpA) (1.2).
Objectives: The aim of the present study is to determine the prevalence of HLAB27 in Moroccan SpA patients and to analyze the correlation between HLAB27 status and different disease parameters.
Methods: It is a multicenter cross-sectional study including 256 SpA patients. Demographic, clinical, paraclinical and therapeutic parameters of the disease were collected. Disease activity was assessed by BASDAI and ASDAS-CRP scores. Patients were classified into two groups: HLAB27(+) and HLAB27(-). A comparison regarding HLA-B27 status was performed using the Mann-Whitney and Chi2 T-student tests. The significance threshold was set at p<0.05.
Results: 256 SpA patients were included in the study, 241 patients have HLAB27 status of which 114 (44.5%) were HLAB27-positive. 46.6% of men and 40.9% of women were HLAB27-positive. 233 patients had axial SpA of which 110 patients (47.21%) were HLAB27-positive. The mean age was 39.58 ±12.89 years. The HLAB27-positive group had a longer diagnostic delay (p= 0.008) with a mean of 4 years. 46 patients had a family history of SpA of which 25.4% were HLAB27-positive and 11.8% HLAB27-negative (p=0.007). The HLAB27-positive patients had more axial manifestations (96.5% vs. 85.9%; p=0.01). While peripheral involvement was more noted in the HLAB27-negative group (90.6% vs 35.1%; p<0.001). Enthesopathy was more observed in the HLAb27-positive group (78% vs 62.2%; p=0.001). HLAB27-positive patients had more active disease defined by ASDAS-CRP (3.13±1.23 vs. 2.24±1.14; p<0.001). Only one case of uveitis was noted in the HLAb27-negative group versus 27 cases in the HLAB27-positive group (p<0.001). 33 HLAB27-positive patients had radiographic coxitis (33 vs16, p=0.002). The bDMARDS were more prescribed in the HLAB27-positive patients (58.8% vs 35.4%; p=0.009).
Conclusion: In our study, the prevalence of HLAB27 was close to the MENA region (3). The presence of HLAB27 is related to an earlier disease onset, higher activity, to the presence of coxitis and uveitis and consequently more use of biotherapy in this group (HLAB27-positive).

AB0857 INCREASED CAROTID INTIMA-MEDIA THICKNESS IS CORRELATED WITH RENAL FUNCTION IN SPONDYLOARTHRITIS

A. Ben Tekaya[1,2], T. Mehmli[1,2], S. Boukriba[2,3], F. Ahmed[2,3], O. Saidane[1,2], R. Leila[1,2], S. Bouden[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], H. Mizouni[2,3], L. Abdelmoula[1,2]. *[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; [2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia; [3]La Rabta Hospital, Radiology department, Tunis, Tunisia*

Background: Cardiovascular diseases are the main cause of mortality in spondyloarthritis and seem to be multifactorial. Due to its easy application and reproductibility, carotid intima-media thickness (CIMT) is increasingly used for assessment of subclinical atherosclerosis and cardiovascular risk stratification.
Objectives: The aim of our study was to investigate the relationship between CIMT and renal function in patients with spondyloarthritis (SpA).
Methods: We performed a cross sectional study including 47 patients with SpA and no history of cardiovascular disease. Clinical and biological data were recorded. Data related to renal involvement and creatinine level were extracted. CIMT was measured in the right and the left common carotid artery by an experienced radiologist; than mean CIMT was calculated.
Results: Our study included 33 men and 14 women with a sex ratio of 2.35, a median age of 36 years (IQR 25-75%: 28-46) and a median duration of the disease of 11 years (IQR 25-75%: 5-16). Renal involvement was found in 6 patients (13%): kidney stones (n=2), tubulo-interstitial nephritis (TIN) (n=2), IgA nephropathy (n=1) and AA amyloidosis (n=1). Median creatinine level was 63 µmol/l (IQR 25-75%: 58.5 - 64). No patient had kidney failure.
Ultrasound examination found median right, left and mean (CIMT) of 0.54 mm (IQR 25-75%: 0.50-0.63), 0.55 mm (IQR 25-75%: 0.49-0.61) and 0.55 mm (IQR 25-75%: 0.48-0.62) respectively. Increased CIMT values were found in 8 patients (17%). No patient had atherosclerotic plaque.

Patients with renal involvement had significantly higher values of CIMT (0.64 mm (IQR 25-75%: 0.56-0.70) vs 0.53 mm (IQR 25-75%: 0.47-0.59); p= 0.045). Significant positive correlation was also detected between CIMT values and creatinine level (p=0.002; r=0.445).

In multivariate linear regression, creatinine level was identified as independent predictor of increased CIMT (B=0.002; 95% confidence interval=0.000-0.005; p=0.035).

Conclusion: Although all patients included have normal creatinine level, we identified creatinine level as independent predictor of subclinical atherosclerosis in SpA patients. This finding highlights the monitoring of this parameter.

AB0858 CLINICAL CHARACTERISTICS OF PATIENTS WITH SPONDYLOARTHRITIS WITH COVID-19 IN ANAMNESIS IN THE REPUBLIC OF TATARSTAN

V. Mukhamadieva[1], S. Lapshina[1], N. Shamsutdinova[2], A. Sagitova[3], A. Zakirova[1], L. Krasnova[1], R. Abdrakipov[4], D. Abdulganieva[1]. *[1]Kazan State Medical University, Department of hospital therapy, Kazan, Russian Federation; [1]Kazan State Medical University, Department of hospital therapy, Kazan, Russian Federation; [1]Kazan State Medical University, Department of hospital therapy, Kazan, Russian Federation; [4]Republican clinical hospital, rheumatology, Казань (Российская Федерация, Республика Татарстан), Russian Federation*

Background: The management of patients with spondyloarthritis (SpA) during the period of the novel coronavirus infection (NCI) pandemic is a significant problem due to insufficient evidence base.

Objectives: To study the features of the course NCI and its influence on the course of SpA.

Methods: From March 2020 to January 2022, 55 patients with SpA who underwent NCI (with a confirmed result of SarsCoV2 PCR and / or using X-ray computed tomography (CT) of the lungs): ankylosing spondylitis (AS) 37 people, with psoriatic arthritis (PsA) 18 people. Of these 32 (58.2%) were men, 23 (41.8%) - women, the average age of patients was 49 [37.5; 57.5] years. The duration of SpA at the time of NCI was 11 [7; 16] years. SpA activity before NCI was low in 15 (34.8%) patients, moderate in 25 (58.1%), and high in 3 (6.9%) patients. The results of clinical and laboratory examinations were evaluated during the NCI and after 1, 3, 6 months.

Results: Symptoms of NCI in patients with SpA were comparable in frequency and severity to the course of infection in the population. 47.3% had a mild course of NCI, and 52.7% of those observed had a moderate course, which is comparable with the general population data. Lung involvement was detected in 29 (52.7%) patients. The outcome of COVID-19 in all patients is recovery. Analysis of the course of SpA showed an increase in activity 1 and 3 months after NCI: BASDAI from baseline to COVID-19 4.3±1.57 to 4.9±1.7 points after 3 months, similar to ASDAS_CRP from 2.6±1, 2 to 3.7±0.2, BASFI from 3.0±1.9 to 3.8±1.8. A positive correlation was found between the severity of NCI and the BASFI index after 3 months (0.870). Analysis of the course of PsA showed an increase in activity 1 and 3 months after NCI: DAS28 from the baseline 2.78±0.98 to 4.15±1.16 points after 3 months. Of the total number of recoveries, 72.2% of patients showed an increase in activity due to clinical and laboratory parameters.

78.1% of patients noted the presence of post-COVID symptoms after NCI, 56.3% had a combination of more than 3 different symptoms. Most often there was an increase/appearance of pain in the joints - in 78.1%: significant - in 61.8%, insignificant - in 16.3% of respondents. Strengthening/appearance of muscle pain and/or headache and/or dysautonomia occurred in 72.7%. This can be assessed as an exacerbation of the underlying disease, or, conversely, the appearance of arthralgia and myalgia could have an impact on the increase in AS and PsA activity indices. The second most frequent were a decrease in the quality of life (QOL) and working capacity in 69.0% of patients: significant in 36.3% of patients, insignificant in 32.7%.

The appearance/intensification of shortness of breath and a decrease in exercise tolerance were noted by 60% of the respondents. Among them, 34.5% of patients with moderate severity, 25.4% - with mild NCI. Appearance/intensification of chest pain and/or palpitations was noted by 16.3% of patients

Conclusion: The prevalence and course of the NCI in patients with SpA did not differ from that in the population. However, coronavirus infection has led to increased pain and an increase in AS activity, long-term persistence of post-COVID manifestations in the form of musculoskeletal pain and asthenic symptoms in the form of a decrease in the quality of life. At the same time, specific respiratory symptoms occurred in a third of patients and were not associated with the severity of the NCI.

AB0859 ASSESSMENT OF SELF-ESTEEM AND REINTEGRATION TO NORMAL LIVING IN SPONDYLOARTHRITIS PATIENTS

T. Mehmli[1,2], A. Ben Tekaya[1,2], O. Saidane[1,2], R. Leila[1,2], S. Bouden[1,2], R. Tekaya[1,2], I. Mahmoud[1,2], L. Abdelmoula[1,2]. *[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; [2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia*

Background: Spondyloarthritis is a chronic inflammatory disease involving sacroiliac joints and spine. It mainly affects young patients typically of working age. Pain, reduced spinal mobility and deformities may lead to psychological distress.

Objectives: The aim of our study was to assess self-esteem and social reintegration in spondyloarthritis patients in comparaison with healthy controls.

Methods: Fifty patients diagnosed with spondyloarthritis and 50 healthy controls aged less than 50 years old, were included in our study. Clinical, biological and radiological data related to disease were recorded. All subjects completed Reintegration to Normal Living Index (RNLI) and Rosenberg self-esteem scale (SES) questionnaires.

Results: Our study population included 39 men (78%) and 11 women (22%) with a mean age of 36.8 years [17-50]. Mean disease duration was 11.3 ± 8.2. Mean disease activity scores BASDAI, ASDAS-CRP and ASDAS-ESR were respectively 4.45 ± 1.84, 3.03± 1.06 and 2.74 ± 1. For inflammatory markers, mean CRP and ESR levels were respectively 29.3 ± 41.8 mg/l and 46.5 ± 35.3. Mean BASFI and BASRI scores were respectively 5.21 ± 2.24 and 5.5 ± 2.38. Forty eight pour cent of patients had an extra-articular feature and 47% had coxitis. Regarding treatment, 47% were on TNF inhibitors.

Mean SES was 30.6 [25-36]. Fifty six per cent of patients had a low self-esteem (SES<31) and 12% had high self-esteem (SES>34). Self-esteem was within the normal ranges (SES between 31 and 34) in 32% of patients. Mean reintegration to normal life (RNL) adjusted score was 72.8 ± 9.3.

Significant association was found between RNL adjusted score and BASDAI (p=0.02, r=0.126) and BASFI (p=0.034, r=0.235). There was no significant association between RNL adjusted score and disease duration (p=0.747), CRP (p=0.213), ESR (p=0.818), ASDAS-ESR (0.747) and ASDAS-CRP (p=0.330) and BASRI scores (p=0.413). No association was found between SES score and disease duration (p=0.447), activity scores BASDAI (p=0.178), ASDAS-ESR (p=0.929) and ASDAS-CRP (p=0.940), ESR (p=0.417) and CRP levels (p=0.828), as well as BASFI (p=0.295) and BASRI (p=0.470).

In comparaison with healthy controls, adjusted RNL score was significantly lower in patients with spondyloarthritis (72.8 versus 77.65; p=0,017). In contrast, no significant difference was found between the two groups when comparing SES score (31.4 in spondyloarthritis patients versus 30.6 in healthy controls, p=0.283).

Conclusion: In our study, spondyloarthritis patients had lower RNL score in comparaison with healthy subjects. Reintegration to normal living was associated with disease activity and functional impairment. In contrast, self-esteem was similar between the two groups.

AB0860 REPERCUSSIONS OF TOBACCO ON SPONDYLOARTHRITIS: THE ICEBERG EFFECT!

L. Kharrat[1], M. Slouma[1], A. Abdennadher[2], K. Amri[2], Y. Mallat[2], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[3]. *[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia; [2]Military Hospital of Instruction of Tunis, Orthopedics, Tunis, Tunisia; [3]Military Hospital of Instruction of Tunis, Internal medecine, Tunis, Tunisia*

Background: The deleterious effect of smoking is frequently studied in inflammatory diseases such as spondyloarthritis (SA) [1].

Objectives: The objective of our study was to identify the consequences of smoking during AS.

Methods: We conducted a cross sectional study including patients followed for spondyloarthritis meeting the ASAS 2009 criteria. For each patient we collected the following parameters: age, age at onset of the disease, duration of progression, disease activity using BASDAI and ASDAS-CRP scores and structural damage using BASRI and mSASSS scores. We also measured sedimentation rate (ESR) and C-reactive protein (CRP).

Statistical analysis was performed using SPSS software.

Results: We included 140 patients. Seventy-three percent were male (n=102). The mean age was 43 ± 12.9 years. The age of onset of the disease was 34.28 ± 12 years. The mean disease duration was 110 ± 107.8 months.

Sixty patients were smokers (43%) at an average of 20.75 ± 16.09 pack-years.

Mean ESR and CRP were 36.49 ± 27.22 mm and 29 ± 44.27 mg/L, respectively.

The mean BASDAI and ASDAS-CRP were 3.68 ± 1.86 and 2.99 ± 0.98, respectively.

The mean BASRI and mSASSS were 4.12 ± 3 and 10.26 ± 15.41, respectively.

Smokers had significantly higher BASRI and mSASSS scores (BASRI: 5.02 ± 3.32 vs 3.47 ± 2.6; p=0.005 and mSASSS: 14.07 ± 17.56 vs 7.02 ± 12 .62; p=0.03). In addition, the number of packets year was correlated to mSASSS (r=0.399; p=0.01).

On the other hand, we did not find any association between smoking and the following parameters: ESR, CRP, BASDAI or ASDAS-CRP.

Conclusion: As reported in other studies, ours' showed that structural damage was correlated with the number of pack-years [2]. Smoking was associated with this structural damage in SA regardless the inflammatory biomarkers and the disease activity. This suggests that control of structural damage in SA requires smoking cessation.

AB0861 INCREASED SERUM INTERLEUKIN 8 LEVELS IN SPONDYLOARTHRITIS

L. Kharrat[1], M. Slouma[1], A. Tezeghdenti[2], E. Ghazouani[2], A. Abdennadher[3], K. Amri[3], Y. Mallat[3], L. Metoui[1], R. Dhahri[1], I. Gharsallah[1], B. Louzir[4]. *[1]Military Hospital of Instruction of Tunis, Rheumatology, Tunis, Tunisia; [2]Military Hospital of Instruction of Tunis, Immunology, Tunis, Tunisia; [3]Military Hospital of Instruction of Tunis, Orthopedics, Tunis, Tunisia; [4]Military Hospital of Instruction of Tunis, Internal medecine, Tunis, Tunisia*

Background: Physipathological mechanisms of spondyloarthritis (SA) are very complex. The role of the interleukin (IL)- 8, which is an angiogenic chemokine, has been suggested [1].

Objectives: We aimed to evaluate the discriminative value of interleukin 8 in SA.

Methods: We conducted a cross-sectional study during two years (2019-2020) including 144 subjects divided into two groups: a group G1 that included 72 patients followed for spondyloarthritis meeting the Assessement of SpondyloArthritis international Society (ASAS) criteria and a group (G2) including 72 healthy controls. The two groups were matched by age and sex.

IL-8 was measured for each participant using chemiluminescence.

We performed a ROC analysis and computed the air under the curve (AUC) at IL-8 to assess the ability of this chemokine to diagnose SA and to distinguish between SA patients from healthy controls. Statistical analysis was performed using SPSS.

Results: We included 57 men and 15 females in each group. The mean age was 44.84 ± 13.42 years. In G1, the mean disease duration was 10.25 ±7.7 years. Axial and peripheral involvements were found in 85% of cases (n=65) and 50% of cases, respectively.

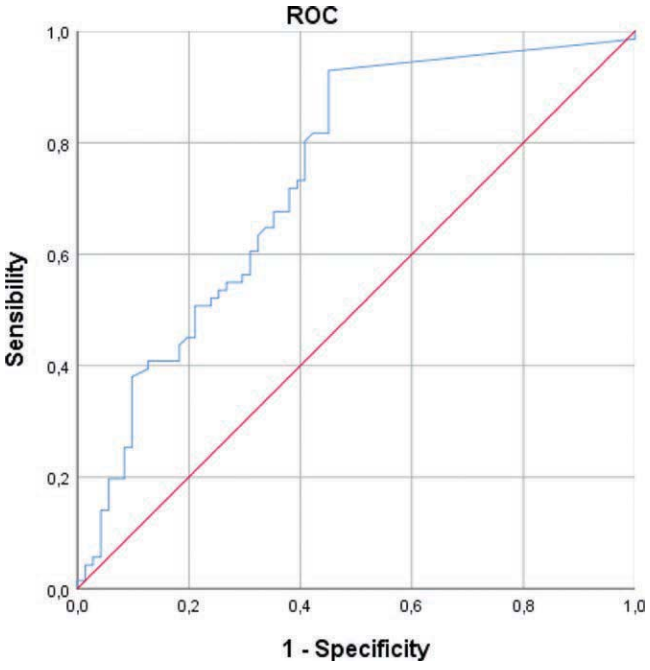

Figure 1. AUC at IL-8 between SA patients and healthy controls 0.855 (p<0.0001)

The mean BASDAI and ASDAS-CRP were 3.21 ± 1.87 and 2.92 ±1.55, respectively.

IL-8 was able to distinguish SA patients from healthy controls with a cutoff of 4.5 pg/mL. The AUC was good at 0.855 (p<0.0001). The sensibility and the specificity were 92.8% and 81.6% (Figure 1).

Conclusion: Several studies have found that IL-8 was significantly higher in SA patients comparing to controls [2,3]. Our study showed that IL-8 could distinguish SA patients from controls with a cutoff of 4.5 pg/mL. This suggests that IL-8 could play a role in the pathophysiology of SA.

AB0862 ASSOCIATION OF EMOTIONAL DYSFUNCTION WITH GASTROINTESTINAL SYMPTOMS AND DISEASE ACTIVITY IN PATIENTS WITH SPONDYLOARTHRITIS

Á. Arzuaga[1,2], J. A. Sucerquia Quintero[3], J. M. Bello-Gualtero[1,2], J. De Avila[4], W. Bautista-Molano[1,4], C. Romero-Sánchez[1,2,4]. *[1]Universidad Militar Nueva Granada, School of Medicine, Clinical Immunology Group, Bogotá D.C., Colombia; [2]Hospital Militar Central, Rheumatology and Immunology Department, Bogotá D.C., Colombia; [3]Fundación Universitaria Juan N Corpas, School of Medicine, Bogotá D.C., Colombia; [4]Universidad El Bosque, Cellular and Molecular Immunology Group - INMUBO-, Bogotá D.C., Colombia*

Background: Spondyloarthritis (SpA) is a heterogeneous condition characterized by chronic back pain, fatigue and progressive loss of mobility, associated to decreasing quality of life, physical and mental health. SpA patients may have a presence of non-specific gastrointestinal symptoms or subclinical intestinal inflammation. Although the association between SpA and high levels of distress has been investigated, few studies have included gastrointestinal involvement among the factors associated with mental health.

Objectives: To evaluate emotional functionality of patients with SpA, and their association with the presence of gastrointestinal symptoms and disease activity.

Methods: In total, 98 patients with SpA (fulfilling ASAS criteria) were assessed by rheumatologists. Patients with two or more gastrointestinal symptoms were referred to gastroenterology. Furthermore, those patients with SpA and concomitant IBD were excluded. BASDAI, BASFI, ASDAS-CRP, ASDAS-ESR were performed. Patient Health Questionnaire (PQH9) for depression and Perceived Stress Scale-10 (PSS10 for Distress and confrontation) were used to assess clinical and psychological status. Fecal Calprotectin, CRP, ESR, and HLA-B*27:05 were assessed. The associations were evaluated using the Chi-square or Fisher's exact test and U de Mann-Whitney. Spearman and Pearson test were made to explore correlations (Ethical/Code. 2017-023).

Results: The average age of patients was 42.3±10.5 years, 58.2% were men and 42.9% presented the HLA-B*27:05 allele. Axial involvement (77.60%), peripheral involvement (46.90%), and ≥2 gastrointestinal symptoms in the last month (65.30%) were found. With regard to outcome measures of disease activity, BASDAI 4.75±2.74 and ASDAS-CRP 2.44 ±0.95 was observed.

In total, 72.4% of patients had some degree of depression: 22.4% mild, 20.4% moderate, 12.2% high moderate and 11.2% severe. Male gender was associated with higher frequency of depression, 51% of them presented with moderate to severe involvement (p=0.036). The presence of ≥2 gastrointestinal symptoms was associated with a higher frequency of depression (p=0.013), taking importance the presence of abdominal pain in 57.2% (p=0.007), it is also associated with fatigue (p < 0.001) and with higher scores of disease activity BASDAI (CC 0.696), ASDAS-CRP (CC 0.590) ASDAS-ESR (CC 0.519) and BASFI (CC 0.737) (p < 0.001 respectively).

Considering the PSS-10 assessment, 21.4% of patients had higher levels of distress, which were associated with the presence of abdominal pain (p=0.038), BASDAI>4 (p=0.047), ASDAS-CPR > 3.5 (p=0.013). Additionally, 57.1% of patients reported more frequency of decreased confrontation capacity which was related with fatigue (p=0.013), BASFI>4 (p=0.028), ASDAS-CRP >2.1 (p=0.03) and HLA-B*27:05 (p=0.06). These variables were simultaneously associated with higher levels of distress (p=0.035, p=0.004, p=0.03 and p=0.06 respectively).

Conclusion: Disease activity and gastrointestinal symptoms in SpA patients without IBD, are associated with emotional dysfunctional outcome related to poor

quality of life. These findings highlight the importance of a holistic monitoring towards remission of SpA patients ensuring an emotional functional balance.

AB0863 EMERGENCE OF SPONDYLOARTHRITIS FOLLOWING B CELL-DEPLETING MONOCLONAL ANTIBODY THERAPY FOR MULTIPLE SCLEROSIS

T. Pham[1], P. Caroline[1], P. Lafforgue[1], C. Barral[2], A. Maarouf[3], J. Pelletier[3], A. Rico[3], B. Audoin[3]. [1]*Aix Marseille Univ, APHM, Rheumatology, Marseille, France;* [2]*Hopital Saint Joseph, Rheumatology, Marseille, France;* [3]*Aix Marseille Univ, APHM, Neurology, Marseille, France*

Background: Anti-CD20 B-cell-depleting therapies, including rituximab and ocrelizumab, have demonstrated their efficacy in patients with relapsing–remitting multiple sclerosis (RRMS).
Objectives: Herein we report a series of patients with RRMS treated with anti-CD20 monoclonal antibodies (mAb) who developed a de novo spondyloarthritis (SpA).
Methods: Following the presentation of an index case, we collected all cases of de novo SpA in the anti-CD20-treated RRMS cohort of our institution's referral center. Clinical, biochemical, and imaging characteristics of the cases were identified through a clinical assessment. Information was collected via a standardized form to obtain key characteristics on the onset and type of disease development at baseline and on outcomes up to 12 months. All patients had a magnetic resonance imaging (MRI) of the sacroiliac joints and, depending on the clinical presentation, a spine MRI and/or a musculoskeletal grayscale and power Doppler (PD) ultrasound (US) examination.
Results: De novo SpA developed in 6 of 480 patients with RRMS treated with anti-CD20 mAb, accounting for an incidence of 1.25%. All but one received rituximab treatment. The median time from the last anti-CD20 mAb infusion to SpA onset was 1.5 months [IQR: 1-4]. At the time of SpA emergence, the RRMS activity was controlled. The most frequent clinical SpA phenotype identified was peripheral SpA (4/6), with Power Doppler ultrasound-detected synovitis. The 2 patients with axial SpA phenotype had bilateral sacroiliitis on MRI. Five of the 6 patients had a personal or family history of psoriasis, whereas the prevalence of psoriasis in the entire RRMS cohort was 3.33% (16/480). No other extra-articular manifestation was observed. All patients were HLA B27 negative and fulfilled at least one classification criteria of SpA. None required hospitalization and the SpA onset did not affect the management of MS. The 2 patients with axial SpA were successfully treated with NSAIDs. Among the patients with peripheral SpA, 3 of four had inadequate response to NSAIDs, 2 were treated with methotrexate and 1 with leflunomide. Only one patient required initiation of an IL-17 inhibitor to control the SpA activity.
Conclusion: We report a pattern of patients with MS successfully treated with B cell-depleting drug developing axial or peripheral SpA, predominantly HLA-B27 negativity and associated with psoriasis.

AB0864 A NOMOGRAM MODEL COMBINING INFLAMMATORY FACTORS AND MRI RADIOMICS TO ASSESS THE DISEASE ACTIVITY OF THE PATIENTS WITH AXSPA IN A PROSPECTIVE STUDY

L. Ye[1], D. Chen[1], S. Miao[2], G. Zhu[2], M. Zheng[2], C. Pan[1], C. Ye[1]. [1]*First Affiliated Hospital, Wenzhou Medical University, Rheumatology, Wenzhou, China;* [2]*First Affiliated Hospital, Wenzhou Medical University, Radiology, Wenzhou, China*

Background: Clinical and magnetic resonance imaging (MRI) disease activity score (DAS) are measuring different aspects of axial spondyloarthritis (axSpA), they are essential in disease activity assessment. The radiomics was on facilitating readings by clinical specialists via enhancing the medical images in which subtle data differences could be distinguished.
Objectives: If the additional information of MRI imaging can be considered as a predictor for axSpA disease activity? In this study, we sought to construct a nomogram integrating the sacroiliac joint (SIJ)- MRI radiomics features and the inflammatory biomarkers to assess disease activity and compare it with clinical disease acitivity index in axSpA patients.
Methods: 203 patients data were collected prospectively and confirmed as axSpA were randomly divided into training (n = 143) and validation cohorts (n = 60). 1316 radiomics features were extracted from the 3.0T SIJ-MRI. A Nomogram model was constructed using multivariate logistic regression analysis Incorporating independent clinical factors and radiomics features score (Rad-score). The performance of clinics, Rad-score and nomogram models were evaluated by ROC analysis, calibration curve and decision curve analysis (DCA), and compared with the disease activity index(Ankylosing Spondylitis DAS (ASDAS)-C reactive protein (CRP), ASDAS-erythrocyte sedimentation rate (ESR), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI)) and Spondyloarthritis Research Consortium of Canada (SPARCC) MRI scoring system.
Results: The Rad-score allowed a good discrimination in the training (AUC, 0.91; 95% CI, 0.85-0.96) and the validation cohort (AUC, 0.84; 95% CI, 0.73-0.96). The CRP-radiomics nomogram model also showed favorable discrimination in the training (AUC, 0.96; 95% CI, 0.93-0.99) and the validation cohort (AUC, 0.89; 95% CI, 0.80-0.98), better than BASDAI(AUC, 0.58), ASDAS-CRP(AUC, 0.72), ASDAS-ESR(AUC, 0.77), ESR(AUC, 0.72), CRP(AUC, 0.77) and BASFI(AUC, 0.73), had no statistical difference with SPARCC(AUC, 0.87). Calibration curves and DCA demonstrated the nomogram fit well ($p > 0.05$) and was useful for activity evaluation.
Conclusion: Rad-score showed good discriminative ability to assess disease activity in axSpA. The nomogram can increase the efficacy for assessment axSpA disease activity, which might simplify clinical evaluation.

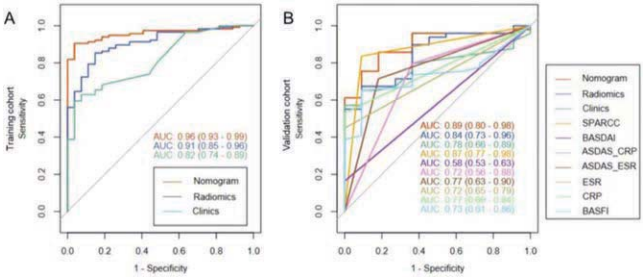

Figure 1. Comparison of ROC curve analyses in prediction models. ROC curves of the clinical features (green curve), radiomics signature model (blue curve), and hybrid model (gold curve) of axSpA in the training cohort (A) and validation cohort (B), respectively. In addition, there are AUC of ASDAS-CRP(pink curve), ASDAS-ESR(brown curve), BASDAI(purple curve), BASFI(azure curve) and SPARCC scoring system(yellow curve) in the validation cohort (B), respectively. AUC: area under the curve; ROC: receiver operating characteristic; SPARCC: Spondyloarthritis Research Consortium of Canada; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; ASDAS: Ankylosing Spondylitis Disease Activity Score; CRP: C reactive protein; ESR: erythrocyte sedimentation rate; BASFI: Bath Ankylosing Spondylitis Disease Activity Index.

AB0865 THE FACTORS AFFECTING PATIENT GLOBAL ASSESMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

E. Durak Ediboglu[1], D. Solmaz[1], H. Cinakli[1], G. Alp[1], E. Otman Akat[1], E. Erpek[1], İ. Kurut Aysin[1], S. Gucenmez[1], S. Ketenci[1], O. Bayindir[1], M. Ozmen[1], S. Akar[1]. [1]*Izmir Katip Çelebi University, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*

Background: The BASDAI is one of the basic scales used in the measurement of disease activity in patients with spondyloarthritis and allows the evalution of various aspects of the disease (axial and peripheral disease as well as

inflammation). The patient global assesment (PGA) is a one-dimensional scale in which patients evaluate how their illness affects their health.

Objectives: In this study, we planned to test and review the possible determinants of PGA and its relation with BASDAI components, BASFI scores and disease-related features both at first visit and at the 2 year follow-up.

Methods: Patients with axSpA whose baseline BASDAI and PGA scores were complated, were included in the analysis. The demographic, clinical and laboratory characteristics of the patients were recorded. The relation between PGA scores and BASDAI sub-score, BASFI score and other patient and disease characteristics were tested both univariate and multivariate analysis methods. The factors affecting the change in the PGA score over 2-year follow-up were also analyzed with GEE analysis method.

Results: In total 313 patients (56.5% of male, 61.7% AS, mean age at diagnosis 34.3±11 years) were included in the analysis. Sperman's rho test was used for correlation analysis. Baseline PGA scores were in correlation with the BASDAI total score (rho:0.71, p<0.001). PGA scores of female patients were found to be significantly higher (p=0.037) and each BASDAI indivual score and BASFI scores were moderately/well correlated with PGA (Table 1). Multivariate analysis revealed that spinal pain (BASDAI Q2), the severity of morning stiffness (BASDAI Q5) and BASFI scores were the main determinants in the global health assesments of patients with axSpA (Table 1). GEE analysis was performed to evaluate the factors affecting the 2 year change in the PGA of the patients, fatigue (BASDAI Q1) (B:1.575, CI%95: [0.241- 2.922]; p=0.021), enthesis (BASDAI Q4) (B:0.888, CI95% [0.049-1.727]; p=0.038) severity of morning stiffness (BASDAI Q5) (B: 2.663, CI%95 [1.447-3.878]; p<0.001),and BASFI scores (B: 2.909, CI95% [1.806-4.011]; p<0.001) were independent determinants of PGA in longitudinal analysis.

Table 1. Baseline PGA related factors

	Sperman Analysis		Model 1		Model 2	
	rho	**p**	**B (%95 CI)**	**p**	**B (%95 CI)**	**p**
sex	0.12	**0.037**	-3.183 (-8.903; 2.538)	0.27	-3.612 (-9.372; 2.148)	0.22
BASDAI Q1	0.59	**<0.001**	0.614 (-0.936;2.175)	0.44	0.861 (-0.686; 2.406)	0.27
BASDAI Q2	0.66	**<0.001**	3.168 (1.536; 4.800)	**<0.001**	3.231 (1.587; 4.874)	**<0.001**
BASDAI Q3	0.43	**<0.001**	0.619 (-0.613; 1852)	0.32	0.538 (-0.703; 1.779)	0.39
BASDAI Q4	0.43	**<0.001**	0.374 (-0.741;1.489)	0.51	0.529 (-0.587; 1.645)	0.35
BASDAI Q5	0.60	**<0.001**	2.088 (0.542; 3.634)	**0.008**		
BASDAI Q6	0.43	**<0.001**	-0.697(-2.053;0.660)	0.31		
BASDAI (Q5+Q6)/2	0.56	**<0.001**			1.195 (-0.218; 2.608)	0.097
BASFI	0.62	**<0.001**	2.097 (0.273-3.921)	**0.02**	2.263 (0.433; 4.094)	**0.016**
BASMI	0.28	**<0.001**	-0.321 (-1.879;1.237)	0.69	-0.319(-1.891; 1.253)	0.69
Serum CRP level	0.23	**<0.001**	0.066 (-0.100;0.233)	0.43	0.073 (-0.094; 0.241)	0.39

Conclusion: The study shows that the patients with axSpA mainly rely on morning stiffness and spinal pain in deciding their global health status. Fatigue, enthesis and morning stiffness were found to be effective factors in the PGA changes of the patients under treatment. Although PGA is unidimentional, its well correlation with the BASDAI total score may be another proof of the validity of both scales.

AB0866 WOMEN SPONDYLOARTHRITIS: EPIDEMIOLOGICAL, CLINICAL AND PARACLINICAL CHARACTERISTICS

H. Bara[1], H. Arabi[1], A. Rafi[1], A. Mougui[1], I. El Bouchti[1]. [1]*CENTRE HOSPITALO-UNIVERSITAIRE MOHAMMED VI MARRAKECH, rheumatology, Marrakech, Morocco*

Background: Spondyloarthritis (SPA) is a chronic inflammatory rheumatism characterized by sacroiliitis and spinal involvement, affecting both genders but more frequent in males.

Objectives: The aim of this study is to analyze the epidemiological, clinical and paraclinical characteristics of Spondyloarthritis in women.

Methods: Retrospective study included 333 patients followed up for SPA at the Rheumatology Department between 2004 and 2021.

Results: Our study involved 153 women and 180 men. In the female population, the mean age was 45.1 years, 12.4% had high blood pressure, 4.8% had a psychiatric comorbidity and none of the patients were smokers, versus a mean age of 36.4 years, 5% of high blood pressure's patients, 1.7% having a psychic comorbidity and 25% of the smokers for the male with SPA. The age of onset of symptoms was 36.5 years for women versus 28 years for men (p =0.001). Axial involvement was 84.3% in women and 85% in men, while peripheral and enthesial involvement was present in 73.8% and 56.8% of female subjects and 58.8% and 46.6% of male subjects (p at 0.004 and 0.064 respectively). Coxitis was present in 13.1% and syndesmophytis in 15.3% of females versus 36.1% and 18.3% of males (p at 0.001 and 0.4 respectively). Mean erythrocyte sedimentation rate was 45.7, mean CRP 28.5 and mean calcemia 92 in the 1st group versus 43, 40.6 and 93.4 in the 2nd (p at 0.4; 0.03 and 0.03 respectively). Relapse was 26.8% in female with SPA and 12.6% in male (p =0.025)

Conclusion: In our study, females SPA patients developed symptoms later than did males, peripheral and enthesial involvement is more common in females while coxitis is more common in males with statistically significant higher CRP and calcemia.

Background: Acute anterior uveitis is the most frequent extra-articular manifestation in spondyloarthritis (SpA). [1]

Objectives: The purpose of this study is to assess the prevalence of uveitis during SpA and to identify associated factors with its presence.

Methods: A cross-sectional multicentric observational study was conducted; the main data source was the Moroccan registry of biological therapies in rheumatic diseases (RBSMR registry). Patients, included from May 2017 to January 2019, were all adult patients (age > 18 years old), presenting SpA, according to ASAS (Assessment of Spondyloarthritis International Society) classification criteria for SpA 2010.

Demographic and clinical characteristics, disease activity, radiographic damage and functional ability have been compared between two groups of patients: Patients with SpA suffering from uveitis and patients without uveitis. General and specific data regarding uveitis were collected.

