Background: Gout is a highly prevalent inflammatory arthritis with increasing global disease burden in recent years.[1,2] Gout prevalence has been reported to be higher among Blacks compared to Whites,[3] and that they are less likely to receive allopurinol in outpatient care.[4] The potential nationwide impact of these racial disparities on emergency department (ED) visits and hospitalizations is unknown.

Objectives: To examine the contemporary racial disparities in ED visits and hospitalizations with a primary discharge diagnosis of gout in the US (2019).
Methods: We compared ED visits and hospitalizations between Blacks and Whites in the latest data (2019) from the US National Emergency Department Sample (NEDS) and National Inpatient Sample (NIS). We focused on encounters for which the primary diagnosis was gout based on ICD codes (M1A.xx, M10.xx). We calculated annual population rates of ED visits and hospitalizations for gout (per 100,000 US adults) using the 2019 US census adult population (>18 years) according to race.
Results: There were a total of 160,759 ED visits and 9,560 hospitalizations among White and Blacks with a gout diagnosis in the US in 2019. The mean age (58.2 years vs. 56.5 years) and male proportion (78.0% vs. 74.8%) tended to be higher among Whites, while more Blacks tended to live in the South (40.7% vs. 66.5%) and reported a median household income of < $50,000 (30.7% vs. 57.1%). Compared to Whites, Blacks had 2.7- and 3.2-fold higher rates of gout ED visits and hospitalizations, respectively, after adjusting for age, sex, payer, region, and household income (Table 1 & Figure 1). Black women, in particular, had 3.4- and 4.0-fold higher rates of ED visits and hospitalizations compared to White women, while the corresponding rate ratios for men were 2.5 and 2.8, respectively. The mean costs per gout ED visit were similar for Blacks compared to Whites (adjusted difference, -$7.6 [95% CI, -25.4 to 1.0]), while hospitalizations were more costly (adjusted difference, $1,055.3 [95% CI, 553.1 to 1557.5]). The duration of ED visits and hospitalizations was also higher among Blacks than Whites (adjusted difference of 0.41 days [95% CI, 0.19 to 0.63] and 0.59 days [95% CI, 0.25 to 0.94], respectively).

Table 1. Racial Disparities in Emergency Department Visits and Hospitalizations with Primary Diagnosis of Gout in 2019

	Emergency Department Visits		Hospitalizations

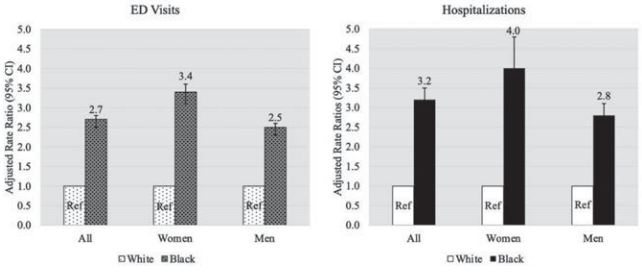
*Adjusted for age and sex for all, adjusted for age for sex-specific rate ratios**Adjusted for age, sex, payment, region, and household income

Figure 1. Racial Disparities in Emergency Department Visits and Hospitalizations with Primary Diagnosis of Gout in 2019



Conclusion: These latest national data indicate that ED visits and hospitalization due to gout are both 3 times higher among Blacks than Whites; this disparity was particularly prominent among women with gout. Higher risk of developing gout[3] and suboptimal care[4] both translate to these avoidable costly healthcare utilizations, calling for improved primary prevention and gout care.

POS1172 RISK OF VENOUS THROMBOEMBOLISM AFTER GOUT FLARES

E. Cipolletta[1,2], G. Nakafero[2], M. Mamas[3], A. Avery[4], L. Tata[5], A. Abhishek[2].
[1]Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Ancona, Italy; [2]University of Nottingham, Academic Rheumatology, Nottingham, United Kingdom; [3]Keele University, Keele Cardiovascular Research Group, Stoke-on-Trent, United Kingdom; [4]University of Nottingham, Division of Primary Care, Nottingham, United Kingdom; [5]University of Nottingham, Division of Epidemiology and Public Health, Nottingham, United Kingdom

Background: Several population-based cohort studies have reported an increased risk of venous thromboembolism (VTE) in gout patients. However, none of these studies has investigated the temporal relationship between gout flares and VTE.
Objectives: To explore whether gout flares increase the risk of VTE in the short-term using the self-controlled case series (SCCS) method.
Methods: We identified participants with incident gout from the Clinical Practice Research Datalink (CPRD). Participants having less than one year of registration in CPRD and patients with a history of VTE or anticoagulant prescription more than one year before the first gout consultation were excluded. Participants with at least one gout flare and a diagnosis of VTE were selected. VTEs and gout flares were ascertained using primary care data, hospitalisation and mortality records, using previously validated algorithms (positive predictive value of 94% for VTE [1] and 68-95% for gout flares [2,3]). SCCS method involves fitting a Poisson model conditioned on the number of VTEs, and it calculates the adjusted incidence risk ratio (aIRR) and its 95% confidence interval (95%CI) for each stratum of the "at-risk" period as compared with the "baseline" period (Figure 1). The analysis was adjusted for age and calendar season.

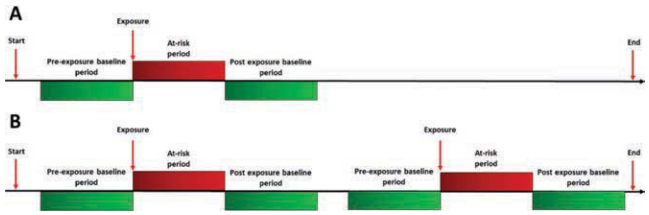

Figure 1. Schematic description of the observation period ("at-risk" and baseline periods).

The "at-risk" period (in red) was defined as the period following the exposure (the gout flare), and it was subdivided as follows: days 0-30, 31-60 and 61-120 after each gout flare. The baseline period (in green) consisted of a pre-exposure and a post-exposure period of 365 days each. The length of each period varied according to the occurrence of the next flare and its timing. Panel A and panel B provide a schematic representation of patients with a single observation period and with multiple "non-overlapping" observation periods, respectively. In such cases, the length of the "at risk" period was 120 days, while the length of the pre-exposure and post-exposure period was 365 days each.
Results: Among the 104,962 patients with an incident diagnosis of gout in CPRD between 1997 and 2020, we identified 2,678 VTE (4.0 events/1,000 person-years). There were 53 VTE (13.3 events/month) during the "at-risk" period and 143 (6.0 events/month) during the "baseline" period (crude incidence rate ratio, 1.75; 95%CI: 1.27-2.42). The rates were highest in the first month after gout flares and then fell progressively (Table 1). Sensitivity analyses were consistent with the main analysis (Table 1).

Table 1.

Gout flare	Number of events per month	aIRR (95%CI)	p_{trend}
Main analysis			
0-30 days	17.0	2.11 (1.27-3.50)	0.01
31-60 days	14.0	1.86 (1.07-3.24)	
61-90 days	11.0	1.50 (0.95-2.37)	
Baseline period	6.0	Reference	
Sensitivity analysis (excluding participants with risk factors for VTE) [4]			
0-30 days	14.0	3.13 (1.77-5.53)	0.01
31-60 days	7.0	1.66 (0.76-3.61)	
61-90 days	8.0	1.75 (0.94-3.37)	
Baseline period	3.4	Reference	

Conclusion: A transitory increase in the risk of VTE was observed after gout flares.

POS1173

CLINICAL PRESENTATION AND TREATMENT OF STERNOCOSTOCLAVICULAR HYPEROSTOSIS (SCCH): A SYSTEMATIC REVIEW AND META-ANALYSIS OF SCATTERED EVIDENCE

A. Leerling[1], O. Dekkers[2], N. Appelman-Dijkstra[1], E. Winter[1]. [1]*Leiden University Medical Center, Internal Medicine, Division of Endocrinology, Center for Bone Quality, Leiden, Netherlands;* [2]*Leiden University Medical Center (LUMC), Internal Medicine, Division of Endocrinology, Leiden, Netherlands*

Background: Sternocostoclavicular hyperostosis (SCCH) is an inflammatory bone disorder within the spectrum of chronic non-bacterial osteomyelitis. SCCH can be a manifestation of SAPHO syndrome, standing acronym for synovitis, acne, pustulosis, hyperostosis and osteitis, but also appears as an isolated clinical entity without joint and skin involvement[1,2]. Consensus on nomenclature, diagnostic classification, and therapy for SCCH is currently lacking[3]. Literature is diffuse, and spreads over a wide range of medical disciplines, calling for a first systematic overview.
Objectives: We critically appraised literature with the aim to i) gain overview on the clinical presentation of SCCH and features leading to diagnosis and to ii) evaluate different treatment modalities and treatment response. We focused on the clinical entity of SCCH in adults, either isolated or as a part of SAPHO syndrome.
Methods: We conducted a systematic review and meta-analysis according to the PRISMA guidelines on the clinical presentation and therapeutic modalities applied in adult SCCH patients. Studies covering these respective domains were selected. Risk of bias was assessed using validated tools according to study type. Untransformed numerical data and double-arcsine transformed proportional data were analyzed in a random effects model in R-4.0.5; pooled proportions were reported with 95% confidence intervals (95%CI). Treatment response was categorized as good, partial, or none.
Results: 28(i) and 12(ii) studies were included, containing heterogeneous data on 1818 patients. A female predisposition (67%, 95%CI 60-73) and major diagnostic delay (5 years 95%CI 3-7) were noted. Clinical presentation was marked by anterior chest pain (89%, 95%CI 79-96), and swelling (79%, 95%CI 62-91). Pustulosis palmoplantaris was present in 53%, 95%CI37-68, whereas acne (8%, 95%CI4-13) and peripheral arthritis (24%, 95%CI 11-39) were less prevalent. Inflammatory markers were inconsistently elevated and autoantibodies and HLA-B27 prevalence normal. Histopathology was unspecific, and cultures almost exclusively negative. Increased isotope uptake (99%, 95%CI96-100) was the most consistent imaging finding. Amongst manifold treatments (see Figure 1), NSAIDs were mainly partially effective. Pamidronate and biologicals (mainly TNF-α inhibitors) yielded good, though heterogeneous, response in 83%, 95%CI 60-98 and 56%, 95%CI 26-85 respectively.

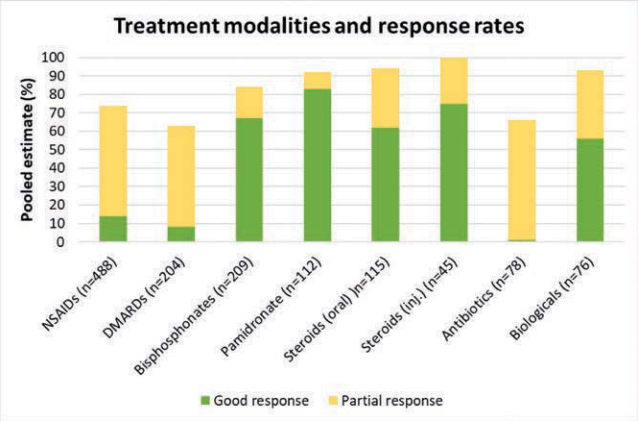

Figure 1. Treatment modalities applied in SCCH and their effects on bone pain (data from trials and several cohort studies combined)

Conclusion: Literature on SCCH is extremely heterogeneous. Timely diagnosis proves challenging and mainly follows from the increased isotope uptake on nuclear examination. Biopsies, autoantibodies and HLA-status are non-contributory, and inflammatory biochemical profiles only variably detected. Pamidronate and TNF-α inhibitors emerged as promising therapies, but powered, placebo-controlled research with standardized measures of response is warranted. Inherently, international consensus on SCCH's diagnostic classification and name appears critical to improve scientific collaboration on this rare disease, and to advance the development of clinical guidelines.

POS1174

COLCHICINE TREATMENT IN GOUT PATIENTS – IMPACT ON CARDIOVASCULAR EVENTS AND ON MORTALITY

Y. Braun-Moscovici[1], L. Gabay[2], Y. Butbul[3]. [1]*Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Rheumatology Institute, Haifa, Israel;* [2]*Kahn-Sagol-Maccabi Research and Innovation Institute, Maccabi Healthcare Services, Tel Aviv, Israel, Epidemiology, Tel Aviv-Yafo, Israel;* [3]*Ruth Rappaport Children's Hospital, Rambam Medical Center, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Pediatric Rheumatology Service, Haifa, Israel*

Background: Gout and hyperuricemia are independent risk factors for cardiovascular events and increased mortality. A significant proportion of gout patients receive colchicine, additionally to urate-lowering therapy.
Recently, colchicine treatment was found to reduce the risk of cardiovascular events in patients with chronic cardiac disease.
Objectives: To assess the incidence of cardiovascular events and the mortality rate among gout patients who received colchicine treatment.
Methods: This retrospective cohort study was conducted using data from the Maccabi Healthcare Services (MHS) central computerized database. MHS is the second largest state-mandated health care provider in Israel, covering >2.5 million members (25% of the population) and is a representative sample of the Israeli population. The study included gout patients from the MHS registry aged ≥40 years who received colchicine for at least 3 months and a control group matched by age, gender and socioeconomic status. The data extracted included smoking status, body mass index (BMI), co-morbidities (diabetes, hypertension, chronic renal disease, hyperlipidemia, malignancy), antiplatelet and anticoagulant treatment, cardiovascular events and mortality rate. The statistical analysis included univariate and cox regression analysis.