Results: 194 patients were included in the study. The mean age was 40.22 ± 13.68 years. The sex ratio was 1, 7 (man/woman). The mean duration of disease was 615.90 ± 349.12 weeks.

96.4 % of the patients had axial involvement, 70 % had peripheral involvement and 61.5 % had enthesic involvement. SpA was radiographic in 88.1 % of the cases and coxitis was found in 40.9 %. The mean erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) was 39.04 ± 27.16 mm/h and 32.87 ± 38.77 mg/l, respectively. HLA B27 was positive in 34 % of patients. The mean ASDAS (Ankylosing Spondylitis Disease Activity Score) ESR, BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) and BASFI (Bath Ankylosing Spondylitis Functional Index) was 3, 19 ± 2,118; 4.8 ± 1.8 and 5.29 ± 2.21, respectively. Uveitis was seen in 14.5% of cases.

The bi-variate analysis did not reveal any statistically significant difference between the two groups regarding demographic and clinical characteristics, disease activity and radiographic damage.

Conclusion: Acute anterior uveitis is the most frequent extra-articular manifestation in spondyloarthritis (SpA). The presence of uveitis in Moroccan patients diagnosed with SpA wasn't associated with specific characteristics. Even though, its screening is systematic because it conditions the treatment.

PREVALENCE AND RISK FOR BUNDLE BRANCH BLOCK, ATRIOVENTRICULAR BLOCK AND PACEMAKER IMPLANTATION IN SPONDYLOARTHRITIS. A SYSTEMATIC REVIEW OF THE LITERATURE

H. S. Park[1], A. Laiz[1], P. Díaz del Campo Fontecha[2], M. A. Martín Martínez[2], M. Guerra-Rodriguez[2], C. Alonso Martín[3], J. Sanchez-Vega[4], H. Corominas[1,5].
[1]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; [2]Sociedad Española de Reumatología, Unidad de Investigación, Madrid, Spain; [3]Hospital de la Santa Creu i Sant Pau, Cardiology, Barcelona, Spain; [4]Hospital de Bellvitge, Cardiology, Cardiac Imaging Unit, Barcelona, Spain; [5]Hospital Dos de Maig, Rheumatology, Barcelona, Spain

Background: Inflammation of the valve attachment site may produce tissue degeneration near the atrioventricular node, which may lead to electrical conduction disturbances, that is to say atrioventricular block (AVB) and bundle branch block (BBB).
Objectives: To evaluate the evidence regarding the prevalence and risk of BB, AVB and pacemaker implantation (PMI) in patients with spondyloarthritis (SpA) compared to a control group without SpA.
Methods: A systematic review of the literature was performed using Pubmed (Medline), EMBASE (Elsevier) and Cochrane Library (Wiley) databases until December 2021. The risk for AVB, BBB and PMI were analyzed. Cohort, case control and cross-sectional studies in patients ≥18 years meeting the classification criteria for SpA were included. The Odds ratio (OR), risk ratio (RR) or Hazard ratio (HR) were considered as outcomes. Data was synthesized in a previously defined extraction form. The risk of bias was assessed by the Newcastle-Ottawa Scale.
Results: In total, eight out of 374 studies were included. As for low grade AVB and BBB, only indirect results comparing prevalences from low to medium quality studies were found. According to population based registries, the sex and age adjusted HR of AVB was 2.3 (95% CI 1.6 - 3.3) in ankylosing spondylitis, 2.9 (95% CI 1.8 - 4.7) in undifferentiated spondyloarthritis and 1.5 (95% CI 1.1 a 1.9) in psoriatic arthritis. The RR for PMI was 1.3 (95% CI 1.16 - 1.46) for groups aged between 65-69 years, 1.33 (95% CI 1.22 - 1.44) for 70-75 years, 1.24 (95% CI 1.55 - 1.33) for 75-79 years and 1.11 (95% CI 1.06 - 1.17) for groups older than 80 years.
Conclusion: The differences of prevalence in AVB and BBB were similar in SpA and control groups even though studies lacked the power. According to population registries there was an two fold-increased risk of high grade AVB in SpA patients. RR for PMI was higher in younger age groups.

IMPORTANCE OF SCREENING OF TRADITIONAL CARDIOVASCULAR RISK FACTORS IN SPONDYLOARTHRITIS

A. Ben Tekaya[1,2], T. Mehmli[1,2], O. Saidane[1,2], S. Bouden[1,2], R. Leila[1,1], R. Tekaya[1,2], I. Mahmoud[1,2], L. Abdelmoula[1,2]. *[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia; [2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia*

Background: Epicardial adipose tissue has been associated with the development of coronary artery disease and recently suggested as a novel marker for evaluating subclinical atherosclerosis.
Objectives: The aim of our study was to assess the relationship between EFT and cardiovascular risk parameters in patients with spondyloarthritis (SpA).
Methods: We performed a case control study including patients meeting ASAS 2009 criteria for SpA, and healthy controls. Subjects were aged less than 50years old and without traditional cardiovascular risk factors. Clinical features related to the disease were recorded. Anthropometric data (body mass index (BMI), waist circumference and hip circumference) and arterial blood pressure of the patients were also recorded. Blood specimens were collected after 12 hours of fasting and total cholesterol, HDL, LDL, triglyceride and fasting glucose were measured. Total cholesterol to HDL ratio and LDL to HDL ratio were calculated. All subjects underwent Doppler echocardiography with measurement of EFT by an experienced cardiologist.
Results: We enrolled 47 SpA patients and 47 controls. Subjects were age, sex and BMI matched (p=0.267, p=0.589 and p=0.238 repectively). Median disease activity scores BASDAI and ASDAS-CRP were 2.6 (IQR 25-75%: 1.8-3.8) and 2.18 (IQR 25-75%: 1.62-2.91) respectively. Median waist and hip circumference

Author	Study design	Population	Sample number	Test	Outcomes	Adjustment
Baniaamam 2021[6]	Cross sectional	AS and osteoarthritis between 50-75 years	267	ECG	Prevalence of AVB, BBB and PMI	Controls matched for age, sex and smoking status
Bengtsson 2017[12]	Cohort	AS, uSpA, PsA, GP from the Swedish national registry	294136	ICD-10	Prevalence, Incidence, HR, for AVB and PMI compared to GP	Age, sex
Dik 2010[9]	Cross sectional	AS	131	ECG	Prevalence of AVB and BBB Association of PR interval with AS disease related variables	Age, sex, disease duration

Yildrir 1999[11]	Case control	AS	88	Holter and ECG	Prevalence of AVB	None

were 88 cm (IQR 25-75%: 82-97) and 100 cm (IQR 25-75%: 91-97), respectively. Median systolic (SBP) and diastolic (DBP) blood pressure were respectively 121 mmHg (IQR 25-75%: 110-130) and 71 mmHg (IQR 25-75%: 67-78). Laboratory findings showed a median fasting glucose level (FG) of 4.93 mmol/l (IQR 25-75%; 4.55-5.1). Median total cholesterol (CT), HDL, LDL and triglyceride levels were respectively 3.66 mmol/l (IQR 25-75%: 3.18-4.28), 1.08 mmol/l (IQR 25-75%: 0.92-1.2), 2.17 mmol/l (IQR 25-75%: 1.78-2.6) and 0.84 mmol/l (IQR 25-75%: 0.79-1.15). CT/HDL ratio and LDL/HDL ratio were 3.48 (IQR 25-75%: 2.95-3.97) and 1.99 (IQR 25-75%: 1.54-2.48), respectively.

Median EFT was significantly increased in patients compared to controls (3.1 mm (IQR: 2.5-4) versus 2.4 mm (IQR: 2-3), p=0.001).

A positive correlation was found between EFT and SBP (p=0.028; r=0.323) and triglyceride level (p=0.022, r=0.349). In contrast, EFT was not associated with DBP (p=0.069, r=0.270), BMI (p= 0.223, r=0.181), waist circumference (p=0.114, r=0.234), hip circumference (p=0.451, r=0.113), CT (p=0.127; r=0.236), HDL (p=0.587; r=0.085), LDL (p=0.342; r=0.149), FG (p=0.104, r=0.248), CT/HDL ratio (p=418; r=0.128) and LDL/HDL ratio (p=0.683;r=0.064).

In multivariate linear regression, triglyceride level was identified as an independently predictor of increased EFT (B=0.676; 95% confidence interval = 0.209-1.143; p= 0.006).

Conclusion: The importance of our results that we identified a traditional cardiovascular risk factor as a predictor of subclinical atherosclerosis in SpA without cardiovascular risk factor and with normal triglyceride level. This finding highlights the importance of regular screening for traditional cardiovascular risk parameters even if the disease in low activity.

AB0870 ASSESSMENT OF FRACTURE RISK IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

H. Ferjani[1], O. Boudrigua[2], W. Triki[3], D. Ben Nessib[3], K. Maatallah[3], D. Kaffel[3], W. Hamdi[3]. *[1]Kassab orthopedics institute, Rheumatology department, Ksair Said, Tunisia; [2]Kassab orthopedics institute, Rheumatology department, Tunis, Tunisia; [3]Kassab orthopedics institute, Rheumatology department, Ksar Said, Tunisia*

Background: Spondyloarthritis (SpA) is a chronic inflammatory disease that predominantly affects the sacroiliac joints and the spine. Patients with SpA have an increased risk of osteoporosis and fracture resulting from a combination of inflammation and immobility. The non-radiographic form for SpA (nr-axSpA) has the same predictors factors of bone fragility however the real fracture risk is unknown in this phenotype.

Objectives: This study aims to investigate BMD and the Fracture Risk Assessment Tool (FRAX) in patients with nr-axSpA.

Methods: We conducted a retrospective study including 40 patients with nr-axSpA, according to the ASAS criteria. For the enrolled patient, we collected the clinical and biological data. We calculated the disease activity using the Bath Ankylosing Spondylitis disease activity (BASDAI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS). Functional impairment was assessed by the Ankylosing Spondylitis Functional Index (BASFI). We measured the bone mineral density using the dual-energy X-ray absorptiometry (DXA) in the anteroposterior lumbar, lateral spine, and hip neck. The ten-year probability of major osteoporotic fracture was calculated using the Tunisian version of Fracture Risk Assessment Tool (FRAX).

Results: Twenty-seven women (67.5%) and thirteen men (32.5%) were enrolled. The mean age was 41.5 years (±11.2), and the mean disease duration was 3,1 years (±2.7). The mean BASDAI and ASDAS CRP was 4.7 ± 2.2 and 3.27 ± 1.29, respectively. The mean BASFI was 3.6 ± 2.5. According to World Health Organization (WHO) criteria, 45% of patients displayed osteopenia and 30% osteoporosis. The mean major osteoporotic fracture (MOF) score was 0,09 ± 0,25 [0-1,3]. The MOF was significantly associated with BMD (p=0.000). The variables associated with MOF were a high physician's global assessment score, a high BASFI, and female gender, but without significant relation. However, no correlation was found between the MOF and the disease duration, the presence of peripheral arthritis or enthesitis, and the ASDAS.

Conclusion: In nr-axSpA, patients with low BMD had a higher calculated 10-year fracture risk. FRAX score is related to functional impairment and gender. Disease activity does not affect the probability of fracture.

AB0871 FACTORS ASSOCIATED WITH RADIOGRAPHIC HIP INVOLVEMENT IN ANKYLOSING SPONDYLITIS

G. Mouna[1], M. Jguirim[1], N. Benchekaya[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. *[1]Fattouma Bourguiba hospital, Rheumatology department, Monastir, Tunisia*

Background: Hip involvement is a classic feature of ankylosing spondylitis (AS). It causes functional impairement and disability in patients with AS. Although, many studies have looked at factors associated with radiographic hip involvement, these remain debated.

Objectives: To define the factors associated with radiographic hip involvement in patients with AS.

Methods: A cross-sectional comparative study of 105 patients was performed. Hip involvement was defined as hip pain considered related to AS inflammation and confirmed radiographically. The patients were classified into two categories: (1) no hip involvement, (2) hip involvement according to a Bath Ankylosing Spondylitis Radiology Index (BASRI)-hip score ≥2. Multivariate logistic regression analyses were used to identify the factors associated with radiographic hip involvement.

Results: Fifty-three patients had radiological hip involvement and 52 patients were whithout hip involvement. Multivariate logistic regression analyses showed male sex (OR 6.383 IC 1.553-26.29, p=0.010), Bath Ankylosing Spondylitis Functional Index (BASFI) score (OR 1.436, IC 1.079-1.913, p=0.013), and BASRI-spine score (OR 1.456, IC 1.190-1.783, p<0.001) to be significantly associated with radiographic hip involvement, and an inverse relation-ship with age at onset (OR 0.955, IC 0.995-0.998, p=0.038) was seen.

Conclusion: Male sex, younger age at onset, worse BASFI score and worse BASRI-spine score are associated with radiographic hip involvement. AS patients with risk factors for radiographic hip involvement should be diagnosed at an early stage to improve their quality of life.

AB0872 INFLUENCE OF JOINT AND ENTHESIS DAMAGE ON THE QUALITY OF LIFE OF PATIENTS WITH INFLAMMATORY BOWEL DISEASES.

G. Gainullina[1], E. Kirillova[1], A. Odincova[2], D. Abdulganieva[1]. *[1]Kazan State Medical University, hospital therapy, Kazan, Russian Federation; [2]Republican Clinical Hospital of the Ministry of Health of the Republic of Tatarstan, gastroenterology, Kazan, Russian Federation*

Background: Inflammatory bowel diseases (IBD) are chronic immune-inflammatory diseases that are often associated with various extraintestinal manifestations [1]. Among them, joint involvement is the most common, occurring in 5–20% of patients with IBD [1], while the prevalence of enthesitis varies in studies from 12.5% to 90% of cases [2].

Objectives: To assess the relationship between the state of peripheral joints and entheses in patients with IBD and their quality of life.

Methods: 95 pts with IBD were prospectively enrolled into the study: 55 of them with ulcerative colitis (UC) and 40 with Crohn's disease (CD). The average age of the pts was 32 (26; 37) years. The average duration of the disease was 44 (12; 95) months. The severity of UC exacerbation was assessed by the Mayo index, in CD – by Harvey-Bradshaw index. In UC, moderate and severe exacerbation was revealed in 40 pts (73%), in CD - in 17 (43%). Among 95 pts with IBD, extraintestinal manifestations occurred in 67 pts (71%), of which 34 (62%) pts with UC and 33 (82%) pts with CD. 14 joints and 68 enthesis were evaluated clinically and by US in each pt. The clinical examination included tenderness of enthesis. US examination with power Doppler detected synovitis with / without vascularization, inflammatory (hypoechogenicity of enthesis, thickening of enthesis, presence of vascularization) and structural (erosion, enthesophyte) changes in enthesis. The quality of life was assessed using the SF-36 questionnaire that covers eight health domains. Scores for each domain range from 0 to 100, with a higher score defining a more favorable health state. Spearman coefficient used to calculate correlations.

Results: 61 pts with IBD (64%) complained of pain in the joints, 49 pts (52%) noted pain on palpation of entheses. As a result of ultrasound examination, synovitis were detected in 41 pts (43%), including synovitis with vascularization in 29 pts (31%). Enthesitis were found in 72 pts (76%), while vascularized enthesitis was detected in 35 pts (37%). Erosions were identified in 76 pts (80%), and enthesophytes were identified in 37 pts (39%). The average level of physical health was 43.53 (35.67; 51.66), mental health 38.53 (31.13; 48.37).

An inverse correlation was observed between the number of extraintestinal manifestations and physical functioning (SR=-0.22; p=0.03). The number of painful joints was inversely correlated with physical functioning (SR=

-0.22; p=0.03), pain intensity (SR= -0.23; p=0.02), vital activity (SR= -0.23; p=0.027), as well as with physical health (SR= -0.21; p=0.04). The number of painful entheses was inversely correlated with physical functioning (SR = -0.21; p = 0.03), pain intensity (SR = -0.3; p = 0.003) and physical health (SR = -0, 21; p=0.03). An inverse correlation was observed between the number of synovitis with vascularization and physical functioning (SR= -0.26; p=0.01), vital activity (SR= -0.29; p=0.005), physical health (SR=-0.23; p=0.024). The number of enthesitis was inversely correlated with the pain intensity (SR = -0.22; p = 0.036).

Conclusion: With an increase in the number of affected joints and enthesis, the physical health of pts decreases, due to physical functioning and pain intensity, as well as their vital activity.

AB0873 ETHNICITY AND PATIENT REPORTED OUTCOME BASDAI IN THE MONITORING OF AXIAL SPONDYLOARTHROPATHY: DOES IT MATTER?

S. Byravan[1], S. Jothimurugan[2], A. Moorthy[1,3]. [1]*University Hospitals of Leicester, Rheumatology, Leicester, United Kingdom;* [2]*University Hospitals of Leicester, Medicine, Leicester, United Kingdom;* [3]*University of Leicester, College of Life Sciences, Leicester, United Kingdom*

Background: The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is a patient reported outcome (PRO) used in the monitoring of axial spondyloarthropathy (axSpA). It is completed by the patient and based on their assessment of disease severity and therefore quite a subjective measure of disease (1). There has been research around the relationship between ethnicity and patient perception in Rheumatology. Many studies have demonstrated that non-Caucasian patients especially South Asians are less likely to engage with patient education, abandon their disease modifying therapy early and have more mistrust with the medical establishment (2). Quite a large population study in America examining axSpA severity in Caucasians, Afro-Caribbean's and Latinos found Afro-Caribbean and Latino patients to score themselves higher on BASDAI compared to Caucasians (3). With Leicester being such a diverse area, with a particularly high South Asian population we took this opportunity to investigate whether there were ethnic variations in disease severity.

Objectives: The aim was to investigate whether there is a relationship between patient-reported outcome BASDAI and ethnicity. The secondary aim was to investigate the relationship between ethnicity and radiographic findings and extra-articular manifestations.

Methods: Data was collected by retrospective analysis of axSpA patients attending University of Leicester (UHL) axSpA services. Inclusion criteria entailed a diagnosis of axSpA with a documented BASDAI within a year of MRI spine + sacroiliac joints, prior to starting any biological treatment. Data of 149 patients was collected on demographic characteristics, extra-articular manifestations (uveitis, inflammatory back pain, enthesitis, peripheral arthritis, dactylitis, psoriasis, and inflammatory bowel disease), family history, response to NSAIDs, and HLA-B27 status. Data was analysed using Statistical Package for the Social Sciences (SPSS) software to assess the relationship between ethnicity and collected data using Pearson's chi squared.

Results: Of the 149 patients 68% were White Caucasian, 30% Asian and 1% Black. The average age was 43 and 66% were male and 34% female. The mean BASDAI was 6.5, there was no observable correlation between BASDAI and ethnicity (p=0.668). There was no significant relationship between ethnicity and active sacroiliitis (p=0.926), chronic sacroiliitis (p= 0.218) or axial disease (p=0.307). 64 Caucasian patients were HLA-B27 positive compared with 27 Asian and no Black patients were positive however there was no statistical correlation between ethnicity and HLA-B27 (p=0.383). Overall, Caucasians consistently had a greater incidence of extra-articular manifestations compared with non-Caucasians however no significant p values were observed here or with response to NSAIDs, family history or familial HLA-B27 and BASDAI scores, results are summarised in Table 1.

Table 1. Correlation with ethnicity and extra-articular manifestations, family history and HLA-B27.

	Number of patients	Correlation with ethnicity
Uveitis	36	p=0.470
Peripheral arthritis	24	p=0.304
Enthesitis	22	p=0.959
Psoriasis	7	p=0.062
Inflammatory bowel disease	7	P=0.947
Dactylitis	6	P=0.173
HLA-B27	103	p=0.383
Inflammatory back pain	139	p=0.062
Response to NSAIDs	46	p=0.718
Family history of axSpA	20	p=0.800
HLA-B27 in family	10	p=0.221

HLA-B27= Human leukocyte antigen B27, NSAIDs= non-steroidal anti-inflammatory drugs, axSpA= Axial Spondyloarthropathy.

Conclusion: This study did not demonstrate statistically significant finding of ethnic variations in BASDAI. There was also no relationship between ethnicity and other data sets. However, the main limitation of this study is the sample size and unequal representation of ethnicities with there being far more Caucasians than non-Caucasian patients. Though this study provides an insight into quite a limited area of research, a larger study with equal ethnic patient population samples is required to obtain more meaningful results.

AB0874 TARSITIS IN MEXICAN PATIENTS WITH SPONDYLOARTHRITIS

L. D. Fajardo Hermosillo[1]. [1]*Centro Médico Nacional de Occidente IMSS, Rheumatology, Guadalajara, Mexico*

Background: Spondyloarthritis (SpA) is a set of auto-immune and auto-inflammatory diseases that share similar manifestations of axial spine and sacroiliac, peripheral joint including oligoarthritis predominantly of lower limbs, dactylitis, enthesitis and fasciitis, and extraarticular manifestations involvement eyes, skin, nails, bowel and the presence of high c-reactive protein (CRP) levels and Human Leucocyte Antigen (HLA)-B27 seropositivity. Peripheral manifestations such tarsitis (mid-foot arthritis) has been reported associated to ankle arthritis, Achilles tendon enthesitis and plantar fasciitis, besides linked mainly to juvenile-onset forms of SpA (18.1%) in contrast with peripheral adult form (13.6%) [1,2]. Tarsitis occurs more frequently in SpA patients of Latin American (23.6%), Asia (9.1%) and less commonly in SpA patients of Europe and North America (5%) and middle-East and North Africa (3.5%) [1,2]. This mid-foot inflammation has not been completely well described in the adult population with SpA, specifically in Mexican adult population [3]. Here is presented the frequency and factors associated to tarsitis in Mexican adult patients with SpA.

Objectives: To determinate the frequency and factors associated to tarsitis in Mexican SpA patients.

Methods: That is a cross-sectional, comparative a retrospective study including 211 (≥18 years) Mexican SpA patients recruited from 2012 to 2021 that fulfilled ASAS criteria. Patients with or without presence of tarsitis are included. This work explores demographic factors, clinical features, c-reactive protein levels and pharmacologic treatments in Spa patients with or without tarsitis. It use Chi-square, Student´s-t, U Mann-Whitney tests to univariate analysis and logistic regression to multivariate analysis adjusted for age and gender. The level of significance of statistical tests is less of 5%.

Results: The present investigation involves 211 patients with SpA and 62.6% of them are men. The mean age [standard deviation (SD)] is 43.72 (13.5) years. The mean of age at onset of SpA (SD) is 31.93 (11.3) years. The SpA distribution is axial (42.2%), peripheral (27%) and both (30.8%). A total of 63 (29.9%) patients has tarsitis; of them

63.5% are men and the mean age at onset of tarsitis (SD) is 26.52 (10.2) years. The seronegative spondyloarhtropathies associated to tarsitis are ankylosing spondylitis (81%), psoriatic arthritis (9.5%), undifferentiated spondyloarthropathy (7.9%), and reactive arthritis (1.6%). In the univariate analysis SpA patients with tarsitis are likely younger at onset of manifestations and diagnosis of disease, present peripheral distribution and unilateral tarsitis, show more frequently knee and ankle arthritis, Achilles and calcaneus tendon enthesitis and plantar fasciitis, have more probably HLA-B27 seropositivity and higher c-reactive protein levels, and use more often oral and intraarticular corticosteroids. On the other hand, SpA patients with tarsitis are less frequently smokers and exhibit less probably cervical and lumbar involvement, dactylitis and family history of SpA. In multivariate analysis, use of intraarticular corticosteroids (OR 61.75, 95% CI 8.46–450, p=<0.001) and calcaneus tendon enthesitis (OR 31.40, 95% CI 4.42–223, p=0.001) remain significant in SpA patients with tarsitis.

Conclusion: This study suggests that SpA patients from Mexico have high prevalence of the tarsitis (29.9%) compare to other populations. Those with tarsitis use more intraarticular corticosteroids and present more often calcaneus tendon enthesitis. However, these observations must be confirmed in larger and prospective studies.

AB0875 ASSESSMENT OF CLINICAL SIGNS OF SPONDYLOARTHRITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

E. Belousova[1], D. Abdulganieva[1], M. Protopopov[2]. [1]*Kazan State Medical University, Hospital Therapy, Kazan, Russian Federation;* [2]*Charité – Universitätsmedizin Berlin, Rheumatology, Berlin, Germany*

Background: Patients with inflammatory bowel disease (IBD), Crohn's disease (CD) and ulcerative colitis (UC), commonly face the presence of extraintestinal manifestations (EIMs). Spondyloarthritis (SpA) is present in about 10-39% of patients with IBD, being the most frequent EIM [1]. Diagnosis of axial SpA (axSpA) in IBD represents a clinical challenge. The diagnostic value of Ankylosing Spondylitis Assessment Society (ASAS) criteria that are used for defining inflammatory back pain (IBP) in axSpA, in patients with the association of axSpA and IBD is not clear.

Objectives: To determine the diagnostic value of ASAS criteria for IBP (2009) and to evaluate factors that are associated with a higher risk of axial SpA in patients with IBD.

Methods: The study included 91 patients with IBD (UC - 52 patients (57.1%), CD - 39 (42.9%), males – 47 (51.6%), mean age 40.2±11.7 years, duration of IBD – 7.7±7.6 years). IPB was defined by ASAS criteria (2009). AxSpA in patients with IBD is recommended to be diagnosed by the combination of Inflammatory Back Pain (IBP), and imaging (MRI and X-ray) [2]. Imaging of lumbar spine and sacroiliac joints was performed to patients, who fulfilled the ASAS criteria for IBP: X-ray - 55 patients; MRI (T1, STIR) - 41 patients. Imaging was considered positive when patients had at least unilateral sacroiliitis stage 2 or higher according to the accepted grading system on X-Ray, or MRI-verified sacroiliitis.

Results: Low back pain was observed in 84 (92.3%) patients with IBD, 39 (42.9%) patients fulfilled the criteria ASAS for IBP. MRI-verified sacroiliitis was present in 26 patients. Changes on X-ray were present in 40 patients. After imaging, 26 patients were diagnosed with axSpA, 14 of them fulfilled the modified New York criteria for the ankylosing spondylitis. Diagnostic value of the ASAS criteria was the following: sensitivity 76.9%, specificity 67.2%, PPV 0.51, NPV 0.87, LR+ 2.3, and LR- 0.3 (ECCO consensus definition used as the "gold standard"). Presence of arthritis - OR 10.77 [95% CI 2.26-44.2], p=0.005, arthralgia - OR 4.12 [95% CI 1.55-10.95], p=0.005, CD - OR 2.92 [95% CI 1.14-7.48], p=0.025 and IBP – OR 8.07 [95% CI 2.8-23.23], p=0.001 was associated with a higher risk of axSpA diagnosis in the univariate logistic regression model. The associations remained statistically significant when multivariate logistic regression model was constructed – arthritis 20.03 [95% CI 3.05 -131.69], CD – 3.51 [95% CI 1.04-11.82], IBP – 8.72 [95% CI 2.64-28.79], R^2=0.486.

Conclusion: The ASAS criteria for IBP had a good diagnostic value in patients with IBD. The diagnostic value of the ASAS criteria for IBP (2009) in patients with IBD was comparable to the following in the patients with chronic back pain. Clinicians should pay attention to the presence of arthritis, arthralgia, IBP and CD, as these factors were associated with a higher risk of being diagnosed with axSpA in patients with IBD.

AB0876 CAN ULTRASONOGRAPHIC PERIPHERAL ENTHESITIS MIRROR SPINAL RADIOGRAPHIC ABNORMALITIES AND OTHER DISEASE PARAMETERS IN PATIENTS RADIOGRAPHIC AXIAL SPA?

A. Moshrif[1], M. I. Abdelkareem[1], S. Rashad[2], A. Negm[3], A. Mosallam[1], H. Bassiouni[3]. [1]*Al-Azhar University, Rheumatology, Assiut, Egypt;* [2]*Suiz University, Rheumatology, Suiz, Egypt;* [3]*Al-Azhar University, Rheumatology, Cairo, Egypt*

Background: Although enthesitis is the hallmark of spondyloarthritides, the association between peripheral enthesitis, radiographic spinal affection and disease assessment parameters is still underestimated.

Objectives: In this cross-sectional prospective study, we aimed to evaluate the relation of US pattern of peripheral enthesitis with the spinal radiographic changes and other disease parameters in patients with radiographic axial spondyloarthritis (SpA).

Methods: Fifty-eight patients with radiographic axial SpA (ASAS criteria) were studied for the presence and pattern of peripheral lower limb enthesitis according to the Outcome Measures in Rheumatology (OMERACT) US definitions: Achilles tendon, plantar fascia, proximal and distal patellar ligaments, and quadriceps tendon insertions. The findings then were correlated with the radiographic spinal abnormalities, Bath AS radiographic index (BASRI), Bath AS disease activity index (BASDAI), Bath AS functional index (BASFI), and Bath AS metrology index (BASMI) together with the HLA-B27 status and inflammatory markers using Spearmann rho correlation co-efficient.

Results: The mean age was 37.96 (±13.1) years, 75.86% were males. Thirty-six patients (62%) had US enthesitis (USE) with a mean age of 39.2 (±12.8). HLA-B27 was positive in 61% of patients with USE and 54.5% in those without. There was no difference between patients with and without USE regarding the disease duration, age at onset but those with USE showed less diagnostic delay (p = 0.03). Clinical enthesitis and peripheral arthritis were more frequent in those with USE (50% vs 22.7% and 25% vs 13.6% respectively). No statistical significant difference has been found between the inflammatory, structural and total scores of USE and BASRI, BASFI and BASDAI (p > 0.05). No correlation could be detected between BASRI and USE scores (rs= 0.12, p =0.45 for inflammatory, rs=0.25, p=0.11 for structural and rs=0.18, p=0.28 for total score). There was a positive correlation between BASMI and both inflammatory and total scores of USE (rs= 0.485, p=0.003). No significant association between BASDAI, CRP or ESR and USE scores.

Conclusion: Ultrasonographic peripheral entheseal abnormalities couldn't reflect the spinal radiographic changes or disease assessment parameters in patients with radiographic axial SpA. However, these results can be considered preliminary and more studies on wider scales are needed to support our findings.

AB0877 QUANTIFICATION OF THE ENTHESIC RESPONSE TO BIOLOGICAL THERAPIES IN PATIENTS WITH SPONDYLOARTHRITIS BY COMPUTER ANALYSIS OF ULTRASOUND IMAGES.

M. Tortosa-Cabañas[1], C. Guillén-Astete[1], Á. Andreu-Suárez[1]. [1]*Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Enthesitis is the base of the pathophysiology of spondyloarthritis. Recently, our group has shown that computer analysis of static images can be used in the evaluation of patients with enthesic inflammatory diseases with good intra-patient and intra-observer validity and sensitivity to change.

Objectives: To determine the enthesic evolution in patients with spondyloarthritis (SpA) treated with three different biological therapies through the computer analysis of ultrasound images.

Methods: We selected patients diagnosed with SpA and enthesitis followed by imaging, who started biological therapy with a TNF inhibitor, an IL17 inhibitor or an IL12/23 inhibitor. For the records to be included, it was necessary to have clinical information from the period of perfoming the ultrasound. All images were obtained from the Achilles tendon, with the same ultrasound equipment, grayscale and settings for each patient. To homogenize the results of the analysis, the gray intensity mean index (iMIG) was used, which has been shown to appropriately discriminate the inflammatory pathology from the mechanical or healthy controls as well as being sensitive to change.

Results: 14 patients were included: 6 treated with a TNF inhibitor, 4 with an IL17 inhibitor and 4 with an IL12/23 inhibitor. Patients 2, 3, 5, 7, 10, 11, and 12 had enthesophytes.

Table 1. List of patients included in the analysis. After the final ultrasound examination, the follow-up time up to the present is recorded in the case of continued treatment (m: months).

	Treatment	Enthesophytes	Basal MIG	Basal iMIG	Intermediate examination	Intermediate iMIG	Final examination	Final iMIG	Treatment follow-up
1	TNFi		71,424	0,85	+6m	0,89	+6m	0,94	Continues +24m
2	TNFi	+	156,415	1,48	+5m	1,51	+6m	1,52	Suspended for inefficacy (enthesitis)
3	TNFi	+	164,323	1,32	+6m	1,34	+6m	1,35	Suspended for inefficacy (enthesitis)
4	TNFi		69,321	0,78	+4m	0,80	+6m	0,94	Suspended for inefficacy (axial pain)
5	TNFi	+	141,473	1,14	+6m	1,19	+4m	1,18	Suspended for inefficacy (enthesitis)
6	TNFi		68,483	0,85	+3m	1,03	+5m	1,05	Continues +20m
7	iIL17	+	135,432	1,34	+5m	1,26	+4m	1,15	Continues +22m
8	iIL17		72,225	0,90	+6m	1,02	+4m	1,06	Continues +20m
9	iIL17		80,465	0,89	+3m	1,03	+6m	1,03	Suspended for inefficacy (arthritis).
10	iIL17	+	122,254	1,16	+6m	1,11	+4m	1,04	Continues +24m
11	iIL12/23		71,401	0,79	+8m	1,01	+4m	1,1	Suspended for inefficacy (axial pain)
12	iIL12/23	+	134,41	1,12	+6m	1,08	+6m	1,07	Continues +18m
13	iIL12/23		75,42	0,94	+4m	1,12	+6m	1,16	Continues +20m
14	iIL12/23		69,112	0,84	+3m	0,9	+8m	1,12	Continues +18m

In the global analysis, the iMIG did not show statistically significant differences between the treatment groups at the start of the treatment, at the intermediate and at the final evaluation (P=.588, .739 and .674, respectively). Patients with enthesophytes presented significantly higher baseline, intermediate and final iMIG than patients without them: 1.26 SD 0.14 vs 0.85 SD 0.05 (t=7.407, P=.001), 1.24 SD 0.15 vs 0.97 SD 0.1 (t=3.659, P=.006); and 1.21 SD 0.12 vs 1.05 SD 0.07 (t=2.342, P=.037), respectively. Analyzing only the patients without enthesophytosis, the final iMIG showed statistically significant differences between the 3 administered treatments (ANOVA, F=8.142, P=.027), being relevant between the use of IL12/23 and TNF inhibitor in favor of the former (Bonferroni, P=.03). In the same subgroup of patients without enthesophytosis, iMIG analysis over time showed statistically significant differences between final and baseline iMIG (Friedman -1.938 P=.000).

Conclusion: Computer analysis of ultrasound images using the iMIG distinguishes therapeutic response in patients without enthesophytosis.

The interposition of enthesophytes impede the correct visualization of the enthesis and does not allow ultrasound changes to be detected in some areas of the image. Although there are indications that the use of this analysis could also predict the behavior of certain therapies, it is convenient to propose prospective studies with homogeneous ultrasound controls.

AB0878

HIGHER VITAMIN D SERUM LEVEL IS ASSOCIATED WITH A BETTER CLINICAL RESPONSE TO BDMARDS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS.

V. Rios Rodriguez[1], M. Torgutalp[1], M. D'urso[1], H. Haibel[1], F. Proft[1], M. Protopopov[1], J. Rademacher[1,2], J. Sieper[1], D. Poddubnyy[1,3]. *[1]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany; [2]Berlin Institute of Health,., Berlin, Germany; [3]Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), ein Institut der Leibniz-Gemeinschaft, Epidemiology Unit, Berlin, Germany*

Background: Vitamin D deficiency has been shown to be associated with higher disease activity and severity of several inflammatory diseases such as rheumatoid arthritis, inflammatory bowel disease and spondyloarthritis (SpA). It is, however, unknown if vitamin D level might affect the response to treatment with biologic disease-modifying anti-rheumatic drugs (bDMARDs) in patients with SpA.

Objectives: To investigate the association between vitamin D serum levels and the response to a bDMARD therapy in patients with axial SpA.

Methods: Patients with a radiographic axial SpA (r-axSpA), fulfilling the modified New York criteria and starting a bDMARD therapy were recruited between 2015 and 2019 in an extension of the prospective German Spondyloarthritis Inception Cohort (GESPIC-AS). All patients were required to have at inclusion high disease activity (BASDAI >=4 and/or ASDAS >=2.1) despite previous treatment with nonsteroidal anti-inflammatory drugs. Demographics, patient clinical characteristics and vitamin D serum levels were collected at baseline. Disease activity measures (BASDAI, CRP, ASDAS) were assessed at baseline and after 6 months of bDMARD treatment. Vitamin D deficiency was defined as serum level of 25-hydroxyvitamin D < 20 ng/mL. A multivariable regression analysis was performed to determine the association between vitamin D serum level at baseline and the treatment response as defined by BASDAI and ASDAS change scores at month 6 as compared to baseline.

Results: A total of 129 patients with r-axSpA were included in the study. No patient took supplements of vitamin D at baseline. Patients had an average age (mean±SD) of 36.5±10.5 years, 64.3% were males and 86.6% were HLA-B27 positive. The prevalence of vitamin D deficiency in our cohort was 54.3%. Patient characteristics and disease activity were comparable with regard to the presence of vitamin D at baseline (Table 1); with the exception of body mass index (BMI), which was higher in patients with vitamin D deficiency. In the multivariable linear regression analysis, baseline serum level of vitamin D was independently and significantly associated with higher change in BASDAI and ASDAS (Figure 1).

Table 1. Baseline characteristics of patients with radiographic axial SpA (n=129) according to vitamin D levels at baseline.

	Patients with vitamin D deficiency (<20 ng/mL) n=70	Patients with normal levels of vitamin D n=59
Age, years	36.6±11.0	36.3±10.0
Male sex	46 (65.7)	37 (62.7)
BMI, kg/m^2	26.0±4.5*	24.0±3.8
Smoking, ever	41 (58.6)	29 (49.2)
Winter and Spring, n (%)	33 (47.1)	23 (39.0)
Symptom duration, years	11.5±11.3	10.3±7.1
HLA-B27 positive	62 (88.6)	50 (84.7)
Uveitis ever	17 (24.3)	12 (20.3)
Psoriasis ever	11 (15.7)	7 (11.9)
IBD ever, n (%)	2 (2.9)	7 (11.9)
CRP, mg/L	12.9±19.3	13.9±15.3
BASDAI	5.7±1.4	5.4±1.4
ASDAS	3.4±0.8	3.5±0.8
BASFI	4.6±2.2	4.4±1.9
BASMI	3.1±1.5	2.7±1.3
NSAID intake, current	50 (71.4)	45 (76.3)
DMARDs intake, ever	9 (12.9)	6 (10.2)
TNFi naive	55 (78.6)	47 (79.7)
Corticoids intake, current	5 (7.1)	2 (3.4)

*p value <0.05. All numerical variables were presented as mean±SD, all categorical variables were presented as n (%). BMI, body mass index; CRP, C-reactive protein; DMARD, disease-modifying antirheumatic drug; IBD, inflammatory bowel disease; NSAID, nonsteroidal anti-inflammatory drug; TNFi, tumor necrosis factor inhibitor.

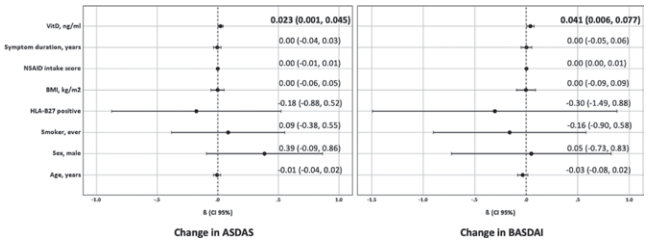

Figure 1. Association between the response to bDMARDs (change in BASDAI and ASDAS after 6 months) and level of vitamin D at baseline in patients with radiographic axial SpA in the multivariable regression analysis.

Conclusion: Higher vitamin D levels at baseline may predict a better treatment response to bDMARDs in patients with r-axSpA. It has to be shown, however, if vitamin D supplementation might result in a better treatment response in axial SpA.

Psoriatic arthritis - treatment

AB0879

INTERIM ANALYSIS OF BASELINE CHARACTERISTICS AND 12-WEEK OUTCOMES FOR A SUBSET OF PATIENTS WITH MODERATE-TO-SEVERE PLAQUE PSORIASIS AND PSORIATIC ARTHRITIS FROM THE PSORIASIS STUDY OF HEALTH OUTCOMES

L. E. Kristensen[1], F. Behrens[2,3], L. Puig[4], A. Reich[5], T. Holzkaemper[6], A. Brnabic[6], K. Ng[6], S. Liu Leage[6], C. Schuster[6,7], A. Pinter[8]. *[1]Bispebjerg and Frederiksberg Hospital,The Parker Institute, Copenhagen, Denmark; [2]Goethe University, Rheumatology University Hospital, Frankfurt, Germany; [3]Goethe University, Fraunhofer Institute for Translational Medicine & Pharmacology (ITMP) and Cluster of Excellence Immune-Mediated Diseases (CIMD), Frankfurt, Germany; [4]Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona, Department of Dermatology, Barcelona, Spain; [5]Medical College of Rzeszow University, Institute of Medical Sciences, Department of Dermatology, Rzeszow, Poland; [6]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America; [7]Medical University of Vienna, Department of Dermatology, Vienna, Austria; [8]University Hospital Frankfurt, Clinic for Dermatology, Venereology and Allergology, Frankfurt, Germany*

Background: Approximately 30% of patients (pts) with plaque psoriasis (PsO) develop psoriatic arthritis (PsA)[1], which is associated with high Psoriasis Area and Severity Index (PASI) and nail involvement. The Psoriasis Study of Health Outcomes (PSoHO) is a 3-year (yr), international, prospective, observational cohort study comparing the effectiveness of anti-IL-17A biologics to all other approved biologics in pts with moderate-to-severe PsO.

Objectives: This interim subset analysis describes the baseline characteristics and Week 12 (W12) effectiveness in pts with moderate-to-severe PsO and PsA in PSoHO.

Methods: Adults with moderate-to-severe PsO for ≥6 months who initiated/switched biologic treatment during routine medical care were enrolled. PsA diagnosis was recorded by the dermatologists based on the medical history and/or information provided by the patient. W12 effectiveness was assessed by the proportion of pts achieving almost clear or clear skin defined by ≥90% improvement in PASI, affected Body Surface Area (BSA), Dermatology Life Quality Index (DLQI), and Patient Global Assessment of Disease Severity (PatGA). Musculoskeletal endpoints were not collected. Data were analysed descriptively, using mean (standard deviation [SD]) or median ([Q1/Q3]) for continuous variables and n, % and 95% confidence limits for categorical variables.

Results: Overall, 1981 pts were enrolled in this study, of whom 461 (23.3%) had a PsA diagnosis and received either anti-IL-17A (n=227; 49.2%) or other biologics (n=234; 50.8%). This subset of pts had a mean age of 48.7 yrs and a median disease duration of 18.9 yrs for PsO and 5.6 yrs for PsA (Table 1).

Table 1. Baseline characteristics for PsO patients with PsA. Mean (SD) reported for all available data for that measure, unless stated otherwise.

	Overall (n=461)	Anti-IL-17A (n=227)	Other Biologics (n=234)
Age, yrs	48.7 (12.9)	50.9 (12.9)	46.6 (12.6)
Male, n (%)	232 (50.3)	112 (49.3)	120 (51.3)
BMI (kg/m^2)	29.7 (6.2)	29.8 (5.9)	29.6 (6.4)
Smoking status – Current, n (%)	100 (25.4)	41 (21.1)	59 (29.5)
Disease duration (PsA), yrs, median (Q1/Q3)	5.6 (2.2/13.1)	5.6 (2.0 / 13.8)	5.5 (2.3 / 12.8)
Disease duration (PsO), yrs, median (Q1/Q3)	18.9 (9.7 / 28.6)	18.9 (9.2 / 30.3)	18.7 (10.1 / 27.3)
Any previous biologic therapy, n (%)	249 (54.0)	123 (54.2)	126 (53.8)
PASI	14.3 (9.3)	13.6 (8.1)	15.0 (10.3)
BSA, %	21.7 (19.4)	19.8 (17.3)	23.5 (21.1)
mNAPSI	16.6 (22.8)	16.5 (25.5)	16.7 (20.1)
Presence of nail PsO, n (%)	217 (47.2)	103 (45.4)	114 (48.9)
PatGA	3.5 (1.2)	3.5 (1.3)	3.6 (1.2)
DLQI	13.6 (7.9)	13.4 (7.8)	13.7 (8.0)
HADS Depression score >10, n (%)	73 (19.3)	38 (20.5)	35 (18.1)
HADS Anxiety score >10, n (%)	124 (32.8)	62 (33.5)	62 (32.1)

BMI = Body Mass Index; BSA = Body Surface Area; DLQI = Dermatology Life Quality Index; HADS = Hospital Anxiety and Depression Scale; HADS >10 indicates significant symptoms of depression/anxiety; mNAPSI = Modified Nail Psoriasis Severity Index; PASI = Psoriasis Area and Severity Index; PatGA = Patient Global Assessment of Disease Severity; Q1/Q3 = Quartile 1/3.

At W12, 62.4% and 42.6% of anti-IL-17A-treated pts achieved PASI90 and PASI100, respectively, compared with 34.2% and 16.8% in the other biologics cohort, respectively (Figure 1). BSA <3% was reached by 70.9% of anti-IL-17A-treated pts and 49.5% in the other biologics cohort, while 71.2% and 44.8%, respectively, reached PatGA 0/1. Among pts with baseline DLQI ≥2, 38.0% and 27.1% of the anti-IL-17A and other biologics cohorts, respectively, reached DLQI 0/1.

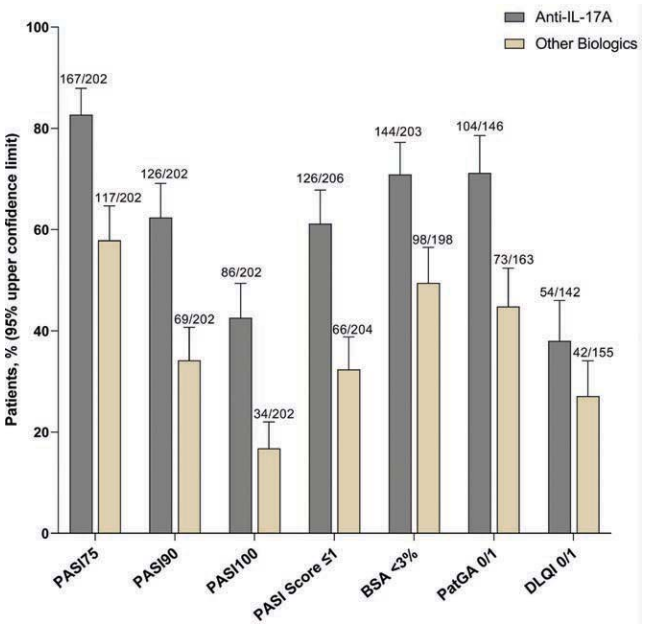

Figure 1. Percentage of patients receiving anti-IL-17A or other biologics who achieved PASI75/90/100, absolute PASI ≤1, BSA <3%, PatGA 0/1 and DLQI 0/1 (baseline DLQI ≥2) at Week 12. Bars represent upper 95% confidence limits.

Conclusion: The effectiveness of blocking IL-17A on skin manifestations and on quality-of-life improvements in pts with PsO and PsA in the real-world study was consistent with observations from clinical trials.

AB0880 **OPTIPSA: NATIONWIDE SURVEY ON CLINICAL/ THERAPEUTIC INERTIA IN PSORIATIC ARTHRITIS**

F. Lioté[1,2,3], E. Dahan[4], A. Constantin[5,6], H. Laouar Bouaziz[7], A. Frazier-Mironer[1], J. Sibilia[8,9]. *[1]Lariboisière Hospital AP-HP, Rheumatology, Paris, France; [2]Inserm, Bioscar U1132, Paris, France; [3]Université de Paris, UFR de médecine, Paris, France; [4]CHU Strasbourg, Rheumatology, Strasbourg, France; [5]Paul Sabatier University, INSERM 1291 Infinity, Toulouse, France; [6]Hospital Pierre Paul Riquet Toulouse, Rheumatology, Toulouse, France; [7]Amgen, Medical Affairs, Boulogne-Billancourt, France; [8]CHU Strasbourg, Centre National de Référence des Maladies Auto-immunes Systémiques Rares Est Sud-Ouest (RESO), Strasbourg, France; [9]Strasbourg University, Laboratoire d'Immuno Rhumatologie Moléculaire, plateforme GENOMAX, INSERM UMR-S1109, Faculté de Médecine, Institut Thématique Interdisciplinaire (ITI) de Médecine de Précision, Transplantex NG, Fédération de Médecine Translationnelle de Strasbourg (FMTS), Strasbourg, France*

Background: Therapeutic inertia (TI), or clinical inertia, is the medical behavior of not initiating or intensifying treatment when recommended by clinical recommendations (1). TI was established in diabetes and then studied in hypertension, multiple sclerosis and psoriasis, and is estimated to affect 30 to 70% of physicians managing patients with chronic diseases (2-4). To our knowledge, no data have reported TI in the setting of psoriatic arthritis (PsA).
Objectives: The OPTI PSA survey was conducted to assess therapeutic inertia around PsA in France.
Methods: 825 French rheumatologists were contacted by e-mail between January and March 2021 and asked to complete an online questionnaire, consisting of 7 clinical vignettes illustrating common situations and reflecting the polymorphic character of PsA: five clinical cases (oligoarthritis, enthesitis, polyarthritis, neoplastic history, cardiovascular risk) requiring treatment optimization in accordance with the latest SFR/EULAR recommendations (5, 6,7) and two "control" clinical cases (DIP arthritis, atypical axial) not requiring any change of treatment. The rheumatologists were also questioned about their routine practice and perception of PsA.
Results: 101 (12%) of the rheumatologists contacted completed the questionnaire. Sixty percent of respondents were men, and 45% of rheumatologists were aged between 46 and 60 years; most practiced exclusively in hospitals (34%), private practice (33%) or in both (34%); the mean duration of clinical practice was 23 years. Almost all of the respondents stated that they were comfortable with the management of PsA (99%) and familiar with French and EULAR recommendations (90%). There was general consensus regarding the difficulties inherent in PsA: therapeutic objectives difficult to achieve (74% of respondents); polymorphism making it difficult to evaluate the effectiveness of a treatment (72%). Almost half the respondents (47%) demonstrated TI on at least one of the 5 vignettes that warranted treatment optimization. The clinical cases that induced the most TI were "oligoarthritis" and "enthesitis" with 20% and 19% of respondents not modifying treatment, respectively. Conversely, the vignettes "polyarthritis in relapse", "neoplastic history" and "cardiovascular risk" generated fewer TIs with 11%, 8% and 6% of respondents, respectively, choosing not to change the current treatment.
Conclusion: Despite a good knowledge of PsA and associated clinical recommendations, almost half of the rheumatologists we surveyed demonstrated at least one TI. The rate of TI we observed for PsA is similar to published data for other chronic diseases (1-4). The clinical profiles for which there was the least uncertainty (comorbidities and polyarticular involvement) generated the least inertia; the more complex profiles oligoarthritis and enthesitis generated more inertia. Our study is the first to show the existence of clinical inertia in PsA and further research is warranted to ascertain the reasons behind this inertia.

Background: Psoriatic arthritis (PsA), a chronic inflammatory disease characterized by peripheral arthritis, axial inflammation, dactylitis, enthesitis, and skin/nail psoriasis, is associated with reduced health-related quality of life (HRQoL).
Objectives: To assess long-term effect of guselkumab (GUS), a human monoclonal antibody that selectively targets the interleukin (IL)-23p19 subunit, on HRQoL of bio-naïve PsA patients (pts) who participated in the Phase 3 2-year DISCOVER-2 trial.[1]
Methods: Pts with active PsA despite nonbiologic disease-modifying antirheumatic drugs (DMARDs) and/or nonsteroidal anti-inflammatory drugs (NSAIDs) received GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO). At W24, PBO pts crossed over to GUS 100 mg Q4W. HRQoL was assessed using the pt-reported EuroQoL-5 Dimension-5 Level (EQ-5D-5L) questionnaire index and EuroQol Visual Analog Scale (EQ-VAS), widely used and complimentary tools that allow pts to provide a global assessment of their HRQoL. The EQ-5D-5L index assesses mobility, self-care, usual activities, pain/discomfort, and anxiety/depression; an index score is derived ranging from 0 (death) to 1 (perfect health).[2] EQ-VAS assesses pt health state on a scale of 0-100, with higher scores indicating better health. Using mixed effects models for repeated measures (MMRM), least squares (LS) mean changes from baseline in the EQ-5D-5L index and EQ-VAS through W100 were assessed. Observed changes from baseline were evaluated; in pts who met treatment failure rules before W24 and in pts who discontinued with missing data after W24, changes from baseline were imputed as 0.
Results: GUS-treated pts achieved greater improvements in pt-reported health status than PBO at both W16 and W24 when evaluated using both the EQ-5D-5L index score and the EQ-VAS. The improvements by GUS in EQ-5D-5L index scores through W24 (0.12 for GUS Q4W/Q8W vs 0.05 for PBO; each nominal $p<0.0001$) were maintained with continued GUS through 2 years (0.15 for GUS Q4W/Q8W) (Table 1). PBO-treated pts who started GUS at W24 reported comparable improvements in their HRQoL by W52 (0.12), with maintenance though W100 (0.14). Similar results were observed with EQ-VAS (Figure 1). W24 improvements in EQ-VAS scores were greater following GUS treatment (18.2/18.4 GUS Q4W/Q8W) vs PBO (6.8; nominal $p<0.0001$). EQ-VAS scores continued to improve with GUS through 2 years (25.0/24.6 GUS Q4W/Q8W). Likewise, PBO-treated pts who crossed over to GUS at W24 experienced improvements in HRQoL by W52 (18.8), with maintenance through W100 (21.2).

Table 1. LS mean change from baseline through W100 in EQ-5D-5L index

	GUS 100mg Q4W (W0-100)			GUS 100mg Q8W (W0-100)			PBO → GUS 100 mg Q4W		
							PBO (W0-24)		GUS (W24-100)
Week	16	24	100	16	24	100	16	24	100
N	243	244	243	247	246	248	244	244	244

AB0882 GUSELKUMAB: DESCRIPTION OF CARDIOVASCULAR RISK AND EFFICACY IN PSORIASIS AND PSORIATIC ARTHRITIS IN REAL CLINICAL PRACTICE

Á. Navarro Gilabert[1], S. Rufián Andújar[2], A. Perez Gil[1], C. Azabal Perez[3], R. Hernández[3]. *[1]Hospital De Valme, Dermatology, Seville, Spain; [2]Hospital De Valme, Cardiology, Seville, Spain; [3]Hospital De Valme, Rheumatology, Seville, Spain*

Background: Guselkumab is the first human monoclonal antibody that binds selectively to the p19 subunit of IL23. It's approved for the treatment of moderate to severe psoriasis and psoriatic arthritis.

Objectives: We present a case series of patients with psoriasis and / or psoriatic arthritis who had a good response to Guselkumab and theirs cardiovascular risk factors.

Methods: An observational and retrospective study of patients with psoriasis and / or psoriatic arthritis under treatment with Guselkumab in the Dermatology and Rheumatology consultation at our hospital. A total of 11 patients were included. Baseline characteristics, comorbidities, and cardiovascular risk were collected. The SCORE (European High Risk Chart) and cardiovascular risk categories (European Society of Cardiology, European Atherosclerosis Society 2019) were used. Disease severity and treatment response were assessed by PASI, DLQI, DAPSA and ASDAS at baseline and after 12, 24 and 36 weeks.

Results: Our cases had a mean age of 52.45 years, 63.6% of them were women. A total of 45.5% had polyarticular psoriatic arthritis. 90.9% were obese, 45.45% were type 2 obesity, with a mean BMI of 34.88. Dyslipidemia and hypertension were observed in 54.5% and 72.7% of the patients, respectively. They all had varying degrees of Non-alcoholic fatty liver disease (NAFLD). A total of 45.5% had SCORE >1% and 90.9% were in moderate category of cardiovascular risk. At baseline their disease parameters were: PASI=11.09 (± 7.01), DLQI=15.09 (± 7.33), DAPSA=19.11 (± 9.95) and ASDAS=2.12 (± 0.43). After 12 weeks of treatment, the mean reduction of PASI and DLQI was 7.09 and 6.45, which continued improving at week 36. None of them were naive. There were no adverse effects, with a treatment survival of 76.73 weeks (± 42.93).

Conclusion: Guselkumab showed excellent results in our clinical practice in the control of psoriasis and / or psoriatic arthritis in non-naive patients with cardiovascular risk factors, with a good safety profile.

AB0883 REAL-WORLD TREATMENT PATTERNS IN PATIENTS WITH PSORIATIC ARTHRITIS

J. Choi[1], A. Sreih[2], T. Lehman[3], M. Suryavanshi[4], Q. Xia[4], M. Nowak[2]. *[1]Bristol Myers Squibb, HEOR, Immunoscience, Princeton, United States of America; [2]Bristol Myers Squibb, Clinical Research & Development, Princeton, United*

States of America; [3]Bristol Myers Squibb, WW Medical Immunology, Princeton, United States of America; [4]Bristol Myers Squibb, CORDS BMS, Princeton, United States of America

Background: Psoriatic arthritis (PsA) is a complex inflammatory disease with manifestations that play an important role in treatment selection.[1] Treatments include oral agents, biologic therapies (inhibitors of tumor necrosis factor [TNFi], interleukin [IL-17Ai, IL-12/23i], cytotoxic T lymphocyte–associated antigen 4 inhibitor [CTLA-4i]), and new targeted oral agents (inhibitors of phosphodiesterase-4 [PDE-4i] and Janus kinase [JAKi]).[1] Few studies have examined real-world treatment patterns of recently approved therapies.
Objectives: Evaluate real-world treatment patterns for branded systemic therapy in patients with PsA.
Methods: In this retrospective study, medical and pharmacy claims from the US IBM MarketScan Commercial and Medicare databases (1/1/2012–12/31/2019) were used to identify patients with PsA who initiated treatment with a TNFi (adalimumab, etanercept, infliximab, golimumab, or certolizumab), IL-17Ai (secukinumab, ixekizumab), IL-12/23p40i (ustekinumab), IL-23p19i (guselkumab), CTLA-4i (abatacept), JAKi (tofacitinib), or PDE-4i (apremilast). Patients (≥18 years) with ≥1 prescription, ≥2 PsA claims separated by ≥1 day on or before the index date (first prescription date [1/1/13–12/31/2018]), and 1-year continuous enrollment before and after the index date were eligible. Treatment patterns were grouped into continuers, discontinuers, and patients with treatment modification (switchers [without a treatment gap], reinitiators [same drug with a treatment gap], and restarters [different drug with a treatment gap]) (Table 1). Patients were followed for 1 year or until treatment modification, whichever came first. Descriptive statistics were used.

Table 1. Terminology

Cohort	Definition	n/N (%)
Continuers	On index treatment during 1-year follow-up with no treatment gaps*	1910/6455 (29.6)
Discontinuers	No prescription claims for any therapy during 1-year follow-up	1614/6455 (25.0)
Patients with treatment modifications	All patients with a change in treatment during 1-year follow-up	2908/6455 (45.1)
Switchers	Prescription claims for treatments different than index therapy before permissible treatment gaps*	794/6455 (12.3)
Reinitiators	Prescription claims for treatments SAME as index therapy AFTER treatment gaps*	1686/6455 (26.1)
Restarters	Prescription claims for DIFFERENT therapy AFTER treatment gap*	428/6455 (6.6)

Note: All terminology applies to cohorts within the first year of treatment.*Treatment gap: gap of 200% of recommended dosing schedule from end of previous prescription's days' supply.

Results: A total of 6455 patients were included (mean age, 50.5 years; 55.5% female; mean Charlson Comorbidity Index score, 0.54). At baseline, the most commonly used therapies were immunosuppressants (58.5%), corticosteroids (52.2%), and nonsteroidal anti-inflammatory drugs (45.9%). Treatments most used at index were TNFi (72.5%; including adalimumab [41.6%] and etanercept [23.8%]) and the PDE-4i apremilast (21.1%). During the 1-year study period, 29.6% of patients maintained their index therapy and 25.0% discontinued. Treatment modification was observed in 45.1% of patients; 12.3% switched to a new therapy without a treatment gap, 26.1% restarted their index therapy, and 6.6% started a new therapy after a treatment gap.
Conclusion: Among patients with PsA, there is substantial variability, including high rates of discontinuation within the first year and after index therapy. Further studies are warranted to understand reasons for these treatment patterns.

AB0884 DISEASE OUTCOMES IN PATIENTS WITH PSORIATIC ARTHRITIS COMPLETING 12 MONTHS OF APREMILAST TREATMENT - REAL-WORLD DATA FROM THE REWARD STUDY

R. Bos[1], T. Jansen[2], I. Bridges[3], S. De Jong[4], M. Vis[5]. *[1]MCL, Rheumatology, Leeuwarden, Netherlands; [2]Viecurie, rheumatology, Venlo, Netherlands; [3]Amgen, Biostatistics, Uxbridge, United Kingdom; [4]Breda, Medical, Breda, Netherlands; [5]Erasmus, rheumatology, Rotterdam, Netherlands*

Background: Patients with moderately active psoriatic arthritis (PsA) and limited joint involvement have considerable disease burden[1,2]. Recent data shows these patients have a high likelihood of achieving treatment goals if treated with apremilast[3]. This is the first report of outcomes in patients with PsA who received apremilast for 12 months in Dutch clinical practice.
Objectives: We report disease outcomes, including the PsA Impact of Disease (PsAID) 12-item questionnaire, swollen joint count (SJC), tender joint count (TJC), dactylitis and enthesitis, among patients in the prospective, multicenter, observational REWARD study who completed 12 months of apremilast treatment.
Methods: The ongoing REWARD study enrolled patients who had initiated apremilast for the treatment of PsA in the Netherlands between 13 April 2017 and 24 March 2021, and includes up to 12 months follow-up[1,4]. We report interim data from patients with data available as of 16 September 2021. Baseline data are summarized separately for patients who discontinued apremilast before their month 12 study visit (stoppers) and patients still receiving apremilast at their month 12 visit (completers). Post baseline data are summarized for completers. Continuous data are summarized using mean and SD, categorical data are summarized using n and percent.
Results: 98 patients were included in this interim analysis; 32 had completed 12 months of apremilast treatment (completers), 54 had discontinued apremilast before month 12 (stoppers), 12 were ongoing in the study. Compared with stoppers, completers were more likely to be biologic naïve and have dactylitis, and had lower BSA. All other baseline characteristics were similar (Table 1). Among completers, all PsAID domains improved after 3 months of apremilast treatment and these improvements were maintained through month 12 (Figure 1). Mean SJC and TJC decreased between baseline and month 12 (SJC, 4.2 and 1.0 at baseline and month 12, respectively; TJC, 7.1 and 3.3, respectively). The proportion of completers with SJC, TJC, enthesitis and dactylitis scores of 0 increased from baseline to month 12 (Figure 1B). The proportion of completers reporting at least one adverse event (AE) was comparable to the overall study population (14/32 [44%] and 48/98 [49%], respectively); the reported adverse events were similar to the known safety profile of apremilast.

Table 1. Baseline characteristics

Baseline Characteristics		All (n=98) N(%)	Completers (n=32) N(%)	Stoppers (n=54) N(%)
Gender	Male	50 (51.0)	18 (56.3)	26 (48.2)
	Female	48 (49.0)	14 (43.8)	28 (51.9)
Age (Years)	Mean (SD)	53.0 (11.6)	52.8 (12.1)	53.2 (12.1)
BMI (kg/m²)	Mean (SD)	28.7 (5.8)	28.9 (4.8)	28.5 (6.5)
Prior Biologicals Given?	Yes	25 (25.8)	1 (3.1)	23 (43.4)
PsO	Yes	77 (78.6)	25 (78.1)	42 (77.8)
BSA PsO (%)	Mean (SD)	5.6 (11.2)	2.2 (4.0)	8.0 (14.2)
SJC (0-66)	Mean (SD)	3.7 (5.2)	4.2 (6.1)	4.0 (5.0)
TJC (0-68)	Mean (SD)	6.9 (9.3)	7.1 (9.8)	7.6 (9.8)
PSAID12 (0-10)	Mean (SD)	4.5 (1.9)	4.3 (1.9)	4.6 (2.1)
VAS Pain	Mean (SD)	43.3 (27.6)	45.3 (25.3)	43.0 (29.8)
CRP (mg/L)	Mean (SD)	7.6 (9.8)	6.0 (7.3)	7.3 (8.6)
Dactylitis (Yes)	(%)	35	53	29
Enthesitis (yes)	(%)	43	47	48
cDAPSA	Mean (SD)	19.8 (15.2)	20.3 (15.5)	20.8 (16.1)
	Rem-Low-Mod	73 (21.5)	24 (77.4)	39 (75.0)
	High	20 (78.5)	7 (22.6)	13 (25.0)
PsA Duration (Years)	Mean (SD)	7.6 (8.0)	7.7 (8.3)	7.5 (7.3)

All=all patients included in this interim analysis; Completers= patients that received apremilast for 12 months; Stoppers= patients that stopped apremilast treatment prior to 12 months.BMI=Body Mass Index, PsO=Psoriasis, BSA PsO= Body Surface Area Psoriasis, SJC=Swollen Joint Count, TJC=Tender Joint Count, PsAID=Psoriatic Arthritis Impact of Disease, VAS=Visual Analog Scale, CRP= C-reactive protein, cDAPSA=Clinical Disease Activity in Psoriatic Arthritis, Rem=Remission, Mod=Moderate, PsA= Psoriatic Arthritis

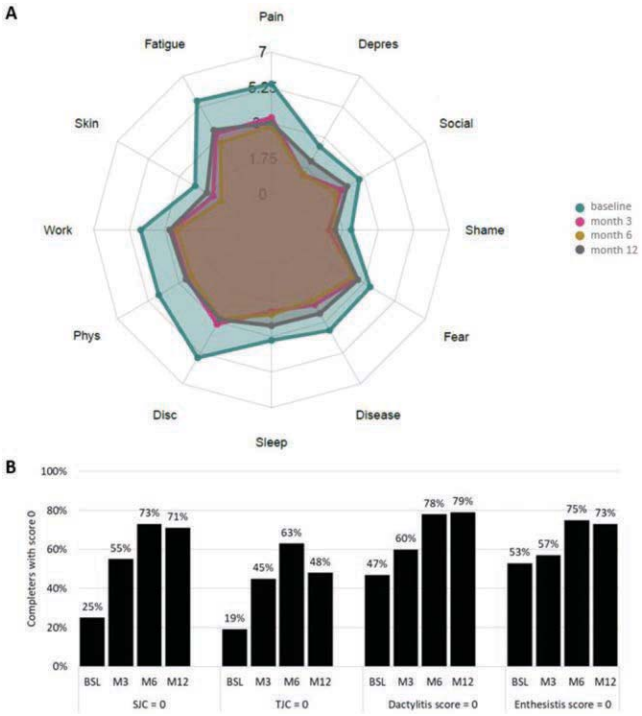

Figure 1. (A) PSAID scores in completers and (B) percentage of completers with no swollen joints, no tender joints, no dactylitis and no enthesitis at baseline (BSL), month 3, 6 and 12 (M3, M6, M12).

Conclusion: In this interim analysis of the REWARD study, patients completing 12 months of apremilast treatment were more likely to be biologic naïve than patients who discontinued apremilast within 12 months of initiation, and had significant decreases in TJC, SJC, dactylitis and enthesis during apremilast treatment. Completed patients also reported decreased PsAID scores during apremilast treatment, indicating improvements in their quality of life.

AB0885

REFRACTORY CHRONIC SYNOVITIS OF THE COMMON FLEXOR SYNOVIAL SHEATH IN PSORIATIC ARTHRITIS PATIENT SUCCESSFULLY TREATED BY ULTRASOUND GUIDED LOCAL METHOTREXATE INJECTION.

A. Abogamal[1,2]. [1]*Al Azhar Faculty of Medicine, Rheumatology, Cairo, Egypt;* [2]*Dr Sulaiman Al Habib Hospital in Dubai, Rheumatology, Dubai, United Arab Emirates*

Background: Psoriatic arthritis (PsA) is a variant of inflammatory musculoskeletal conditions that usually associated with skin psoriasis. PsA is typically heterogenous in comparison to other rheumatic diseases, It affects multiple musculoskeletal domains including synovitis of peripheral and axial joints, entheses, and tendons with tenosynovitis. [1,2]

Persistent cases of arthritis or tenosynovitis usually controlled by local injection with corticosteroids, though some refractory cases of chronic synovitis still not sufficiently controlled by corticosteroid local injection with some case series shows a significant response to local DMARDs and even local Biologics. [3-6]

Objectives: To describe a case of psoriatic arthritis with chronic synovitis of the common flexor synovial sheath successfully treated by ultrasound guided local Methotrexate injection.

Methods: 31 Years old female with psoriatic arthritis in the form of symmetrical hand arthritis for the last 10 years, and extensive nail disease shows partial control under treatment with Methotrexate after failure of sulfasalazine. Her DAPSA score usually ranges between 16 to 18 with tender persistent fluctuating cystic swelling overlying her right palm extending proximally to the distal third of the forearm that becomes more tens on fingers flexion. Ultrasound examination shows hypoechoic distension of the right common flexor synovial sheath, that is partially compressible and partially displaceable with highly positive Doppler signals indicating active synovitis. Figure 1

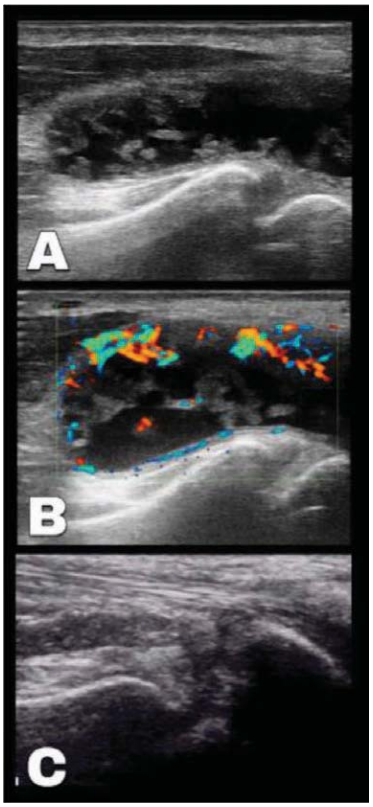

Figure 1. palmar longitudinal ultrasound scan over the radio-carpal region, A: Synovitis with effusion in the common flexor Sheath, B: Positive Color Doppler denoting active synovitis, C: Follow up ultrasound scan showing resolution of synovitis and effusion.

October 2019, ultrasound guided aspiration and local corticosteroid injection applied for the common flexor sheath with escalation of her treatment to Ixekizumab plus Methotrexate to achieve clinical remission. January 2020, patient achieve DAPSA 8 with resolution of have nail lesions, though her right hand function was still significantly impaired due to the refractory persistent synovitis of the Common flexor sheath. Two doses 15mg Methotrexate one week apart inserted into the common flexor sheath under ultrasound imaging.

Results: April 2020, on regular follow up patient achieve DAPSA remission <4, with complete resolution of the right palm swelling and she reports complete recovery of her hand function which is maintained up to January 2022 in her last

follow up visit. Follow up ultrasound scan shows normalization of the common flexor sheath with disappearance of the mixed picture of synovitis and effusion. Figure 1

Conclusion: Refractory synovitis of the common flexor sheath in PsA successfully treated with ultrasound guided local methotrexate injection with persistence of improvement for one year.