Results: 3671 individuals were included in each group (mean(SD) age 56(12.5), 87% males, mean(SD) follow-up 2744.7(1616.2) days). The gout group had a statistically significant higher incidence (p<0.001) of cardiovascular events (14.7% vs 10.8%), high BMI (35.1% vs 15%), diabetes (17% vs 12.7%), hypertension (52% vs 32.4%), chronic renal disease (35% vs 15%), hyperlipidemia (65% vs 46%). The mortality rate was similar (8.9% vs 7.9%, p=0.11) for both groups. The mortality hazard ratio (95% CI) for gout patients was 1.18 (1-1.39, p=0.05), for diabetes 1.6 (1.3-1.9, p<0.0001), for hypertension 1.38 (1.1-1.67, p=0.002).
Conclusion: Although the gout patients had a higher incidence of co-morbidities and cardiovascular events, the mortality rate was not significantly different compared to the matched group. Chronic colchicine treatment might have a protective effect. Further long-term studies are required.

POS1175 IMPACT OF COVID-19 ON THE CLINICAL COURSE OF GOUT AND THE OVERALL USAGE OF MEDICATION IN PATIENTS WITH GOUT

S. Smiyan[1], O. Makhovska[1]. *[1]Ternopil National Medical University, Internal Medicine No. 2, Ternopil, Ukraine*

Background: Data on the course and outcomes of the coronavirus disease 2019 (COVID-19) in patients with gout are scarce, as gout is underrepresented in leading COVID-19 and rheumatological scientific publications [1].
Objectives: To describe clinical changes, quality of life, therapy of gout before and after COVID-19, and the clinical course of severe acute respiratory syndrome-related coronavirus 2 (SARS-Cov-2) infection in the cohort of patients with gout.
Methods: In total, 84 males with gout were examined before the pandemic, during COVID-19 (March 2020 to December 2021) and 6 months after SARS-Cov-2 infection. The severity of COVID-19 in our cohort was determined. We conducted a comparative analysis of clinical and laboratory data, Gout Activity Score (GAS), urate-lowering (UST) and symptomatic therapy, Physical Component Summary (PCS) and Mental Component Summary (MCS) of the Short Form 36 (SF-36) Health Survey Questionnaire. Statistical difference of qualitative indicators was carried out using the Pearson Chi-square test ($\chi 2$), quantitative indicators using the Student's or the Wilcoxon test between groups.
Results: The mean age (mean±SD) of the study patients was 51.07±7.45 years and the disease duration was 9.84±6.02 years. Most SARS-CoV-2 infected patients with gout exhibited a moderate illness (40.48%), almost every third (28.57%) had mild, 21.43% had severe and 9.52% had critical illness. Comparison of pre-COVID-19 vs 6-month post-COVID-19 data demonstrated an increase of gout flares in preceding 6 months (0.7±0.59 vs 4.35±2.25, p<0.001), serum uric acid level (5.9±1.54 vs 7.62±1.99, p<0.01), GAS (3.83±0.4 vs 6.1±1.63, p<0.01), non-steroidal anti-inflammatory drug intake (19.05% vs 72.62%, p<0.001), colchicine (27.38% vs 53.6%, p<0.001), and corticosteroid use (5.95% vs 34.52%, p<0.001), but decreased intake of ULT (88.09% vs 77.38%, p>0.05), SF-36 PCS (43.7 ± 6.19 vs 36.08±6.54, p<0.01) and SF-36 MCS (48.35±5.89 vs 40.13±6.84, p<0.01).
Conclusion: The current study identified the majority of patients with gout had a moderate course, every fifth had a severe course and 9.52% had a critical course of COVID-19. In the post-COVID-19 period, we found a six-fold increase in gout flares, rising gout activity by 59.3%, more frequent medication use for symptomatic therapy of gout, decreased physical and mental health in the cohort of patients with gout.

POS1176 EFFECT OF LIFESTYLE CHANGE ON INCIDENT GOUT: A NATIONWIDE POPULATION-BASED COHORT OF YOUNG MEN

Y. Eun[1], K. D. Han[2], S. W. Lee[3], S. Y. Kang[4], S. Lee[4], H. S. Cha[4], E. M. Koh[4], H. Kim[4,5], J. Lee[4]. *[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea); [2]Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea); [3]College of Medicine, Catholic University of Korea, Department of Biomedicine & Health Science, Seoul, Korea, Rep. of (South Korea); [4]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of (South Korea); [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medical Humanities, Seoul, Korea, Rep. of (South Korea)*

Background: Although gout in young people is increasing, studies on the risk factors for gout in these people are lacking.
Objectives: In this study, we explored the risk factors of gout and effect of lifestyle change on the development of gout in large nationwide population-based cohort of young men.
Methods: Between 2009–2012, men aged 20–39 years who participated in two national health examinations at 2-year intervals were included in the study. The outcome was occurrence of gout, which was defined using the diagnosis code of gout (ICD-10 code M10) in the claims database. Cox proportional hazard model was used to evaluate the association between incident gout and baseline factors or lifestyle change.
Results: A total of 1,977,849 subjects were included in the study, and the mean follow-up period was 5.5 ± 4.3 years. Gout occurred in 38,839 subjects (incidence rate = 3.59/1,000 person-years). A high body mass index, alcohol drinking, and comorbidities such as hypertension, diabetes mellitus, and hyperlipidemia were associated with an increased risk of gout. Among lifestyle factors, change in obesity had the greatest impact on gout, followed by drinking. Development of obesity increased the risk of gout by 1.75 times (95% CI 1.68–1.81), and recovery from obesity decreased the risk of gout by 40% (aHR 0.60, 95% CI 0.57–0.64). Heavy drinking increased the risk of gout by 38% (aHR 1.38, 95% CI 1.33–1.43), and stopping heavy drinking decreased the risk of gout by 11% (aHR 0.89, 95% CI 0.85–0.94). The effect of obesity on gout was evident in the younger age group, and the effect of heavy drinking on gout was weak in the severely obese group.
Conclusion: Obesity and heavy drinking in young men are important modifiable risk factors for gout. Therefore, the management of these risk factors in young men should be emphasized.

POS1177 TREATMENT OF GOUTY ARTHRITIS IS ASSOCIATED WITH RESTORING GUT MICROBIOTA AND PROMOTING PRODUCTION OF SHORT CHAIN FATTY ACIDS

S. J. Lee[1], H. K. Park[1]. *[1]School of Medicine, Kyungpook National University, Korea, Internal Medicine, Daegu, Korea, Rep. of (South Korea)*

Background: Although factors initiating the inflammatory response to monosodium urate crystals have been identified, the role of the gut microbiota and their metabolites on gout remain unknown.
Objectives: This study aimed to investigate changes in both gut microbiota and short chain fatty acids (SCFAs) according to inflammatory states of gout in the same patients.
Methods: This study enrolled 20 patients with gout in the acute state who had active joints and were followed-up until the recovery state with no active joints. Blood and fecal samples were simultaneously collected within 3 days for each disease state. The stool microbiome was analyzed using 16S rRNA sequencing, and serum SCFAs were measured by gas chromatography-mass spectrometry. Differences in gut microbiome and serum SCFAs were compared between the acute and recovery states.
Results: Beta diversity of the microbiome was significantly different between the acute and recovery states in terms of weighted UniFrac distance. In the recovery state, Prevotellaceae (p = 0.006) and the genus *Prevotella* (p = 0.009) were significantly enriched, whereas Enterobacteriaceae (p = 0.019) and its derivative genus *Shigella* (p = 0.023) were significantly decreased compared to the acute state. Similarly, the levels of acetate was dramatically increased in the recovery state compared to the acute state (p < 0.010). Levels of propionate and butyrate tended to increase but without statistical significance.
Conclusion: Substantial alterations of bacterial composition with promotion of SCFA formation (especially acetate) were found after treatment in patients with gouty arthritis.

Background: Rituximab (RTX) induces rapid, usually complete and prolonged depletion of circulating B cells, and also hypogammaglobulinemia in some patients. There are limited data regarding the risk of severe infection events (SIE) when initiating or continuing rituximab in patients with acquired hypogammaglobulinemia, especially in patients suffering from autoimmune diseases (ADs) other than rheumatoid arthritis (RA) (1).
Objectives: To describe the risk of severe infectious events (SIE) following initiation (rituximab-naïve patients [RNP]) or continuation of RTX therapy (rituximab-continuing patients [RCP]) in patients suffering from severe ADs other than RA and acquired hypogammaglobulinemia.
Methods: We conducted a single-center retrospective cohort study at the University Hospital of Toulouse (France) between 2010 and 2018. Patients were included if they had received at least one dose of RTX in the year following the evidence of hypogammaglobulinemia (defined as gammaglobulins [GG]≤ 6g/L on serum protein electrophoresis) in the setting of ADs other than RA. The primary outcome was the occurrence of a SIE within 2 years after the date of first RTX infusion (T0) prescribed after the evidence of hypogammaglobulinemia. SIE were infections either fatal or requiring hospitalization.
Results: We included 121 patients (37 RNP and 84 RCP): 48 had ANCA-associated vasculitis (AAV), 48 multiple sclerosis (MS, n=41) or neuromyelitis optica (NMO, n=7), and 21 another severe AD. RTX was prescribed as induction therapy in 39 patients and as maintenance therapy in 82; 112/121 patients were followed for 2 years. Mean GG level were 5.5 g/L (IQ_{25-75} 4.6-5.7) at T0, 5.5 g/L (IQ_{25-75} 5-6.4) at one year, 5.7g/L (IQ_{25-75} 4.8-6.1) at two years and 8 patients had a decrease of their GG level below 4g/L. Ten patients received immunoglobulin replacement therapy (IGRT) mostly after infection (n=6). Twenty-six patients (23.2%) had at least one SIE during follow-up: 12.8 % in the MS/NMO group with a 2-year incidence at 6.9 (3.1-15.3) per 100 person-years, 29.5 % in the AAV group with a 2-year incidence at 18.3 (9.3-20.1) per 100 person-years, 33.3 % in the 'other ADs' group with a 2-year incidence at 22.2 (10.6-46.5) per 100 person-years. Infection was opportunistic in 8 patients (33.3%) and 4 died from SIE. Risk factors of SIE at T0 were male gender (61.5% vs. 39.5% p<0.05), lung disease (65.4% vs. 37.2% p=0.01), renal failure (59.1% vs. 28.6% p=0.01), a higher Charlson comorbidity index (p=0.001), a previous treatment by cyclophosphamide (53.8% vs. 30.2%; p=0.03), ≥ 5 mg/d prednisone (69.2% vs. 33.7%, p=0.003), lack of pneumococcal vaccination (61.5% vs 31.4%, p=0.01). GG level was 5.3 g/l [4.1-5.6] in the 'SIE' group vs 5.6 g/l [4.8-5.8] in the 'no SIE' group (p=0.04). Incidence of SIE was 46% and 20.2% among patients with GG< 4 g/L or GG≥ 4 g/L, respectively (p=0.07). No multivariable analysis provided reliable results.
Conclusion: Our study provides useful information for clinicians considering initiating or continuing rituximab therapy in patients with acquired hypogammaglobulinemia before Sars-Cov2 era. Prospective studies are necessary to improve the knowledge on outcome of patients treated by rituximab despite low immunoglobulins levels. Prophylactic IGRT may be appropriate in higher risk patients, especially if the GG level is below 4 G/L.

POS1179 SYSTEMATIC LITERATURE REVIEW ON THE SCREENING AND PROPHYLAXIS OF CHRONIC AND OPPORTUNISTIC INFECTIONS

G. E. Fragoulis[1], M. Dey[2], S. S. Zhao[3], D. Courvoisier[4], J. Galloway[5], K. Hyrich[6], E. Nikiphorou[5]on behalf of EULAR Task Force for the screening and prophylaxis of chronic and opportunistic infections in Autoimmune Rheumatic Diseases.. *[1]National and Kapodistrian University of Athens, Joint Academic Rheumatology Programme, Athens, Greece; [2]University of Liverpool, Institute of Life Course & Medical Sciences, Liverpool, United Kingdom; [3]University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [4]University of Geveva, Department of Medicine, Geneva, Switzerland; [5]King's College London, Centre for Rheumatic diseases, London, United Kingdom; [6]University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom*

Background: Opportunistic and chronic infections can arise in the context of treatment used for Autoimmune Rheumatic Diseases (ARDs). Although it is recognized that screening procedures and prophylactic measures must be followed, clinical practice is largely heterogeneous, with relevant recommendations not currently developed or disparately located across the literature.
Objectives: To conduct a systematic literature review (SLR) focusing on the screening and prophylaxis of opportunistic and chronic infections in ARDs. This is preparatory work done by members of the respective EULAR task force (TF).
Methods: Following the EULAR standardised operating procedures, we conducted an SLR with the following 5 search domains; **1) Infection:** infectious agents identifed by a scoping review and expert opinion (TF members), **2) Rheumatic Diseases**: all ARDs, **3) Immunosuppression:** all immunosuppressives/immunomodulators used in rheumatology, **4) Screening:** general and specific (e.g mantoux test) terms, **5) Prophylaxis:** general and specific (e.g trimethoprim) terms. Articles were retrieved having the terms from domains 1 AND 2 AND 3, plus terms from domains 4 OR 5. Databases searched: Pubmed, Embase, Cochrane. Exclusion criteria: post-operative infections, pediatric ARDs, not ARDs (e.g septic arthritis), not concerning screening or prophylaxis, Covid-19 studies, articles concerning vaccinations and non-English literature. Quality of studies included was assessed as follows: Newcastle Ottawa scale for non-randomized controlled trials (RCTs), RoB-Cochrane tool for RCTs, AMSTAR2 for SLRs.
Results: 5641 studies were initially retrieved (Figure 1). After title and abstract screening and removal of duplicates, 568 full-text articles were assessed for eligibility. Finally, 293 articles were included in the SLR. Most studies were of medium quality. Reasons for exclusion are shown in Figure 1. Results categorized as per type of microbe, are as follows: For *Tuberculosis*; evidence suggests that tuberculin skin test (TST) is affected by treatment with glucocorticoids and conventional synthetic DMARDs (csDMARDs) and its performance is inferior to interferon gamma release assay (IGRA). Agreement between TST and IGRA is moderate to low. Conversion of TST/IGRA occurs in about 10-15% of patients treated with biologic DMARDs (bDMARDs). Various prophylactic schemes have been used for latent TB, including isoniazide for 9 months, rifampicin for

4 months, isoniazide/rifampicin for 3-4 months. For *hepatitis B (HBV)*: there is evidence that risk of reactivation is increased in patients positive for hepatitis B surface antigen. These patients should be referred for HBV treatment. Patients who are positive for anti-HBcore antibodies, are at low risk for reactivation when treated with glucocorticoids, cDMARDs and bDMARDs but should be monitored periodically with liver function tests and HBV-viral load. Patients treated with rituximab display higher risk for HBV reactivation especially when anti-HBs titers are low. Risk for reactivation in *hepatitis C* RNA positive patients, treated with bDMARDs is low. However, all patients should be referred for antiviral treatment and monitored periodically. For *pneumocystis jirovecii*: prophylaxis with trimethoprim/sulfamethoxazole (alternatively with atovaquone or pentamidine) should be considered in patients treated with prednisolone: 15-30mg/day for more than 4 weeks. Few data exist for screening and prophylaxis from viruses like *EBV, CMV and Varicella Zoster Virus*. Expert opinion supports the screening of rare bugs like *histoplasma* and *trypanosoma* in patients considered to be at high risk (e.g living in endemic areas).