AB0886 THE IMPACT OF DEUCRAVACITINIB ON HEALTH-RELATED QUALITY OF LIFE MEASURED BY THE SHORT FORM HEALTH SURVEY 36-ITEM QUESTIONNAIRE: ANALYSIS OF A PHASE 2 TRIAL IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

V. Strand[1], P. J. Mease[2], A. Deodhar[3], J. Ye[4], M. Nowak[5], J. Choi[6], B. Becker[7]. *[1]Stanford University School of Medicine, Immunology/Rheumatology, Palo Alto, United States of America; [2]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America; [3]Oregon Health & Science University,Arthritis and Rheumatic Diseases, Portland, United States of America; [4]Bristol Myers Squibb, Medical Affairs, Princeton, United States of America; [5]Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; [6]Bristol Myers Squibb, HEOR, Immunoscience, Princeton, United States of America; [7]Bristol Myers Squibb, HEOR, Princeton, United States of America*

Background: Patients (pts) with psoriatic arthritis (PsA) experience pain, loss of physical function, joint damage, and significant impairments in social and emotional well-being. The Short Form Health Survey 36-item questionnaire (SF-36v2), a generic measure of pt-reported health-related quality of life (HRQOL), includes 36 items and measures 8 domains—physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role-emotional (RE), and mental health (MH)—that contribute to both physical component summary (PCS) and mental component summary (MCS) scores. Deucravacitinib (DEUC) is a novel, oral, selective, allosteric inhibitor of tyrosine kinase 2 (TYK2), an intracellular kinase that mediates cytokine signalling pathways implicated in PsA pathogenesis. In a Phase 2 trial in pts with active PsA, DEUC was well tolerated and significantly more efficacious than placebo (PBO) after 16 weeks (wks) of treatment.[1]

Objectives: To further evaluate the effect of DEUC treatment on SF-36 scores.

Methods: This double-blind Phase 2 trial (NCT03881059) enrolled pts with a PsA diagnosis ≥6 months who fulfilled Classification Criteria for Psoriatic Arthritis at screening and had active joint disease (≥3 tender and ≥3 swollen joints), high-sensitivity CRP ≥3 mg/L, and ≥1 plaque psoriasis lesion (≥2 cm). Pts failed or were intolerant to ≥1 nonsteroidal anti-inflammatory, conventional synthetic DMARD, and/or 1 TNF inhibitor (≤30%). Pts were randomised 1:1:1 to DEUC 6 mg once daily (QD) or 12 mg QD, or PBO. Changes from baseline (BL) in SF-36 PCS and MCS scores at Wk 16 were prespecified key secondary and additional endpoints, respectively. The 8 SF-36 domain scores were evaluated at Wk 16. The proportions of pts reporting improvements ≥2.5 and ≥5 points (the minimum clinically important difference [MCID]) in SF-36 summary and domain scores, respectively, were evaluated.

Results: Of 203 pts randomised, 180 (89%) completed 16 wks of treatment (DEUC 6 mg QD, 63/70 [90%]; DEUC 12 mg QD, 59/67 [88%]; PBO, 58/66 [88%]). Demographic and BL disease characteristics were similar across groups. BL mean SF-36 PCS and MCS scores were similar among DEUC 6 mg QD, 12 mg QD, and PBO groups (PCS: 34.0, 34.5, and 33.4; MCS: 45.4, 46.9, and 47.5, respectively). At Wk 16, adjusted mean changes from BL in SF-36 PCS and MCS scores were significantly improved with DEUC 6 and 12 mg QD treatment vs PBO (PCS: 5.6, 5.8, and 2.3; MCS: 3.6, 3.5, and 0.7, respectively; $P<0.05$). Reported improvements in domain scores with both doses exceeded MCID and were significant in 5 of 8 domains with DEUC 6 mg QD (PF, RP, BP, VT, and SF) and 6 of 8 domains with DEUC 12 mg QD (RE in addition; Figure 1 **and** Table 1).

Table 1. Improvements reported in SF-36 domains with deucravacitinib 6 mg QD and 12 mg QD vs placebo at Week 16

	PF	RP	BP	GH	VT	SF	RE	MH
Deucravacitinib 6 mg – BL	41.9	42.9	32.5	39.6	39.0	57.0	69.5	58.4
Deucravacitinib 12 mg – BL	44.1	46.0	33.4	38.5	43.0	65.5	71.5	59.2
Placebo – BL	42.4	42.8	31.7	40.3	38.8	63.8	75.1	59.9
Deucravacitinib 6 mg – LSM Wk 16	14.6	12.3	15.9	9.5	11.7	13.2	6.9	8.1
Deucravacitinib 12 mg – LSM Wk 16	13.3	13.5	19.5	8.4	12.1	10.5	8.7	8.2
Placebo – LSM Wk 16	3.3	5.3	7.0	6.2	4.2	-0.2	1.6	3.6
Protocol A/G norms	81.1	81.9	72.5	70.2	59.1	85.1	88.0	76.2

Domain scores range from 0-100, with higher scores indicating better health status.A/G, age/gender; BL, baseline; BP, bodily pain; GH, general health; LSM, least square mean change; MH, mental health; PF, physical functioning; QD, once daily; RE, role-emotional; RP-role-physical; SF, social functioning; SF-36, Short Form-36; VT, vitality; Wk, week.

Conclusion: Pts with PsA treated with DEUC reported clinically meaningful and significant improvements in HRQOL, including fatigue, social functioning and role emotional in addition to physical functioning, role physical and pain, at Wk 16.

Background: Tumor necrosis factor inhibitors (TNFi) are frequently chosen as the first biologic therapy for patients (pts) with psoriatic arthritis (PsA), though a sizeable proportion of pts have an inadequate response (IR), and some may also have intolerance. Guselkumab (GUS), a human mAb that targets the IL-23 p19 subunit, provides an alternative mechanism of action to treat PsA. In the Phase 3 (Ph3) DISCOVER-1 study of GUS in active PsA, GUS every 4 weeks (Q4W) and Q8W clinical response rates were generally consistent between TNFi-naïve (263 pts) and TNFi-experienced (118 pts) cohorts. In the TNFi-experienced cohort and the limited number of DISCOVER-1 pts with IR to their prior TNFi (N=44), American College of Rheumatology 50% improvement (ACR50) and ACR70 response rates at W24 were numerically higher in GUS Q4W- than Q8W-treated pts.[1]
Objectives: To further investigate whether GUS Q4W could provide incremental benefit to some TNFi-IR PsA pts by analyzing the existing DISCOVER-1 dataset to facilitate the design of a new clinical trial.
Methods: Study feasibility assessments included comparison of key efficacy endpoints by treatment group at W24 among TNFi-experienced pts receiving GUS Q8W and Q4W in DISCOVER-1. Results from the DISCOVER-1 study also informed sample size power calculations for a primary endpoint of ACR20 response at W24 in a future study in a TNFi-IR PsA pt population.
Results: Comparison of several efficacy endpoints (ACR70 response, minimal disease activity, Investigator's Global Assessment [IGA] of psoriasis 0/1 response) across treatment groups in the TNFi-experienced DISCOVER-1 cohort supports a potential dose response, with more frequent GUS administration eliciting numerically higher response rates (Table 1). A similar trend was observed for ACR20/50/70 responses in the smaller TNFi-IR population[1], though these findings should be interpreted with caution due to limited sample size. ACR20 response rates at W24 of DISCOVER-1 were employed to estimate sample size requirements for a new study. Assuming comparable rates of GUS treatment effect seen in DISCOVER-1, a sample size of 150 randomized pts per group for PBO, GUS Q8W, and GUS Q4W would provide >90% power to detect a significant difference between each GUS group and PBO for ACR20 response at W24. Based on these findings, a new Ph3b, multicenter, randomized, double-blind, PBO-controlled study, SOLSTICE, was designed to further evaluate the efficacy and safety of GUS in approximately 450 pts with active PsA who had IR to one prior TNFi, and to investigate the effect of GUS dosing interval in this important cohort of pts with PsA (Figure 1).

Table 1. Clinical efficacy at W24 among DISCOVER-1 TNFi-experienced pts

	Placebo	GUS Q8W	GUS Q4W
ACR20	17.9% (7/39)	56.1% (23/41)	57.9% (22/38)
ACR50	5.1% (2/39)	26.8% (11/41)	34.2% (13/38)
ACR70	2.6% (1/39)	2.4% (1/41)	21.1% (8/38)
MDA	2.6% (1/39)	17.1% (7/41)	26.3% (10/38)
IGA 0/1[a]	7.7% (2/26)	48.3% (14/29)	67.9% (19/28)

[a]IGA score of 0 (clear) or 1 (almost clear) among pts with ≥3% body surface area of psoriatic involvement and an IGA score ≥2 (mild-to-severe psoriasis) at baseline.ACR20/50/70, American College of Rheumatology 20%/50%/70% improvement; GUS, guselkumab; IGA, Investigator's Global Assessment; MDA, minimal disease activity; Q4W, every 4 weeks; Q8W, every 8 weeks; TNFi, tumor necrosis factor inhibitor; W, week

Conclusion: PsA pts with TNFi-IR are typically difficult to treat. Overall data from the pivotal DISCOVER-1 study of GUS in pts with active PsA showed consistent clinical response between doses and between TNFi-naïve and TNFi-experienced pts. Analyses based on limited numbers of TNFi-experienced pts from DISCOVER-1 demonstrated potential incremental benefit for achievement of higher response criteria with more frequent dosing in some TNFi-IR pts. SOLSTICE, a Ph3b, randomized, placebo-controlled study, will test this hypothesis.

Background: Psoriatic arthritis (PsA) impacts patients' (pts) work productivity (WP) and daily activity.[1] DISCOVER-2 (D2), a Phase 3 trial of the selective interleukin-23 p19-subunit inhibitor guselkumab (GUS) in biologic-naïve pts with PsA,[2] demonstrated significant improvements in pt-reported WP and daily activity following 1 year (Y) of GUS treatment.[3]

Objectives: Assess WP and daily activity impairment in D2 pts through 2Y. Estimate indirect savings associated with GUS treatment and assess changes in employment status.

Methods: Pts with active PsA received GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO). At W24, PBO pts crossed over to GUS 100 mg Q4W. WPAI-PsA assesses PsA-related work time missed (absenteeism), impairment while working (presenteeism), and impaired overall WP (absenteeism + presenteeism) for pts employed at baseline (EBL) and daily activity for all pts, including those unemployed at baseline (UBL) during the previous week. Mean changes in WPAI-PsA domains were calculated for each multiple imputation (MI) dataset using an analysis of covariance (ANCOVA); the reported LS mean is the average of all MI datasets. Significance was defined as $p<0.05$. Among pts EBL, potential indirect savings from improved overall WP were estimated using 2020 European Union mean yearly wage estimate (all occupations) combined with LS mean change from BL in WPAI-PsA overall work impairment.[4] A shift analysis evaluated proportions of pts employed vs unemployed by treatment group using observed data over time.

Results: Pts EBL comprised 64% of the analysis cohort. Significant improvements in WP in pts EBL and in daily activity among all pts were observed with GUS Q4W/Q8W vs PBO at W24;[3] mean improvements in WP and daily activity increased with continued GUS through 2Y (Table 1). Potential annual indirect savings from improved overall WP in pts EBL were *€10,826* GUS Q4W, *€12,712* GUS Q8W, and *€10,948* PBO→ GUS Q4W at 2Y. Shift analysis showed relatively stable employment in pts EBL with GUS up to 2Y (>83% continued to work). Among pts UBL (36% of cohort), the proportion of pts employed increased by >20% through 2Y of GUS (Figure 1).

Conclusion: In GUS-treated bio-naïve PsA pts, robust improvements in WP and daily activity seen at W24 were maintained and increased through 2Y of GUS. Long-term improvements in WP achieved may result in substantial indirect cost savings for GUS-treated pts. Rates of employment remained stable in pts employed and increased in those unemployed at BL.

ASSOCIATION BETWEEN CLINICALLY MEANINGFUL IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES AND STRINGENT MEASURES OF DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH UPADACITINIB VERSUS PLACEBO OR ADALIMUMAB: RESULTS FROM A PHASE 3 TRIAL

L. Gossec[1], N. Damjanov[2], S. Tsuji[3], A. Lertratanakul[4], R. Lippe[5], J. Patel[4], P. Zueger[4], K. De Vlam[6]. *[1]Sorbonne Université, Pitié Salpêtrière Hospital, Paris, France; [2]University of Belgrade School of Medicine, Institute of Rheumatology, Belgrade, Serbia; [3]Department of Orthopaedics/Rheumatology, National Hospital Organization, Osaka Minami Medical Center, Osaka, Japan; [4]AbbVie Inc., Immunology, North Chicago, United States of America; [5]AbbVie Deutschland GmbH & Co. KG, Immunology, Berlin, Germany; [6]Department of Rheumatology, Universitaire Ziekenhuizen Leuven, Leuven, Belgium*

Background: The achievement of disease control has been shown to be associated with improved prognosis in PsA, though no single measure of low disease activity or remission is currently universally accepted. Patient-reported outcomes

(PROs) have been well-established in PsA and are important indicators of patient improvement while on treatment. To date, the association between PROs and disease control in PsA has not been fully characterized.

Objectives: We examined the association between clinically meaningful improvement in PROs and stringent measures of disease control among patients with PsA enrolled in the Phase 3 SELECT-PsA 1 trial.

Methods: Patients with active PsA and an inadequate response to ≥1 non-biologic DMARDs were randomized to receive upadacitinib (UPA) 15 mg once daily (QD), UPA 30 mg QD, adalimumab (ADA) 40 mg every other week, or PBO for 24 weeks. PROs included: Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), 36-Item Short-Form Health Survey (SF-36), and Work Productivity and Activity Impairment (WPAI). Measures of stringent disease control included achievement of minimal disease activity (MDA), ACR70 response, and remission based on Disease Activity Index in PsA (DAPSA ≤4.0) or PsA Disease Activity Score (PASDAS ≤1.9). The percentage of patients achieving stringent disease control was determined among patients reporting vs not reporting PRO improvements ≥ minimal clinically important differences (MCID) in the combined active treatment and PBO group at Week 24.

Results: A total of 1704 patients were included in the SELECT PsA 1 trial, of whom 59.2%, 72.4%, 51.3%, 62.3%, 64.6%, and 63.9% reported improvements ≥ MCID (MCID responders) in FACIT-F, SF-36 physical component summary score, SF-36 mental component summary (MCS) score, WPAI activity impairment, WPAI overall work impairment, and WPAI presenteeism, respectively, at week 24. The percentage of patients achieving MDA, ACR70 or DAPSA remission at week 24 was significantly higher (nominal $P \leq 0.01$) among patients who reported improvements ≥ MCID for all PROs vs those who did not (Figures 1, 2). Similar results were seen in patients achieving PASDAS remission except for SF-36 MCS score (Figure 2). Among patients reporting improvements ≥ MCID across all PROs, more patients achieved ACR70 and MDA responses (29%-49%) with fewer patients achieving DAPSA or PASDAS remission (14%-19%).

Conclusion: PsA patients who reported clinically meaningful improvements in key PROs: fatigue, quality of life, and work productivity were more likely to achieve stringent measures of disease control. These results suggest a close association between meaningful improvements in patient-centric outcomes and achievement of stringent disease control.

Background: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates signaling of key cytokines (eg, interleukin [IL]-23 and Type I interferons) involved in the pathogenesis of immune-mediated diseases including plaque psoriasis and psoriatic arthritis (PsA). Deucravacitinib is a novel, oral, selective, allosteric inhibitor of TYK2 that achieves high selectivity by uniquely binding to the regulatory domain of the enzyme, rather than to the more conserved active domain. Deucravacitinib showed superior efficacy compared with placebo at 16 weeks in a Phase 2 trial in patients with PsA (NCT03881059). Results from the 16-week, placebo-controlled periods of two 52-week, Phase 3 trials in psoriasis (POETYK PSO-1 and POETYK PSO-2) previously showed that deucravacitinib was significantly more efficacious than placebo and apremilast based on the coprimary endpoints of ≥75% reduction from baseline in Psoriasis Area and Severity Index (PASI 75) and a static Physician's Global Assessment (sPGA) score of 0 or 1 (clear or almost clear) at Week 16.

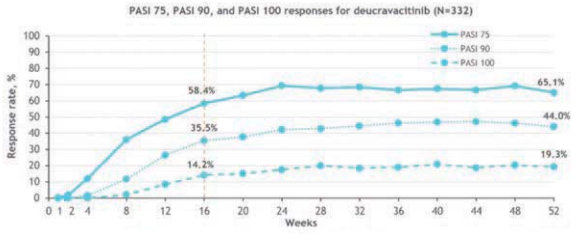
Objectives: To evaluate the efficacy of deucravacitinib over 52 weeks in the POETYK PSO-1 and POETYK PSO-2 trials.

Methods: POETYK PSO-1 (NCT03624127) and PSO-2 (NCT03611751) were double-blinded trials that randomised patients with moderate to severe plaque psoriasis (body surface area involvement ≥10%, PASI ≥12, sPGA score ≥3) 2:1:1 to deucravacitinib 6 mg once daily, placebo, or apremilast 30 mg twice daily. Patients receiving placebo were switched to deucravacitinib at Week 16 in both trials. Patients randomised to deucravacitinib in PSO-1 received deucravacitinib continuously through Week 52. PSO-2 included a randomised withdrawal phase in which patients originally randomised to deucravacitinib who had achieved PASI 75 response at Week 24 were rerandomised 1:1 to placebo or deucravacitinib, whereas those who did not achieve PASI 75 response at Week 24 continued receiving deucravacitinib. The proportions of patients achieving PASI 75 and sPGA 0/1 responses were evaluated up to Week 52. Secondary efficacy endpoints evaluated over this period included PASI 90, PASI 100, percentage change from baseline in PASI, sPGA 0 (clear), change from baseline in the Psoriasis Symptoms and Signs Diary (PSSD) symptom score, and Dermatology Life Quality Index (DLQI) 0/1 (no impact on patient's life).

Results: A total of 666 and 1020 patients were randomised in PSO-1 and PSO-2, respectively. Demographic and baseline disease characteristics were balanced across treatment groups; mean age was 46.6 years, mean disease duration was 18.6 years, 18.4% of patients had PsA, and 34.8% had previously used biologic therapy. PASI 75, PASI 90, and PASI 100 responses were maintained from Week 16 to Week 52 in PSO-1 (Figure 1). Additionally, sPGA responses were maintained during this period (sPGA 0/1: 53.6% to 52.7%; sPGA 0: 17.5% to 23.5%, respectively). Patients who switched from placebo to deucravacitinib at Week 16 demonstrated PASI 75 and sPGA 0/1 responses at Week 52 (68.3% and 53.8%, respectively) comparable to those observed in patients who received continuous deucravacitinib treatment from Day 1 (65.1% and 52.7%, respectively). In PSO-2, among deucravacitinib-treated patients who achieved PASI 75 at Week 24 and were rerandomised to continue treatment, responses were maintained at Week 52 in the majority of patients (PASI 75, 80.4% [119/148]; sPGA 0/1, 70.3% [83/118]). Results for percentage change from baseline in PASI, change from baseline in the PSSD symptom score, and DLQI 0/1 were consistent with those reported for PASI and sPGA responses.

Conclusion: Results from the Phase 3 POETYK PSO-1 and PSO-2 trials demonstrated that deucravacitinib was efficacious through 52 weeks in patients with moderate to severe plaque psoriasis. Clinical responses were maintained in patients who received continuous deucravacitinib treatment and were improved in patients who switched from placebo at Week 16 to deucravacitinib treatment.

Figure. PASI responses with deucravacitinib 6 mg QD through Week 52 - POETYK PSO-1 (NRI)



NRI, nonresponder imputation; PASI, Psoriasis Area and Severity Index; PASI 75, ≥75% reduction from baseline in PASI; PASI 90, ≥90% reduction from baseline in PASI; PASI 100, 100% reduction from baseline in PASI; QD, once daily.

DEUCRAVACITINIB EFFICACY IN PSORIATIC ARTHRITIS BY BASELINE DMARD USE: EXPLORATORY ANALYSIS FROM A PHASE 2 STUDY

A. Deodhar[1], M. Nowak[2], J. Ye[3], T. Lehman[4], L. Wei[5], S. Banerjee[6], P. J. Mease[7]. *[1]Oregon Health & Science University, Arthritis and Rheumatic Diseases, Portland, United States of America; [2]Bristol Myers Squibb, Clinical R&D, Princeton, United States of America; [3]Bristol Myers Squibb, Medical Affairs, Princeton, United States of America; [4]Bristol Myers Squibb, WW Medical Immunology, Princeton, United States of America; [5]Bristol Myers Squibb, Medical Immunology, Princeton, United States of America; [6]Bristol Myers Squibb, Rheumatology and Dermatology, Princeton, United States of America; [7]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology Research, Seattle, United States of America*

Background: Psoriatic arthritis (PsA) treatment guidelines recommend that patients (pts) inadequately responding to conventional synthetic DMARDs (csDMARDs) can be treated with targeted synthetic DMARDs with or without background use of csDMARDs. Deucravacitinib (DEUC) is a novel, oral, selective, allosteric inhibitor of tyrosine kinase 2 (TYK2) that binds to the unique TYK2 regulatory domain, thereby suppressing signaling of key cytokines (eg, IL-23) involved in PsA pathogenesis. In a Phase 2 trial in pts with active PsA, DEUC was well tolerated and significantly more efficacious than placebo (PBO) after 16 weeks of treatment.[1]

Objectives: This analysis further evaluated the effect of DEUC in this Phase 2 trial in pts treated with and without background csDMARDs for 16 weeks.

Methods: This double-blind trial (NCT03881059) enrolled pts with active PsA who had either failed or were intolerant to ≥1 nonsteroidal anti-inflammatory drug, corticosteroid, csDMARD, and/or 1 TNF inhibitor (TNFi; up to 30%). Pts were randomised 1:1:1 to DEUC 6 mg once daily (QD) or 12 mg QD, or PBO. A post hoc subgroup analysis in pts with and without background csDMARD use assessed improvements in select clinical outcomes (ACR 20 response, and change from baseline in ACR components, Psoriasis Area and Severity Index total score, and Psoriatic Arthritis Disease Activity Score) at Week 16.

Results: Baseline (BL) demographics, clinical characteristics, and disease activity were generally similar among pts with and without background csDMARD use. At BL, background csDMARD use was 64.3%, 64.2%, and 66.7% and methotrexate use was 50.0%, 55.2%, and 59.1% in the DEUC 6 mg QD, 12 mg QD, and PBO groups, respectively. Pts with and without background csDMARD use showed similar improvements at Week 16 with DEUC treatment versus PBO

on most clinical measures, pt-reported outcomes, and composite measures (Table 1 **and** Figure 1). No clinically meaningful differences in adverse events (AEs) were observed in pts with or without background csDMARD use.

Table 1. Adjusted mean (SE) change from baseline at Week 16 in clinical outcomes by csDMARD use

	PBO w/o csDMARD (n=22)	PBO w csDMARD (n=44)	DEUC 6 mg QD w/o csDMARD (n=25)	DEUC 6 mg QD w csDMARD (n=45)	DEUC 12 mg QD w/o csDMARD (n=24)	DEUC 12 mg QD w csDMARD (n=43)
Swollen joint count	-4.7 (1.4)	-5.0 (0.9)	-7.4 (1.4)	-6.8 (0.9)	-8.4 (1.3)	-7.7 (1.0)
Tender joint count	-5.3 (2.2)	-6.6 (1.3)	-6.4 (2.2)	-11.3 (1.3)	-11.5 (2.0)	-11.6 (1.4)
Physician's Global Assessment of Disease Activity	-20.6 (5.6)	-20.6 (3.7)	-29.1 (5.8)	-32.6 (3.5)	-30.1 (5.3)	-32.1 (3.9)
Patients' Global Assessment of Disease Activity	-14.9 (5.8)	-13.4 (3.9)	-23.0 (5.9)	-28.4 (3.8)	-28.2 (5.4)	-24.9 (4.2)
Pain	-14.7 (5.6)	-14.6 (3.9)	-22.7 (5.7)	-26.2 (3.7)	-25.5 (5.3)	-25.5 (4.2)
HAQ-DI	-0.23 (0.11)	-0.04 (0.09)	-0.31 (0.11)	-0.38 (0.08)	-0.48 (0.10)	-0.34 (0.09)
hsCRP	12.0 (5.3)	-4.4 (2.1)	-10.1 (5.3)	-13.3 (2.0)	-4.9 (4.9)	-10.0 (2.2)
PASI total score	2.5 (1.4)	-2.3 (0.7)	-3.7 (1.4)	-4.0 (0.6)	-4.0 (1.3)	-4.9 (0.7)
PASDAS	-0.9 (0.4)	-1.2 (0.3)	-1.8 (0.4)	-2.1 (0.2)	-2.2 (0.3)	-2.1 (0.3)

The number of patients with data available for individual endpoints may vary.csDMARD, conventional synthetic disease-modifying antirheumatic drug; DEUC, deucravacitinib; HAQ-DI, Health Assessment Questionnaire-Disability Index; hsCRP, high-sensitivity C-reactive protein; PASDAS, Psoriatic Arthritis Disease Activity Score; PASI, Psoriasis Area and Severity Index; PBO, placebo; QD, once daily; SE, standard error; w, with; w/o, without.

Conclusion: These analyses demonstrate that the efficacy of DEUC for the treatment of PsA was similar in pts with and without background csDMARD use. The AE profile of DEUC treatment with and without csDMARD use was consistent with findings from the overall Phase 2 PsA trial population.

TARGETED SAFETY ANALYSES OF GUSELKUMAB: LONG-TERM RESULTS FROM RANDOMIZED CLINICAL TRIALS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND MODERATE TO SEVERE PSORIASIS

P. J. Mease[1], P. Foley[2], K. Reich[3], S. D. Chakravarty[4,5], M. Shawi[6], Y. W. Yang[6], M. Miller[7], A. Kollmeier[7], X. L. Xu[7], J. Yu[7], Y. Wang[7], S. Sheng[7], Y. You[7], I. Mcinnes[8]. *[1]Swedish Medical Center/Providence St. Joseph Health, University of Washington, Department of Rheumatology Research, Seattle, WA, United States of America; [2]The University of Melbourne, St. Vincent's Hospital Melbourne and Probity Medical Research, Skin Health Institute, Department of Medicine (Dermatology), Melbourne, Australia; [3]University Medical Center Hamburg-Eppendorf, Institute for Health Services Research in Dermatology and Nursing, Translational Research in Inflammatory Skin Diseases, Hamburg, Germany; [4]Janssen Scientific Affairs, LLC, Department of Immunology, Horsham, PA, United States of America; [5]Drexel University College of Medicine, Department of Rheumatology, Philadelphia, PA, United States of America; [6]Janssen Global Services, LLC, Department of Immunology, Horsham, PA, United States of America; [7]Janssen Research & Development, LLC, Department of Immunology, San Diego, CA, United States of America; [8]University of Glasgow, Institute of Infection, Immunity and Inflammation, Glasgow, United Kingdom*

Background: Guselkumab (GUS) demonstrated efficacy and a favorable safety profile in active PsA in the Phase (Ph) 2[1] and Ph3 DISCOVER-1&2 trials[2,3] and in moderate-to-severe plaque psoriasis (PsO) in the Ph3 VOYAGE-1&2 trials.[4,5]

Objectives: To assess long-term safety of GUS across PsA/PsO trials.

Methods: Using pooled safety data through 2 years (yrs) from PsA trials (N=1229; GUS 100 mg every 4/8 weeks [Q4W/Q8W])[1-3] and through 5 yrs from PsO trials (N=1721; GUS 100 mg Q8W),[4,5] incidences of serious adverse events (SAEs); gastrointestinal (GI)-related SAEs and other targeted AEs; including candidiasis, uveitis, and opportunistic infections (OIs) were evaluated. Incidence rates (IRs) were calculated as the number of events per 100 pt-yrs (PY) of follow-up with 95% CI. Patients (pts) with an IBD history were not excluded in PsA/PsO trials. Max exposure duration was W100 for PsA trials and W252 for PsO trials.

Results: The PsA and PsO populations had comparable mean age and BMI. IRs of SAEs and GI-related SAEs were generally similar between GUS- and PBO-treated pts during PBO-controlled periods, and between PsA pts receiving GUS Q4W/Q8W for up to 2 yrs and PsO pts receiving GUS Q8W for up to 5 yrs (Table 1). IRs of other targeted AEs of interest were low. OIs did not occur in PsO pts and were infrequent in PsA pts (Table 1). Candidal infections were infrequent and non-serious. Iridocyclitis was reported in 1 PBO- and 1 GUS Q8W-treated PsA pt. No exacerbations or new onset of IBD or active tuberculosis was reported in GUS-treated PsA/PsO pts.

Conclusion: IRs of SAEs; GI-related SAEs; and AEs of interest including candidiasis, uveitis, and OIs were low, or no cases were reported. No new safety concerns were identified with GUS treatment through 2 yrs and 5 yrs of follow-up in the pooled PsA and PsO trials, respectively, supporting a durable and favorable GUS safety profile consistent between pts with active PsA and moderate-to-severe PsO.

AN ANALYSIS OF FATIGUE IN PATIENTS WITH PSORIATIC DISEASE UTILIZING SF-36 VITALITY SCORES: RESULTS THROUGH WEEK 24 IN PHASE 3 TRIALS OF GUSELKUMAB IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS

J. F. Merola[1], Y. H. Liu[2], Y. W. Yang[3], M. Miller[4], M. Shawi[3], D. Chan[5], S. Khattri[6], L. Savage[7], W. H. Boehncke[8], C. Han[2]. *[1]Harvard Medical School, Brigham and Women's Hospital, Department of Dermatology, Boston, MA, United States of America; [2]Janssen Global Services, LLC, Department of Immunology, Raritan, NJ/Malvern, PA, United States of America; [3]Janssen Pharmaceutical Companies of Johnson & Johnson, Immunology Global Medical Affairs, Horsham, PA, United States of America; [4]Janssen Research & Development, LLC, Department of Immunology, Spring House, PA, United States of America; [5]Janssen Scientific Affairs, LLC, Department of Dermatology, Horsham, PA, United States of America; [6]Icahn School of Medicine at Mount Sinai, Department of Immunology, New York, NY, United States of America; [7]University of Leeds, Department of Dermatology, Leeds, United Kingdom; [8]Geneva University Hospitals, University of Geneva, Division of Dermatology and Venereology, Geneva, Switzerland*

Background: Patients with chronic inflammatory diseases can experience significant fatigue, negatively impacting health-related quality-of-life.[1,2]

Objectives: This post-hoc analysis evaluated baseline fatigue severity among patients with psoriasis and/or psoriatic arthritis (PsA) and the effect of guselkumab treatment on patient-reported fatigue.

Methods: VOYAGE-2 evaluated guselkumab every 8 weeks (Q8W) versus placebo (W16→guselkumab) and adalimumab in treating moderate-to-severe psoriasis.[3] DISCOVER-1[4] and DISCOVER-2[5] evaluated guselkumab Q4W and Q8W versus placebo in treating active PsA. Fatigue was assessed using 36-item Short Form (SF-36) vitality scale score (includes 4 questions on fatigue/energy level); the US population norm=50±10; 5-10-point decrements are typically observed in conditions known to cause fatigue[2]; scores ≤35 indicate clinically important fatigue[1]; increases ≥5 indicate clinically meaningful improvement.[2]

Results: Across randomized groups at baseline, mean SF-36 vitality scores were 47.7-48.5 in psoriasis and 42.2-44.0 in PsA patients; 11%-15% of psoriasis and 20%-28% of PsA patients had scores <35. In psoriasis patients, mean increases in SF-36 vitality score at W16 were: placebo, 1.1; adalimumab, 3.9 (p<0.001 versus placebo); guselkumab, 5.6 (p<0.001 versus placebo); at W24: placebo→guselkumab, 4.6; adalimumab, 3.9; guselkumab, 5.8 (p=0.0148 versus adalimumab). In PsA patients, mean increases at W24 were: placebo, 2.3-4.0; guselkumab, 5.5-7.5 (p≤0.001 versus placebo). Through the placebo-controlled periods, significantly greater proportions of guselkumab-treated patients achieved clinically meaningful improvement in fatigue versus placebo (W16 psoriasis: guselkumab, 48%; placebo, 32%; p<0.001; W24 PsA: guselkumab, 53%-55%; placebo, 34%-44%; p<0.05).

Conclusion: At baseline, patients with psoriatic disease experienced clinically important fatigue, more so with PsA (20%-28%) than psoriasis (11%-15%). In guselkumab-treated psoriasis and PsA patients, clinically meaningful improvements in fatigue were achieved at W16 and W24, respectively.

Background: Established criteria for classifying axial psoriatic arthritis (PsA) are lacking, and assessments of disease activity often rely on measures developed for ankylosing spondylitis (AS). There is an unmet need to systematically identify and measure efficacy of treatments for axial PsA patients (pts). Guselkumab (GUS), a selective interleukin (IL)-23p19 inhibitor, was efficacious in improving signs and symptoms of active PsA in 2 phase 3, randomized, placebo (PBO)-controlled studies: DISCOVER-1 and DISCOVER-2. In a post-hoc pooled analysis of DISCOVER-1&2 pts with investigator-confirmed sacroiliitis, GUS-treated pts had greater improvements in axial symptoms compared with PBO.[1] Imaging in DISCOVER-1&2 was restricted to the sacroiliac (SI) joints, occurring prior to/at screening as confirmed by the investigator, and locally read.

Objectives: To design a new, dedicated study to evaluate the effects of GUS on axial PsA prospectively.

Methods: Cumulative evidence from DISCOVER-1&2, including exposure–response relationship, covariate adjustment for modest baseline imbalances across treatment groups, subgroup analyses, and comparisons within and across these studies, was considered in designing a new trial. Data from the pivotal registrational studies suggest similar efficacy with GUS every-4-weeks (Q4W) and Q8W regimens in treating PsA signs and symptoms, including symptoms of axial involvement. Power calculations were based on mean changes in Bath AS Disease Activity Index (BASDAI) scores in DISCOVER-1&2.

Results: The phase 4, randomized, PBO-controlled STAR study is specifically designed to prospectively assess efficacy outcomes in PsA pts with magnetic resonance imaging (MRI)-confirmed axial inflammation. Based on observed mean (SD) changes from baseline in BASDAI score from DISCOVER-1&2 (Table 1), 405 pts, randomized (1:1:1) to GUS Q4W, GUS at W0, W4, then Q8W, or PBO →GUS Q8W at W24, are planned for enrollment (Figure 1). STAR eligibility criteria include PsA ≥6 months and active disease (≥3 swollen & ≥3 tender joints, C-reactive protein [CRP] ≥0.3 mg/dL) despite prior non-biologic disease-modifying antirheumatic drugs, apremilast, and/or non-steroidal anti-inflammatory drugs. Pts will be naïve to biologics and Janus kinase inhibitors and have BASDAI ≥4, spinal pain score (visual analog scale [VAS]) ≥4, and screening MRI-confirmed axial disease (positive spine and/or SI joints defined as centrally read Spondyloarthritis Research Consortium of Canada [SPARCC] score ≥3). Follow-up MRIs of spine and SI joints will be obtained at W0, W24, and W52 and also centrally read, with readers blinded to treatment group and timepoint. Spinal/SI joint inflammation will be scored using the SPARCC method, with the former also assessed using the CAN-DEN method. The primary endpoint is mean change in BASDAI at W24; controlled (hierarchical) secondary endpoints, all at W24, include AS Disease Activity Score (ASDAS-CRP), Disease Activity Index for PsA (DAPSA), ≥40% improvement in Assessment in AS criteria (ASAS40), and mean changes in spine/SI joint SPARCC scores.

Table 1. Power calculations for the primary endpoint in the Phase 4 STAR study.

AB0895

RESIDUAL BURDEN AND DISEASE ACTIVITY OF CANADIAN PSA PATIENTS TREATED WITH ADVANCED THERAPIES: PRELIMINARY RESULTS FROM A MULTIPLE REGISTRY ANALYSIS (UNISON-PSA)

D. Choquette[1], V. Chandran[2], M. C. Laliberté[3], P. A. Fournier[3], T. Girard[3], M. Sutton[4], D. D. Gladman[2]. *[1]CHUM, University of Montreal, Institut de Rhumatologie de Montréal, Montreal, Canada; [2]University Health Network, Institute of Medical Science, University of Toronto, Schroeder Arthritis Institute, Krembil Research Institute, Toronto, Canada; [3]AbbVie Corporation, Medical Affairs, Saint-Laurent, Canada; [4]Toronto Western Hospital, University Health Network, Centre for Prognosis Studies in the Rheumatic Diseases, Psoriatic Disease Program, Toronto, Canada*

Background: Given the availability of advanced therapies in PsA with different modes of action, it is of interest to characterize their impact on overall clinical outcomes.