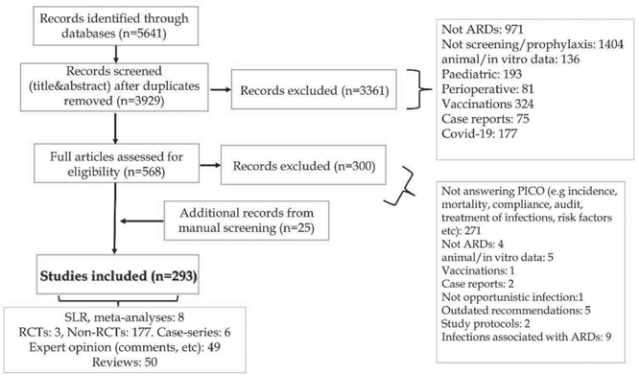

Figure 1. SLR flowchart

Conclusion: The risk of chronic and opportunistic infections should be considered in all patients prior to treatment with immunosuppressives/immunomodulators. Different screening and prophylaxis approaches are described in the literature, partly determined by individual patient and disease characteristics. Collaboration between different disciplines is important.

POS1180 AUTOIMMUNE SYNDROMES WITH CHRONIC HEPATITIS C VIRUS INFECTION AND DIRECT-ACTING ANTIVIRAL TREATMENT.

R. H A Mohammed[1], D. Hassan Attia[2], M. Abdelazeem[2], A. Elsayed Taha[3], D. Rasheed Bahgat[4], H. Ibrahim I Elmakhzangy[3]. *[1]School of Medicine- Cairo University, Rheumatology and rehabilitation, Cairo, Egypt; [2]School of Medicine-Cairo University, Rheumatology and Rehabilitation, Cairo, Egypt; [3]School of Medicine- Cairo University,Tropical medicine, Cairo, Egypt; [4]School of Medicine- Cairo University, Chemical and clinical pathology, Cairo, Egypt*

Background: Chronic hepatitis C virus (HCV) infection is a multifaceted disease that has been associated with systemic as well as organ-specific, autoimmune manifestations with increasing virologic, and clinical evidence supporting the association. The development of direct-acting antivirals (DAAs) is considered an advent that might aid the clearance of extrahepatic immune manifestations of HCV.[1,2,3]

Objectives: Investigate the effect of directly acting antiviral drugs (DAA) on the different autoimmune manifestation and serologic changes associating chronic HCV infection.

Methods: Inclusion criteria: This is a cohort study that included adult patients aged ≥18 years, of either sex, having CHCV with detectable HCV ribonucleic acids (RNA) by Polymerase Chain Reaction (PCR) and eligible for the DAAs treatment. Exclusion criteria: Patients with established rheumatological disease prior to the onset of HCV diagnosis. Patients with decompensated cirrhosis**.** Patients with platelet count less than 50000/ mm^3.Patients with HCC (except after 6 months of curative intervention). All patients were subjected to full history taking, clinical and laboratory investigations.

Results: The study enrolled 130 chronic HCV patient (90 patients completed follow up). 66.7 % females and 33.3% males (ratio 2:1), the mean age was 49.2±12.3 years. The study found 77/ 90 (85.55%) patients to have immune mediated manifestations and associated serological changes prior to DAA. The most prevalent were musculoskeletal manifestations in 56 patients (72.7%), arthralgia (66.2%), fatigue (54.5%) and myalgia (50.6%), xerophthalmia (24.7%), neuritis (28.6%) (P-value > 0.01), and a positive RF in 33.8% (P-value 0.013). HCV Among patients who achieved sustained viral response, autoimmune manifestations persisted in 66 out of 71 patients (92.9%) who were positive at baseline. The most prevalent autoimmune manifestations after therapy were musculoskeletal manifestations 53 patients (68.8%). Responders with persistent autoimmune manifestations had an observable rise in inflammatory biomarkers posttreatment erythrocyte sedimentation rate was (46.22±19.62) became (56.05±25.45),C reactive protein titer was (8.46±12.76) became (20.01±25.92), P >0.01. Predictors for persistence of autoimmune manifestation were older age ≥ 49 years P-value 0.009, female sex P= 0.026, tobacco consumers P= 0.043.

Conclusion: The introduction of directly acting antiviral drugs wasn't associated with a significant change in the prevalence of autoimmune manifestations in our population of Egyptian patients with chronic HCV who attained a sustained viral response.

POS1181 INFECTIOUS COMPLICATIONS OF BIOLOGIC THERAPY IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM

F. Idrissi Zaki[1], F. E. Chekkouri[1], A. Mougui[1], I. El Bouchti[1]. *[1]Centre Hospitalo-Universitaire Mohammed Vi Marrakech, Department of Rheumatology, Marrakech, Morocco*

Background: The appearance of biological disease-modifying drugs (bDMARDs) has revolutionized the treatment of rheumatic diseases. However, their functions in modulating pro-inflammatory cytokines and acquired immunity largely increase the risk of infections.

Objectives: The aim of this work is to study the epidemiological, clinical and biological characteristics of infections occurring under biotherapies, and to identify the factors associated with its occurrence.

Methods: It is a retrospective descriptive study including patients with chronic inflammatory rheumatism between 2006 and 2021 and who were placed during their follow-up under a biotherapy. Statistical data analysis was performed using SPSS version 20 software. The bivariate study was performed by Chi-square test.

Results: Of the 106 cases reported, 68 infectious episodes were counted in 46 patients (43.4%) who had at least one infection with biotherapy: 56.5% women and 43.5% men with an average age of 50.9 ± 14.29 years. These included rheumatoid arthritis in 16 patients (34.8%), spondylarthritis in 29 patients (63%) and one case of psoriatic arthritis. All patients were on conventional treatments before switching to biotherapy. The infections occurred under Rituximab in 43.8% of the cases, under Infliximab in 33.3% of the cases, under Etanercept in 25% of the cases (a total of 60.9% of the cases were under anti-Tumor Necrosis Factor) and tocilizumab in 12.5% of cases. The infection was of bacterial origin in 40.7% of cases: 27.3% urinary tract infections, 20.5% bronchial infections, 11.4% skin infections, 6.8% septic arthritis. Fungal infections were found in 33.3% of cases in relation to dermatophyte infections and intertrigo. A viral origin was noted in 25.9% of the cases: 5 cases of labial herpes and only one case on herpes zoster. C-reactive protein was increased in 47.2% of cases with a mean value of 36 ± 29.6 mg /L, the hemogram showed hyperleukocytosis in 50% of cases with neutrophil predominance. The treatment was medical in the majority of cases (94.9%), it was both medical and surgical in one case. The favorable outcome in all patients was marked by a temporary interruption of 3.27 ± 1.84 weeks of biotherapy. In multivariate analysis, an association was found between bacterial infection and both female gender (p=0.033), low socioeconomic level (p=0.033), Methotrexate + bDMARDs intake (p=0.027), corticosteroids + bDMARs intake (p=0.014) and Between fungal infection and bDMARs +corticosteroids intake (p=0.044).

Conclusion: The risk of infection is higher in patients with chronic inflammatory rheumatism, especially if they are under biotherapy. It turns out that bacterial and fungal infections are the most common in this study. Patients taking Rituximab or Infliximab are the most affected by these infectious episodes.

POS1182 EPIDEMIOLOGICAL, CLINICAL AND THERAPEUTIC ASPECTS OF TABETIC ARTHROPATHY IN A POPULATION OF SOUTHERN MOROCCO

P. C. Mouele Mboussi[1], F. E. Bennani[1], S. Belouaham[1], H. Bara[1], A. Mougui[1], I. El Bouchti[1]. [1]*centre Hospitalo-Universitaire Mohammed Vi Marrakech, Rheumatology, Marrakech, Morocco*

Background: Tabetic arthropathies (TA) are a destructive neurogenic disease complicating 10% of syphilis at the tertiary stage. Although they have become exceptional due to early and appropriate treatment of syphilis, they are still relevant in undeveloped countries and remain difficult to manage due to the severity of the handicap and the absence of a specific treatment.
Objectives: We described épidemiological, clinical, biological, radiographic, and therapeutic characteristics of TA.
Methods: Retrospective study, from 2004 to 2021 includind patients with tabetic arthropathy, whose diagnosis was retained on clinical criteria (discordance between the importance of joint deformities and indolence), radiological (lesions destructive and constructive), biological (positive syphilitic serology in joint fluid, blood and/or cerebrospinal fluid).
Results: A total of 21 cases were collected, 15 men and 6 women, the mean age was 52.14 years. The history of syphilitic chancre was found in 9 patients, sexual risk behavior was noted in 8 patients, no other STI was found. Joint swelling with painless deformation was the main mode revealing the disease (76.1%), followed by pathological fracture in 3 cases and then mechanical arthralgia with neuropathic pain in 2 patients. The delay diagnosis was 6.8 years. TA concerned lower limb in 81,5%. The knee was the most affected site in 15 cases (71.4%),followed by the hip,ankles, MTP, in respectively 4(19%), 3(14%), 2(9,5%) cases. The upper limb was involved in 4 cases, with MCP involvement in one patient. TA was bilateral in 29% and multifocal in 19%. Joint instability was found in 16 patients. Involvement of the thoracolumbar spine was noted in one case. Tabetic neurological involvement was found in 16 patients (76.1%) with an Argyll Robertson sign noted in 6 cases (28.6%), a radiculocordonal posterior syndrome in 10 cases (47.6%). TPHA and VDRL were positive in blood in 21 patients, in cerebrospinal fluid in 11 patients and in synovial fluid in 9 cases. Radiological exams showed destructive and constructive lesions with the presence of intraosseous and periarticular fragments, damage to small joints was noted in two patients, bilateral talocrural involvement in one patient, a fracture with dislocation and calcification of the soft tissues was noted in two cases. Axial tabetic involvement made of vertebral compression D12, L1 L2 L3 was found in one case (4.8%). Nineteen patients (90.4%) were treated with Penicillin G and two patients with C3G. Orthopedic immobilization with weight-bearing was prescribed to all patients, the surgical indication was posed in 11 patients, 4 of whom benefited from surgery: total hip prosthesis in 3 cases, knee arthrodesis in one case. The serological evolution at the end of treatment showed a decrease in the VRDL titer in the blood, CSF, synovial fluid in 10 patients and negativity in 4 patients.
Conclusion: Tabetic arthropathy, one of the exceptional complications of neurosyphilis, is still relevant. Its diagnosis must reffered to any destructive and painless joint damage. Given the difficulty of treating this articular form, prevention based on the management of syphilis at an early stage before the occurrence of joint and neurological complications is essential.

POS1183 RISK FACTORS FOR CYTOMEGALOVIRUS INFECTION IN PATIENTS WITH RHEUMATIC DISEASE; SINGLE-CENTER PROSPECTIVE COHORT STUDY.