Objectives: To describe residual disease activity in Canadians with PsA treated with advanced therapies.

Methods: Multi-region, observational, retrospective analysis of data from Rhumadata (Quebec) and International Psoriasis and Arthritis Research Team (IPART) Canadian registries was performed. Data from each registry and region were analyzed separately using a common statistical analysis plan to generate descriptive statistics. Patients included in the registries were eligible if they were adults at the time of PsA diagnosis and were treated with an advanced therapy for ≥6 months initiated between January 2010 and December 2019. Residual disease activity was defined as failing to achieve MDA (defined as achieving ≥5 of: TJC ≤1; SJC ≤1; PASI ≤1 or BSA ≤3%; patient pain VAS score of ≤15 mm; patient global disease activity VAS score of ≤20 mm; HAQ score ≤0.5; and tender entheseal points ≤1) (primary endpoint), or DAPSA score ≥14 (secondary endpoint) within 6 months of initiation of an advanced therapy (TNFi, IL-12/23i, IL-17i, PDE4i, CTLA4i or JAKi).

Results: 1,866 subjects (Atlantic [IPART; Newfoundland]: N=83; Quebec [Rhumadata]: N=687; Ontario [IPART]: N=966; West [IPART; British Columbia, Manitoba]: N=130) were included in this preliminary analysis. Baseline characteristics are presented in Table 1. Overall, 899 were receiving their 1st advanced therapy, 464 were receiving their 2nd, and 264 had received ≥3. The most common therapy class was TNFi, followed by IL-17i. 18/21 (85.7%) subjects in the Atlantic region with an assessment, 184/246 (74.8%) in Quebec, 391/571 (68.1%) in Ontario, and 30/43 (69.8%) in Western Canada failed to achieve MDA within 6 months following advanced therapy initiation. Failure to achieve MDA within the allotted period was higher among patients receiving an IL-17i compared with a TNFi. There was no appreciable effect of lines of therapy. Also, 74 of 110 (67.3%) patients with an assessment in Quebec, 201/365 (55.1%) in Ontario and 3/3 (100%) in the West failed to achieve at least low disease activity (LDA; DAPSA ≤14) within 6 months following initiation of an advanced therapy. Data were not available for the Atlantic region. The proportion of patients not achieving LDA by advanced therapy was similar for those receiving a TNFi and IL-17i but increased with line of therapy.

Conclusion: Preliminary data show approximately three quarters of Canadians with PsA failed to achieve MDA or LDA within 6 months of initiating an advanced therapy. Disease duration is a possible explanation for not achieving MDA or LDA; better therapeutic approaches are needed to achieve these outcomes in patients with PsA.

Acknowledgements: The authors wish to thank Dr. Steve Ramkissoon, for supporting the statistical analysis of the IPART registry. Medical writing and statistical support (funded by Abbvie) were provided by John Howell and Hong Chen, respectively, from McDougall Scientific. Financial support for the study was provided by AbbVie. AbbVie participated in the design of the study, interpretation of data, review, and approval of this publication. All authors contributed to the development of the publication and maintained control over the final content.

Ritchlin[11]. *[1]Swedish Medical Center/Providence St. Joseph Health & University of Washington, Rheumatology Research, Seattle, WA, United States of America; [2]University of Glasgow, Institute of Infection, Immunity and Infection, Glasgow, United Kingdom; [3]The Chinese University of Hong Kong and The Prince of Wales Hospital, Department of Medicine & Therapeutics, Hong Kong, Hong Kong (SAR); [4]EVERSANA, Department of Immunology, Burlington, Canada; [5]Janssen Global Services, LLC, Department of Immunology, Horsham, PA, United States of America; [6]Janssen EMEA, Department of Immunology, High Wycombe, United Kingdom; [7]Janssen Scientific Affairs, LLC, Department of Immunology, Horsham, PA, United States of America; [8]Drexel University College of Medicine, Division of Rheumatology, Philadelphia, PA, United States of America; [9]Janssen Pharmaceutical Companies of Johnson & Johnson, Department of Immunology, Issy-les-Moulneaux, France; [10]Geneva University Hospitals, Department of Dermatology, Geneva, Switzerland; [11]University of Rochester, Department of Medicine - Allergy/Immunology and Rheumatology, Rochester, NY, United States of America*

Background: The efficacy of guselkumab (GUS), an interleukin (IL)-23 p19-subunit inhibitor, has been demonstrated for psoriatic arthritis (PsA) in two pivotal phase 3 trials (DISCOVER-1&2). A third phase 3b trial (COSMOS) evaluated GUS in patients with PsA who had an inadequate response (IR) to tumor necrosis factor inhibitors (TNFi). GUS has previously been compared to targeted PsA therapies through network meta-analysis (NMA).
Objectives: This NMA update was to include data for GUS in TNFi-IR patients from COSMOS, as well as two additional key comparators, risankizumab (RIS), an IL-23 inhibitor, and upadacitinib (UPA), a Janus kinase inhibitor (JAKi).
Methods: A systematic literature review identified PsA randomized controlled trials up to February 2021. A subsequent hand-search identified data for newer agents, including congresses up to July 2021. Bayesian NMAs were performed to compare treatments on American College of Rheumatology (ACR) response, Psoriasis Area and Severity Index (PASI) response, modified van der Heijde-Sharp (vdH-S) score, and serious adverse events (SAEs). Analyses used fixed or random effects models and adjusted for placebo response via meta-regression on baseline risk when feasible. Multinomial models were used for ACR and PASI. Results were summarized by ranking treatments in league tables according to results derived from NMAs. Conclusions (ie, comparable or better/worse) for GUS 100 mg every 8/4 weeks (Q8W/Q4W) versus comparators were based on overlap of pairwise 95% credible intervals (CrIs) (ie, treatments are comparable if CrIs overlap 1 [dichotomous outcomes] or 0 [continuous outcomes]).
Results: Thirty-three phase 3 studies were included in the NMAs. Studies were placebo-controlled up to 24 weeks except for 2 head-to-head studies, and evaluated 15 targeted PsA therapies in TNFi naïve, IR, or mixed populations. For ACR 20 response, GUS Q8W and Q4W ranked 14th and 12th among 23 treatments and were comparable to most other active agents, including RIS and UPA, subcutaneous (SC) TNFi, and most IL-17A inhibitors (IL-17Ai), as demonstrated by overlap in pairwise 95% CrIs with unity. Results were similar for ACR 50 and 70 responses. For PASI 90, GUS Q8W and Q4W ranked 2nd and 1st among 23 treatments and were better than multiple agents, including all SC TNFi, JAKi, including UPA, and other small molecules, as demonstrated by nonoverlap in pairwise 95% CrIs with unity. GUS Q8W and Q4W were similar to RIS and most IL-17Ai for PASI 90, but point estimates consistently favored GUS. For vdH-S score, GUS Q8W and Q4W ranked 8th and 3rd among 18 treatments; GUS Q4W was better than RIS, and both GUS Q8W and Q4W were comparable to most other agents, including UPA. SAEs were comparable across most agents.
Conclusion: GUS demonstrated better skin efficacy than most other targeted PsA therapies, including UPA. For vdH-S, both GUS dose regimens were comparable to most treatments, with both GUS dose regimens ranking higher than most, including UPA and RIS. Both GUS dose regimens demonstrated ACR responses that were comparable to most other agents, including UPA and RIS, and ranked favorably in the network for SAEs.

AB0897 IMPACT OF RISANKIZUMAB ON IMPROVING SYMPTOMS AND HEALTH-RELATED QUALITY OF LIFE AND REDUCING FATIGUE AND PAIN AMONG PSORIATIC ARTHRITIS PATIENTS WITH MODERATE-TO-SEVERE SKIN INVOLVEMENT: EVIDENCE FROM TWO PHASE III TRIALS

K. Papp[1], A. M. Soliman[2], C. Kaufmann[2], L. Barcomb[2], Z. Wang[2], D. White[3], A. Ostor[4], L. E. Kristensen[5]. *[1]Probity Medical Research, K Papp Clinical Research, Waterloo, Canada; [2]AbbVie Inc., Immunology, North Chicago, United States of America; [3]Rheumatology Department, Waikato Hospital, Hamilton, New Zealand; [4]Cabrini Hospital, Monash University, Emeritus Research, Melbourne, Australia; [5]The Parker Institute, Copenhagen University Hospital, Copenhagen, Denmark*

Background: Psoriatic arthritis (PsA) greatly affects patient-reported health-related quality of life (HRQoL).
Objectives: To assess the impact of risankizumab (RZB) on patient-reported outcomes (PROs) in patients with high skin burden using integrated efficacy data from two Phase III clinical trials (KEEPsAKE-1 and KEEPsAKE-2).
Methods: Adult patients with PsA with inadequate response or intolerance to disease-modifying antirheumatic drugs were randomized 1:1 to receive RZB (150 mg) or placebo (PBO). Improvement from baseline in PROs (Patient's Global Assessment of Disease Activity [PtGA] by visual analog scale [VAS], Short-Form 36 Health Questionnaire physical and mental component summary scores [SF-36 PCS and MCS], Health Assessment Questionnaire – Disability Index [HAQ-DI], EQ-5D 5-Level questionnaire [EQ-5D-5L] index and by VAS, Functional Assessment of Chronic Illness Therapy – Fatigue [FACIT-Fatigue], and pain by VAS) were assessed at Week 24 in patients with high skin burden (body surface area involvement ≥3% and Psoriasis Area Severity Index >10). Least squares mean (LSM) difference (95% confidence interval [CI]) between RZB and PBO groups based on mixed-model repeated measures regression is reported.
Results: RZB- vs PBO-treated patients demonstrated greater improvements in PROs with notable LSM differences (95% CI) between groups ($P<0.01$) in PtGA (-18.7 [-25.1, -12.2]), SF-36 PCS (6.3 [4.2, 8.4]) and MCS (4.4 [2.3, 6.6]), HAQ-DI (-0.4 [-0.5, -0.3]), EQ-5D-5L index (0.1 [0.1, 0.2]) and VAS (8.2 [2.5,13.9]), FACIT-Fatigue (4.9 [2.7, 7.2]), and pain (-18.9 [-25.1, -12.7]).
Conclusion: In patients with PsA with high skin burden, 24 weeks of RZB treatment, as compared with PBO, improved patients' HRQoL, including fatigue and pain.

GUSELKUMAB IMPROVES DACTYLITIS IN PSA PATIENTS WITH INADEQUATE RESPONSE TO TNFI: DATA FROM THE PHASE 3B COSMOS TRIAL

H. Marzo-Ortega[1], E. Theander[2], M. Neuhold[3], P. Bergmans[4], M. Shawi[5], M. Perate[6], C. Contre[7], I. Mcinnes[8], G. Schett[9]. Background: Dactylitis is a biomarker of disease severity in psoriatic arthritis (PsA) associated with functional disability, impaired quality of life and radiographic progression. The COSMOS study demonstrated the efficacy and safety of guselkumab (GUS), an IL-23 p19 subunit inhibitor (i), in patients (pts) with PsA who had inadequate response (IR; insufficient efficacy or intolerance) to 1–2 TNFi.[1]

Objectives: Evaluate the effect of GUS 100 mg Q8W on dactylitis, and assess the relationship between dactylitis resolution and improvement in other clinical outcomes, through 1 year in TNFi-IR PsA pts.

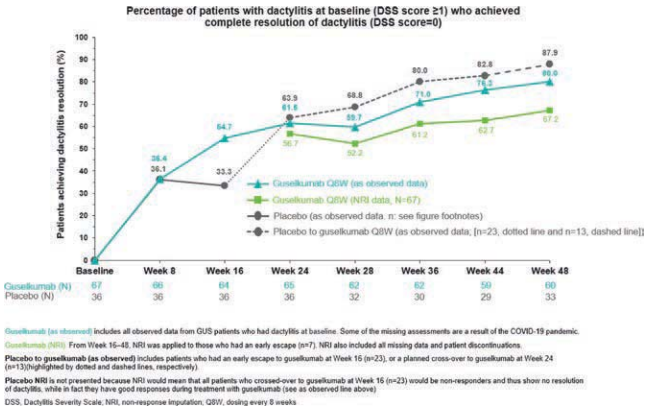
Methods: Pts received GUS or placebo (PBO); PBO pts crossed over to GUS at either Week (W) 16 (early escape [EE], n=45/96) or W24 (planned, n=51/96). Each of 20 digits was determined by the investigator to have no (0) to severe (3) dactylitis (Dactylitis Severity Scale [DSS]; total score: 0–60). Presence of dactylitis was defined by DSS score ≥1; complete or partial resolution was defined as a DSS score=0, or lower than baseline (BL), respectively. Change in DSS from BL at W24 was a secondary endpoint. Other clinical response outcomes including DAPSA LDA/remission, MDA and enthesitis resolution (Leeds Enthesitis Index score=0) were assessed by dactylitis resolution status. Both as observed and non-responder imputation (NRI; for missing data or EE) data are presented.

Results: Of 285 pts, 103 (36%; 67 GUS, 36 PBO) had dactylitis and 190 (67%) had enthesitis at BL. The majority of pts with dactylitis (76%) also had enthesitis. Pts with dactylitis had more severe joint and skin disease than those without (Table 1).

Table 1. BL characteristics for TNFi-IR PsA pts with/without dactylitis

	With dactylitis	Without dactylitis
N	103	182
Age, mean years (SD)	48.3 (11.8)	49.6 (12.5)
Sex: male, %	50	48
Years since PsA diagnosis; mean (SD)	8.1 (7.2)	8.6 (7.8)
BMI, mean kg/m^2 (SD)	28.5 (5.8)	30.1 (6.6)
PsA characteristics		
Swollen joint count, 0–66; mean (SD)	12.3 (8.1)	8.5 (4.8)
Tender Joint count, 0–68; mean (SD)	22.0 (12.9)	19.1 (12.2)
DAPSA score; mean (SD)	48.6 (20.9)	41.2 (16.8)
Spondylitis with peripheral arthritis, %	28	24
Enthesitis, %	76	62
Psoriasis characteristics, mean (SD)		
PASI score, 0–72	14.5 (12.7)	8.8 (9.6)
BSA, %	23.4 (23.6)	12.4 (17.1)
DLQI score, 0–30	14.1 (7.0)	12.6 (6.9)

In an as-observed analysis of pts with BL dactylitis, numerically more GUS- (55%) than PBO- (33%) treated pts achieved complete dactylitis resolution at W16. By W48, 80% of GUS-randomized pts achieved complete resolution (NRI: 57% at W24, 67% at W48; Figure 1).



Among 12 GUS pts with persistent dactylitis at W48, 9 (75%) had partial resolution. The 36 PBO pts with dactylitis crossed over to GUS at W16 (n=23; EE) or W24 (n=13; planned). As observed, 88% of these PBO→GUS pts had complete resolution of dactylitis at W48 (Figure 1). Of 105 dactylitis-free pts at BL in the GUS arm, 8 (8%) developed dactylitis before W48: 4 at W4, 2 at W8 and 1 each at W16 and 36. Complete resolution was seen in 6 (75%) of the 8 pts by W48, when 1 further new-onset case occurred. Utilizing observed data among GUS-randomized pts with and without BL dactylitis, 32% and 34%, respectively, achieved MDA at W48. Respective response rates were 59% and 55% for DAPSA LDA, and 28% and 15% for DAPSA remission. In those who did and did not achieve complete dactylitis resolution at W48, respective response rates were 38% and 0% for MDA, 68% and 13% for DAPSA LDA, and 31% and 0% for DAPSA remission. Of 69 pts with both enthesitis and dactylitis at BL who continued to receive GUS through W48, GUS resolved both manifestations in 72%, neither in 16%, only enthesitis in 4%, and only dactylitis in 7% of pts.

Conclusion: Complete dactylitis resolution was achieved in ≥80% of pts who continued to receive GUS at W48, with partial resolution seen in most remaining pts in an as-observed analysis. Response rates increased through W48. Dactylitis resolution in this difficult-to-treat TNFi-IR PsA population was frequently associated with enthesitis resolution and achievement of clinical outcomes representing low levels of disease activity.

AB0899 A 24-MONTH PROSPECTIVE PSORIATIC ARTHRITIS OBSERVATIONAL STUDY OF PERSISTENCE OF TREATMENT (PRO-SPIRIT) - INTERIM ANALYSIS OF BASELINE CHARACTERISTICS

J. Morel[1,2], L. Dagna[3,4], B. Joven-Ibáñez[5], T. Holzkaemper[6], C. El Baou[6], L. Unger[7], A. Semeraro[8], N. Gullick[9,10], T. Treuer[6]. *[1]University of Montpellier, Montpellier School of Medicine, Montpellier, France; [2]CHU and University of Montpellier, Department of Rheumatology, Montpellier, France; [3]IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR),, Milano, Italy; [4]Vita-Salute San Raffaele University, /, Milano, Italy; [5]Hospital Universitario, /, Madrid, Spain; [6]Eli Lilly and Company, Lilly Corporate Center, Indianapolis, United States of America; [7]1.Medizinische Klinik, Klinikum Dresden, Dresden, Germany; [8]Presidio ospedaliero Valle d'Itria, OU Reumatologia, Martina Franca (TA), Italy; [9]University Hospitals Coventry & Warwickshire NHS Trust, /, Coventry, United Kingdom; [10]University of Warwick, Warwick Medical School, Warwick, United Kingdom*

Background: Ixekizumab (ixe), a highly selective interleukin (IL)-17A monoclonal antibody, has been approved for treatment of psoriatic arthritis (PsA). However, there is limited real-world evidence (RWE) available for ixe. PRO-SPIRIT is the first large-sample prospective observational study to provide RWE for ixe in patients (pts) with PsA.

Objectives: PRO-SPIRIT's primary objective is to describe treatment persistence at 24 months (M) among pts with PsA who initiate or switch to a new biologic Disease Modifying Arthritis Rheumatic Drugs (bDMARDs) or targeted synthetic (tsDMARDs), including ixe. This abstract describes the interim baseline (BL) characteristics.

Methods: PRO-SPIRIT is a prospective observational study, conducted in FR, ES, IT, DE, UK, and CA, enrolling adults with PsA (≥6M) to be initiated or switched to a new b/tsDMARD, locally approved for PsA. Treatment groups include ixe, secukinumab, IL-12/IL-23 inhibitors (i) (ustekinumab) or IL-23i (guselkumab), tumour necrosis factor (TNFi) (adalimumab, etanercept, infliximab or biosimilar), Janus kinase (JAKi) (tofacitinib or upadacitinib). Pt demographic, disease activity and therapy characteristics are collected at BL; clinical and patient-reported outcomes measures are collected at BL and at a routine post-BL visit. BL descriptive statistics are reported.

Results: From December 2019 until this interim data cut (June 2021), a total of 477 pts (305 female; mean age 52) were enrolled. Mean age ranged from 48 (IL-12/23i and IL-23i) to 55 (JAKi), with a majority of female pts in each group (Table 1). Pts in the IL-12/23i and IL-23i and TNFi groups showed the shortest time since PsA diagnosis (5.2±4.5; 6.5±7.9), while pts in the JAKi group showed the longest time (10.6±9.4). The lowest proportion of pts with a prior b/tsDMARDs use was observed in the TNFi group (31%), the highest in the IL-12/23i and IL-23i group (71%). Pts in the ixe and IL-12/23i and IL-23i groups were more likely to be on monotherapy. Tender Joint Count (9.1-11.3) and Swollen Joint Count (3.3-5.8) were comparable across groups, with the highest values in the ixe and JAKi groups, respectively. Pt proportion with enthesitis and dactylitis was higher in the ixe, secukinumab and JAKi groups. Percentage of Body Surface Area affected by psoriasis was higher in the ixe, secukinumab and IL-12/23i and IL-23i groups. Pt proportion with nail psoriasis was higher in the ixe and secukinumab groups. Physician's Global Assessment Visual Analog Scale (VAS), Patient's Global Assessment VAS and Patient's Assessment of Joint Pain VAS reflected a high burden of illness.

Table 1. Baseline characteristics

	bDMARDs				tsDMARDs
	Ixekizumab	**Secukinumab**	**IL-12/23 and IL-23 inhibitors**	**TNF inhibitors**	**JAK Inhibitors**
	N=137	N=46	N=24	N=211	N=40
Age	52.8±12.2	52.8±13.1	47.6±13.4	50.3±11.7	55.3±9.9

Patient's Assessment of Joint Pain VAS	62.7±21.3	58.4±27.1	55.7±28.3	59.4±22.9	57.5±24.0

Mean±SD, unless otherwise stated

Conclusion: The reported BL characteristics offer preliminary information about which pts initiate or switch to a b/tsDMARD in a real life-setting. Future disclosures (at 12 and 24M) will provide RWE regarding persistence, effectiveness, and health care resource use of available treatments for PsA, which will help pts and physicians to make better informed treatment decisions.

AB0900 A TEMPORARY ANTIRHEUMATIC DRUGS WITHDRAWAL DOES NOT CAUSE AN EXCESS OF DISEASE FLARES IN PATIENTS WITH PSORIATIC ARTHRITIS UNDERGOING COVID-19 MRNA VACCINATION

R. Bixio[1], A. Milanesi[2], O. Viapiana[1], C. Montecucco[2], S. Bugatti[2], M. Rossini[1]. *[1]Università degli studi di Verona, Rheumatology section, Verona, Italy; [2]IRCCS Policlinico San Matteo Foundation, Division of Rheumatology, Pavia, Italy*

Background: The best way to manage disease-modifying antirheumatic drugs (DMARDs) in patients with rheumatic and musculoskeletal diseases (RMDs) undergoing the Coronavirus disease (Covid)-19 vaccination and the recommendations regarding the use and timing of immunomodulatory therapies around the time of vaccination are still a matter of debate, due to the difficulties in balancing the vaccination efficacy and safety.

Objectives: To assess the impact of different strategies of antirheumatic treatment management on disease activity around the time of vaccination for Coronavirus disease (Covid)-19 in patients with psoriatic arthritis (PsA).
Methods: We prospectively evaluated patients with PsA in remission or low-disease activity candidate to receive Covid-19 vaccination with mRNA vaccines. Methotrexate (MTX) and leflunomide were withheld 7 days after each dose, whilst biological DMARDs (bDMARDs), were either continued (46.8% of the patients) or withheld (53.2%) from the day of the first dose until 7 days after the second dose. Patients were reassessed after 3 months from enrollment or in case of disease flare.
Results: After the second dose of Covid-19 vaccination 7 patients (5.6%) (6 females) had an articular disease flare each (mean involved joints: 1.29), one patient presented a concomitant worsening of psoriasis, and four patients had an isolated worsening of their psoriasis. All patients received additional treatments with oral GC (n=2) or non-steroidal anti-inflammatory drugs (n=5). Two flares lasted more than one week and required a modification of the ongoing bDMARD. Articular flare incidence (6.8% vs 3%, p=0.259), involved joints (1.4 vs 1.5, p=0.846), disease flare severity, and changes in antirheumatic therapies (1 vs 1, p=0.928) did not differ significantly between the two different bDMARD management strategy groups (continued vs temporary withheld). There was no significant difference in disease activity score for psoriatic arthritis (DAPSA) and C-reactive protein (CRP) after vaccination, but patients who flared up had a higher mean basal DAPSA (7.3 vs 4.1, p=0.046). On binomial logistic regression analysis, we did not find any significant association with gender, age, basal CRP, basal DAPSA, active psoriasis, conventional synthetic DMARDs, or bDMARDs and disease flare.
Conclusion: Our findings suggest that a temporary short halt of bDMARDs could be a viable option in patients with well-controlled PsA undergoing Covid-19 vaccination without increasing the risk of flares, which could be useful to increase T cell response and antibody titres after Covid-19 vaccination.

AB0901 EFFECTS OF TREATMENT WITH RISANKIZUMAB ON REDUCING PAIN AND INFLAMMATION IN PATIENTS WITH PSORIATIC ARTHRITIS: AN ANALYSIS OF THE KEEPSAKE -1 AND -2 TRIALS

A. Ostor[1], S. Kwatra[2], C. Nduaka[3], M. Patel[3], A. M. Soliman[3], L. Barcomb[3], Z. Xue[3], H. Photowala[3], K. Papp[4]. [1]*Monash University, Cabrini Hospital, and Emeritus Research, Melbourne, United States of America;* [2]*Department of Dermatology, Johns Hopkins University School of Medicine, Baltimore, United States of America;* [3]*AbbVie Inc., Immunology, North Chicago, United States of America;* [4]*K Papp Clinical Research, Probity Medical Research, Waterloo, Canada*

Background: Risankizumab (RZB), a monoclonal antibody that specifically inhibits interleukin 23, is being investigated as a treatment for adults with psoriatic arthritis (PsA).
Objectives: Evaluate the efficacy of RZB treatment on the reduction in pain and inflammation in patients with active PsA
Methods: KEEPsAKE-1 and -2, double-blind, phase 3 trials, evaluated the efficacy of RZB versus placebo (PBO) for the treatment of adult patients with active PsA. Patients were randomized (1:1) to receive subcutaneous RZB 150 mg or PBO at weeks 0, 4, and 16. A reduction in pain visual analogue (VAS) score of 30% (meaningful), 50% (substantial) from baseline, and achievement of a minimal clinically important difference (MCID) in pain VAS was analyzed using NRI. High-sensitivity C reactive protein (hsCRP) was analyzed using mixed-effect model repeated measurement. Results are reported from the 24-week timepoint.
Results: A total of 1407 patients were included in the 24-week assessment (KEEPsAKE-1 RZB=483, PBO=481; KEEPsAKE-2 RZB=224, PBO=219). Patients receiving RZB achieved significantly higher levels of meaningful pain reduction than did patients receiving placebo (KEEPsAKE-1 54.7% vs 31.1%, P<0.001; KEEPsAKE-2 43.3% vs 22.2%, P<0.001). Similar trends were noted for substantial pain reduction (KEEPsAKE-1 37.7% vs 18.5%, P<0.001; KEEPsAKE-2 31.9% vs 15.2%, P<0.001). Patients receiving RZB were also significantly more likely to achieve a MCID than patients receiving PBO in both KEEPsAKE-1 (72.9% vs 56.2%, P<0.001) and KEEPsAKE-2 (64.6% vs 46.0%, P<0.001). A numerically greater reduction in hs-CRP was demonstrated in both studies for patients receiving RZB compared to PBO (KEEPsAKE-1 -4.32 vs -0.20; KEEPsAKE-2 -1.14 vs 0.25).
Conclusion: RZB treatment resulted in clinically meaningful improvements in pain and inflammation for patients with active PsA.

AB0902 EFFICACY OF IL-17 INHIBITORS IN PSORIATIC ARHTRITIS. SISTEMATIC REVIEW OF SCIENTIFIC LITERATURE AND META-ANALYSIS

A. Gonzalez Alonso[1], D. Fernández Fernández[2], R. Dos-Santos[2], I. González Fernández[2], P. Castro-Santamaria[2], M. Sanchez-Wonenburger[2], J. L. Puga Guzmán[2], A. Mata[2], E. Perez-Pampín[2], A. Souto Vilas[2], A. Mera Varela[1,2]. [1]*University of Santiago de Compostela, Medicine, Santiago de Compostela, Spain;* [2]*Santiago Clinic Hospital CHUS, Rheumatology, Santiago de Compostela, Spain*

Background: Psoriatic arthritis is a chronic inflammatory joint disease with a great heterogeneity of manifestations both at the musculoskeletal (arthritis, enthesitis, dactylitis, axial skeleton involvement) and dermatological (skin, nail involvement) domain. The main goal of treatment is to maximize quality of life by controlling symptoms and preventing structural damage. For this, multidisciplinary management must be carried out without forgetting non-musculoskeletal manifestations and considering comorbidities. Regarding pharmacological therapy to control arthritis, non-steroidal anti-inflammatory drugs (NSAIDs) and/or intra-articular corticosteroid injections are proposed as initial therapy. When symptoms are not controlled or there are associated poor prognostic factors, conventional disease-modifying antirheumatic drugs (DMARDs) are recommended, especially methotrexate. When the classic DMARDs do not achieve good control of the disease, the next step will be the biological DMARDs, among which are TNF-alpha inhibitors, interleukin-17 inhibitors or inhibitors of the IL12/IL23 axis. Other molecules such as janus kinase (JAK) inhibitors or phosphodiesterase-4 inhibitors such as Apremilast also continue to be incorporated into treatment alternatives. Although these drugs provide a promising result, the scarcity of direct comparative studies implies a need for more research to determine better treatment strategies.
Objectives: To analyze the efficacy of IL-17 inhibitors (Secukinumab, Ixekizumab, Brodalumab and Bimekizumab) in the treatment of patients diagnosed with psoriatic arthritis based on data published in randomised clinical trials (RCTs).

Methods: We perform a systematic review of the scientific literature using the Pubmed, Cochrane Library, Embase and Web of Science electronic databases, selecting RCTs evaluating the efficacy of IL-17 inhibitors for the treatment of psoriatic arthritis. A meta-analysis was performed using the random-effects model for each efficacy measure evaluated at different weeks.

Results: 23 studies met the selection criteria from a total of 2198 references identified in the search. 14 references contained data on the use of Secukinumab from 7 RCTs. Ixekizumab was the second IL-17 inhibitor most identified with 6 references with data from 5 RCTs. Bimekizumab with 2 references and Brodalumab with 1 reference completed the review. Despite extracting efficacy data in nail, enthesitic and PROs manifestations. We were only able to perform meta-analyses of the ACR 20, AC50, ACR70 and PASI75 response rates at week 12 of treatment, due to the lack of statistically comparable data. The meta-analysis performed demonstrated that IL-17 inhibitors are effective in psoriatic arthritis, compared to placebo in the different efficacy outcomes evaluated (ACR20 12 wk (OR: 3.60 [95%CI: 2.85-4. 55]), ACR50 12 wk (OR: 10.85 [95%CI: 6.20-18.94]), ACR70 12 wk (OR: 7.94 [95%CI: 4.23-14.91]) and PASI75 12 wk (OR: 21.26 [95%CI: 13.72-32.95])

Conclusion: Our review concluded that IL-17 inhibitors are effective in the treatment of patients who have shown intolerance or had an unsatisfactory response to other lines of treatment in Psoriatic arthritis.

AB0903 DUAL IMMUNOMODULATORY THERAPIES IN PSORIATIC DISEASE

S. Sundanum[1], A. Gorman[1], D. Veale[1], C. Orr[1], L. O'neill[1]. *[1]Centre for Arthritis and Rheumatic Diseases, Dublin Academic Medical Centre, University College Dublin, Rheumatology, Dublin, Ireland*

Background: Since the advent of numerous biologic therapies and small molecular drugs targeting specific cytokines and signalling pathways; the management of patients with psoriatic arthritis (PsA) has significantly improved. However, at least 40% of PsA patients exhibit an incomplete or failure to respond to these treatments. While the outcomes of patients with psoriasis (Pso) has dramatically improved with monoclonal antibody therapies targeting IL-23 and IL-17A; achieving a measurable low disease activity state such as minimal disease activity (MDA) for musculoskeletal manifestations of psoriatic disease is infrequent. Given the complex and heterogeneity of signalling pathways, cytokines and cell types resulting in synovio-entheseal disease in PsA; new treatment strategies must be evaluated to induce deep and sustainable clinical responses in all the phenotypic domains of psoriatic disease (cutaneous, synovium, entheseal and axial). (1) In patients who do not achieve remission in all clinical domains on a biologic monotherapy or combination of a biologic therapy with an oral synthetic agent; dual targeted anti-cytokines strategies or combined biologic with a targeted oral small molecule are a possible treatment option.

Objectives: To describe a series of four patients with recalcitrant psoriatic disease and failure to respond to previous treatment regimens who were successfully treated with dual immunomodulatory therapies.

Methods: Patients on dual immunomodulatory therapies attending our department were prospectively followed and clinical response monitored.

Results:

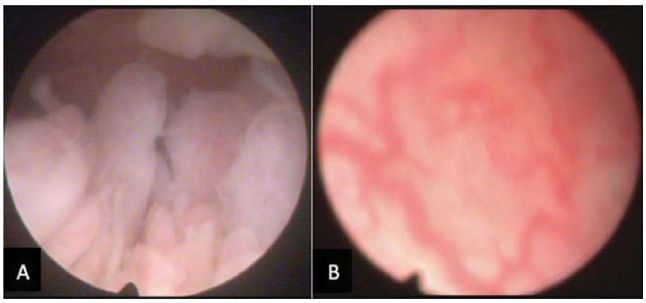

Figure 1. Mini-Arthroscopy of left knee for Case 3 prior to starting dual immunomodulator therapy.**(A)** Macroscopic aspects of synovitis **(B)** Synovium vascularization

Conclusion: Multiple pathways and mediators are responsible for the initiation of and sustained joint inflammation and damage seen in PsA. A phase II trial of ABT-122, a biologic engineered to target both TNF and IL-17A showed statistically significant superior efficacy outcomes at multiple time points based on ACR50, ACR70 and psoriasis outcome measures (PASI75/PASI90) when compared to adalimumab, with similar safety profile.(2)

Safety concerns such as infectious risks are important considerations with such strategies; however, the targeted second-generation anti-cytokine biologics and targeted JAK-I have exhibited improved safety profiles.(3) In our small case series, patients have not, to date, experienced adverse events of combination therapy.

Background: The multifaceted nature of psoriatic arthritis (PsA) can make it challenging to evaluate treatment targets and disease activity. Moreover, most existing assessment tools are time-consuming and not always feasible in routine clinical care, indicating a need for new disease measures that are easy to perform and calculate. Composite measures using 3-visual analog scale (VAS;

Table 1.

	Age/gender	Diagnosis	prior therapies	combination therapy	dose	adverse events
Case 1	49/ Male	PsA + PsO	Methotrexate, adalimumab, etanercept, infliximab, golimumab, certolizumab, ustekinumab, secukinumab, ixekizumab	Baracitinib + infliximab	4mg OD + 5mg/kg Q8W	None
Case 2	51/ Male	PsA + PsO	Methotrexate, etanercept, adalimumab, ustekinumab, infliximab, secukinumab, apremilast, ixekizumab, brodalumab, guselkumab	Adalimumab + guselkumab	40mg QoW +100mg Q8W	None
Case 3	51/ Female	PsA + PsO	Methotrexate, sulphasalazine, etarnercept, certolizumab, leflunomide, infliximab, adalimumab, secukinumab, ustekinumab, tofacitinib, abatacept, baracitinib	Adalimumab + tofacinitib	40mg QoW + 5mg BD	None

physician's global assessment, patient's global assessment, and skin) or 4-VAS (physician's global assessment, joints, skin, and pain) have been proposed as simpler alternatives.[1] Given potential advantages of numeric rating scales (NRS) over VAS, we here adapted 3/4-VAS for use with NRS components and tested its validity via post hoc analysis of the upadacitinib (UPA) SELECT-PsA program.

Objectives: Evaluate the ability of 3/4-NRS scores to assess treatment response in SELECT-PsA 1 and 2, as well as the correlation of 3/4-NRS with other common disease activity measures.

Methods: Data are from the SELECT-PsA 1 and 2 phase 3 trials in patients with prior inadequate response or intolerance to ≥1 non-biologic DMARD or ≥1 biologic DMARD, respectively. In both trials, patients received once daily UPA 15 mg, UPA 30 mg, or placebo (PBO); SELECT-PsA 1 also included the active comparator adalimumab (ADA) 40 mg every other week (wk). 3-NRS scores were determined using the mean of SAPS questions 1–10, physician's global assessment of disease activity, and patient's global assessment of disease activity; 4-NRS scores were determined using the mean of SAPS questions 1–10, physician's global assessment of disease activity, patient's assessment of pain, and BASDAI question 3 related to joint pain and swelling. The 3/4-NRS scale ranges from 0 (no disease activity) to 10 (severe activity). 3/4-NRS and cDAPSA (DAPSA without the CRP component) were assessed at all available visits through wk 56. Correlations between 3/4-NRS with PsA disease activity score (PASDAS), routine assessment of patient index data 3 (RAPID3), DAPSA, cDAPSA, and other disease activity measures were determined using the nonparametric Spearman rank correlation coefficient for UPA 15 mg patients from both trials and ADA for SELECT-PsA 1. All data are shown as observed; nominal p-values are provided throughout.