Y. Ota[1], Y. Kondo[1], S. Saito[1], J. Kikuchi[1], H. Hanaoka[1], Y. Kaneko[1]. [1]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Cytomegalovirus (CMV) infection is one of serious opportunistic infections for immunosuppressed patients, therefore, identifying patients at risk for CMV infection is of importance. However, no prospective study about CMV infection in systemic rheumatic disease has been reported.
Objectives: To identify risk factors relevant with CMV infection in patients with systemic rheumatic disease during intensive remission induction therapy.
Methods: Consecutive systemic rheumatic disease cases who started intensive immunosuppressive therapy from February 2017 until February 2019 were enrolled. Serum CMV-IgG was measured before the induction therapy, and subsequently, CMV pp65 antigen was monitored weekly. Patients were divided into 2 groups according to the presence or absence of CMV infection, and risk factors for CMV infection were analyzed.
Results: 157 patients consisting of 136 CMV-IgG positive and 21 CMV-IgG negative patients were enrolled in the study. Mean age was 60.8 ± 17.4 y/o, and female was 70.7%. The underlying diseases were following; vasculitides 54, systemic lupus erythematosus 27, polymyositis/dermatomyositis 25, rheumatoid arthritis 14, IgG4-related disease 13, mixed connected tissue disease 6, Behçet disease 5, adult-onset Still's disease 4, and others 9. The initial dose of glucocorticoid (GC) was 48.4 ± 11.5 mg/day (0.91 ± 0.16 mg/kg/day) as prednisolone (PSL) with additional methylprednisolone (mPSL) pulse therapy being conducted in 44 (28.0%). Concomitant immunosuppressive therapies were intravenous cyclophosphamide (IVCY) in 55, calcineurin inhibitor 27, mycophenolate mofetil 16, hydroxychloroquine 5, and methotrexate 4. Concomitant biological agents were rituximab 12, tocilizumab 6, infliximab 2, golimumab 1, and abatacept 1. CMV infection occurred in 52 patients (33.1%), and all of them were CMV-IgG positive before induction therapy (38.2% in the CMV-IgG positive patients). Univariable analysis revealed initial PSL dose >0.91 mg/kg/day (odds ratio [OR] 5.2, p<0.01), IVCY (OR 3.4, p<0.01), diabetes mellitus (OR 5.2, p<0.01), and a history of malignancy (OR 2.9, p=0.02) were independent risk factors for CMV infection. CMV antiviral drugs were administered in 22 patients (42.3%). At the first detection of CMV pp65 antigen, PSL dose ≥37.5 mg/day (OR 5294.8, p<0.01), CMV pp65 antigen-positive cells ≥2 cells/2 slides (OR 16.0, p = 0.04), and serum albumin levels <3.0 g/dL (OR 26.3, p=0.01) were associated with subsequent CMV antiviral drug administration.
Conclusion: CMV infection occurred only in CMV-IgG positive patients with systemic rheumatic diseases who were undergoing intensive remission induction therapy. CMV infection was related with treatment regimen and comorbidities, and the necessity of CMV antiviral treatment was predicted with prednisolone dose, the number of CMV pp65 antigen positive cells, and albumin levels at the first detection of CMV pp65 antigen.

Background: Recent epidemiological data on HBV and HCV in Turkey revealed that the seroprevalence rates of hepatitis B surface antigen and antibody against HCV were 4% and 1%, respectively, and seropositivity rates for hepatitis B surface antibody and hepatitis B core antibody were 31.9% and 30.6%, respectively. A previous multicenter nationwide study conducted in Turkey reported that the HBsAg positivity was determined in 2.3% of patients with rheumatoid arthritis (RA) and 3% of patients with ankylosing spondylitis (AS), and the anti-HCV positivity was detected in 1.1% of patients in each group. Given these rates, viral hepatitis is still considered a potential threat to patients with rheumatic diseases, specifically for the treatment-related viral reactivation.
Objectives: This study aimed to evaluate the serologic HBV and HCV frequency and clinical characteristics among our patients with RA or SpA and receive biological treatments based on this background.
Methods: The prospective TReasure database, which observationally collects data of patients with rheumatic diseases from fifteen centers across Turkey, was analyzed for viral hepatitis, patient characteristics, and treatments used. TReasure registry study protocol, and the data collection was started on December 2017. At the time of the analysis for this study was performed, the registry database included 3147 patients with RA and 6071 patients with SpA. For hepatitis B; Hepatitis B surface antigen (HBsAg), anti-HBV core antibody (anti-HBc) and anti-HBV surface antibody (Anti-HBs) tests were evaluated. HBV-DNA was studied in HBsAg positive patients. Anti-HCV antibody has been studied for HCV. The clinical and serological HBV reactivation in the follow-up of the patients was evaluated by looking at the HBV-DNA viral loads.
Results: A total of 9218 patients (3147 RA and 6071 patients with SpA) were included in the analyses. The screening rate for HBV was 97% in RA and 94.2% in SpA groups. HBsAg positivity rates were 2.6% and 2%, anti-HBs positivity rates were 32.3% and 34%, anti-HBc positivity rates were 20.3% and 12.5%, HBV DNA positivity rates were 3.5% and 12.5%, and anti-HCV positivity rates were 0.8% and 0.3% in these groups, respectively (Table 1).

Table 1. Serological analyses in the study group

	RA		SpA		
	N	n (%)	N	n (%)	p
Hepatitis testing	2896	2809 (97.0)	5444	5130 (94.2)	<0.001
HBsAg positivity	2750	71 (2.6)	5017	99 (2)	0.080
Anti-HBs positivity	2708	876 (32.3)	4893	1663 (34)	0.147
Anti-HBc positivity	2362	480 (20.3)	4194	524 (12.5)	<0.001
HBV-DNA positivity	454	16 (3.5)	637	35 (5.5)	0.129
Anti-HCV positivity	2602	22 (0.8)	4627	16 (0.3)	0.005

The HBsAg (+) patients were older and had higher comorbidities, including hypertension, diabetes, and coronary artery disease. In addition, RF positivity was more in HBsAg(+) cases. The most frequently prescribed bDMARDS were adalimumab (28.5%), etanercept (27%), tofacitinib (23.4%), and tocilizumab (21.5%) in the RA group, whereas adalimumab (48.1%), etanercept (31.4%), infliximab (22.6%), and certolizumab (21.1%) in the SpA group. HBV reactivation was observed in one patient with during RA treatment, who received rituximab and prophylaxis with tenofovir.

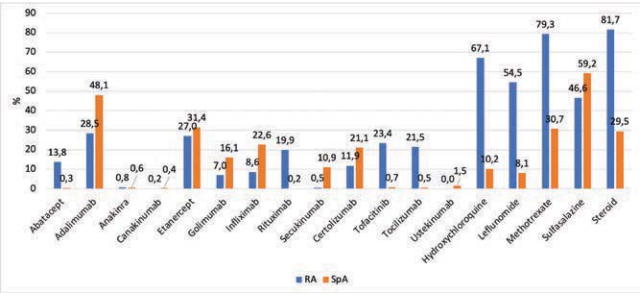

Figure 1. Prescription proportions of medications in the rheumatoid arthritis (RA) and spondyloarthritis (SpA) groups

Conclusion: The epidemiological characteristics of patients with rheumatic diseases and viral hepatitis are essential for effective patient management. This study provided the most recent epidemiological characteristics from the prospective TReasure database, one of the most comprehensive registries in rheumatology practice. According to the results of our study; It can be thought that there is no risk in the choice of treatment by the rheumatologist in patients who receive appropriate prophylaxis.

POS1185 PERFORMANCE OF ADENOSIN DEAMINASE ACTIVITY IN SYNOVIAL FLUID FOR THE EARLY DIAGNOSIS OF TUBERCULOUS ARTHRITIS: A META-ANALYSIS

J. Ena[1], J. C. Cortés-Quiroz[2], J. A. Bernal[2], A. Pons[2], J. M. Senabre-Gallego[2], G. Santos Soler[2], C. Raya-Santos[2], J. Rosas[2]. *[1]Hospital Marina Baixa, Internal Medicine, Villajoyosa, Spain; [2]Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain*

Background: Adenosin deaminase activity (ADA) has shown good performance in diagnosing pleural, peritoneal and meningeal tuberculosis. Still, the performance of ADA activity in synovial fluid for the diagnosis of tuberculous arthritis has received less attention.
Objectives: To analyze the performance of ADA in synovial fluid to diagnosis tuberculous artrhritis.
Methods: We research Medline and EMBASE from the inception to October 2021 and the American College of Rheumatology and European League Against Rheumatism for conference abstracts (2012-2021) to assess the accuracy of ADA activity in synovial fluid compared to a composite reference standard (necrotizing granulomas in a synovial biopsy; acid-fast stain, Mycobacterium culture or RT-PCR assay for tuberculosis and/or clinical response to tuberculosis treatment) to early diagnosis tuberculous arthritis. We performed meta-analysis using a random-effects model and evaluated the sources of heterogeneity via subgroup analysis and meta-regression.
Results: Seven independent studies (N= 307 subjects) that compared ADA activity in synovial fluid with the composite reference standard were included. The pooled sensitivity and specificity of ADA activity was 0.939 (95% confidence Interval [CI], 0,873-0,977; heterogeneity p=0.297; I2=17.4%) and 0.885 (95% confidence Interval [CI], 0.833-0.925; heterogeneity p=0.002; I2=85.3%) compared to the composite reference standard, respectively. The random-effects model for pooled diagnostic Odds Ratio was 74.582 (95% CI, 19.826-280.57; heterogeneity p=0.133; I2=38.8%). The receiver operating characteristic curve area was 0.9617 (95% CI, 0.925-1.000). Meta-regression did not identify the type of study (prospective or retrospective), country of publication, type de assay, or cut-off value as sources of heterogeneity.
Conclusion: Measuring adenosine deaminase activity in synovial fluid demonstrates good performance for the early diagnosis joint tuberculosis.

POS1186 STUDY OF SPONDYLODISCITIS WITHOUT BACTERIOLOGICAL DOCUMENTATION FROM A COHORT OF 142 PATIENTS WITH SUSPECTED INFECTIOUS SPONDYLODISCITIS ON IMAGING

G. Aline[1], M. Desvaux[1], C. Delepine[1], M. Lanquetuit[1], C. Patenere[1], N. Sens[1], M. Kozyreff-Meurice[1], S. Pouplin[1], T. Lequerre[1], O. Vittecoq[1], G. Avenel[1]. *[1]Hospital Center University De Rouen, Rheumatology, Rouen, France*

Background: The incidence of infectious spondylodiscitis was estimated at 2.4/100,000 people in 2002. When faced with an image of spondylodiscitis on imaging, infectious spondylodiscitis is the most feared etiology. In recent years, several non-infectious spondylodiscitis etiologies have been described: Andersson lesion, crystal-induced discopathy, degenerative changes, etc (2). The identification of the germ by blood cultures or disc-vertebral puncture-biopsy allows the treatment to be best adapted antibiotic. Bacteriological investigation is inconclusive in about 30% (1). More and more undocumented spondylodiscitis are described.
Objectives: The aim of this study is to describe a cohort of spondylodiscitis without bacteriological documentation and to compare it to spondylodiscitis with bacteriological documentation.

Methods: Using a "clinical data warehouse", we searched for the key word "spondylodiscitis" in the documents associated with hospitalisations in the Rheumatology department of the Rouen University Hospital between 2010 and 2020. Four hundred and twenty-two records were analysed: 196 were excluded because they were not hospitalizedn in Rheumatology, among the 226 suspected spondylodiscitis, imaging allowed us to exclude 84 records for which there was no infectious spondylodiscitis and to retain 142 records. We collected demographic data, history, clinical symptoms, results of imaging, biological and bacteriological examinations. Statistical analysis was performed by Fisher's exact test for qualitative data and by Mann-Whitney test for quantitative data.

Results: Four hundred and twenty-two patients were collected, 142 were analyzed. The average age was 65.5 +/- 14 years, 64.1% were male. Spinal pain was present in 96.5% of the cases without any difference between the two groups. One hundred and nine cases of spondylodiscitis were documented, of which 72 were confirmed by blood cultures and 36 by spinal disc biopsy. Thirty-three were not documented. Documented spondylodiscitis was more often febrile (41.3% vs 15.21% in undocumented cases, p = 0.006), had a greater biological inflammatory syndrome (mean CRP 152.4 +/- 112.6 mg/L versus 73 +/- 73.1 mg/L, p < 0.0001), and had been evolving for a shorter period of time than undocumented spondylodiscitis (54.1% vs 24.2% less than one month). *Staphylococcus aureus* was the most frequently retrieved bacteria 27.5%, followed by coagulase-negative staphylococci and streptococci (18.3% and 19.3% respectively). One hundred and twenty-one patients (85%) had an MRI at diagnosis; one hundred and two (71.8%) had a CT scan; and 81 patients (57%) had both examinations. The imaging analysis showed that there was no difference in soft tissue infiltration, erosions and abscesses. Probabilistic antibiotic therapy was proposed in 28/33 (84.5%) of cases. After collegial discussion, the alternative diagnoses retained were degenerative disc disease (4 cases), spinal gout (1 case), spondyloarthritis (1 case).

Conclusion: Undocumented spondylodiscitis is a recurrent problem in hospital practice. Alternative diagnoses are increasingly reported, their diagnosis is based on a collegial discussion.

POS1187 DO IMMUNOSUPPRESSIVE AGENTS AFFECT IGRA TESTS IN PATIENTS WITH RHEUMATOID ARTHRITIS?

Z. Özsoy[1], A. Özdemir[2], M. Ekici[1], E. Bilgin[1], L. Kılıç[1], S. Kiraz[1], Z. Sarıbaş[2], B. Şener[2], O. Karadag[1]. *[1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; [2]Hacettepe University, Faculty of Medicine, Department Of Medical Microbiology, Ankara, Turkey*

Background: Tuberculin skin test (PPD) or interferon gamma release assays (IGRAs) are used to detect latent tuberculosis infection. Induration of 15 mm or more is considered positive in any person whereas this cut-off is ≥5 mm for immunosuppressed individuals such as Rheumatoid arthritis. Since IGRAs are dependent on normal T-cell function, it may result in false-negatives for among RA patients due to disease itself and immunosuppressive drugs.

Objectives: We aimed to compare IGRA results of RA patients using high dose DMARDS vs. not using any of them.

Methods: Totally 534 RA patients among Hacettepe University Rheumatology Biologic Registry Database (HURBIO) database was enrolled into this study. QFT-Plus test of patients with rheumatoid arthritis (RA) between January 2018 and March 2021 during work up before biologic/targeted therapy were analysed, retrospectively. The patient group was divided into two according to the drugs have been using at the time of IGRA test. Patients using methotrexate ≥ 10 mg or leflunomide (any dose) or steroids (≥7.5 mg prednisolone) or any combination thereof were classified as the "High Dose" group. The other group consisted of patients who did not take these drug doses. Demographic characteristics, comorbidities, drugs and doses used, and hemogram, sedimentation, and CRP values of the patients were recorded. QuantiFERON test was recorded as positive, negative, indeterminate.

Results: 353(66.1%) RA patients were in the high dose patient group and also 287(81.3%) of these patients were female, the median age was 55 years (min:19- max:82). The high dose group was older than the other group. When the two groups were compared, no statistically significant difference was found between comorbidity, and smoking (Table 1). While QFT positivity was detected in 37 (10.5%) patients in the high-dose group, it was found to be positive in 37 (20.4%) patients in the other group (p<0.001). However, there was no significant difference regarding acute phase reactants, hemogram including lymphocyte counts and IFN-gamma levels in the tubes between these two groups.

Table 1. Comparison of RA patients' groups using high-dose immunosuppressives and not using any of them

		High Dose Methotrexate or Leflunomide or Steroid (+), (%) 66.1	High Dose Methotrexate or Leflunomide or Steroid (-), (%) 33.9	P Value
Female		81.3	75.1	0.09
Age, med (min-max)		55 (19-82)	52 (19-81)	0.01
Diabetes Mellitus		11	10.5	0.84
Hypertension		30.6	24.9	0.16
Chronic Renal Failure		0.3	0	0.66
Chronic Obstructive Pulmonary Disease		4.2	3.3	0.59
Coronary Artery Disease		3.7	6.1	0.20
History of malignancy		0.8	1.7	0.40
Smoking	**Never**	49	52.5	0.19
	Ever	24.1	27.6	
	Quit	26.3	18.8	
Leukocyte,*10^3/ml	Median	7.6 (2.8-28.8)	7.9 (3.5 – 20.8)	0.26
Neutrophil,*10^3/ml	(min-max)	4.8 (0.2-23.0)	5.0 (1.5-19.1)	0.18
Lymphocyte,*10^3/ml		1.9 (0.4-5.9)	1.8 (0.5-5.3)	0.67
Thrombocyte,*10^3/ml		285 (117-669)	285.5 (60-724)	0.79
Hemoglobine,g/dL		12.8 (7.7-17.9)	12.8 (9.3-16.6)	0.41
Sedimentation,mm/saat		30 (2-294)	28 (2-104)	0.27
C Reactive Protein,mg/dl		1.1 (0.1-62.8)	1.1 (0-20.7)	0.96
QuantiFERON-TB Gold-Plus (QFT-Plus)		10.5	20.4	0.00
Nil med (min-max)		0.07 (0-2.7)	0.05 (0-0.85)	0.48
QFT-Plus TB-1 med (min-max)		1 (0->10)	0.99 (0->10)	0.25
QFT-Plus TB-2 med (min-max)		1 (0->10)	1.1 (0->10)	0.42
Mitogen med (min-max)		10 (0->10)	9.5 (0->10)	0.27
Methotrexate	Not Taking	31.4	33.7	
	Less than 10 mg	44.2	66.3	
	10 mg and more	24.4	0	
Leflunomide	Not Taking	25.8	100	
	Taking	74.2	0	
Hydroxychloroquine	Not Taking	25.2	40.9	
	Taking	74.8	59.1	
Sulfasalazine	Not Taking	62.6	61.9	
	Taking	37.4	38.1	
Steroids	Not Taking	4.2	19.9	
	Less than 7.5 mg	66.3	80.1	
	7.5 mg and more	29.5	0	

Conclusion: Our results confirmed a significantly lower QFT-Plus positivity in patients with RA taking methotrexate ≥ 10 mg or leflunomide (any dose) or steroids (≥7.5 mg prednisolone). Physicians should be careful in interpretation of QFT-Plus in patients with rheumatoid arthritis. Further analysis including flow cytometry analysis is required to better identifying cut-offs for immunosuppressive individuals and patients with inflammatory rheumatic diseases.

POS1188 INCIDENCE AND MANIFESTATIONS OF LYME DISEASE: A SINGLE-CENTER RETROSPECTIVE ANALYSIS.

S. Pūce[1], A. Pūce[2], A. Mihailova[1]. *[1]Riga Stradins University, Internal diseases, Rīga, Latvia; [2]Riga Stradins University, Family Medicine, Rīga, Latvia*

Background: Lyme disease is widespread throughout the world, including Latvia. On average period 2009 to 2018, there have been 613 cases of Lyme disease registered in Latvia every year according to data from the Center for Disease Prevention and Control. Mainly early skin manifestations such as erythema migrans and neurological manifestations such as meningitis, cranial neuropathy and motor or sensor radiculoneuropathy of this disease are being discussed and emphasized. Therefore, undiagnosed and unexamined often remain articular manifestations of Lyme disease, leading to prolonged treatment and reduced patient quality of life.
Objectives: To investigate clinical presentation, immunological changes, and response to therapy in patients with Lyme disease.
Methods: A retrospective single center study was performed in the outpatient clinic Orto (Riga, Latvia) in the period from January 2018 until December 2021. Medical records from patients with diagnosed Lyme disease and articular symptoms, based on epidemiological, clinical and immunological findings, were analyzed. Patients who had other types of arthropathies were excluded.
Results: In total 76 patients were included in the study (54 females, 22 males, age range 19-84 years, median age 48.5 years), of whom 48 patients had arthritis and 28 arthralgias. Out of all patients with arthritis - 25 had monoarthritis, 16 - had oligoarthritis and 7 had polyarthritis. At the first visit patients with arthralgia had a median IgM 28.2 Au/ml (IQR 15.27- 47.35) and IgG 25.00 Au/ml (IQR 5.00 – 142.30) and patients with arthritis had a median IgM 14.7 Au/ml (IQR 5.50 - 28.80) and IgG 142.7 Au/ml (IQR 82.32-237). After the treatment with Doxycycline 200 mg QD for 30 days, 52 patients came to the 2nd visit, of them 41 patients with improvement of symptoms and 11 without. More improvement was seen in the arthritis group. After treatment the median IgM in arthralgia/ arthritis groups was 22.5 Au/ml (IQR 8.72-38.82) / 13.8 Au/ml (IQR 6.03-24.15) and IgG was 42.4 Au/ml (IQR 8.15 – 90.60) / 106.7 Au/ml (IQR 23.57-203.95). In both groups with arthralgias or arthritis, patients who had a positive clinical response after treatment had a significantly lower post-treatment IgG than before treatment ($p < 0.05$, Wilcoxson signed rank test). At the same time patients who did not respond to the treatment had no significant difference between pre- and post-treatment IgG antibodies ($p > 0.05$, Wilcoxson signed rank test).
Conclusion: In all patients with musculoskeletal complaints the possibility of Lyme disease should be evaluated. The decrease of antibody titers may indicate a positive prognosis in patients with musculoskeletal manifestations of Lyme disease.

POS1189 RHEUMATIC FEVER AND CUTANEOUS STREPTOCOCCAL INFECTION: A CASE-CONTROL STUDY IN THE LOYALTY ISLANDS, NEW CALEDONIA

Q. Amic-Desvaud[1,2], O. Maillard[3], S. Iacobelli[4], T. Bardin[5], Y. M. Ducrot[6]. *[1]Hôpital Intercommunal Des Vallées De L'Ariège, Endocrinologie, Saint-Jean-de-Verges, France; [2]Direction de l' Action Communautaire et de l'Action Sanitaire, Centre Médico Social de Wé, Lifou, New Caledonia; [3]Université de la Réunion, INSERM CIC 1410 Clinical and Epidemiology, Saint-Denis, La Réunion, France; [4]Centre Hospitalier Universitaire Sud Réunion, Service de Néonatologie, Saint-Pierre, La Réunion, France; [5]Université de Paris, INSERM UMRS1132, Hôpital Lariboisière,, Paris, France; [6]Direction de l' Action Communautaire et de l'Action Sanitaire, Centre Médico-Social de Wé, Lifou, New Caledonia*

Background: Acute Rheumatic Fever (ARF) and Rheumatic Heart Disease (RHD) remain major public health problems in the South Pacific. Triggering by group A beta hemolytic streptococcal (GAS) skin infection has been suspected but little documented[1]. Very high incidences of ARF (106/100 000) and cutaneous infections have been reported in the Loyalty islands (New Caledonia), where health care of the 20,000 Melanesian inhabitants is centralized in a few locations and provides an extensive electronic database since 1998, and systematic screening for RHD is regularly performed.
Objectives: To explore the link between ARF, RHD and skin infections by a retrospective case-control study.
Methods: The study was approved by the New Caledonian committee of Ethics and dealt with patients aged 6 to 26 years, seen from 1998 to 2018. Cases were ARF and/or RHD. Definite ARF was diagnosed according to the Jones criteria[2]; additional cases with strong clinical suspicion were also included as probable cases. RHD was diagnosed by cardiac ultrasound scan allowing definite and borderline diagnosis[2]. Sore throat and presumed streptococcal cutaneous infections were diagnosed by an algorithm, previously validated on a sample of 3000 events by an experimented clinician, which identified specific medical terms and ICD-10 codes in the electronic medical records. Each case was matched with 3 controls (without ARF and RHD) of same age, sex and living location. Infections were retrieved from the electronic medical records during the month, 6 months, one year, 5 years preceding the date of the first ARF/RHD diagnosis, for each case with the same index date for its matched control, and since birth. Numbers of infections per these time intervals were compared between cases and controls by univariate and multivariate conditional regression analysis in the total study population and its various subcategories (definite or probable ARF, definite or borderline RHD).
Results: 311 cases of ARF and RHD including 206 definite cases were identified. Polyarthralgias (48%) were the main clinical presentation. Marginal erythema was not seen and Sydenham chorea was rare (6.8%). Mean age of diagnosis was 10.6 ±3.8 years. Skin infection episodes were 3 to 4 times more frequent than sore throats in all studied time-intervals. Multivariate analysis showed an increased exposure to skin infections and sore throats in the year preceding ARF/RHD diagnosis in the whole population of cases as compared to controls (OR 2.18, 95% CI 1.46, 3.26) and 1.54, 95% CI 1.01, 2.36] respectively); skin infections (but not sore throat) were also increased the 206 definite cases (OR 1.34, 95% CI 1.01, 1.80) and in the 220 definite and probable ARF (OR 1.47, 95% CI 1.11, 1.94). In addition we observed a correlation between the seasonality of ARF and skin infections, which were both more frequent during the rainy season, and an overlap of areas with high incidence of ARF and areas with high incidence of skin infections.
Conclusion: Our results support the hypothesis that GAS skin infections play a role in the pathophysiology of ARF/RHD. In view of these results, there is an urgent need to implement preventive measures to reduce the incidence of skin infections in the Loyalty Islands.

COVID-19

POS1190 IMPACT OF COVID-19 PANDEMIC ON PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: DISRUPTIONS IN CARE AND SELF-REPORTED OUTCOMES

A. M. Fouad[1], S. F. Elotla[1], E. Nourhan Elameen[2], A. E. Mohamed[2]. [1]*Faculty of Medicine, Suez Canal University, Department of Public Health, Occupational and Environmental Medicine, Ismailia, Egypt;* [2]*Faculty of Medicine, Suez Canal University, Department of Physical Medicine, Rheumatology and Rehabilitation, Ismailia, Egypt*

Background: The COVID-19 pandemic represents a challenge to the care of patients with rheumatic and musculoskeletal diseases (RMDs).
Objectives: This study aimed to evaluate the impact of the pandemic on the care of RMD patients, their health and wellbeing.
Methods: This cross-sectional study involved 120 RMDs patients at the rheumatology department at Suez Canal University Hospital in Ismailia, Egypt. Patients were interviewed for sociodemographic and disease-related history. Further assessments were performed using Kessler 6-items (1), Fear of COVID-19 scale (2), and COVID-19–Impact on Quality-of-Life scale (3).
Results: Patients with rheumatoid arthritis and systemic lupus erythematosus made up most of our sample (72.5%, 19.2% respectively). About 50% of patients were experiencing limitation in the access to rheumatologic care, and a similar percentage had changed or discontinued their medications. DMARDs shortage and concerns about the increased risk of COVID-19 infection because of immunosuppressive drugs were the most frequently reported reasons for non-adherence to medication. The percentage of patients with uncontrolled disease had significantly increased from 8.3% prior to the COVID-19 pandemic to 20% during the pandemic. Patients perceived their overall quality of life as average (4.93 on a rating scale from 0 to 10). The Fear of COVID-19 score ranged from 7 to 35 with a mean of 26 (±7.6), while the COV19–Impact on Quality of Life score ranged from 6 to 30 points with a mean of 22.6 (±6.7). About 60% of patients reported a high level of psychological distress.
Conclusion: The pandemic negatively influenced the mental health, quality of life, adherence to medications, access to rheumatology care, and disease control of RMDs patients.