Results: A total of 1281 and 423 patients were included from SELECT-PsA 1 and 2, respectively. For both cDAPSA and 3/4-NRS scores, patients receiving UPA 15 mg showed clear numerical improvements compared with PBO at wk 24 in both trials (Table 1). 3/4-NRS scores were highly correlated with RAPID3 and PASDAS measures (r >0.6, *P* <0.0001) for UPA 15 mg patients at baseline (Figure 1). Moderate correlations were observed between 3/4-NRS and DAPSA/cDAPSA (r = ~0.4, *P* <0.0001), as well as physical function (HAQ-DI) and quality of life measures (SF-36). Nominally significant but weaker correlations were detected for joints, skin, and other disease activity assessments. Similar overall results were observed for patients receiving ADA.

Table 1. 3/4-NRS and cDAPSA Disease Activity Scores at Week 24 and 56 (As Observed)

SELECT-PsA 1

	Wk 24			Wk 56	
Mean score [n]	PBO	UPA 15 mg	ADA	UPA 15 mg	ADA
3-NRS	3.7 [370]	2.2 [398]	2.4 [398]	1.8 [372]	2.0 [359]
4-NRS	3.8 [367]	2.3 [392]	2.6 [395]	1.9 [367]	2.2 [357]
cDAPSA	24.0 [372]	14.9 [399]	16.6 [400]	10.2 [372]	11.3 [358]
SELECT-PsA 2					
	Wk 24			**Wk 56**	
Mean score [n]	**PBO**	**UPA 15 mg**		**UPA 15 mg**	
3-NRS	4.7 [172]	2.9 [190]		2.4 [164]	
4-NRS	4.9 [170]	3.1 [188]		2.7 [162]	
cDAPSA	37.1 [172]	21.6 [190]		15.3 [166]	

3/4-NRS ranges from 0–10; cDAPSA ranges from 0–154. Lower scores indicate decreased disease activity.

Conclusion: 3/4-NRS was able to successfully discriminate between PBO and therapeutic groups in SELECT-PsA 1 and 2. 3/4-NRS scores correlated well with other clinical and patient reported outcome measures, including those focused on joints (DAPSA) or multiple manifestations (PASDAS), supporting 3/4-NRS as a viable and easy to use tool in daily clinical practice.

ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3 (RAPID3) IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS (PSA) AFTER INADEQUATE RESPONSE OR INTOLERANCE TO DMARDS: POOLED RESULTS FROM THE PHASE 3, RANDOMIZED, DOUBLE-BLIND KEEPSAKE 1 AND 2 TRIALS

A. Ogdie[1], L. Coates[2], R. Acayaba DE Toledo[3], A. Biljan[4], H. Jones[4], K. Tacelosky[4], C. Yue[4], B. Padilla[4], M. Bergman[5]. [1]*University of Pennsylvania Perelman School of Medicine, Division of Rheumatology, Department of Medicine, Philadelphia, United States of America;* [2]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom;* [3]*São José do Rio Preto, Medical School, São José do Rio Preto, Brazil;* [4]*AbbVie Inc., Immunology, North Chicago, United States of America;* [5]*Drexel University College of Medicine, Department of Medicine, Philadelphia, United States of America*

Background: PsA is a chronic, systemic inflammatory disease with diverse clinical manifestations that can impact a patients' quality of life. Risankizumab (RZB), a humanized immunoglobulin G1 monoclonal antibody that specifically inhibits interleukin 23 by binding to its p19 subunit, is approved for the treatment of active PsA in adults. In the phase 3 KEEPsAKE 1 and 2 studies, RZB treatment resulted in significantly greater improvements in signs and symptoms of active PsA compared with placebo (PBO).[1,2] RAPID3 is frequently used in clinical practice to evaluate PsA disease activity and consists of 3 key patient-reported measures (physical function, pain, and patient's global assessment of disease activity [PtGA]).[3]

Objectives: To evaluate short- (24 week) and long-term (52 week) improvements in RAPID3 scores and achievement of RAPID3 minimal clinically important difference (MCID) across the RZB KEEPsAKE 1 and 2 clinical program.

Methods: In KEEPsAKE 1 (NCT03675308) and KEEPsAKE 2 (NCT03671148), patients with active PsA who experienced inadequate response or intolerance to ≥ 1 csDMARD (KEEPsAKE 1) and/or ≤ 2 biological therapies (KEEPsAKE 2) were randomized to PBO or RZB 150 mg from baseline to week (W) 24; from W28–W52, all patients received open-label RZB 150 mg. At W16, nonresponders could add or modify rescue therapy. This post hoc analysis assessed the mean change from baseline to W24 and W52 in RAPID3 scores and the proportion of patients who achieved a RAPID3 MCID (defined as a decrease of ≥3.8 points[4]). Modified RAPID3 scores (range: 0–30) were calculated using pain scores, PtGA, and HAQ-DI, each rescaled to 0–10 and summed together.[3]

Results: A total of 961 and 443 patients were included from KEEPsAKE 1 and 2, respectively. At baseline, mean RAPID3 scores were 15.3 in both treatment arms of KEEPsAKE 1 (PBO n = 479, RZB n = 482) and 15.1 (PBO n = 219) and 14.8 (RZB n = 224) in KEEPsAKE 2. From W4 to W24, RAPID3 scores were significantly reduced with RZB treatment compared with PBO in both KEEPsAKE 1 (mean change from baseline at W24 of –5.3 vs –2.4, respectively, *P* <.001) and KEEPsAKE 2 (–3.8 vs –1.6, *P* <.001; Figure 1 **A, B**), and a significantly greater proportion of patients achieved MCID at W24 with RZB than with PBO in KEEPsAKE 1 (57.0% vs 36.4%, *P* <.001) and KEEPsAKE 2 (48.8% vs 32.8%, *P* <.001; Table 1). At W52 among patients who received RZB from W0–W52, mean change from baseline was –7.0 (KEEPsAKE 1) and –5.2 (KEEPsAKE 2; Figure 1 **C, D**), and MCID was achieved by 67.5% (KEEPsAKE 1) and 56.5% (KEEPsAKE 2) of patients. Patients who switched from PBO to RZB at W24 experienced similar and substantial improvements in RAPID3 scores by W52.

Table 1. Proportion of Patients Achieving a Minimal Clinically Important Difference From Baseline in RAPID3 (AO).

Patients, % (n/N) [95% CI]	KEEPsAKE 1		KEEPsAKE 2	
	PBO	RZB 150 mg	PBO	RZB 150 mg
W24	36.4 (166/456) [32.0, 40.8]	57.0 (262/460) [52.4, 61.5]***	32.8 (64/195) [26.2, 39.4]	48.8 (104/213) [42.1, 55.5]***
	PBO to RZB 150 mg[a]	**RZB 150 mg**	**PBO to RZB 150 mg[a]**	**RZB 150 mg**
W52	59.8 (260/435) [55.2, 64.4]	67.5 (297/440) [63.1, 71.9]	57.4 (105/183) [50.2, 64.5]	56.5 (109/193) [49.5, 63.5]

[a]Patients randomized to PBO at W0 switched to open-label RZB 150 mg at W24.***, *P* < .001 vs PBO.AO, as observed; PBO, placebo; RAPID3, Routine Assessment of Patient Index Data 3; RZB, risankizumab; W, week.

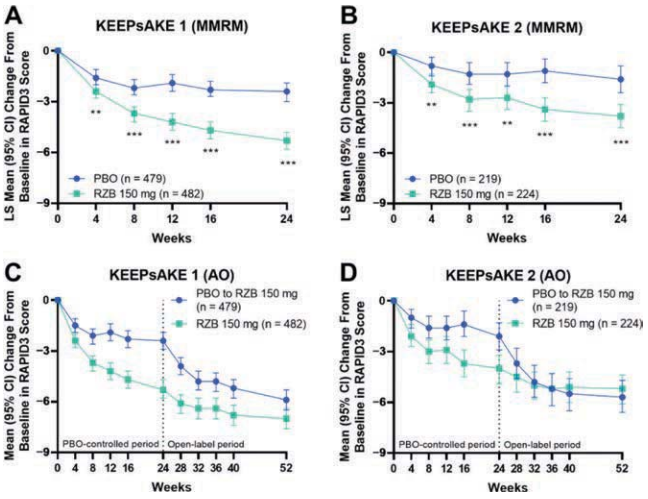

Figure 1. Mean Change From Baseline in RAPID3 Scores During KEEPsAKE 1 and 2.**, *P* < .01; ***, *P* < .001 vs PBO.AO, as observed; LS, least squares; MMRM, mixed-effect model repeated measurement; PBO, placebo; RAPID3, Routine Assessment of Patient Index Data 3; RZB, risankizumab.

Conclusion: RZB 150 mg was associated with improvement in RAPID3 total scores over 24–52 weeks of treatment in patients with active PsA in KEEPsAKE 1 and 2.

Background: Upadacitinib (UPA) is an inhibitor of JAK kinases recently approved by EMA for the treatment of psoriatic arthritis (PsA) in Europe (January 2021) [1]. UPA has shown efficacy in refractory patients to anti-TNF [2].

Objectives: A) to assess efficacy and safety of UPA in the first cases in Spain in clinical practice. **B)** to compare the profile of clinical practice patients with clinical trial of UPA in PsA refractory to biologics [2].

Methods: Study of 39 patients of clinical practice with PsA treated with UPA in Spain. The diagnosis of PsA was made using CASPAR criteria. Patients who received at least one dose of UPA were included. Results are expressed as percentage, mean±SD or median [IRQ].

Results: 39 patients (29♀/10♂), mean age of 51.5 ± 11.4 years (Table 1**).** Pattern joint involvement was as follows: peripheral (n=19), axial (3) and mixed (17) During the PsA evolution, patients also presented enthesitis (59%) nail involvement (28.2%) and dactylitis (35.9%).

Table 1.

	CLINICAL PRACTICE N=39	CLINICAL TRIAL N=211	p

HAQ-DI Health Assessment Questionnaire-Disability Index, PASI Psoriasis Area Severity Index, CRP C-reactive protein, DMARD disease-modifying antirheumatic drug

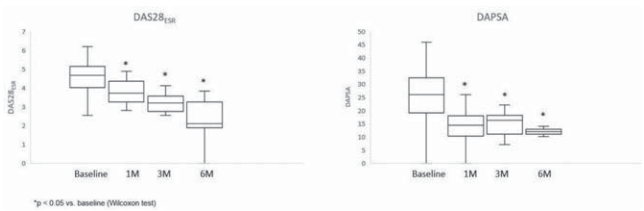

Figure 1.

Prior to UPA, most patients (59%) had received oral prednisone or equivalent (max 9.03±12.12mg/d), synthetic immunosuppressants (mean1.8±0.9) and biological therapy (TB) (4.5±2.1). TB were as follows: etanercept (25), adalimumab (28), infliximab (12), golimumab (16), certolizumab (15), secukinumab (29), ustekinumab (21) Abatacept (2), brodalumab (1) and ixekizumab (17). Apremilast was used in 13, Tofacitinib in 11 and filgotinib in 1. After a mean follow-up of 12.41± 8.68.3 years after the PsA diagnosis, UPA was started (15 mg/24 h), 43.6% associated prednisone (7.35±3.36 mg/d). In 16 (41%) UPA was started in combined therapy: methotrexate (9), salazopyrin (3) and leflunomide (4); in the remaining 23 (59%), monotherapy was prescribed. At UPA onset patients presented peripheral arthritis (76.9%), axial involvement (35.8%), skin involvement (25.6%), enthesitis (41%), and dactylitis (10.3%). Patients of clinical practice compared with clinical trial there were more women, have a longer duration of PsA, and received a higher proportion of previous TB (Table 1**).** After a median follow-up of 4.28 ± 2.6 months, patients showed prompt improvement in activity indexes (DAS28, DAPSA) (Figure 1) and laboratory test (CRP mg/L decreased from 4.00 [1.5;10.0] to 0.40 [0.30;4.00] (p 0.024) at the sixth month. Extra-articular manifestations also improved: dactylitis in 25% patients, enthesitis (43.8%), skin involvement (40%) and onychopathy (50%). No serious events were reported. Minor side effects were reported in 7 patients (17.9%), and UPA was discontinued in 9 due to inefficiency.

Conclusion: In this preliminary study, first patients of clinical practice in Spain with UPA in PsA had a longer evolution and received a greater number of TB than those of clinical trial. As in the UPA clinical trial, it seems effective, rapid and relatively safe in daily clinical practice for refractory PsA.

M Medhat[8], J. Jamaleldeen[6], Y. Adel Abdelsalam Hussein[11], R. M. Ghaleb[12], E. Nourhan Elameen[13], E. Dessouki[14], S. Saber[4]on behalf of Egyptian Academy of Rheumatology. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom; [2]Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; [3]Ain Shams University, Community and Public health, Cairo, Egypt; [4]Ain Shams University, Rheumatology and Rehabilitation, Cairo, Egypt; [5]Assiut university, Rheumatology and Rehabilitation, Assiut, Egypt; [6]Benha University, Rheumatology and Rehabilitation, Benha, Egypt; [7]Zagazig University, Rheumatology and Rehabilitation, Zagazig, Egypt; [8]Kasr Elainy Cairo University, Rheumatology and Rehabilitation, Cairo, Egypt; [9]Tanta University, Rheumatology and Rehabilitation, Tanta, Egypt; [10]Fayoum University, Rheumatology and Rehabilitation, Fayoum, Egypt; [11]Mansoura, Rheumatology and Rehabilitation, Mansoura, Egypt; [12]Minia University, Rheumatology and Rehabilitation, Minia, Egypt; [13]Suez Canal University, Rheumatology and Rehabilitation, Ismailia, Egypt; [14]Alexandria University, Ophthalmology, Alexandria, Egypt*

Background: The Tight Control of psoriatic arthritis (TICOPA) trial revealed a treat to target (T2T) strategy has led to improved clinical outcomes in psoriatic arthritis (PsA). The heterogeneity of the disease, the feasibility of therapy and the associated comorbidities made the implementation of such strategy in routine care a real challenge. There is a high need for establish real world recommendations for the T2T approach in PsA tailored to the disease activity status, the Psoriasis manifestations as well as the individual patient's requirements.

Objectives: to provide up-to-date, evidence-based and consensus-based recommendations for Treat-to-Target management of psoriatic arthritis (PsA) and its associated clinical manifestations.

Methods: 14 key clinical questions were identified by scientific committee according to the Patient/ Population, Intervention, Comparison, Outcomes and Timing (PICOT) approach. Literature Review team performed a systematic review to summarize evidence advocating the benefits and harms of available pharmacologic and nonpharmacologic therapies for PsA. Subsequently, recommendations were formulated. The level of evidence was determined for each section using the Oxford Centre for Evidence-based Medicine (CEBM) system. A 3-round Delphi process was conducted with 19 experts. All rounds were conducted online. A consensus was achieved on the direction and the strength of the recommendations.

Results: An online questionnaire were sent to expert panel who participated in the three rounds (response rate 100%). At the end of round 3, a total of fifty-one recommendation items, categorized into 6 sections to address the main 6 PsA categories, were obtained. Agreement with the recommendations (rank 7-9) ranged from 89.5-100%. Consensus was reached (i.e.≥75%of respondents strongly agreed or agreed) on the wording of all the 51 clinical standards identified by the scientific committee. Algorithms for the management of PsA have been suggested.

Conclusion: These recommendations provide an updated consensus on the pharmacological treatment of PsA and strategies to reach optimal treat to target outcomes

in in common clinical scenarios, based on a combination of evidence and expert opinion. Best treatment decisions should be tailored to each individual patient situation.

AB0909 RETENTION RATE OF APREMILAST AND RISK FACTORS FOR INADEQUATE RESPONSE IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM AN ITALIAN MONOCENTRIC COHORT

L. Moschetti[1], F. Crisafulli[1], F. Canova[1], F. Franceschini[1], L. Andreoli[1], M. Frassi[1]. [1]*ASST Spedali Civili, University of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy*

Background: Apremilast (APR) is an oral PDE4 inhibitor approved for the treatment of Psoriatic Arthritis (PsA). Its effectiveness has been assessed in clinical trials[1,2], but real-life data are still scarce.
Objectives: To evaluate the retention rate (RR) of APR in PsA patients and the risk factors associated to APR inadequate response.
Methods: Retrospective monocentric analysis of PsA patients (CASPAR criteria 2006) treated with APR between 2017 and 2021. Disease activity was evaluated at baseline (T0) and after 6 (T6), 12 (T12) and 24 (T24) months of therapy using DAPSA score. Data are expressed as median [IQR].
Results: The cohort included 79 patients (41% males; age at PsA onset: 47 [37-58] years). PsA domains were: oligoarticular involvement (58%), enthesitis (42%), dactylitis (6%), axial involvement (13%), psoriasis (62%). Half patients presented dysmetabolic traits: 47% overweight/obesity, 34% arterial hypertension, 20% dyslipidemia. APR was prescribed mainly as first-line targeted therapy; in 42% APR was administered after the failure of ≥1 bDMARD. Contraindications to bDMARDs (47%) especially increased infectious risk (19/37) and current/previous malignancy (15/37), and mild PsA phenotype (27%) were the main reasons for APR choice. APR was discontinued in 61% after 4 [1-10] months because of inefficacy (25/48) or adverse events (AEs) (21/48; 81% gastrointestinal complaints). Patients who discontinued APR were compared with patients who continued APR (Table 1).

Table 1.

	APR WITHDRAWAL n=48	APR CONTINUATION n=31	p value
Females	28 (58)	19 (61)	0.79
Age at T0, years	51 [44-58]	57 [53-71]	**0.03**
PsA duration at T0, years	5 [2-11]	5 [0-12]	0.81
Oligoarticular involvement	24 (50)	20 (65)	0.21
Axial involvement	6 (13)	4 (13)	1.00
Enthesitis / dactylitis	26 (54)	11 (36)	0.10
DAPSA at T0	22 [16-28]	18 [13-26]	0.27
APR in monotherapy	26 (54)	23 (74)	0.07
bDMARDs naïve	24 (50)	22 (71)	0.07

Results are presented as median [IQR] or number (%). Continuous variables were compared with Mann-Whitney test; categorical variables were compared with Chi Squared/exact Fisher test.

The RR of APR was 62% at T6, 51% at T12 and 38% at T24 (Figure 1*a*).

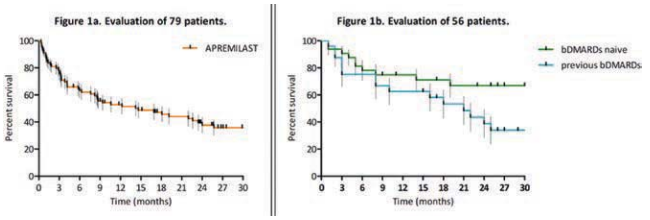

Figure 1. a) Overall RR of APR b) RR of APR in bDMARDs naïve vs previously treated with bDMARDs patients (exclusion of withdrawals for intolerance).

In patients continuing therapy, APR showed a good efficacy, with a significant reduction of DAPSA score observed at T6 (13 [9-19]), T12 (11 [4-18]) and T24 (8 [3-10]) as compared to T0 (21 [14-28]) (p<0.01). An overall trend of reduction of the BMI (kg/m^2) was observed (T0: 25 [22-28], T6: 24 [21-27], T12: 23 [21-26]); in overweight patients the BMI decreased significantly (28 [26-31] at T0 vs 27 [26-29] at last evaluation; p<0.01). Because of the high rate of discontinuations due to intolerance in the first months of therapy, we conducted a sub analysis: patients who continued APR (n=31) vs patients who discontinued it for inefficacy (n=25). A higher frequency of APR withdrawal was registered in younger patients (51 [47-57] vs 57 [53-71] years; p:0.01) previously treated with bDMARDs (71% vs 40%; p:0.02). Multivariate analysis confirmed these associations (OR [95% CI]: 0.1 [0.89-0.99], p:0.03 and 2.3 [1.70-59.17], p:0.01; respectively). The RR was higher in bDMARDs naïve patients compared with patients previously treated with bDMARDs (T6: 75% vs 67%, T12: 71% vs 63%, T24: 67% vs 34%; log-rank test= p:0.05) (Figure 1*b*).
Conclusion: This study confirms the safety and effectiveness of APR in a real-life scenario. We experienced a higher APR withdrawal rate for AEs (44%) in the first months of therapy, compared to registration studies in which APR was suspended in (8%). However, when tolerated, APR maintained efficacy over time, as demonstrated by progressive DAPSA reduction. The higher RR in bDMARDs naïve patients suggests the early use of APR. Moreover, the reduction of BMI could favor APR use in dysmetabolic patients. These data need to be confirmed in larger studies.

AB0910 EVALUATION OF NON-ALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH PSORIASIC ARTHRITIS UNDER TREATMENT WITH METHOTREXATE

L. Pérez Albaladejo[1], I. Añón Oñate[1], M. J. Perez Galan[1], C. Caro Hernandez[1]. [1]*Hospital Universitario de Jaen, Reumatologia, Jaen, Spain*

Background: Nowadays, non-alcoholic fatty liver is the most common hepatic disease. In patients with psoriatic arthritis with metabolic syndrome or obesity, there is a state of inflammation that produces the existence of a replacement of normal hepatic tissue by connective tissue, creating a non-alcoholic fatty liver disease (NAFLD). Disease Modifying Anti- Rheumatic Drugs (DMARDs) are widely used in the treatment of psoriatic arthritis. Among these drugs, we find methotrexate, chosen as the primary treatment for such pathologies. This DMARD must be administrated cautiously in patients with risk of developing fatty liver since it is hepatotoxic and it might cause the development of a hepatic disease.
Objectives: Measure the risk of developing hepatic fibrosis in patients with psoriatic arthritis under methotrexate.
Methods: It is a study of retrospective cohorts to determine the existence of NAFLD in patients with psoriatic arthritis under methotrexate through fatty index biomarkers (FIB-4). 41 patients have been studied for more than a year. Demographical & clinical variables have been collected (sex & gender) and (BMI, tobacco, use of alcohol, dyslipidemia and AHT), scales of disease activity and the FIB-4 (transaminases, age, platelets). A baseline evaluation was made at 6 and 12 months with a 3 years extension of the treatment.
Results: A total of 41 patients (17 women & 24 men), with an average age of 50.3 years (minimum 18 and maximum 80) and a BMI of 28.16 has been studied. 4.9% consumed alcohol habitually, 17.1% were smokers, 39% had hypertension, 41.5% had hypercholesterolaemia and 17.1% hypertriglyceridemia. Most patients had a moderate disease (DAPSA 20.9) at the beginning of treatment and kept a low activity in posterior months (DAPSA 6-8). The results of the Friedman's test indicate that there are no significant statistic differences on the different measurements of FIB-4 (P=0.575). In the study can be seen an increasing evolution of the FIB-4 values through the first months that is later stabilized through time. When studying if the evolution of FIB-4 is related to the evolution of BMI, it can be observed that exists a significant statistic relation in the evolution of both measures but being such relation quite weak. The evolution of the classification of the patients' FIB-4 at the beginning, at 6 months, at 1 year and at 3 years of treatment with methotrexate does not present significant statistic differences.
Conclusion: In patients with psoriatic arthritis, the treatment with methotrexate does not seem to increase the risk of developing a non alcoholic fatty liver disease.

AB0911 **SHORT-TERM RESULTS OF GUSELKUMAB EFFICACY FOR PSORIATIC ARTHRITIS IN REAL LIFE.**

M. Navidad Fuentes[1], V. Ruiz DEL Valle[1], S. Quirosa Flores[1]. [1]*HOSPITAL VIRGEN DE LAS NIEVES, RHEUMATOLOGY, Granada, Spain*

Background: Psoriatic arthritis is a chronic immune-mediated disease that mainly affect joints, but is associated with a significant increase in cardiovascular risk and other comorbidities. In the last decades, some pathogenic pathways of these diseases have been identified and have led to the development of new therapeutic strategies such as biologic drugs. Early treatment and treat-to-target strategies have achieved a great improvement in the management of the disease, but there are still many refractory cases and further research is needed. Guselkumab is a human IgG1λ monoclonal antibody that selectively binds to interleukin 23, a regulatory cytokine that affects the activity of T lymphocyte subsets. In this way, blockade of IL-23 normalizes the production of pro-inflammatory cytokines. Guselkumab was approved by FDA to psoriatic arthritis treatment in 2020.
Objectives: To analyze the real-life effectiveness of guselkumab in a cohort of patients with psoriatic arthritis.
Methods: A prospective observational study was conducted in psoriatic arthritis patients who received treatment with guselkumab in a hospital center in the southeastern area of Spain, from April 2020. Patient demographic and baseline data were recorded and response variables such as DAPSA index, presence of enthesitis and dactylitis, skin affection by BSA, and drug persistence at 12 and 24 weeks of treatment were analyzed. In addition, adverse events were recorded.
Results: Twenty-nine psoriatic arthritis patients, 20 women, mean age at entry 52 ± 2.47 years, were included in this analysis. The mean of years since psoriatic arthritis diagnosis was 10.14 ± 1.68 years. Demographic and baseline variables of the patients are detailed in Table 1. The mean DAPSA value at the start of treatment was 25.02 ± 2.446. After 12 weeks, it was 17.51 ± 2.855, and after 24 weeks of treatment, it had dropped to 12.37 ± 3.547 points, this difference was statistically significant with p<0.01. The percentage of enthesitis presented a significant reduction, from 37.93% at baseline to 3.84% at 24 weeks of treatment. BSA index had a mean of 12.54 ± 5.94 at baseline, with a significant reduction at 12 weeks (2.136 ± 1.214) and at 24 weeks (0.4167 ± 0.4167). According to their DAPSA index score, patients were classified into remission, low activity disease, and active disease categories. One third of patients achieved complete remission, and another third achieved low disease activity at 24 weeks, as reflected in Figure 1. Treatment persistence was 89.65% at both 12- and 24-week reviews, as only 3 patients dropped out of treatment at 12 weeks. No drug-related adverse events, including local injection site reactions, were recorded.

Table 1. Demographics and baseline patient characteristics.

Baseline Patient Characteristics	guselkumab 100 mg/8 W (n = 29)
Age at inclusion, mean (95% CI), years	52 ± 2.47
Sex	
Female, *n* (%)	20, 68.9 %
Male, *n* (%)	9, 31.1 %
Disease duration of PsA mean [95% CI], years	10.14 ± 1.68
DAPSA mean [95% CI]	25.02 ± 2.44
Enthesitis, *n* (%)	11, (37.93 %)
Dactylitis, *n* (%)	
BSA mean [95% CI]	3, (10.34 %)
Line of treatment	12.54 ± 5.94
Second, *n* (%)	2, (6.89 %)
Third, *n* (%)	8, (27.58 %)
Fourth, *n* (%)	8, (27.58 %)
Fifth, *n* (%)	2, (6.89 %)
Sixthh, *n* (%)	3, (10.34 %)
Seventh, *n* (%)	5, (17.24 %)
Eighth, *n* (%)	1, (3.44 %)

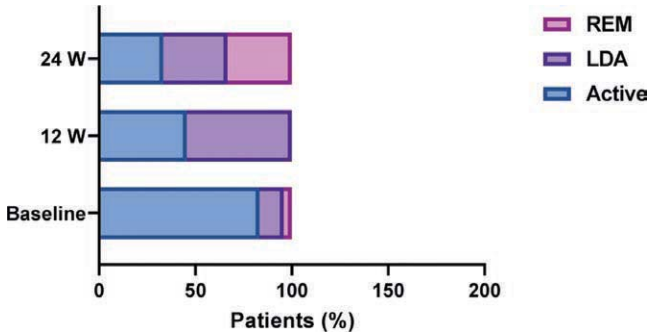

Figure 1. Percentage of patients reaching remission (REM), low disease activity (LDA) or active disease at baseline, 12 and 24 weeks after guselkumab treatment.

Conclusion: Guselkumab is effective and safe for the manifestations of psoriatic arthritis in a real-life cohort of patients.

AB0912 **SWOLLEN AND TENDER JOINTS IMPROVEMENT IN THE RANDOMIZED CONTROLLED TRIALS OF PSORIATIC ARTHRITIS**

M. Ekici[1], E. Unaldi[1], G. Ayan[1], E. Bilgin[1], U. Kalyoncu[1]. [1]*Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, ANKARA, Turkey*

Background: The ACR response is used to evaluate peripheral joints in psoriatic arthritis. However the main component in ACR treatment response is swollen (SJ) and tender joints (TJ), therewithal patient and physician global assessment, acute phase response, pain and function are included in this treatment response. Therefore, it can be thought that peripheral arthritis can best evaluated over SJ and TJ. Although ACR treatment responses are generally found to be similar between anti-TNF and anti-IL17/anti-IL23 in PsA, there is a general opinion that anti-TNF treatments may be more effective on the peripheral joint. (1).
Objectives: In this study, it was aimed to evaluate the efficacy on SJ and TJ in RCTs performed in PsA.
Methods: We was searched with the keywords 'psoriatric arthritis' and 'randomized controlled trial' in Pubmed. All studies between 1975 and 31.10.2021 were screened for TJ count (SD) and SJ count (SD) values at treatment initiation and primary endpoint. The 2 studies with anti-TNFs and the SPIRIT-1 study comparing ixekizumab with placebo and adalimumab showed the number of SJ and TJ at baseline and primary endpoint. Effect size calculated separately according to Morris and Klauer formula. (2,3) We can interpret the effect size according to Cohen as follows: 0-0,1 no effect; 0,2-0,4 small effect; 0,5-0,7 intermediate effect; 0,8-≥1 large effect. (4)
Results: Certolizumab study, ES was found at a good level in the number of TJ and SJ at 200 and 400 mg doses. (ES 0.84 for SJ). The study comparing ixekizumab with adalimumab and placebo, it was observed that administration of ixekizumab every 4 weeks was minimally more effective in the number of TJ (ES 0.16) and SJ (ES 0.13) than adalimumab. The effect of ixekizumab over placebo is also slightly better than that of Adalimumab over placebo. (0.51 vs 0.36 in TJ, 0.38 vs 0.29 in SJ)
Conclusion: Changes in the number of SJ and TJ that directly assess the peripheral joint have not been reported enough in RCTs in PsA patients. According to a limited number of reports, Anti-TNFs (eg, certolizumab) cause significant improvement in the number of SJ and TJ in the primary endpoint. On the other hand, Ixekizumab has as much effect on SJ and TJ as Adalimumab. The effect of anti-IL 17 treatments on the peripheral joint is not less than that of anti-TNFs, as thought.

AB0913

EFFICACY AND SAFETY OF SWITCHING FROM FILGOTINIB TO TOFACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS AFTER 6 MONTHS OF FOLLOW-UP

I. Gonzalez-Mazon[1], J. Loricera[1], L. Sanchez-Bilbao[1], A. Corrales[1], M. A. González-Gay[1], R. Blanco[1]. *[1]Universitary Hospital Marques de Valdecilla, Rheumatology, Santander, Spain*

Background: Phase 2 studies have shown that Filgotinib (FIL), a JAK-inhibitor (JAKi), significantly improves signs and symptoms of psoriatic arthritis (PsA) in patients with active disease. PENGUIN 1 and 2 were two phase III trials of FIL in PsA that were stopped. We considered Tofacitinib (TOFA) the best alternative drug for these patients because TOFA is the only JAKi approved so far in Spain for PsA. However, data in clinical practice about switching from FIL to TOFA have not been reported.

Objectives: To assess the efficacy and safety of switching FIL to TOFA in patients with PsA.

Methods: Prospective Single-University-hospital study of PsA patients diagnosed according to CASPAR criteria, and previously treated with FIL 100 mg and 200 mg/day in two clinical trials (PENGUIN 1 and 2). Based on a shared decision between the patient and the physician, once the trial was finished, patients receiving FIL were switched to TOFA (5 mg/12h) with a 7 days wash-up period. PsA activity, analytical and ultrasound outcomes were assessed at baseline and after 1, 3 and 6 months of treatment with TOFA. A power doppler ultrasound score (PDUS) was obtained using a scoring system which assessed bilateral midline wrists, metacarpophalangeal joints 1-5, proximal and distal interphalangeal joints 2–5 in hands and feet, bilateral knees, ankles and metatarsophalangeal joints 2-5 (apart from any other painful joint). Each image was scored semi-quantitatively on a scale of 0-3. We used MASEI index for the enthesis US evaluation (that includes entheses at 6 sites: proximal plantar fascia, distal Achilles tendon, distal and proximal patellar tendon insertion, distal quadriceps tendon and distal brachial triceps tendon). We also evaluated in these enthesis the presence/absence (0/1) of PD signal as it is the main activity signal.

Table 1. Psoriatic Arthritis activity, ultrasound and analytical outcomes at baseline, month 1, 3 and 6.

	Baseline	Month 1	Month 3	Month 6	p
Musculoskeletal activity scores, median [IQR]					
TJC – no.	2 [0-3]	3 [1.5-16]	1 [0-12]	2 [0-5]	0.22
SJC – no.	0 [0-0]	0 [0-5]	0 [0-6]	0 [0-2]	0.09
Ultrasound exam, median [IQR]					
PDUS score (0-90)	2 [1-9]	3 [1-6]	2 [0-4]	2 [2-9]	0.99
Enthesitis according to PDUS (n)	1 [0-2]	1 [0-2]	0 [0-2]	1 [0-1]	0.85
MASEI index	16.5 ±10.5	19.6 ± 14.5	15.5 ± 4.8	17.5 ± 11.8	0.82
Laboratory values					
Hemoglobin (g/dl) - mean±SD	13.96 ± 1.40	13.54 ± 1.38	13.79 ±1.60	14.40 ± 1.75	0.64
Leucocytes (x103/µL) - mean±SD	7.10 ± 3.40	7.27 ± 2.96	7.14 ± 2.89	8.20 ± 2.87	0.89
Lymphocytes (x103/µL) - mean±SD	2.03 ± 1.01	1.94 ± 0.95	2.16 ± 0.86	1.96 ± 0.45	0.94
Neutrophils (x103/µL) - mean±SD	4.24 ± 2.92	4.54 ± 1.97	4.18 ± 1.84	5.30 ± 2.37	0.85
Platelet count (x103/µL) - mean±SD	266.44 ± 57.35	250.67 ± 53.29	264.90 ± 56.78	287.20 ± 25.58	0.69
CRP (mg/dl) - median [IQR]	0.00 [0.00-1.70]	0.00 [0.00-0.00]	0.00 [0.00-0.00]	0.00 [0.00-0.00]	0.12
ESR (mm/h) - median [IQR]	15 [6-19]	9 [5-15]	12 [4-15]	13 [5-45]	0.12

CRP: C-reactive protein; ESR: Erythrocyte sedimentation rate; MASEI: Madrid Sonographic Enthesis Index; TJC: Tender joint count; PDUS: Power doppler ultrasound; SJC: Swollen joint count.

Results: We included 11 patients (6 women/5 men) with a mean age of 52.5±6.5 years who had received FIL during a mean time of 16.0±9.3 weeks. JAKi was used in monotherapy or combined with sulfasalazine (n=2), methotrexate (n=1) and apremilast (n=1). Disease activity, US scores and laboratory values during the follow-up are shown in Table 1. No significant changes were observed in any case. No adverse events were reported during the 6 month of follow-up except for 1 patient with lymphopenia (500/µL). TOFA was discontinued after 1 month in 1 patient because of lypmphopenia and inefficacy and after 3 months in 4 patients for worsening of the joint pain. It was remarkable that in some of the patients who reported a worsening of painful joints we did not observed a higher inflammatory activity in the SJC or US exam, and this incongruity could be due to the role that JAK/STAT inhibition plays in pain signaling pathways.

Conclusion: Switching from FIL to TOFA appears to be an effective and safe therapeutic option.