POS1191 IMMUNE RESPONSES TO MRNA VACCINES AGAINST SARS-COV2 IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY RHEUMATIC DISEASES

C. Sieiro Santos[1], C. Moriano[1], E. Diez Alvarez[1], S. Calleja Antolín[2], I. González Fernández[1], C. Álvarez Castro[1], J. M. Garcia Ruiz de Morales[2]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain;* [2]*Complejo Asistencial Universitario de León, Immunology, León, Spain*

Background: Patients with immune-mediated rheumatic diseases (IMRD) are commonly treated with immunosuppressors and prone to infections. Recently introduced mRNA SARS-Cov2 vaccines have demonstrated extraordinary efficacy across all ages. Immunosuppressed patients were excluded from phase III trials with SARS-Cov2 mRNA vaccines.
Objectives: To fully characterize B and T cell immune responses elicited by mRNA SARS-Cov2 vaccines in patients with rheumatic diseases under immunotherapies, and to identify which drugs reduce vaccine´s immunogenicity.
Methods: Humoral, CD4 and CD8 immune-responses were investigated in 100 SARS-Cov2-naïve patients with selected rheumatic diseases under immunosuppression after a two-dose regimen of SARS-Cov2 mRNA vaccine. Responses were compared with age, gender, and disease-matched IMRD patients not receiving immunosuppressors and with healthy controls.
Results: IMRD patients showed decreased seroconversion rates (80% vs 100%, p= 0.03) and cellular immune responses (75% vs 100%, p= 0.02). Patients on methotrexate achieved seroconversion in 62% of cases and cellular responses in 80% of cases. Abatacept decreased humoral and cellular responses. Rituximab (31% responders) and belimumab (50% responders) showed impaired humoral responses, but cellular responses were often preserved. Antibody titers were reduced with mycophenolate and azathioprine but preserved with leflunomide and anticytokines.
Conclusion: IMRD patients exhibit impaired SARS-CoV-2 vaccine-immunogenicity, variably reduced with immunosuppressors. Among commonly used therapies, abatacept and B-cell depleting therapies show deleterious effects, while anticytokines preserved immunogenicity. The effects of cumulative methotrexate and glucocorticoid doses on immunogenicity should be considered. Humoral and cellular responses are weakly correlated, but CD4 and CD8 tightly correlate. Seroconversion alone might not reflect the vaccine's immunogenicity.

POS1192 INCIDENCE AND RISK FACTORS OF COVID-19 IN PATIENTS WITH VASCULITIS: A DANISH NATIONWIDE COHORT STUDY

S. Kristensen[1,2], R. L. Cordtz[1,3], K. Duch[1,4], J. Lindhardsen[5], C. Torp-Pedersen[6,7], L. Dreyer[1,2]. [1]*Aalborg University Hospital North, Rheumatology, Aalborg, Denmark;* [2]*Aalborg University, Clinical Medicine, Aalborg, Denmark;* [3]*Gentofte Hospital, Center for Rheumatology and Spine Diseases, Hellerup, Denmark;* [4]*Aalborg University Hospital, Unit of Clinical Biostatistics, Aalborg, Denmark;* [5]*Rigshospitalet, Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases,, København, Denmark;* [6]*North Zealand Hospital - Hillerød, Cardiology, Hillerød, Denmark;* [7]*Copenhagen University, Department of Public Health, København, Denmark*

Background: Patients with small vessel vasculitis (SVV) and large vessel vasculitis (LVV, including giant cell arteritis (GCA)) are considered at higher risk of infections compared to the general population, owing to their underlying condition and the use of immunosuppressive drugs. Thus, the risk of COVID-19 infection and related outcomes during the global pandemic is of immediate concern to rheumatologists worldwide.
Objectives: To estimate the incidence of COVID-19 hospitalisation in patients with vasculitis, and to evaluate the impact of glucocorticoid treatment on the outcome between March 2020 and February 2021.

	Abatacept	HCQ	Cumulative glucocorticoid dose	Cumulative methotrexate dose	Age > 65 years	Disease duration >10 years
Seronversion	β - 0.1 p= 0.04	β 0.22 p= 0.01	β - 0.26 p= 0.44	β - 0.19 p= 0.03	β - 0.27 p= 0.002	β - 0.10 p= 0.22
IgG anti-spike levels	β - 0.13 p= 0.001	β 0.27 p= 0.01	β - 0.25 p= 0.004	β - 0.29 p= 0.001	β - 0.19 p= 0.02	β - 0.14 p= 0.04
CD4 T-cell response	β - 0.1 p= 0.03	β 0.10 p= 0.24	β - 0.04 p= 0.61	β - 0.03 p= 0.64	β - 0.05 p= 0.56	β - 0.14 p= 0.11
CD8 T -cell response	β - 0.08 p= 0.02	β 0.20 p= 0.12	β - 0.1 p= 0.43	β - 0.02 p= 0.24	β - 0.1 p= 0.56	β - 0.1 p= 0.15

Methods: With use of the Danish nationwide registers, a cohort of patients with LVV and SVV, respectively, and general population controls (GPCs) matched on age and gender was established. Hazard ratios (HR) for COVID-19 hospitalisation was estimated. National COVID-19 surveillance data was used to calculate the odds ratio (OR) of having had a positive SARS-CoV2 PCR test. Lastly, a nested case-control design and conditional logistic regression was used to estimate the impact of glucocorticoids on the risk of hospitalisation.
Results: Patients with SVV (n=1090) had an increased incidence of COVID-19 hospitalisation compared with GPCs (comorbidity-adjusted HR 2·73; 95% CI 1·64-4·55), whereas no increased risk was seen in patients with LVV. Patients with vasculitis had similar likelihoods of having had a positive PCR test as GPCs. Glucocorticoids did not increase the HR of hospitalisation among patients with LVV or SVV.
Conclusion: Patients with SVV were more likely to be admitted with COVID-19 than the GPCs. The impact of glucocorticoid treatment on the risk of hospitalisation needs further investigation.

POS1193 COVID-19 IN PATIENTS WITH GIANT CELL ARTERITIS

J. Kramarič[1], R. Jese[2], M. Tomsic[1,3], Z. Rotar[1,3], A. Hočevar[1,3]. [1]*University Medical Centre Ljubljana, Department of Rheumatology, LJUBLJANA, Slovenia;* [2]*Modra Jagoda d.o.o., -, LJUBLJANA, Slovenia;* [3]*Medical Faculty, University of Ljubljana, Internal Medicine, LJUBLJANA, Slovenia*

Background: Patients with giant cell arteritis (GCA) represent a fragile population with an increased infection risk. In a recent study[1] older age, a higher number of comorbidities, higher disease activity, and prednisolone ≥10 mg qd were associated with worse COVID-19 outcomes.
Objectives: We aimed to evaluate the frequency and severity of COVID-19 in a well-defined GCA cohort.
Methods: We reviewed medical records of histologically and/or by imaging proven GCA patients diagnosed between September 2011 and February 2020 at our secondary/tertiary center and followed during the COVID-19 pandemic between March 2020 and December 2021 (22 months). Descriptive statistics was used to analyze the studied population.
Results: Of 314 GCA patients diagnosed for the first time during a 102-month period, 49 patients died before March 2020. Of the remaining 265 patients (69.4% females), SARS-CoV-2 infection was proven by PCR test in 39 (14.7%) patients (74.2% females, mean (SD) age at infection 76.2 (±9.6 years), 13 (33.3%) with large vessel GCA and 16 with cranial limited GCA). At the time of SARS-Cov-2 infection GCA was in a stable remission in 38 patients (13 without therapy, 10 on steroids alone, 9 on leflunomide monotherapy, 6 on steroids plus leflunomide (10 or 20 mg qd), 1 on ustekinumab; mean prednisolone equivalent dose of 4.6 mg qd) and relapsed in one patient 6 weeks earlier (prednisolone 30 mg plus leflunomide). Data on clinical manifestations of COVID-19 were available for 33 (84.6%) patients and are presented in Table 1, part A. Twenty-nine/39 (74.4%) patients had mild COVID-19 and were symptomatically treated at home, while 10 patients had severe infection (defined as a need of hospitalization and/or death), and one of those patients died due to COVID-19. One patient developed a transient neurologic ischemic attack related to COVID-19. Table 1, part B shows differences in GCA demographic and treatment at the time of mild vs. severe infection. We found no differences in gender, age, GCA type and GCA treatment between those with mild vs. severe COVID. Three patients developed COVID-19 after receiving two doses of anti-COVID vaccine (1.4% breakthrough rate). Overall, of 257 GCA patients eligible for vaccination, 210 (81.7%) were vaccinated by the end of December 2021.

PART A

Characteristics of COVID (33 GCA patients)	%		%
Symptom duration (d)	12±10	Respiratory insufficiency	27.3%
Fever	48.5%	Chest pain	21.2%
Headache	24.2%	Abdominal pain	18.2%
Rhinitis	27.3%	Nausea/vomiting	0%
Smell loss	39.4%	Diarrhoea	18.%
Taste loss	33.3%	Malaise/fatigue	66.7%
Cough	48.5%	Myalgia	42.4%
Dyspnoea	30.3%	Arthralgia	36.4%

PART B

Characteristics of GCA (39 GCA with COVID)	Mild COVID (29 pts.)	Severe COVID (10 pts.)	P value
Gender	22 (75.9%)	6 (60.0%)	0.423
Age (years)	75.2±9.8	78.9±9.0	0.865
LVV	10 (34.5%)	3 (30.0%)	1.0
No treatment	8 (27.6%)	5 (50.0%)	0.254
Steroids	12 (41.4%)	4 (40.0%)	1.0
Leflunomide	10 (34.5%)	5 (50.0%)	0.463
Ustekinumab	1	0	1.0

Conclusion: A quarter of our GCA patients had severe COVID-19. Low doses of glucocorticoids and treatment with leflunomide were not associated with severe COVID-19 course in our cohort.

POS1194 COVID-19 IN PATIENTS WITH INFLAMMATORY MYOPATHY

A. Hočevar[1,2], B. Radič[3], M. Krosel[1], M. Tomsic[1,2], Z. Rotar[1,2]. [1]*University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia;* [2]*Medical Faculty, University of Ljubljana, Internal Medicine, Ljubljana, Slovenia;* [3]*Celje General Hospital, Department of Rheumatology, Celje, Slovenia*

Background: Older age, male sex, multimorbidity and glucocorticoids emerged in rheumatic patients as risk factors for severe COVID-19.
Objectives: We aimed to evaluate the frequency and severity of COVID-19 in a well-defined cohort of patients with idiopathic inflammatory myopathy (IIM).
Methods: We analyzed medical records of IIM patients diagnosed and followed at our secondary/tertiary center between January 2005 and December 2021.
Results: During the 204-month period IIM was newly diagnosed in 191 patients, of whom 52 died before COVID-19 pandemic. Of the remaining 139 patients (69.8% females; 9 polymyositis, 47 dermatomyositis; 38 antisynthetase syndrome, 26 overlap syndrome; 17 immune mediated necrotizing myopathy; 2 inclusion body myositis), SARS-CoV-2 infection was proven in 13 (9.4%) patients (61.5% females, mean (SD) age at infection 62.9 (±16.8 years)). Seven/13 COVID-19 patients (53.8%) had a diagnosis of antisynthetase syndrome. At the time of infection IIM was in a remission in 12/13 patients and relapsed 5 weeks earlier in one patient. Seven patients were without immunomodulatory therapy, 1 patient was on steroids alone, 2 on DMARD alone, 3 on steroids and DMARD; a mean daily prednisolone equivalent dose was 5 mg). Eleven/13 (84.6%) patients had mild COVID-19 (one had an asymptomatic infection) and were treated symptomatically, while 2 patients were hospitalized due to severe infection (respiratory insufficiency). Table 1 shows clinical characteristics and duration of COVID-19 symptoms. During pandemic overall 9/139 (6.5%) patients with IIM died, including one patient due to COVID-19.

Table 1. Characteristics of COVID-19 in IIM patients

Characteristics (13 patients)	No.	Characteristics (13 patients)	No.	Characteristics (13 patients)	No.
PM/DM/ASyS/OS/IMNM	1/1/7/1/3	COVID duration (days)	14 (±5)	Respiratory insufficiency	2
F / M gender	8 / 5	Fever	9	Nausea	1
Age (years)	62 (±16)	Headache	4	Diarrhoea	1
IIM therapy		Rhinitis	1	Malaise/fatigue	7
Steroids	1	Smell loss	3	Vertigo	1
DMARD	2	Taste loss	3	Myalgia	2
Steroids+DMARD	3	Cough	4	Arthralgia	2
No treatment	7	Dyspnea	5		

Legend: IIM idiopathic inflammatory myopathy; PM polymyositis, DM dermatomyositis; ASyS antisynthetase syndrome, OS overlap syndrome; IMNM immune mediated necrotizing myopathy; F female; M male; DMARD immunomodulatory drug.

Conclusion: In our IIM cohort, antisynthetase syndrome represented a higher relative risk for COVID-19 compared to other IIIM subtypes.