AB0914

IS TENDER TO SWOLLEN JOINT COUNT RATIO A USEFUL CLINICAL MARKER OF RESPONSE TO BIOLOGICAL TREATMENT IN PSORIATIC ARTHRITIS PATIENTS?

M. Rato[1], F. Oliveira Pinheiro[1], A. Martins[1], D. Santos Oliveira[1,2], F. R. Martins[3], B. Samões[4], R. Nicolau[5], R. Gaio[6], A. Bernardo[1], M. Bernardes[1,7], L. Costa[1]. *[1]Centro Hospitalar Universitário São João, Rheumatology, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto - FMUP, CINTESIS - Centro de Investigação em Tecnologias e Serviços de Saúde, Porto, Portugal; [3]Centro Hospitalar Universitário do Algarve, Rheumatology, Faro, Portugal; [4]Centro Hospitalar Vila Nova de Gaia/Espinho, Rheumatology, Vila Nova de Gaia, Portugal; [5]Centro Hospitalar Tondela Viseu, Rheumatology, Viseu, Portugal; [6]Faculdade de Ciências da Universidade do Porto, Mathematics, Porto, Portugal; [7]Faculdade de Medicina da Universidade do Porto - FMUP, Medicina, Porto, Portugal*

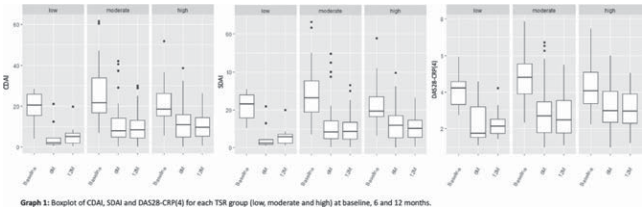
Background: Chronic inflammation in psoriatic arthritis (PsA) may trigger both peripheral and central sensitization via central modifications of pain pathways that can lead to disconnection between tender and swollen joint count. This can result in increased difficulties for the clinician in the assessment of the disease and response to treatment.

Objectives: To study the impact of tender to swollen joint count ratio (TSR) on treatment response to a first course of biologic disease-modifying antirheumatic drug (bDMARD) therapy in PsA patients.

Methods: Observational study including PsA patients under bDMARD, followed with clinical and laboratory examination at baseline, 6 and 12 months of treatment. All patients meet the CASPAR classification criteria. TSR was defined as the tender joint count divided by the swollen joint count, using the 68/66 joint assessment. Patients with no tender nor swollen joints at baseline were excluded. TSR was categorized into 3 groups, based on the empirical distribution, with cuts corresponding to the 20th and 70th percentiles. Disease activity was assessed using the *Clinical Disease Activity Index* (CDAI), the *Simplified Disease Activity Index* (SDAI) and *Disease Activity Score based on 28 joints* (DAS28-CRP(4)). Individual time profiles were plotted within each TSR group. CDAI, SDAI and DAS28-CRP(4) individual time profiles within each TSR group were modelled by mixed-effects linear regression using the TSR group and time as fixed factors and a random factor at the intercept level (accounting for the intra-individual correlation structure). The identification of the statistically significant pairwise differences was obtained from the Tukey's method for multiple comparisons.

Results: We included 113 patients, 62 (54.0% females) with a mean age of 48.1±10.8 years-old at the start of the first bDMARD. Sixty-four patients (56.6%) had symmetric polyarthritis, 19 (16.8%) spondyloarthritis, 25 (22.1%) asymmetric oligoarthritis, 2 (1.8%) distal arthritis and 1 (0.9%) arthritis mutilans. Forty-three percent were under corticosteroid therapy and 57.5% under conventional synthetic DMARD (csDMARD) therapy at baseline (mostly methotrexate, in 45.1% of patients under csDMARD). Etanercept (n=35, 31.0%), adalimumab (n=34, 30.1%), golimumab (n=25, 22.1%), infliximab (n=6, 5.3%), certolizumab (5, 4.4%), secukinumab (n=8, 7.1%) were the bDMARD started in these patients. TSR was categorized into 3 groups, namely low [TSR < 1], moderate [1 ≤ TSR ≤ 2.2] and high [TSR > 2.2], with frequencies 15 (13.3%), 66 (58.4%) and 32 (28.3%), respectively. Whenever the number of tender joints was different from 0 and that of swollen joints equal to 0, patients were included in the group high TSR. All TSR groups, with initiation of bDMARD, showed significantly decreases at 6 months in CDAI (low: p=0.006, moderate: p<0.001, high: p<0.001), SDAI (low: p<0.001, moderate: p<0,001, high: p<0.001) and DAS28-CRP(4) (low: p<0.001, moderate: p<0.001, high: p<0.001). From 6 to 12 months of treatment, the differences were not significant in any of the groups (p>0.05). At baseline, CDAI, SDAI and DAS28-CRP(4) means did not differ between groups (p>0.05). There were also no differences in the means of outcome measures at 6 months as well as at 12 months of treatment (p>0.05). Despite this, patients with low baseline TSR had lower mean values of CDAI, SDAI and DAS28-CRP(4) at 6 and 12 months of treatment, consistent with a low disease activity.

Conclusion: To our knowledge this is the first study exploring the TSR on treatment response in samples of patients exclusively with PsA. All patients benefited from bDMARD therapy, regardless of the group, suggesting that TSR might not be a good predictor of treatment response in patients with PsA.



Graph 1: Boxplot of CDAI, SDAI and DAS28-CRP(4) for each TSR group (low, moderate and high) at baseline, 6 and 12 months.

Background: Psoriasis (PSO) is a systemic immune-mediated disorder, characterized by inflammation skin and joint manifestations: it is known that up to 30% of PsO patients develop PsA. PsO and PsA share common etiopathogenetic pathways, as IL-23/IL-17 axis. In Italy, Guselkumab (GUS), a selective IL-23 inhibitor, was approved in 2018 for the treatment of PsO, and recently it was also approved for PsA therapy. Today, there are few "real-world" studies regarding the use of GUS in PsA patients.

Objectives: A multicenter Italian study group of dermatologists and rheumatologists aimed at evaluate GUS efficacy and safety in patients with concomitant PsO and PsA in real word setting on both skin and joint domains.

Methods: An observational retrospective, multicentric study was performed in 69 PsO patients with a confirmed diagnosis of moderate to severe PsA. PASI and DLQI were used for the evaluation of skin response, and the number swollen/tender joints, presence or absence of dactylitis or enthesitis or axial involvement and painVAS were evaluated for the articular and periarticular efficacy. These analyses were performed at baseline T0 (beginning of the therapy), T1 (12 weeks) and T2 (24 weeks).

Results: 38/69 patients (55,1%) presented oligoarthritis, 31/69 (44,9%) showed polyarthritis, none of the patients had enthesitis or axial involvement. Moreover, co-morbidities were diagnosed: hypertension (52,2%), hypercholesterolemia (34,8%), Hypertriglyceridemia (29%), diabetes (24,6%), obesity (23,2%), HIV-positive (20,3%), psychiatric disorders (17,4%), cardiopathies (15,9%), inflammatory bowel disease (7,3%), Latent Tubercolosis (4,4%), Chronic B-Hepatitis (2,9%), Chronic C-Hepatitis (1,5%). In all these patients, skin and joint responses were evaluated at week 12 and week 24.

Concerning skin efficacy, PASI 90 was achieved at week 24. Concerning Joint response: painVAS progressively improved till T2, tender joint count decreased in patients with oligo and polyarthritis at T1 and maintained at T2, while swollen joint count decreased in polyarthritis patients at T1 and maintained at T2. In oligo-arthritis patients, this parameter was not improved. The number of dactylitis did not decrease during the period of study (see Table 1). No safety concerns were reported in this population.

Conclusion: Efficacy and safety of GUS was confirmed in this study group of PsO patients with concomitant PsA and several comorbidities in a real-life setting.

	Male	Female	Total
Time point 0 (T_0): beginning of the therapy			
PASI	15,5	16,8	13,1
DLQI	15,8	16,9	15,3
Oligo-arthritis: number of tender joints (mean)	1,8	1,9	1,85

AB0916 ASSESSMENT OF PSORIATIC ARTHRITIS IMPACT OF DISEASE (PSAID-12) QUESTIONNAIRE FOR EVALUATIONS OF 6-YEARS TREAT-TO-TARGET STRATEGY OUTCOMES

P. Tremaskina[1], E. Loginova[1], L. Vorobyova[1], T. Korotaeva[1], M. Chamurlieva[1], S. Glukhova[2], A. Lila[3]. *[1]V. A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation; [2]V. A. Nasonova Research Institute of Rheumatology, medical and social problems in rheumatology, Moscow, Russian Federation; [3]V. A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: The 12-item psoriatic arthritis impact of disease questionnaire (PSAID-12) have been found to be a reliable instrument to specifically assess the impact of psoriatic arthritis (PsA) for the patients (pts) as well as predictive of long-term outcomes [1]. There are no data about use of the PsAID-12 for evaluation of long-term outcomes of treat to target (T2T) strategy in PsA pts.

Objectives: to assess the PSAID-12 for evaluations of 6-years outcomes of T2T strategy in PsA.

Methods: 50 (M/F–24/26) PsA pts fulfilling CASPAR criteria were included. Mean age 45±12.1 yrs, median (Me) PsA duration 82 [66;97] month (mos), Me follow-up 72 [58;89] mos. At the early stage (PsA duration≤2 yrs) all pts were treated according to T2T study within 24 mos. At 6 years follow-up all pts underwent standard clinical examination (tender joint count (TJS), swollen joint count (SJC), patient global assessment disease activity (PtGA), CRP (mg/l), skin psoriasis (PsO) by BSA (%), presence of nail PsO, enthesitis dactylitis, DAPSA and completed PsAID-12. PsAID-12 score≤ 4 is considered as a "patient-acceptable status symptoms" (PASS). PsAID-12 > 4 is considered as worse quality of life. DAPSA remission (REM-DAPSA) ≤4 and low disease activity (LDA) ≤14, moderate activity (Mo)≤28, high activity >28 were calculated. Me [Q25-Q75], M±SD, Spearman's correlation, Mann-Whitney test were performed. All p<0.05 were considered to indicate statistical significance.

Results: At 6 yrs follow-up REM-DAPSA were seen in 17 out of 50 pts (34%), LDA in 15 out of 50 (30%) pts. Mean total PsAID-12 score was 2.62±2.1. PASS was seen in 38 out of 50 pts (76%). PsAID-12 significantly associated with the PsA activity parameters: TJC (r=0.73, p<0.05), SJC (r=0.55, p<0.05), PtGA (r=0.77, p<0.05), CRP (r=0.55, p<0.05) and DAPSA (r=0.75, p<0.05). PsAID>4 significantly correlated with presence of dactylitis (r=0.33, p<0.05), skin severity (BSA>3) and presence nails PsO (r=0.41/r=0.38) accordingly. In pts with REM/LDA by DAPSA total PsAID score was significantly lower compare to pts with Mo/High activity - 1.34±0.99 and 4.89±1.84, accordingly (p<0.0001). All pts with REM/LDA status is achieved PASS by PsAID.

Conclusion: In our clinical practice PsAID-12 associated with joint and skin severity in PsA pts. PsAID-12 is useful instrument for evaluating of the long-term T2T outcomes, including REM/LDA by DAPSA.

AB0917 A RANDOMIZED, USUAL CARE CONTROLLED, PARALLEL-GROUP PRAGMATIC CLINICAL TRIAL IN AN INTERDISCIPLINARY COMBINED DERMATOLOGY–GASTROENTEROLOGY–RHEUMATOLOGY CLINIC; PRELIMINARY DATA ON BASELINE CHARACTERISTICS OF 128 PATIENTS AND QUESTIONNAIRE-BASED QUALITATIVE DATA FROM 30 PATIENTS AND 15 HCPS

T. B. Laurberg[1,2], A. G. Loft[2,3], A. K. Dige[2,4], J. S. Agnholt[2,4], L. F. Møller[2,5], K. F. Hjuler[2,5], L. Iversen[2,5]. *[1]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [2]Aarhus University Hospital, National Center for Autoimmune Diseases, Aarhus, Denmark; [3]Aarhus UniversityHospital, Department of Rheumatology, Aarhus, Denmark; [4]Aarhus University Hospital, Department of Gastroenterology and Hepatology, Aarhus, Denmark; [5]Aarhus University Hospital, Department of Dermatology, Aarhus, Denmark*

Background: Immune-Mediated Inflammatory Diseases (IMIDs), including psoriatic arthritis (PsA), axial spondyloarthritis (AxSpA), psoriasis, hidradenitis suppurativa, and inflammatory bowel disease share both pathophysiological and environmental factors, individuals with one IMID have an increased risk for developing other IMIDs, and are associated with reduced health-related quality of life, increased risk of comorbidities, and reduced socioeconomic status.

Unmet needs in care of patients with IMIDs may result from lack of patient-centricity in the usual mono-disciplinary siloed approach to these diseases.

Objectives: The overall aim of this study is to determine the effectiveness of an interdisciplinary combined clinic intervention compared to usual care in patients with the aforementioned IMIDs.

Table 1. Advantages and challenges on feedback from 15 HCPs and feedback from 30 patients.

Advantages - HCP	Challenges - HCP	Themes mentioned by the patients
Professional development	Culture -Old habits from regular departments -"This is how we usually do this"	Communication between HCOs improved treatment
Satisfying to work on a high professional level	Create a new culture takes time and patience -Large differences between specialties and subject areas	Collaboration between HCPs improved treatment
Improved perspective on diseases and patients	Logistics, physical requirements	Holistic approach –patients felt HCPs cared for all health aspects
Collaboration – professional, personal, team spirit	Shared goals	Confidence in living with diseases
Meaning full to work with all aspects of disease	Time and patience	Coherence
Effective communication	Optimal use of time and resources	Treatment optimization
Learning can be brought back to "monodisciplinary" work (improved treatment in respective departments)		Clarification about diet, mastering fatigue and work-related problems
Broader disease focus		Avoid patient being information carrier
Reflection		

Methods: This is a randomized, usual care controlled, parallel-group pragmatic clinical trial. 300 consecutively enrolled participants with co-occurrence of at least two IMIDs are randomly assigned 2:1 to either treatment in the interdisciplinary combined clinic or usual care. The study consists of a 6-month active intervention period and a 6-month follow-up period. Primary outcome is change from baseline to 24-Weeks on the Short-Form Health Survey (SF-36). Additional questionnaire-based qualitative date from 30 patients and 15 health-care professional (HCP)s involved in the center are reported.

Results: Here we report baseline characteristics of the first 128 patients (mean age: 45.4y, 18–74.2, females (83, 64.8%)). All patients had ≥2 IMIDs: Psoriasis (99, 77.3%), PsA (peripheral) (72, 56.3%), AxSpA (34, 26.6%), Hidradenitis (16, 12.5%), Crohn (35, 27.3%), Colitis (20, 15.6%), AxPsA (9, 7.0%), IBD-associated arthritis (10, 7.8%), HS-associated arthritis (1, 0.8%). HLA-B27 was positive in 24 (22.2%) patients. Advantages, challenges and themes mentioned by the patients are listed in Table 1.

A statement from a patient: "It gave me much more peace of mind that I should not "split" my health problems and run errands between different departments. Didn't have to tell the same issues in several places or even try to figure out who to say what to, or who can answer a given question."

Conclusion: In conclusion, an interdisciplinary combined clinic based on an inflammation medicine holistic concept has been successfully established. Preliminary results indicate a high value of an interdisciplinary combined clinic in patients with IMIDs, and HCPs find both advantages and challenges in establishing a combined clinic.

AB0918 EVALUATION OF X-RAY PROGRESSION AT 6 YEARS FOLLOW-UP OF TREAT-TO-TARGET STRATEGY IN EARLY PSORIATIC ARTHRITIS

P. Tremaskina[1], E. Loginova[1], T. Korotaeva[2], A. Sukhinina[3], S. Glukhova[4], A. Smirnov[3], A. Lila[4]. *[1]V.A.Nasonova Research Institute of Rheumatology, spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation; [2]V.A.Nasonova Research Institute of Rheumatology, medical and social problems in rheumatology, Moscow, Russian Federation; [3]V.A.Nasonova Research Institute of Rheumatology, Radiology, Moscow, Russian Federation; [4]V.A.Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation*

Background: In Psoriatic arthritis (PsA) patients (pts) persistence inflammation in the peripheral joins leading bone erosions, joint space narrowing and new bone formation. Tight control of PsA disease improved joint and skin outcomes, but the number of pts with erosions increased [1]. Despite of clinical improvement no long-term treat to target (T2T) strategy data on radiographs progression yet [2].

Objectives: To study X-ray progression in PsA pts treated according to T2Tstrategy at the early stage of disease at 6 years (yrs) follow-up.

Methods: 30 (M/F–17/13) PsA pts fulfilling CASPAR criteria, mean age 44.7±11.4 yrs, median (Me) PsA duration 78.5 [66;95] month (mos), Me follow-up 71 [60;86] mos, Me DAPSA 24 [7;45]. All pts was treated according to T2T strategy at the early stage with MTX alone or in combination with iTNF within 2 yrs. When T2T study was ended all pts were treated according to standard care. All pts underwent standard clinical examination of PsA activity, DAPSA was calculated. Radiographs of the hands and feet were available for 30 pts at baseline and 26 (86.6%) at 6-yrs follow-up. Radiographs of the hands and feet were scored using the modified van der Heijde-Sharp (m-v-d-HS) scoring method for PsA assessing both erosion, joint space narrowing (JSN) and total score (TS) m-v-d-HS. Scoring was done by two readers. The number of pts with erosions was calculated at baseline and 6 yrs later. M±SD, Me [Q25; Q75], Me (Min-Max), Mann-Whitney test were performed. All p<0.05 were considered to indicate statistical significance.

Results: At 6 yrs follow-up Me TS m-v-d-HS and JSN significantly increased from 34 (0-104) to 50 (6-253) and from 34 (0-97) to 50 (6-127) accordingly (p=0.006 and p=0.011); count of erosion from 0 (0-13) to 4 (0-128), p=0.002. In 19 out of 26 pts significantly negative X-Ray progression in the feet and hands by TS m-v-d-HS, count erosion, joint space narrowing was seen (for all p<0.05). In 7 out of 26 pts no X-Ray progression was found. PsA activity by DAPSA was significantly higher in pts with X-ray progression compare to those without progression 14.1 [5.19;33.67] and 2.22 [0.55;13.54] accordingly (p=0.04). 6 yrs later the number of pts with erosions significantly increased from 12 out of 26 (46%) at baseline to 22 out of 26 (85%) pts accordingly (p=0.002).

Conclusion: At 6 yrs follow-up negative radiographic progressions in the hand and feet found in mostly early PsA pts despite of tight control treatment strategy within 2 yrs.

AB0919 PSORIATIC ARTHRITIS: FACTORS ASSOCIATED WITH THE USE OF BIOTHERAPY

S. Sayouri[1], N. Akasbi[1], H. Bourkhime[2], I. El Mezouar[1], T. Harzy[1]. *[1]Hassan II University Hospital, Department of Rheumatology, fez, Morocco; [2]Faculty of Medicine and Pharmacy of Fez, Sidi Mohammed Ben Abdellah University, Laboratory of Biostatistical, Clinical and Epidemiological Research, fez, Morocco*

Background: The use of biological treatment in psoriatic arthritis has revolutionized its management with both joint and skin efficacy [1].
Objectives: The goal of our study was to evaluate the use of biological treatment in these patients and to assess the factors associated with it.
Methods: Retrospective study conducted within the rheumatology department of the University Hospital of Fez. Patients were recruited from January 2011 to January 2021. We included patients with psoriatic arthritis according to CASPAR criteria and assessed the use of biotherapy as well as the epidemiological, clinical and biological factors associated with it.
Results: There were a total of 98 patients with psoriatic arthritis, 21 of whom had been put on biological treatment. Of the total of 21 patients, there were 42.9% women and 57.1% men, the average age was 51.1 (± 9.92) years. 20% of patients had a history of tuberculosis, 14.3% had diabetes, 10% had hypertension and 30% had dyslipidemia. 60% of patients had an inflammatory syndrome, 73% had radiographic sacroiliitis and 63.2% had functional repercussions. In bivariate analysis, the value of the initial C-reactive protein CRP (p = 0.04), the initial disease activity score DAS 28 CRP (p = 0.0001) and the value of the initial erythrocyte sedimentation rate ESR (p = 0.02) were significantly associated with the use of biotherapy, there was no significant association with the other parameters. In multivariate analysis, no factor was significant.
Conclusion: An active psoriatic arthritis predicts the prescription of a biological treatment, other studies with a larger sample would be necessary to confirm our results.

AB0920 SAFETY OF APREMILAST IN PSA PATIENTS WITH HISTORY OF MALIGNANCIES OR ACTIVE CANCER: A RETROSPECTIVE STUDY

D. V. A. Sabella[1], V. Venerito[1], M. Fornaro[1], F. Cacciapaglia[1], M. G. Anelli[1], F. Arezzo[1], V. Internò[2], G. Lopalco[1], F. Iannone[1]. *[1]University of Bari Aldo Moro, D.E.T.O., Bari, Italy; [2]University of Bari Aldo Moro, D.I.M.O., Bari, Italy*

Background: One of the most intriguing aspects in the management of patients with inflammatory arthritis is the safety of novel therapies in those with a recent history of malignancy or active neoplasm. In this regard, apremilast (APR), an oral PDE4 inhibitor, is emerging as one of the safest therapeutic options in patients with PsA with comorbid cancer.
Objectives: This retrospective study aims to assess the effectiveness and safety of APR in PsA patients with a recent history of malignancy or active cancer.
Methods: We retrospectively observed patients with a history of neoplasm diagnosed from 1997 to 2021, who underwent apremilast treatment from 2017 to 2021 in a tertiary care centre. We recorded demographic and clinical characteristics at APR baseline and last visit. Furthermore, we recorded the eventual recurrence of primary cancer or the onset of new neoplasms. Paired t-test was used to assess the difference of continuous variables at different follow-ups.
Results: Thirteen patients (sex: female 6/13, 46,15%; mean age (mean ± 63,7 years sd ± 9,9 years)) started Apremilast between 2017 to 2021 in a tertiary care center. We assessed their clinical condition using DAPSA, LEI and PASI score in the baseline and in the last visit. Mean follow-up time was 32,02 ± 18,92 months. Mean DAPSA at baseline 20,55 ± 9,15 decreased to 16,21 ± 1,73 at last visit. Similarly mean LEI at baseline was 1,23 ± 1,58 and decreased to 0,61 ± 0,35 at last visit, even in absence of statistical significance (p=0,15). Conversely mean PASI at baseline (1,76 ± 2,57) did not show a decrease (1,61 ± 0,93);
Ten patients were still treated with apremilast at last available follow-up. Patient 6 (Table 1) experienced the relapse of Ductal Breast Papilloma. For patient 8, a relapse of primary cancer occurred. Patient 9 had the onset of a new neoplasm. The APR was not discontinued as such malignancies were not considered as treatment associated. Three patients (4, 6, 10) discontinued APR due to intolerance or lack of efficacy.

Table 1.

	DIAGNOSIS OF NEOPLASM	YEAR OF DIAGNOSIS	TREATMENT	RELAPSES/NEW OCCURRENCES
1	MENINGIOMA	2019	FOLLOW-UP	N
2	PROSTATE ADENOCARCINOMA	2017	PROSTATECTOMY (2017) RADIOTHERAPY	N
3	DUCTAL BREAST CANCER	2019	RADICAL MASTECTOMY (2019) CHEMOTHERAPY	N
4	DUCTAL BREAST PAPILLOMA	1997	FOLLOW-UP	Y
5	BLADDER CARCINOMA	2012	RESECTED (2013)	N
6	FOLLICULAR LYMPHOMA	2014	STEM CELLS (2014)	N
7	OSTEOID OSTEOMA	2017	FOLLOW-UP	N
8	FOLLICULAR LYMPHOMA IIIA	2017	CHEMOTHERAPY	Y
9	PULMONARY NODULE	2019	CHEMOTHERAPY, RESECTED	Y
10	BLADDER CARCINOMA	2017	RESECTED (2017)	N
11	ONCOCITOMA	2016	RESECTED (2016)	N
12	COLON CARCINOMA	2020	RESECTED (2020), CHEMOTHERAPY (2021)	N
13	BREAST CANCER	2018	RESECTED (2018)	N

Ten patients were still treated with apremilast at last available follow-up. Patient 6 (Table 1) experienced the relapse of Ductal Breast Papilloma. For patient 8, a relapse of primary cancer occurred. Patient 9 had the onset of a new neoplasm. The APR was not discontinued as such malignancies were not considered as treatment associated. Three patients (4, 6, 10) discontinued APR due to intolerance or lack of efficacy.
Conclusion: APR seems a safe option in PsA patients with a recent history of malignancy or active cancer, improving articular involvement.

AB0921 EFFECTIVENESS OF GUSELKUMAB IN PSORIATIC ARTHRITIS IN DAILY CLINICAL PRACTISE

N. Costas Torrijo[1], I. De la Morena[1], D. Bedoya-Sanchis[2], J. J. Sanmartín Martinez[2], E. Montesinos Villaescusa[3], L. Martinez Casimiro[3], S. Porcar Saura[3], P. Trenor Larraz[1]. *[1]Hospital Clínico Universitario, Reumatología, Valencia, Spain; [2]INCLIVA Institut d'investigació sanitària, Reumatología, Valencia, Spain; [3]Hospital Clínico Universitario, Dermatología, Valencia, Spain*

Background: Guselkumab is a monoclonal antibody against interleukin-23, biological agent approved for the treatment of plaque psoriasis and psoriatic arthritis. There are two randomised, double-blind, placebo-controlled phase III studies (DISCOVER 1 and DISCOVER 2) that evaluated the efficacy and safety of guselkumab versus placebo. Treatment with guselkumab resulted in significant improvements in the measures of disease activity compared to placebo at Week 24. [1]
Objectives: To evaluate the response to Guselkumab in patients with Psoriatic Arthritis, according to CASPAR criteria, undergoing treatment by dermatology indication.
Methods: This is an observational descriptive retrospective study that includes patients with Psoriatic Arthritis (acording to CASPAR criteria) who are being treated with Guselkumab under dermatology indication due to skin involvement. In this study, the epidemiological and clinical characteristics of the patients are assessed: IMC, affected domains, previous treatments, concomitant treatments, PASI before begining the treatment, at 12 week and 24 week, and joint activity mesured by DAPSA at the beggining, after 12 and 24 week.
Results: There are 7 patients included, 5 women and 2 men, the mean age were 50 ± 7.9 years old, with a BMI (body mass index) average of 33.13 ± 6.26. All the patients presented skin involvement: 4 of 7 with plaque psoriasis (2 of them with scalp psoriasis, and one of those two with inverse psoriasis), 3 of 7 with psoriasis in palms and soles (one with scalp psoriasis and inverse psoriasis), and 2 of 7 pacients with nail involvement. Regarding joint damage, all the patients presented peripheral joint involvement, 2 of 7 with axial too. For the other domains: 2 of 7 have had recurring uveitis, 1 of 7 one episode of dactylitis, and none of them any episode of enthensitis nor inflammatory bowel disease. All the patients had received at least 1 bDMARD (average of 2.8 ± 2.23, but one of them have used 7 before). All the patients received the standard dose of Guselkumab 100mg sc (week 0 and 4) and later each 2 months, with a duration of treatment in months with an average of 6.3 ± 2.88. At the same time, 1 of 7 patient used Methotrexate concomitantly, 2 of 7 with leflunomide, and 1 of 7 with NSAIDs. The PASI average at the beggining of the treatment with Guselkumab was 9.25 ± 4.99, at 12 week all the patients had obtain a PASI 0, and remained in remission. Regarding joint damage measured with DAPSA, at the beggining of Guselkumab treatment the average was 24.15 ± 22.02, at 12 week 12.19 ± 5.56, at the 24 week 8.86 ± 1.6, all of the patients improved, without any inflammatory flares. Any of them presented uveitis, enthensitis nor dactylitis. Drug retention rate of 100%, all the patients are still in treatment with Guselkumab, any side effect was detected.
Conclusion: Guselkumab is a very effective drug for the treatment of psoriasis, but also for the joint involvement in patients with failure to bDMARD. We need more real life studies to determinate the effectiveness in daily clinical practise.

Psoriatic arthritis - clinical aspects (other than treatment)

AB0922 PSORIATIC ARTHRITIS DISEASE ACTIVITY DIFFERS BY RACE/ETHNICITY

F. Ahmed[1], A. Ogdie[2], R. Fitzsimmons[1], D. Shin[1], J. Takeshita[1]. [1]*University of Pennsylvania, Department of Dermatology, Philadelphia, United States of America;* [2]*University of Pennsylvania, Department of Rheumatology, Philadelphia, United States of America*

Background: Psoriatic arthritis (PsA) affects up to 30% of individuals with psoriasis. Studies have demonstrated that the presenting disease severity and quality of life impact of psoriasis differs by race/ethnicity in patients with and without PsA, but little is known about disease activity among different racial/ethnic groups [1-3].
Objectives: The objective of our study was to evaluate disease activity by race/ethnicity among patients with PsA.
Methods: We performed a cross-sectional study of adult (≥18 years old) patients with PsA who had at least one outpatient visit within the University of Pennsylvania health system between 2010 and 2019. Patients with PsA were identified by the presence of at least two International Classification of Diseases (ICD)-9 or ICD-10 codes for PsA associated with two different healthcare encounters. The primary outcome was disease activity as measured by the Routine Assessment of Patient Index Data 3 (RAPID3) assessment. The RAPID3 score is a validated patient-reported measure of physical function, pain, and global status [4]. RAPID3 scores range from 0 to 30, with higher scores indicating greater disease activity. Patients were included if they had at least one documented RAPID3 score. For patients with multiple RAPID3 scores, the median value was used. The primary independent variable was race/ethnicity categorized as White (reference), Black, Asian, Hispanic, or other race. Multivariable linear regression was used to assess the relationship between race/ethnicity and RAPID 3 score.
Results: The study population included 742 patients. Mean (standard deviation [SD]) age was 47.2 (13.3) years and 57.4% were female. The racial/ethnic distribution was 79.4% White, 7.0% Black, 5.0% Asian, 3.1% Hispanic, 2.6% other race, and 3.0% missing race/ethnicity. The means of the median Rapid3 scores were statistically significantly different across racial/ethnic groups (p<.001): White mean (SD) 9.79 (6.02), Black mean (SD) 14.86 (14.86), Asian mean (SD) 9.79 (5.44), Hispanic mean (SD) 15.09 (7.11), other race mean (SD) 10.57 (6.91). In an adjusted multivariable model controlling for other sociodemographic factors, body mass index, treatment history, and medical comorbidity, Hispanic patients had higher RAPID3 scores compared to White patients, indicating greater disease activity (β 3.36; 95% confidence interval [CI] 1.04 – 5.67, p <.005). In exploratory stratified analyses to evaluate effect modification by sex, among males, Black (β 3.43; 95% CI 0.23 – 6.63, p=.04) and Hispanic (β 5.94; 95% CI 2.18 – 9.70, p <.005) patients had higher RAPID3 scores than White patients. Among females, no significant racial/ethnic differences in RAPID3 scores were identified.
Conclusion: Black and Hispanic patients report greater disease activity as indicated by higher RAPID3 scores compared to White patients. Larger studies are necessary to confirm our findings and understand the causes of racial/ethnic differences in disease activity among patients with PsA.

AB0923 ASSESSMENT OF FOUR SCREENING TOOLS AND RETRIEVAL OF KEY QUESTIONS TO DETECT UNDIAGNOSED PSORIATIC ARTHRITIS IN CHINESE PATIENTS WITH PSORIASIS: A MULTICENTER STUDY

R. Cui[1], M. Chen[1], S. M. Dai[1]. [1]*Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Department of Rheumatology and Immunology, Shanghai, China*

Background: The available data showed great discrepancies in the performance of screening tools in detecting psoriatic arthritis (PsA) in patients with psoriasis, and those including the diagnosed PsA in the validation might exaggerate/overestimate the performance. The key questions in each tool were unclear and their contributions were not systematically assessed. Here the performance of four different screening tools were validated and compared in detecting undiagnosed PsA, and the key questions with different weights of them were retrieved and evaluated.
Objectives: To compare and validate the performance of the four screening tools in detecting undiagnosed psoriatic arthritis (PsA) in Chinese patients with psoriasis, and to determine the key questions and their weights.
Methods: Consecutive patients with psoriasis but no prior diagnosis of PsA from dermatology clinics and patients with newly diagnosed PsA from rheumatology clinics who were blind to the diagnosis were recruited to complete questionnaires, including early psoriatic arthritis screening questionnaire (EARP), psoriatic arthritis screening and evaluation questionnaire (PASE), psoriasis and arthritis screening questionnaire (PASQ), and psoriasis epidemiology screening tool (PEST). The receiver operator characteristic (ROC) curve with area under curve (AUC) was used to determine sensitivity, specificity and accuracy. The LASSO and logistic regression were utilized to retrieve key questions, and a nomogram was utilized to visualize their weights.
Results: Of 482 psoriasis patients from dermatology clinics, 77 patients were newly diagnosed with PsA. Another 68 patients with newly diagnosed PsA from rheumatology clinics were incorporated in the analysis. ROC analysis indicated that the optimal cut-off values for EARP, PASE, PASQ and PEST were 3, 40, 7 and 3, with corresponding sensitivities of 91.4%, 88.6%, 86.2% and 88.5%, and specificities of 88.6%, 75.2%, 80.2%, and 83.6%, respectively. The AUC of EARP (0.925) was higher than those of PASE (0.885), PASQ (0.905) and PEST (0.827). A total of twelve key questions were retrieved from these four tools, and their relative weights were scored as 5~100 individually with a nomogram.
Conclusion: To screen undiagnosed PsA, EARP have slightly better balanced sensitivities and specificities. The retrieved twelve key questions may be helpful in proposing a new questionnaire with different scores of each question to screen PsA more efficiently.

AB0924 INDIVIDUAL DIGIT LEVEL NAIL INVOLVEMENT AND JOINT ASSESSMENT IN PATIENTS WITH NAIL PSORIASIS

C. T. Ritchlin[1], L. E. Kristensen[2], B. Strober[3,4], A. Kavanaugh[5], R. Bolce[6], J. Lisse[6], J. Pustizzi[6], N. Somani[6], C. Sapin[6], J. F. Merola[7]. [1]*University of Rochester Medical Center, Allergy, Immunology, and Rheumatology, Rochester, United States of America;* [2]*Bispebjerg and Frederiksberg Hospital, Muscoloskeletal Statistics Unit, The Parker Institute, Copenhagen, Denmark;* [3]*Yale University, Yale University, New Haven, United States of America;* [4]*Central Connecticut Dermatology,., Cromwell, United States of America;* [5]*University of California San Diego, Department of Rheumatology, Allergy, and Immunology, La Jolla, United States of America;* [6]*Eli Lilly and Company, Corporate Center, Indianapolis, United States of America;* [7]*Brigham and Women's Hospital, Department of Medicine, Division of Rheumatology, and Department of Dermatology, Boston, United States of America*

Background: The relationship between the evolution of nail disease and the articular features of Psoriatic Arthritis (PsA) is poorly understood. There is a lack of data on the relationship between nail and joint disease, important clinical parameters of disease activity, specifically at the individual digit level.
Objectives: To evaluate the level of association, at digit level, between nail involvement and joint disease at baseline, with a special focus on distal interphalangeal joint (DIP) assessment.
Methods: SPIRIT-H2H (NCT03151551) was a 52 week, multicenter, randomised, open-label, parallel-group, assessor-blinded study evaluating the efficacy and safety of IXE vs ADA in PsA.[1] Nail psoriasis was measured using Nail Psoriasis Severity Index (NAPSI). Joint involvement was measured by tender/swollen joint count (TJC/SJC) scores. Here we examine both baseline tenderness and swollenness at the DIP joint, proximal interphalangeal (PIP) joint and metacarpophalangeal (MCP) joint level for each digit and evaluate the level of association

between nail involvement (NAPSI>0 vs NAPSI=0) and joint assessment using Chi-square tests and/or Fisher's exact test where relevant.