POS1195 CAN PRE-TREATMENT INFLAMMATORY BIOMARKER LEVELS GUIDE TO DETERMINE APPROPRIATE TIME OF TOCILIZUMAB THERAPY IN COVID-19

D. Tecer[1], M. Çınar[1], M. N. Kaya[1], F. Bıcakcı[1], S. Colak[1], E. Tekgoz[1], S. Yilmaz[1]. [1]*University of Health Sciences Turkey, Gülhane Training and Research Hospital, Rheumatology, Ankara, Turkey*

Background: Due to the pleiotropic cytokine interleukin-6 (IL-6) plays a pivotal role in the pathogenesis of COVID- 19, tocilizumab, an inhibitor of the IL-6 receptors, was considered as an attractive therapeutic option. When the inflammation cascade is excessive and therapy is delayed, the efforts for suppression of inflammation does not necessarily reduce mortality in all cases. Besides, early using anti-cytokine therapy may lead to both increased cost and risks including iatrogenic immunosuppression (1). Defining of patients who will benefit from tocilizumab and determining optimal timing of tocilizumab will prevent drug-related side effects and increased costs due to unnecessary drug use.
Objectives: To investigate the reliability of pre-treatment levels of prognostic nutritional index (PNI), C-reactive protein/albumin ratio (CAR), systemic immune-inflammatory index (SII), IL-6, lactate dehydrogenase (LDH) as a treatment response biomarker in hospitalized COVID-19 patients who administered tocilizumab.
Methods: One hundred thirty three COVID-19 patients received tocilizumab were included. The end-points of treatment effectiveness were evaluated with the rate of death and emerging need for mechanical ventilation at 28 days of hospitalization. To determine independent mortality risk factors, multivariate logistic regression analyzes were performed for statistically different variables among groups that were statistically different in univariate analysis. The capacity of IL-6, CAR, PNI, SII and LDH values in predicting of tocilizumab response in COVID-19 patients were analyzed using receiver operating characteristic (ROC) curve analysis.
Results: 34 (25.56%) patients died after tocilizumab therapy. Patients who improved after tocilizumab were significantly younger and had significantly lower IL-6, LDH, SII, CAR and higher PNI than patients who died. In univariate analyses, mortality was significantly associated with age, IL-6, LDH, PNI, SII, CAR and CRP. In multivariate analysis, age (OR:1.070, 95%CI:1.019-1.124, p:0.007) and LDH (OR:1.006, 95CI%:1.003- 1.010, p<0.001) were found to be independent predictors of mortality after tocilizumab therapy. To identify of tocilizumab response in COVID-19 patients, IL6 had the highest area under curve (AUC) value (AUC:0.782, 95%CI:0694-0.870), followed by LDH (AUC:0.761, 95%CI:0.661-0.861), PNI (AUC:0.696, 95%CI:0.584-807), SII (AUC:0.671, 95%CI:0.551–0.790), CAR (AUC:0.682, 95%CI:0.578– 0.786) and CRP (AUC:0.643, 95%CI:0.535–0.751). Predictive performance of inflammatory biomarkers in the prediction of mortality after tocilizumab therapy was presented in Table 1.

Table 1. Predictive performance of inflammatory biomarkers in the prediction of mortality after tocilizumab therapy

	Sensitivity	Specificity	PLR	NLR	PPV	NPV	Accuracy	DOR
IL-6 (pg/mL) >143.12	64.71%	84.85%	4.27	0.42	59.46%	87.50%	79.70%	10.27
LDH (U/L)	73.53%	71.72%	2.60	0.37	47.17%	88.75 %	72.18%	7.04
>460								
PNI<31.35	55.88%	79.80%	2.77	0.55	48.72%	84.04%	73.68%	5.00
SII>3895.92	47.06%	90.91%	5.18	0.58	64.00%	83.33%	79.70%	8.89
CAR>61.15	61.76%	67.68%	1.91	0.56	39.62%	83.75%	66.17%	3.38

CAR: C-reactive protein/albumin ratio; DOR: diagnostic odds ratio; IL-6: interleukin-6; LDH: lactate dehydrogenase; NLR: negative likelihood ratio; NPV: negative predictive value; PLR: positive likelihood ratio; PNI: prognostic nutritional index; PPV: positive predictive value; SII: systemic immune-inflammatory index.

Conclusion: Although the patients with significantly lower IL-6, LDH, SII, CAR and higher PNI levels improved after tocilizumab therapy, only serum LDH levels and age were found to be as independent predictors of mortality. To specify the optimal time interval and the patients who will benefit from tocilizumab, these biomarkers may be used.

SARS-COV-2 VACCINE ACCEPTANCE AND ASSOCIATED PSYCHOLOGICAL FACTORS IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES

H. Sugawara[1], H. Doi[1], T. Iwasaki[2], Y. Nakayama[2], Y. Nishida[2], Y. Gon[2], M. Kamakura[3], K. Ohbori[3], N. Sakane[1], N. Nakamura[3], T. Utsumi[1], A. Morinobu[2]. *[1]Shiga General Hospital, Department of Immunology, Moriyama, Japan; [2]Graduate School of Medicine, Kyoto University, Department of Rheumatology and Clinical Immunology, Kyoto, Japan; [3]Shiga General Hospital, Department of Pharmacy, Moriyama, Japan*

Background: The mortality rate of coronavirus disease 2019 (COVID-19) in patients with rheumatic and musculoskeletal disease (RMD) is as high as approximately 10% [1]. Therefore, vaccination promotion is a critical issue. However, there are few reports on the psychological aspects of patient vaccine acceptance.
Objectives: To investigate the intention of patients with RMD to receive the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccine and explore the psychological factors related to vaccine acceptance.
Methods: We conducted a questionnaire-based survey of 406 outpatients with RMD at Shiga General Hospital from July to October 2021. The questionnaire included the following sections: (1) vaccination status; (2) expectation of susceptibility to severe COVID-19; (3) expectation of vaccine efficacy; and (4) anxiety about the vaccine, which included concerns on I) the diminishing effect of the vaccine due to current treatment and II) the influence of vaccination on: i) primary disease status, ii) treatment, and iii) adverse reaction.
Results: There were 305 vaccinated and 101 unvaccinated individuals. Unvaccinated individuals were classified into the acceptance group (n=60) and hesitancy group (n=41) according to their vaccination status (Figure 1).

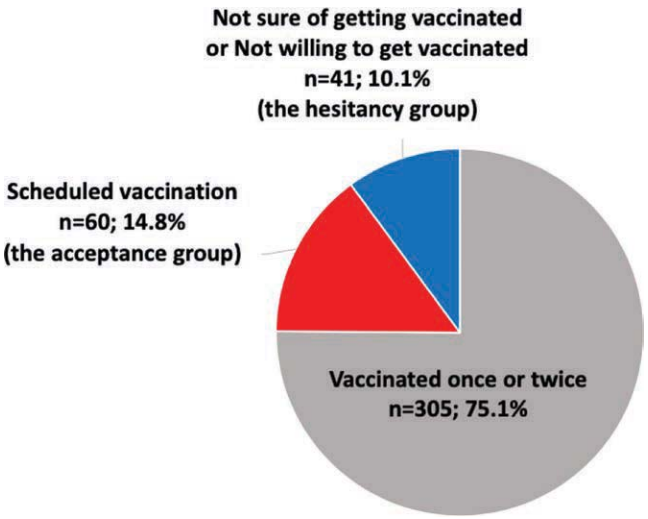

Figure 1. SARS-CoV-2 vaccination status (n=406)

We compared the backgrounds and awareness of the patients on vaccination between the two groups. Univariate analysis did not show any difference in the backgrounds. The expectation of susceptibility to severe COVID-19 was similar

Table 1. Awareness towards COVID-19 and SARS-CoV-2 vaccine associated with vaccination intention

Awareness towards COVID-19 and SARS-CoV-2 vaccine	Acceptance (N=60)		Hesitancy (N=41)		Univariate Analysis§	Multivariate Analysis‖
	Median	[IQR]	Median	[IQR]	*p*-value	*p*-value
Expectation of susceptibility to severe COVID-19 *	2.0	[1.0-3.0]	2.0	[1.5-2.5]	0.8472	0.3440

Concern about the effect of vaccination on primary disease status‡	3.0	[1.0-3.0]	3.0	[2.0-3.0]	0.0576	0.7134
Concern about the effect of vaccination on adverse reaction‡	3.0	[3.0-3.0]	3.0	[3.0-4.0]	0.0093	0.8335

*0: Less likely to become severe~3: Very likely to become severe, †0: Not expected at all~4: Highly expected, ‡0: Not concerned at all ~4:Very concerned§Pearson's chi-square test or Wilcoxon test, ‖Nominal logistic regression analysis, ¶ $p<0.008$ (after Bonferroni correction), ** $p<0.05$.

in both groups. There were also no significant differences in the vaccine-related anxiety levels. However, the expectation of vaccine efficacy was higher in the acceptance group and significantly influenced vaccination intention as revealed by multivariate analyses (Table 1).

Conclusion: The perception of vaccine efficacy is strongly correlated with vaccine acceptance. In order to promote vaccination in patients with RMDs, this study suggests that emphasizing the efficacy of the vaccine may be more effective than alleviating anxiety about the adverse effects of the vaccine.

Hetland[1,2]. *[1]University Hospital of Copenhagen Rigshospitalet, DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark; [2]University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark; [3]Gentofte and Herlev Hospital, Department of Rheumatology, Center for Rheumatology and Spine Diseases, Gentofte, Denmark; [4]University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark; [5]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark; [6]Zealand University Hospital, Department of Rheumatology, Køge, Denmark; [7]Odense University Hospital, Department of Rheumatology, Odense, Denmark; [8]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [9]Aarhus University, Department of Clinical Medicine, Health, Aarhus, Denmark; [10]Odense University Hospital and University of Southern Denmark, Rheumatology Research Unit, Odense, Denmark; [11]Odense University Hospital and Svendborg Hospital, Rheumatology Section, Department of Medicine M, Odense, Denmark; [12]University of Southern Denmark, Department of Clinical Research, Odense, Denmark; [13]Silkeborg Regional Hospital, Diagnostic Center, Silkeborg, Denmark; [14]Horsens Regional Hospital, Department of Medicine, Horsens, Denmark; [15]Zitelab, Zitelab, Copenhagen, Denmark; [16]Gigtforeningen, Danish Rheumatism Association, Copenhagen, Denmark*

Background: During COVID-19 related lockdowns, physical attendance may be replaced by remote (by telephone, email, video consultations in patients with inflammatory rheumatic diseases (IRD). During re-opening of society, reallocation of health-care resources could potentially cause persistent changes in access to physical consultations.

Objectives: To explore use of remote consultations in patients with IRD followed in the nationwide DANBIO registry at three time points (lockdown from spring 2020 followed by gradual reopening of society) during the COVID-19 pandemic. Furthermore, to explore satisfaction with treatment access, and preferred mode of consultation including potentially associated clinical factors.

Methods: We performed a nationwide survey where three times, an online questionnaire (Q) "*You and your arthritis in times of COVID-19"* with questions regarding use of and access to remote and physical consultations was sent to all patients in DANBIO (Q1: March-April 2020, Q2: November 2020, Q3: May 2021). (ref)

Patient characteristics were captured in DANBIO (gender/age/diagnosis/biological therapy) and from the questionnaire (work status/comorbidities/EQ-5D). Use of physical and/or remote consultations 0-3 months before surveys and satisfaction with access was identified. Clinical factors associated with a preference for physical consultations at time of Q3 (versus remote contact (telephone/e-mail/video)) were explored with multivariable logistic regression analysis.

Results: Totally, 12,789/14,755/13,921 patients responded to Q1/Q2/Q3, respectively, with 23,311 unique patients participating in at least one survey. Characteristics of patients responding to Q3 are shown in Table 1.

Table 1. Respondents to questionnaire 3, n=13,921.

EQ-5D, median (IQR)		0.8 (0.7-0.9)

EQ-5D: EuroQol quality of life (5-dimension)*By March 2020

During the preceding 3 months, proportions of patients with physical/remote consultations were 22%/45%, 41%/38%, 40%/39% for Q1, Q2, Q3, respectively. Remote consultations were mainly by telephone, whereas email (<5%) and video (<1%) were rarely used. In all three surveys, only 7% of respondents found that access to counseling with their rheumatologist had deteriorated during the pandemic (Figure 1A) whereas the majority found it to be unchanged or did not know. The preferred contact form was physical consultations (68-74%, Figure 1B, not available for Q1). Factors associated with preference for physical consultation were female gender, higher age (>60 years), biological treatment, low EQ-5D and not having axial spondyloarthritis, whereas work status and comorbidities were without significance (logistic regression analyses, details not shown).

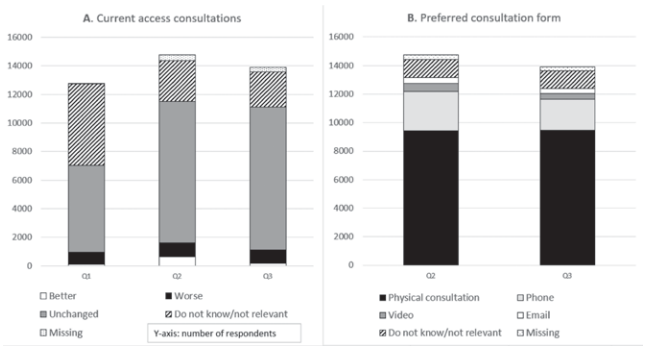

Figure 1.

Conclusion: Despite a widespread use of remote consultations during the pandemic, nationwide questionnaire surveys performed at three time-points during the COVID-19 pandemic showed that most patients were satisfied with access to rheumatic counseling. Nevertheless, in-person contacts were preferred by most patients, mainly women and elderly.

POS1198

VACCINATION AGAINST COVID-19 SHOULD BE ENCOURAGED IN PATIENTS WITH RHEUMATIC DISEASE, AS MOST PATIENTS DEVELOP A SEROLOGICAL RESPONSE AGAINST THE VACCINE AND VACCINATION REDUCES SELF-IMPOSED ISOLATION AND SHIELDING BEHAVIOR

C. Ammitzbøll[1], M. K. Thomsen[2], J. B. Andersen[1], L. E. Bartels[1], M. L. F. Hermansen[1], A. D. Johannesen[1], C. M. Jørgensen[1,3], S. Mikkelsen[4], S. R. Vils[3], C. Erikstrup[4], E. M. Hauge[1], A. Troldborg[1,3]. *[1]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [2]Aarhus University Hospital, Microbiology, Aarhus, Denmark; [3]Aarhus University, Biomedicine, Aarhus C, Denmark; [4]Aarhus University Hospital, Clinical Immunology, Aarhus, Denmark*

Background: Vaccine trials of the SARS-CoV-2 mRNA vaccines were encouraging but excluded most patients with rheumatic diseases (RD) and patients treated with immunosuppressive therapy. However, reports of a more severe COVID-19 disease course in patients with RDs prompted strategies for expediting vaccination of RD patients in most countries. In addition to the impact experienced by most people of the pandemic, patients with RDs were adversely impacted by the potential risk of severe COVID-19 due to their disease and immunosuppressive treatment. Fear of COVID-19 led to disproportionate anxiety, self-isolation, and shielding behavior for many RD patients at the beginning of the pandemic.