Results: Overall, 368 patients (IXE N=191, ADA N=177) out of 566 had a baseline NAPSI >0. The overall level of nail involvement ranged from 52.7% (n=194) (right 5th finger) to 67.9% (n=250) (right 1st finger). When considering a digit-wide assessment of joints (DIP, PIP, and MCP), in general, no clear association was found between NAPSI >0 and joint involvement. However, there was more frequent DIP joint involvement in patients with nail involvement compared to patients without nail involvement. When taking only the DIP joint into account, nail involvement was found to be statistically associated with tenderness and/or swelling at the DIP level (Figure 1), with differences between patients with nail involvement vs. without nail involvement ranging from 7.9% (p=0.023) (right 5th finger) to 19.4% (p<0.001) (left 3rd finger). These differences are mostly driven by tenderness rather than swelling, irrespective of digit. For tenderness, differences (with vs. without nail involvement) ranged from 7.0% (right 2nd finger) to 18.0% (left 3rd finger). Differences due to swelling ranged from 5.0% (left 1st finger) to 12.2% (left 3rd finger).

Conclusion: In SPIRIT-H2H, tenderness and/or swelling at the DIP joint was significantly associated with nail involvement in individual digits.

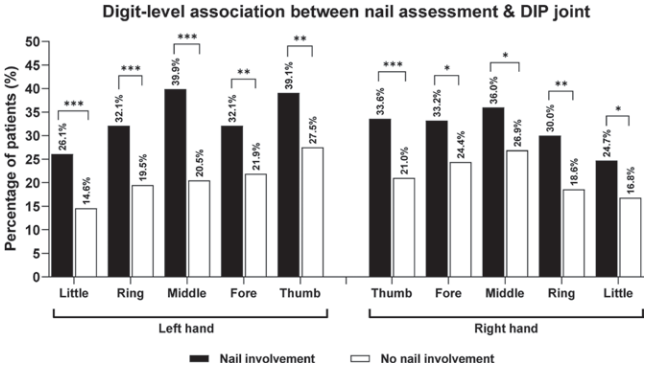

Figure 1. Digit level association between nail assessment and DIP joint.Significant difference between nail involvement and no nail involvement denotated by * (p≤0.05), ** (p≤0.01), *** (p≤0.001). Abbreviation: DIP= Distal interphalangeal joint.

AB0925 ADVANTAGES OF COMBINED DERMA-RHEUMATOLOGICAL EVALUATION IN EARLY PSORIATIC ARTHRITIS

S. Panaro[1], F. Franceschini[1,2], A. Tincani[1,2], L. Andreoli[1,2], M. Venturini[1,3], M. Filippini[2], M. Frassi[2]. *[1]University of Brescia, Clinical and Experimental Sciences, Brescia, Italy; [2]Spedali Civili di Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy; [3]Spedali Civili di Brescia, Dermatology Unit, Brescia, Italy*

Background: Psoriatic Arthritis (PsA) is a challenging diagnosis both for the absence of specific biomarkers and for its clinical heterogeneity, especially in its initial phases. Early onset of PsA is mostly characterized by mono-oligoarthritis, enthesitis, dactylitis, onychopathy, modest cutaneous involvement. At least 50% of early-PsA patients initially come at dermatologist's attention because they carry only few musculoskeletal symptoms such as enthesitis and dactylitis. Rheumatological evaluation and ultrasound (US) demonstration of articular and entheseal inflammation allows to augment the probability of an early diagnosis in a short period of time.

Objectives: We described patients referred to our derma-rheumatological clinic. We focused our attention on the main affected domain and on the advantages of a combined evaluation in terms of diagnosis, access to advanced therapies and short-term outcome.

Methods: All patients referred to our derma-rheumatological clinic by dermatologists from July 2017 to July 2019 for suspected PsA were considered in the present study. 55% of them were studied with US, according to clinical necessity. All the suspected domains were studied using both B-mode and Power Doppler.

Results: 81 patients, sent to our attention for suspected PsA, were included. In 18 (37%) of them diagnosis was confirmed (Caspar criteria were satisfied). In these patients oligoarthritis (80%), enthesitis (40%), dactylitis (23%), sometimes in combination, were the most frequent presentations. In 25% of cases enthesitis was the only clinical feature. Articular disease activity was low to moderate in most of patients (DAPSA 14,83 ± 10,08). Disease duration at the diagnosis was 12 months in 90% of cases and the time occurring between symptoms and the first advanced therapy was 18 months in 50% of cases. US study allowed to redefine disease status in 30% of cases. Arthritis and enthesitis were the main domains where US evaluation gave more diagnostic value.

Conclusion: Literature reports a mean time to diagnosis and to start advanced pharmacological therapy respectively of 1,5 and 5 years. In our report, time to start advanced therapy was much lower than expected, falling in the so-called window of opportunity. US study importantly contributed to reach this target, allowing us to identify as soon as possible sub-clinical and pauci-symptomatic forms (low disease activity, prevailing entheseal domain), which could otherwise be misdiagnosed or have an important diagnostic delay. The attention of dermatologist and integrated evaluation allowed us to optimize our diagnostic-therapeutic work-up in patients affected by early PsA, allowing them to receive sooner advanced therapies, according to recent EULAR and GRAPPA recommendations.

AB0926 ENTHESITIS OF THE HAND IS A DOMINANT LESION IN PSORIATIC ARTHRITIS AND MAY HELP DISTINGUISH IT FROM RHEUMATOID ARTHRITIS: CASE-CONTROL, SINGLE-CENTRE, ULTRASOUND STUDY

D. Esperança Almeida[1], A. M. Gomes Correia[1], E. Costa[1], J. Neves[1], J. Silva[1], A. R. Ribeiro[1], M. Cerqueira[1]. *[1]Hospital de Braga, Rheumatology, Braga, Portugal*

Background: Enthesitis is the hallmark of psoriatic arthritis (PsA) and may assist in distinguishing PsA from other forms of arthritis (1,2). Its clinical evaluation is hampered by lack of specificity of physical examination (3). Ultrasound (US) may provide information about its presence and response to treatment. Although some previous works have shown that enthesitis of the hand is important in PsA (4), most US studies and scores focused on greater size entheses.

Objectives: To explore the prevalence of enthesitis of the hand in PsA patients as evaluated by US, and compare it with other inflammatory arthritides, namely rheumatoid arthritis (RA).

Methods: Cross-sectional study in which consecutive patients with PsA and RA were recruited for an US protocol evaluating 4 entheses of the hand including: 1. measurement of the extensor digitorum tendon central slip at its insertion at the middle phalanx of the 2nd and 3rd finger bilaterally; 2. search for the presence of power-Doppler (PD) sign; 3. identification of structural lesions. Linear regression models were built to test if diagnosis (PsA vs RA) explained part of the variance of the thickness of tendons insertion while controlling possible influences of age, type of work and body surface area. A ROC curve was built to find a mean thickness cut-off allowing distinction between PsA and RA. The prevalence of PD sign and structural lesions of the entheses was compared between groups.

Results: Fifty-eight patients were recruited (29 with PsA and 29 with RA) and a total of 232 entheses were evaluated. Mean thickness of the interest entheses was superior in PsA patients compared to RA patients (2nd finger – 0.96 ± 0.16mm vs. 0.74 ± 0.09mm; 3rd finger – 0.96 ± 0.20mm vs. 0.76 ± 0.11mm). Linear regression models including diagnosis and potential confounders significantly explained mean thickness of both entheses (2nd finger – R^2=0.56, p<.001; 3rd finger – R^2=0.41, p<.001), with the diagnosis group being the most important predictor (Table 1). ROC curve (AUC 0.897, p<.001) showed a cut-off value of 0.925mm for the mean of the 4 entheses had a specificity of 93.1% for the identification of PsA patients.

Table 1. Multiple linear regression models explaining thickness of the entheses.

	2nd finger (mean of both sides)	3rd finger (mean of both sides)
Linear regression model	R^2=0.56 p<.001***	R^2=0.39 p<.001***
Diagnosis (PsA vs RA)	β=0.587; B=0.203mm p<.001***	β=0.483; B = 0.182mm p<.001***

In our sample, 8 (3.5%) entheses had a measured thickness above mean + 2 SD, all belonging to PsA patients; 6 (75%) had signs of ongoing inflammatory process as proved by the presence of PD sign (Figure 1). Regarding structural lesions, enthesophytes or bone irregularities/erosions were found in 13.8% of PsA entheses, which compared to 1.7% of RA entheses.

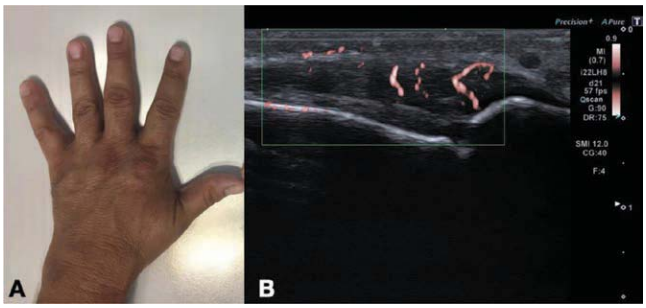

Figure 1. Enthesitis of the central slip of extensor digitorum of the 3rd finger in a patient with PsA: swelling of the 3rd proximal interphalangeal joint (A) due to inflammatory process originating in the enthesis, with no signs of synovitis, as evaluated by US (B).

Conclusion: This work reinforces enthesitis as a key lesion in PsA. It also shows enthesitis occurs significantly in small entheses, like the ones of the hand and that, in some instances, it may be the dominant lesion in a swollen joint. US may be valuable for establishing a diagnosis in the setting of inflammatory arthritis of unknown etiology.

AB0927 CLINICAL AND RADIOGRAPHIC PHENOTYPE OF AXIAL PSORIATIC ARTHRITIS

E. Gubar[1], T. Korotaeva[1], Y. Korsakova[1], E. Loginova[1], S. Glukhova[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Medical and social problems in rheumatology, Moscow, Russian Federation*

Background: The latest data show that axial psoriatic arthritis (PsA) is less symptomatic, as compared with ankylosing spondylitis, and is associated with distinct radiographic features (1).
Objectives: To analyze clinical characteristics of PsA patients (pts) with axial involvement, using data from a real-life outpatient cohort.
Methods: 50 pts (M/F–30 /20) with PsA according to CASPAR criteria were included. All pts had either a present or past history of back pain, which rheumatologist suspected to be axial involvement. Pts' age 42.0 [34.0; 54.0], disease duration 3.5 [0.3; 32.5] years. Pts underwent standard clinical examination of PsA activity: Me BASDAI was 6.2 [3.8; 8.0], ASDAS-CRP 3.5 [2.5; 4.8], DAPSA 38,1 [20,2; 52,2], CRP 12.4 [0.3; 94.6] mg/L. All pts were evaluated for presence of inflammatory back pain (IBP) by ASAS criteria. HLA B27 antigen status was observed. Physical examination included Bath Ankylosing Spondylitis Metrology Index (BASMI). Pts underwent X-ray of sacroiliac joints (pelvic radiographs), cervical and lumbar spine, and hands and feet. Radiographic sacroiliitis (rSI) was defined as bilateral grade ≥ 2 or unilateral grade ≥ 3. All radiographs were interpreted by two experienced musculoskeletal radiologists. Me [Q25; Q75], Pierson-χ2 tests were performed. All p<0.05 were considered to indicate statistical significance.
Results: IBP was detected in 31 (62.0%) pts, while 19 (38.0%) pts didn't meet IBP criteria – they had chronic back pain (CBP); 12 (24.0%) of all pts had episodic mild back pain. In 15 (30.0%) pts back pain started at age of above 40. RSI was found in 29 (58.0%) pts, while mostly symmetrical in 23/29 (79.3%) cases. Unilateral grade 2 sacroiliitis was found in 4 (8.0%) pts. 13/29 (44.8%) pts developed rSI without IBP. 38 (76%) pts had erosive arthritis, 18 (36%) pts had numerous erosions. HLA-B27 antigen was positive in 16 (32.0%) of pts. A correlation was revealed between the presence of rSI and limited spine mobility by BASMI (r=0.347). Association was found between rSI and numerous erosions (p=0.003), as well as between rSI and juxtaarticular new bone formation on hands and feet X-rays (p = 0.02). Syndesmophytes were found in 28 (56%) cases. 11 (22%) pts developed syndesmophytes without rSI. Asymmetrical syndesmophytes in the lumbar spine were found in 7/13 (53.8%) pts, vertebral non-bridging syndesmophytes in the lumbar and/or cervical spine in 16 (57.1%) pts. Restricted neck rotation was found in 85% of cases. Syndesmophytes in the cervical spine were found twice as often (26 pts) as in the lumbar spine (13 pts); 14 (28%) pts had isolated involvement of the cervical spine. An association was detected between asymmetrical syndesmophytes and radiographic changes on hands and feet X-rays such as osteolysis (p = 0.005) and juxtaarticular new bone formation (p = 0.05).
Conclusion: Axial PsA is often asymptomatic, one third of pts develop back pain at age above 40. HLA-B27 positivity was found in only 32% of pts. Pts with rSI are more likely to have severe peripheral arthritis with multiple joint erosions. Radiographic SI is associated with juxtaarticular new bone formation, which may indicate common mechanisms of bone formation in axial and peripheral skeleton. Syndesmophytes may occur in absence of sacroiliitis. Cervical spine involvement is more frequent in axial PsA pts. Asymmetrical syndesmophytes characteristic of PsA, are associated with typical, for PsA, radiographic changes on hands and feet X-rays, such as osteolysis and juxtaarticular new bone formation.

AB0928 CHARACTERISTICS OF AXIAL PSORIATIC ARTHRITIS PATIENTS WITH SYMMETRICAL AND ASYMMETRICAL SACROILIITIS

E. Gubar[1], T. Korotaeva[1], Y. Korsakova[1], E. Loginova[1], L. Vorobyova[1], S. Glukhova[2], E. Nasonov[3], V. Sorotskaya[4], I. Kushnir[5], I. Shchendrigin[6], I. Umnova[7], P. Shesternya[8]. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation; [2]V.A. Nasonova Research Institute of Rheumatology, Medical and social problems in rheumatology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russian Federation; [4]Medical Institute of the Tula State University, Rheumatology, Tula, Russian Federation; [5]Kuzbass Regional Clinical Hospital S.V.Belyaev, Rheumatology, Kemerovo, Russian Federation; [6]Center of responsible rheumatology "Induktsia", Rheumatology, Stavropol, Russian Federation; [7]Omsk region "Regional clinical hospital», Rheumatology, Omsk, Russian Federation; [8]Krasnoyarsk State Medical University Krasnoyarsk, Rheumatology, Krasnoyarsk, Russian Federation*

Background: The latest data show that psoriatic arthritis (PsA) patients (pts) with asymmetrical sacroiliitis (SI) have clinical and genetic features which are considered typical for PsA (1).
Objectives: To analyze comparative clinical characteristics of PsA pts with symmetrical and asymmetrical SI.
Methods: 287 pts (M/F–147/140) with PsA according to CASPAR criteria were examined. Data was collected from 6 rheumatology clinics of the Russian Federation. Pts' age 45.6±12.2 years (yrs), disease duration 10.9±6.7 yrs. Pts underwent standard clinical examination of PsA activity. Disease activity was measured by DAPSA, BASDAI, ASDAS-CRP. The examination involved

determining HLA B27 antigen status and X-rays of sacroiliac joints (SIJs) (pelvic radiographs), hands and feet. Bilateral changes in SIJs of grades 2-2, 3-3 and 4-4 were defined as symmetrical SI (sym-SI). Changes in SIJs of grades 2-1, 2-3, 3-1, 1-4, 2-4 and 3-4 were defined as asymmetrical SI (asym-SI). Skin lesion severity was evaluated in terms of body surface area (BSA) affected and Psoriasis Area Severity Index (PASI). When BSA was ≥ 3%, PASI was calculated. Me [Q25; Q75], Pierson-$\chi 2$ tests were performed. All $p<0.05$ were considered to indicate statistical significance.

Results: Sym-SI was found in 187 (65.1%) pts, asym-SI – in 100 (34.8%) pts. In group (gr) of pts with asym-SI there were more females than in the sym-SI gr: 63 (63.0%) vs 77 (41.2%; p = 0.0004). Pts with asym-SI had more severe peripheral arthritis as measured by Tender Joint Count (TJC68) and Swollen Joint Count (SJC66). These values were higher in asym-SI gr: 9 (4-16) vs 6 (2-14; p = 0.007) and 5 (2-12) vs 3 (0-9; p = 0.004), respectively. High activity according to DAPSA was found in 53 (54.6%) pts in the asym-SI gr vs 71 (38.8%) in the sym-SI gr (p = 0.01); low activity and remission by DAPSA– in 16 (16.5%) pts vs 51 (28.3%; p = 0.028), respectively. The frequency of enthesitis was higher in the asym-SI gr: 50 (57.5%) pts vs 57 (38.5%) pts (p = 0.005). Pts' functional capacity as measured by Health Assessment Questionnaire (HAQ) was worse in the asym-SI gr: HAQ>0.5 values were found in 83 (84.7%) pts vs 130 (72.6%) pts (p = 0.023). No significant differences were found between HLA B27 positivities in sym-SI and asym-SI groups (which were 54.2% and 44.0%, respectively; p = 0.23).

Conclusion: Asym-SI in PsA pts is associated with female gender, more severe peripheral arthritis, higher activity according to DAPSA, more frequency of enthesitis and reduction of pts' functional capacity.

AB0929 IS THERE A CORRELATION BETWEEN SKIN SEVERITY AND JOINT ACTIVITY IN PSORIATIC ARTHRITIS (PSA)?

G. Aldabie[1], M. Sutton[1], D. D. Gladman[1,2]. [1]*University Health Network, Schroeder Arthritis Institute, Toronto, Canada;* [2]*University of Toronto, Division of Rheumatology, Department of Medicine, Toronto, Canada*

Background: The majority if patients with PsA present with skin manifestations first. Few studies have examined the relationship between severity of skin and joint manifestations, but the results have been variable.

Objectives: To assess the correlation between the extent and severity of skin psoriasis and musculoskeletal manifestations of PsA over time.

Methods: This study is a retrospective analysis of prospectively collected data at a single center cohort study of patients who enrolled within 12 months of PsA diagnosis from 2000-2020. Patients are assessed according to a standard protocol which includes demographics, clinical assessment including skin and joint assessments, laboratory evaluation at 6–12-month intervals and radiographs every 2 years. Skin severity is measured by the PASI score, joint disease severity is measured by the number of tender and swollen joints. Axial disease was defined by the presence of bilateral grade sacroiliitis or unilateral grade 3 or 4. The Bath Ankylosing Spondylitis Metrology Index (BASMI) was also measured. Spearman correlations were calculated between PASI scores and joint counts and BASMI (in patients with axial disease). Multivariable analysis was done using negative binomial model for the joint counts and a linear regression for BASMI. This preliminary analysis includes only the baseline information.

Table 1. Baseline characteristics of 397 patients

Variable	Mean (SD)*, Number (%)** N=397
Age (years)	44.97 (13.01)*
PsA duration (years)	0.43 (0.66)*
Psoriasis duration (years)	14.64 (13.65)*
Married	236 (60.5)**
Smoker ever	193 (48.7)**
Alcohol intake	246 (62.3)**
Employed	309 (78.4)**
Post secondary education	277 (71.0)**
BMI	29.21 (8.85)*
PASI	6.11 (9.03)*
Nail	238 (61.2)**
Active joint count (tender ± swollen)	7.3 (13/15)*
Swollen joint count	2.96 (4.93)*
Axial disease	53 (17.8%)**
Treatment level	
None/NSAIDS only	272 (68.2)**
DMARDS ± NSAIDs	98 (24.7)**
Biologics ± DMARDs	27 (6.80)**

Results: 397 patients were included. Characteristics are shown in the Table 1. There was a correlation significant correlation between PASI score and the active joint count (AJC) (ρ 0.14, p=0.0095), swollen joint count (ρ 0.15, p=0.0071). Among the patients with axial disease there was a strong correlation between the PASI and BASMI scores ((ρ 0.58, p=0.0001). Multivariable analysis for AJC revealed traditional DMARDs (0.85 p=0.000). PASI score when patients were on no therapy (0.02 p=0.01) and those on biologics 0.04 p<0.05) were associated with higher AJC. Similarly for swollen joints the use of traditional DMARDs (0.85 P0.00), and the PASI score in those taking biologic DMARDs (0.07 p=0.003) were associated with higher swollen joint count. In patients with axial disease Age (0/05, p=0.004), PASI score in patients on no treatment (0.06 p=0.000) or those taking biologics (0.28 p=0.000) were associated with higher BASMI scores.

Conclusion: In patients presenting within 12 months of diagnosis of PsA, there is a correlation between the severity of skin and joint disease. Further studies will assess whether this correlation persists over time.

AB0930 PSORIATIC ARTHRITIS DISEASE FLARES: IS COVID-19 VACCINATION JUST AN INNOCENT BYSTANDER?

R. Bixio[1], I. Gavioli[1], D. Bertelle[1], F. Pistillo[1], D. Rotta[1], E. Bertoldo[1], E. Fracassi[1], M. Rossini[1], O. Viapiana[1]. [1]*Università degli studi di Verona, Rheumatology section, Verona, Italy*

Background: So far, few studies provided detailed data for the incidence of disease flare after the vaccination against Coronavirus (Covid)-19 in patients with psoriatic arthritis (PsA). Results from small cohorts report an incidence of flares after Covid-19 vaccination of 0-7.7% and disease activity does not seems to be influenced by Covid-19 vaccination in patients with PsA. However, since PsA is a highly fluctuating disease with prolonged remission and irregular reactivation, it is difficult to establish a causal relationship between the Covid-19 vaccination and disease flares.

Objectives: To define the impact of Covid-19 vaccination and disease activity on the incidence of disease flare in patients with psoriatic arthritis (PsA).

Methods: We prospectively evaluated patients with PsA in remission or low-disease activity candidate to receive Covid-19 vaccination with mRNA vaccines, collecting demographic, clinical, and therapeutic data and assessing DAPSA 28, PCR before and after vaccination. We assessed flares using patients and clinician concordance. We retrospectively evaluated flare incidence in the same timeframe of the previous year. We performed statistical analysis to find possible predictors of flares after vaccination.

Results: A total of 57 patients with PsA were prospectively evaluated, and retrospective analysis was possible for 53 of them. DAPSA 28 and CRP did not differ significantly before and after the vaccination. The incidence of flares in the two periods (2020 vs 2021) did not differ significantly (18.8% vs 8.8%, p=0.166). We found a higher basal mean DAPSA 28 in patients who flared up after vaccination (7.3 vs 4.1, p-value 0.046). Only having a flare in the previous year was associated with a higher chance of recurrence after Covid-19 vaccination (p=0.02) in the logistic regression analysis, while other predictors (age, gender, disease activity, ongoing DMARD therapy, ongoing bDMARD therapy) did not.

Conclusion: Our findings suggest that, in patients with PsA, disease activity could be the main driver of disease flares rather than Covid-19 vaccination.

Background: The Psoriatic Arthritis Impact of Disease (PsAID) questionnaire is the standard tool for evaluating the impact of psoriatic arthritis (PsA) on quality of life [1]. Variables associated with high disease impact were studied in patients with long-standing established disease. The characteristics associated with high-impact PsAID in recent-onset PsA remain unknown.
Objectives: To evaluate which patient and disease characteristics are associated with the perception of high-impact disease (PsAID ≥4) in recent-onset PsA. All patients gave their informed consent. The study was approved by the Clinical Research Ethics Committee of the Principality of Asturias. We conducted a cross-sectional analysis. The dataset was generated using data for the independent variables at the 3 visits (baseline, first year, and second year of follow-up) matched with the PsAID values at each of the 3 visits. PsAID was categorized into two groups, namely, <4 and ≥4 [1]. We trained logistic regression models and a random forest–type machine learning algorithm to analyze the association between the outcome measure and the variables selected in the bivariate analysis (statistical significance defined as p value <0.05). We used a confusion matrix to visualize the performance of the final model. This matrix shows the real class of the data items, together with the class predicted by the machine learning algorithm, and records the number of hits and misses.
Results: The sample comprised 158 patients. 20.9% were lost to follow-up. Of the patients who attended the clinic, 45.8% scored PsAID ≥4 at baseline; 27.1%, at the first follow-up visit, and 23.0%, at the second follow-up visit. The variables associated with PsAID ≥4 selected in the logistic regression analysis were HAQ, patient global pain during the previous week, educational level, and level of physical activity in the previous week. The association was positive for the first 2 variables and for level of physical activity and negative for educational level. When physical activity was introduced as a categorical variable, a possible negative association was observed for a moderate level (although this was not statistically significant) and a positive association was observed for a high level (Table 1).

Table 1. Variables associated with PsAID ≥4: Logistic regression analysis.

Variable	Regression coefficient	95% CI	p value (Wald test)
HAQ	10.394	[7.777, 13.011]	<0.001
Patient global pain in the previous week	5.668	[4.016, 7.320]	<0.001
Educational level	-2.064	[-3.515, -0.613]	0.005
Moderate level of physical activity in the previous week	-0.341	[-1.255, 0.573]	0.465
High level of physical activity in the previous week	1.221	[0.158, 2.283]	0.024

When the random forest–type machine learning algorithm was trained with these 4 variables, the order of importance (from more to less) attributed by the model was: patient global pain, HAQ, educational level, and physical activity. The percentage of hits in the confusion matrix was 86.14%.
Conclusion: Pain control and control of the disease as a whole, preventing patients from suffering a decrease in their functional capacity, are first-order treatment objectives. PsA patients should take regular physical exercise, but with a moderate or low impact on their joints and entheses.

AB0932 PATIENT AND LEARNER EXPERIENCE IN A NEW SET UP OF A RHEUM-DERM COMBINED CARE MODEL FOR PSORIATIC ARTHRITIS

C. Hong[1], L. Fang[1], Y. W. Yeo[2], H. Y. Lee[2], A. Low[1], Y. Y. Leung[1]. *[1]Singapore, Rheumatology & Immunology, Singapore, Singapore; [2]Singapore, Dermatology, Singapore, Singapore*

Background: Psoriasis (PsO) and musculoskeletal manifestations are common among patients with psoriatic arthritis (PsA). A shared-care model between rheumatologists and dermatologists has been advocated to promote early diagnosis and improve management care. Data from Asia is scanty. Patients' and learners' experience of shared-care models are seldom explored.
Objectives: We described the set-up of a new shared-cared PsA-PsO clinic incorporating service, education and research between rheumatologist and dermatologist for PsA. We describe the patients' and learners' experience of this shared-care model.
Methods: A combined care clinic was newly set up in 2019. Referrals were internal through either specialty. Each patient was first seen by a trainee, followed by both a dermatologist and rheumatologist simultaneously in the same consultation room. We collected patients' and learners' experience through self-administered survey.
Results: From May 2019 to January 2020, data from 44 visits (55% new referrals, 45% follow-up) from 28 patients were captured in the PsA-PsO clinic. 50% of cases were referred from either specialty. 34% were referred for diagnostic doubts, 66% were for therapeutic issues. 61% of patients continued follow-up in the PsA-PsO clinic, and 39% discharged back to respective care. From patients' experience rated on scale from 0-10, median (interquartile range, IQR) rating of the care was 8 (7, 8). 69.2% and 96% of patients would recommend the care to others. Free text comments included enhanced convenience, time saving, and having both specialties input on management. From 20 learners (3 medial students, 12 residents, 4 senior residents and one scientist), 95% reported extremely or very beneficial to training, 77.8% reported improved confidence in care for PsA and/or PsO patients. The PsA-PsO clinic was temporally suspended during the Covid-19 viral pandemic since February 2020 due to lack of manpower and not fulfilling the spacing out requirement for infectious control. The service was resumed gradually from May 2021.
Conclusion: Despite challenges, we report the setup of a new care model between dermatologists and rheumatologists for care of patients with psoriatic disease. The care model was well received by patients. Learners from various levels reported benefit from the learning experience.

AB0933

DEVELOPMENT AND VALIDATION OF A NOMOGRAM FOR PREDICTION OF NONALCOHOLIC FATTY LIVER DISEASE IN PSORIATIC ARTHRITIS

B. C. LI[1], R. Su[1], H. Yan[1], J. Liu[2], C. Wang[1]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China;* [2]*The Second Hospital of Shanxi Medical University, Department of General, Taiyuan, China*

Background: Psoriatic arthritis (PsA) has been linked to an increased risk of metabolic syndrome (MetS). Non-alcoholic fatty liver disease (NAFLD), the hepatic manifestation of MetS, is now the commonest liver disease worldwide. About 65% of PsA patients suffer from NAFLD, and chronic systemic inflammation may be an important predisposing factor.
Objectives: The purpose of this study was to establish and validate a diagnostic model nomogram for predicting the occurrence of NAFLD in patients with PsA.
Methods: A total of 127 PsA patients (46 had NAFLD and 81 had no NAFLD) were enrolled in this study. Retrospectively collected clinical and serological parameters of these patients. The percentage and absolute number of lymphocytes and CD4+T cells were determined by Flow cytometry. The independent risk factors for NAFLD were screened in the PsA patients using univariate and multivariate binary logistic regression analyses and were used for construction of the nomogram prediction model. The AUROC (C index) was used to verify the model discrimination; the calibration curve and Hosmer-Lemeshow test were used to verify the model calibration; and the DCA curve was used to verify the clinical validity of the model.
Results: Univariate and multivariate logistic regression analyses showed that Body Mass Index (BMI) (OR=1.25, *P*=0.001), serum triglyceride (TG) (OR=3.51 , *P*=0.015) and peripheral blood Th1 cell percentage (OR=1.12, *P* < 0.001) is an independent risk factor for NAFLD in PsA patients, and an individualized nomogram prediction model was successfully established. The prediction model had a good discrimination power with AUROC (C-index) of 0.83 (95% *CI*: 0.76-0.90); the P value in the Hosmer-Lemeshow test was 0.683, suggesting a high reliability of the predicted probability by the model; the DCA curve indicating a good clinical efficiency of the model.
Conclusion: Our study shows that the establishment of a nomogram prediction model of PsA complicated with NAFLD patients is helpful for early clinical screening and identification of such high-risk patients.

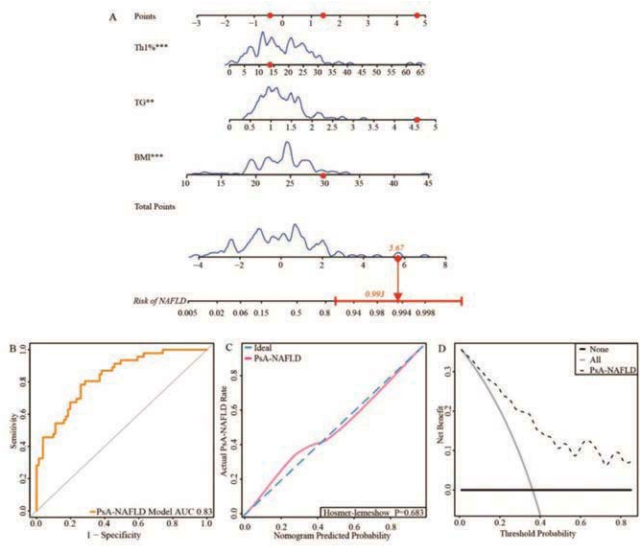

Figure 1. A. Example of prediction nomogram for risk of PsA complicated with NAFLD patients; B. The ROC curve of the prediction model; C. The calibration curve of the prediction model; D. The decision curve analysis of the prediction model.

DOES THE SEVERITY OF PSORIASIS IMPACT ON PSORIATIC ARTHRITIS ACTIVITY? DATA FROM RHEUMATOLOGICAL CLINICAL PRACTICE

M. Chamurlieva[1], E. Loginova[1], T. Korotaeva[1], Y. Korsakova[1], E. Gubar[1], L. Vorobyova[1], P. Tremaskina[1], S. Glukhova[2], A. Lila[2,3], I. Patrikeeva[4], P. Shesternya[5]on behalf of RU-PsART. [1]*V.A.Nasonova Research Institute of Rheumatology, Department of spondyloarthritis and psoriatic arthritis, Moscow, Russian Federation;* [2]*V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation;* [3]*Russian Medical Academy of Continuing Professional Education, Rheumatology, Moscow, Russian Federation;* [4]*Tyumen Regional Clinical Hospitai №1, Rheumatology, Tyumen, Russian Federation;* [5]*Krasnoyarsk State Medical University V.F. Voino-Yasenetsky, Rheumatology, Moscow, Russian Federation*

Background: Psoriatic arthritis (PsA) is a chronic, musculoskeletal inflammatory disease that develops in up to 30% of patients (pts) with psoriasis (PsO). There are conflicting data about correlations between skin and joint severity from the observational cohort [1, 2]. But it's very important for clinical phenotyping and treatment PsA pts.
Objectives: to evaluate association between PsO severity and PsA activity.
Methods: 778 (M/F=357/421) PsA pts fulfilling the CASPAR criteria were included into Russian rheumatological observational cohort. Mean age 46.7±13 years (yrs), DAPSA 29.05±19.7, CRP - 15.3±23 mg/l, SJC/66 - 6.6±7.5, TJC/68 – 10.6±10.2, LEI – 1.06±1.4. All pts underwent standard clinical examination: tender joins count (TJC)/68, swelling joints count (SJC)/66, CRP (mg/l), DAPSA, dactylitis, enthesitis by LEI, nail/skin PsO was evaluated. All pts were divided in two groups based on BSA≤3% (mild PsO) and BSA>3% (moderate/severe). M±SD, Me [Q25; Q75], Min-Max, %, t-test, Pierson-χ2, Manna-Whitney tests, ORs with 95% CI were performed. All p<0.05 were considered to indicate statistical significance.
Results: BSA≤3% was found in 427 out of 778 pts (54.9%), BSA>3% in 352 pts out of 778 (45.2%). Nail PsO were seen in 258 out of 778 (33.2%). Among these pts with BSA>3% nail PsO were seen in significantly more cases - 135 out of 258 pts (52.3%) (p=0.03). In pts with BSA>3% all parameters of PsA activity (DAPSA, SJC, TJC, CRP) was significantly higher compare to pts with BSA≤3% (for all p<0.0001). The one-factor model of logistic regression shown that PsO severity significantly associated with nail PsO, higher PsA activity by DAPSA, CRP, SJC, TJC and smoking (OR analysis with CI 95% for all parametres are shown on Figure 1).

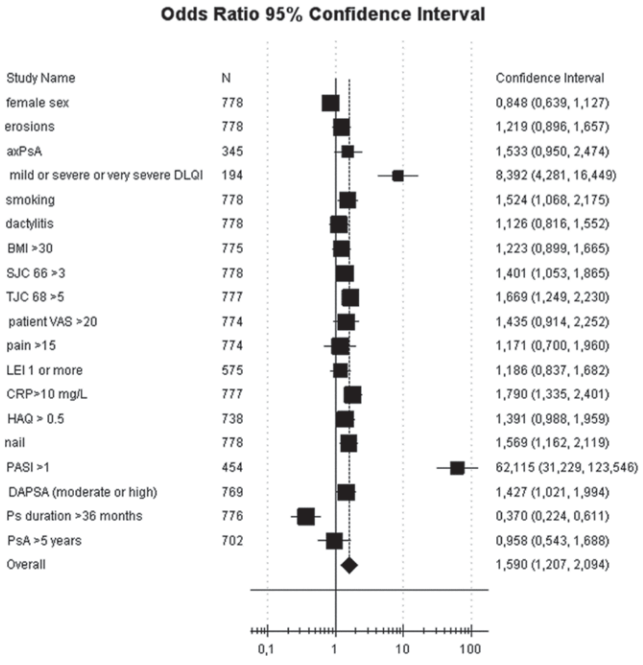

Figure 1. Forest plot of factors associated with psoriasis severity in PsA pts.

Conclusion: In our observational cohort about half of PsA pts had severe PsO. Skin severity associated with higher PsA activity. It should be taken into account for choice of properly treatment both for skin and joint in clinical practice.