Objectives: We investigated antibody levels in serum against SARS-CoV-2 after a two-dose vaccination with an mRNA vaccine in patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Further, we examined the association between reactogenicity and immunogenicity and how vaccination influenced patient behavior concerning fear of COVID-19 and shielding.

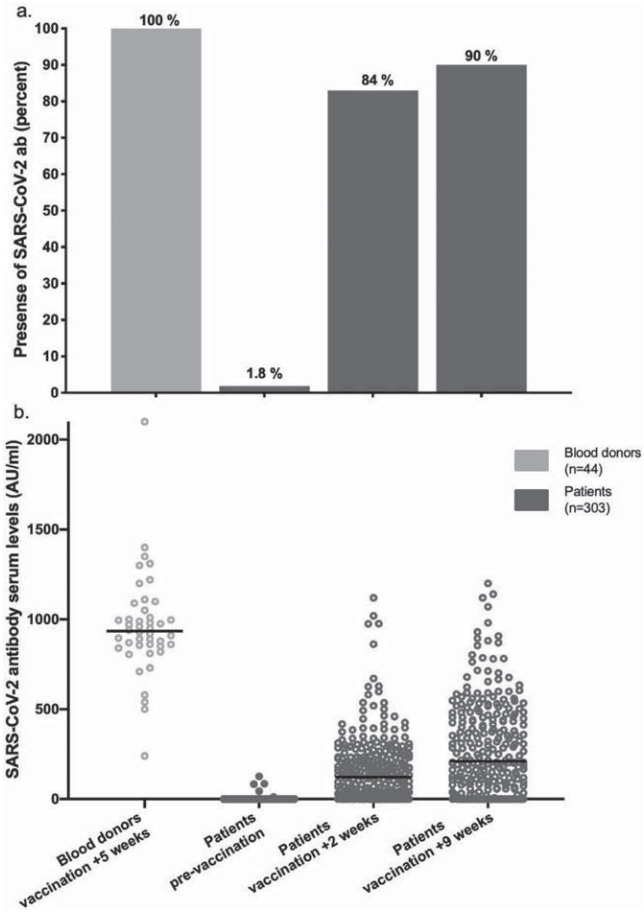

Figure 1. Total antibody response against SARS-CoV-2 after two mRNA vaccines. Antibody response against mRNA COVID-19 vaccine pre-vaccination, 1 and 9 weeks after in patients with rheumatic diseases and 5-6 weeks after vaccination in blood donors. (A) Percentage with measurable SARS-CoV-2 antibody results after vaccination. (B) Levels of SARS-CoV-2 antibodies in serum.

Methods: Patients with SLE or RA from the COPANARD (Corona PANdemic Autoimmune Rheumatic Disease)[1] cohort received two doses of an mRNA vaccine between January and August 2021 and had total antibodies against SARS-CoV-2 measured before vaccination and 2 and 9 weeks after the second vaccination. In addition, patients answered an electronic questionnaire before and eight weeks after vaccination concerning behavior, anxiety, and symptoms of depression (PHQ-9).

Results: Three-hundred-and-three patients and 44 blood donors (healthy controls) were included. Significantly fewer patients (90%) had measurable antibodies against SARS-CoV-2 compared to blood donors (100%) after the second vaccination (p<0.001) (Figure 1). Treatment with Rituximab was the strongest predictor of unfavorable vaccine response, as only 27% were seropositive after vaccination. We found a negative effect of prednisone and methotrexate but no effect of age, comorbidity, or pausing medication on seroconversion. Patients experienced significant improvement after vaccination in 10 out of 12 questions regarding behavior and fear of COVID-19, but no change was observed in symptoms of depression (p=0.62) or anxiety (p=0.46).

Conclusion: The majority of patients with SLE or RA had a measurable serological response to the COVID-19 mRNA vaccine after two doses. Treatment with Rituximab was the strongest predictor of no seroconversion. Our findings warrant encouragement of vaccination against COVID-19 for patients with RD, as most patients benefits with both a serological immune response and reduced isolation and shielding behavior.

Subils[3], R. Gallo[3], S. I. Pineda Vidal[3], J. L. Velasco Zamora[3], N. Lloves Schenone[3], V. Cosentino[3], F. Rodriguez[3], M. P. Diaz[3], M. Viola[3], M. L. Mamani Ortega[3], E. Buschiazzo[3], G. Gómez[4], K. Roberts[4], R. Quintana[4], C. A. Isnardi[4], G. Pons-Estel[4]. *[1]Córdoba Hospital, Rheumatology, Córdoba, Argentina; [2]Universidad Nacional de Córdoba, Facultad de Ciencias Médicas, Córdoba, Argentina; [3]On behalf of the SAR-COVID Registry, Sociedad Argentina de Reumatología, Buenos Aires, Argentina; [4]Argentine Society of Rheumatology, Research Unit, Buenos Aires, Argentina*

Background: Comorbidities, particularly cardio-metabolic disorders, are highly prevalent in patients with psoriatic arthritis (PsA) and they were associated with an increased risk of atherosclerotic cardiovascular disease, which have been associated with higher morbidity and mortality. Whether PsA enhances the risk of SARS-CoV-2 infection or affects the disease outcome remains to be ascertained.

Objectives: To describe the sociodemographic, clinical and treatment characteristics of patients with PsA with confirmed SARS-CoV-2 infection from the SAR-COVID registry and to identify the variables associated with poor COVID-19 outcomes, comparing them with those with rheumatoid arthritis (RA).

Methods: Cross-sectional observational study including patients ≥18 years old, with diagnosis of PsA (CASPAR criteria) and RA (ACR / EULAR 2010 criteria), who had confirmed SARS-CoV-2 infection (RT-PCR or serology) from the SAR-COVID registry. Recruitment period was between August 13, 2020 and July 31, 2021. Sociodemographic variables, comorbidities, and treatments were analyzed. To assess the severity of the infection, the ordinal scale of the National Institute of Allergy and Infectious Diseases (NIAID)1 was used, and it was considered that a patient met the primary outcome, if they presented criteria of categories 5 or higher on the severity scale. For this analysis, Chi2 test, Fisher's test, Student's test or Wilcoxon test, and binomial logistic regression using NIAID>=5 as dependent variable were performed.

Results: A total of 129 PsA patients and 808 with RA were included. Clinical characteristics are shown in Table 1. Regarding PsA treatment, 12.4% of PsA were receiving IL-17 inhibitors, 5.4% IL12-23 inhibitors, one patient apremilast and one abatacept. The frequency of NIAID≥5 was comparable between groups (PsA 19.5% vs RA 20.1%; p=0.976). (Figure 1).

Table 1. Characteristics of patients with PsA and RA who presented COVID-19 in the SAR-COVID registry.

	Psoriatic arthritis (n=129)	Rheumatoid arthritis (n=808)	P value	Total (n=937)
Age (years), mean (SD)	51.7 (12.7)	53.1 (12.9)	0.239	52.9 (12.9)
Female	72 (55.8)	684 (84.7)	<0.001	756 (80.7)
Comorbidities	65 (50.4)	355 (43.9)	0.203	420 (44.8)
Obesity (BMI ≥30)	19 (15.2)	102 (13.4)	0.692	121 (13.7)
Morbid obesity (BMI ≥40)	1 (0.8)	10 (1.3)	1	11 (1.25)
Hypertension	35 (28.5)	205 (26.8)	0.783	240 (27.0)
Diabetes	16 (13.0)	67 (8.8)	0.188	83 (9.39)
Dyslipidemia	24 (19.5)	102 (13.5)	0.106	126 (14.4)
Cardiovascular or cerebrovascular disease	5 (11.4)	32 (3.9)	0.033	37 (4.2)
Two or more comorbidities	55 (42.6)	219 (27.1)	<0.001	274 (29.2)
Current smoking	4 (3.6)	60 (8.4)	0.79	64 (7.7)
High disease activity	0 (0)	29 (3.8)	0.027	29 (3.23)
Glucocorticoids treatment	5 (20.0)	95 (60.1)	<0.001	100 (54.6)
Conventional DMARDs	47 (36.4)	443 (54.8)	<0.001	490 (52.3)
Biologic DMARDs	60 (46.5)	193 (23.9)	<0.001	253 (27.0)
JAK inhibitors	4 (3.10)	72 (8.9)	0.038	76 (8.1)
Full recovery of COVID-19	105 (84.0)	644 (81.7)	0.127	749 (82.0)
COVID-19 complications	16 (12.5)	68 (8.7)	0.227	84 (9.2)
Death due to COVID-19	1 (0.8)	34 (4.3)	0.074	35 (3.8)

Notes=values n (%) unless otherwise indicated; BMI: Body Mass Index; DMARDs: disease-modifying antirheumatic drugs; JAK inhibitors: Janus kinase inhibitors.

PsA patients with NIAID≥5 in comparison with NIAID<5 were older (58.6±11.4 vs 50±12.5; p=0.002), had more frequently hypertension (52.2% vs 23%; p=0.011) and dyslipidemia (39.1% vs 15%; p=0.017). In the multivariate analysis, age (OR 1.06; 95% CI 1.02–1.11) was associated with a worse outcome of the COVID-19 (NIAID≥5) in patients with PsA, while those who received methotrexate (OR 0.34; 95% CI 0.11–0.92) and biological DMARDs (OR 0.28; 95% CI 0.09–0.78) had a better outcome.

Graphic 1. COVID -19 severity according to the ordinal scale of the National Institute of Allergy and Infectious Diseases (NIAID) in PsA and RA patients.

Conclusion: Although PsA patients have a higher frequency of cardiovascular and metabolic comorbidities than those with RA, the COVID-19 severity was similar. Most of the patients had mild SARS-CoV-2 infection and a low death rate.

DIFFERENCES BETWEEN THE FIRST AND THE SECOND WAVE OF SARS-COV-2 INFECTION IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES IN ARGENTINA: DATA FROM THE SAR-COVID REGISTRY

A. Bertoli[1], L. Muñoz[1], M. J. López Pérez[1], L. Sanchez Freytes[1], M. S. Castaño[1], V. Saurit[2], G. Berbotto[2], G. Alle[2], M. Severina[2], R. Nieto[2], F. Maldonado[2], M. Pera[2], A. K. Cogo[2], A. R. Baños[2], F. Vivero[2], D. A. Pereira[2], M. Cosatti[2], V. Savio[2], R. Perez Alamino[2], M. A. Medina[2], M. Schmid[2], F. Risueño[2], M. I. Quaglia[2], G. P. Pendon[2], L. Casalla[2], M. Delavega[2], M. A. Lazaro[2], P. Finucci[2], J. Morbiducci[2], C. Romeo[2], N. Cucchiaro[2], S. Moyano[2], T. Barbich[2], S. M. Conti[2], C. Goizueta[2], E. R. Tralice[2], C. Maldini[2], J. Rebak[2], R. Gallo[2], P. Maid[2], J. L. Velasco Zamora[2], N. Lloves Schenone[2], S. Porta[2], N. S. Morales[2], M. P. Diaz[2], M. Viola[2], E. Buschiazzo[2], G. Gómez[2], K. Roberts[2], R. Quintana[2], C. A. Isnardi[2], G. Pons-Estel[2], C. E. Matellan[2]on behalf of UNISAR - SAR COVID Registry. [1]*Clínica Universitaria Reina Fabiola, Universidad Católica de Córdoba., Rheumatology Division, Córdoba, Argentina;* [2]*On behalf of the SAR-COVID Registry, Sociedad Argentina de Reumatología, Buenos Aires, Argentina*

Background: In Argentina we have witnessed two COVID 19 waves between 2020 and 2021. The first wave occurred during the spring of 2020 and it was related to the wild type of the virus, the second occurred during the fall/winter of 2021 when the gamma variant showed a clear predominance. During the first wave, patient with rheumatic diseases showed a higher frequency of hospitalization and mortality (4% vs 0.26%) when compared to the general population[1]; at that time, however, vaccination was not yet available.

Objectives: To compare sociodemographic and disease characteristics, course and outcomes of SARS-CoV-2 infection in patients with immune-mediated/auto-inflammatory diseases (IMADs) during the first and second waves in Argentina.

Methods: SAR-COVID is a national, multicenter, longitudinal and observational registry, in which patients ≥18 years of age, with a diagnosis of a rheumatic disease who had confirmed SARS-CoV-2 infection (RT-PCR or positive serology) were consecutively included since August 2020. For the purpose of this report, only patients with IMADs who had SARS-CoV-2 infection during the first wave (defined as cases occurred between March 2020 and March 2021) and the second wave (cases occurred between April and August 2021) were examined. Sociodemographic characteristics, disease diagnosis and activity, comorbidities, immunosuppressive treatment and COVID 19 clinical characteristics, complications and outcomes: hospitalization, intensive care unit (ICU) admission, use of mechanical ventilation and death were compared among groups. Descriptive statistical analysis was performed. Variables were compared with Chi squared test and Student T test or Mann Whitney test. Multivariable logistic regression models with forward and backward selection method, using hospitalization, ICU admission and death as dependent variables were carried out.

Results: A total of 1777 patients were included, 1342 from the first wave and 435 of the second one. Patients had a mean (SD) age of 50.7 (14.2) years and 81% were female. Both groups of patients were similar in terms of socio-demographic features, disease diagnosis, disease activity, the use of glucocorticoids ≥ 10 mg/day and the immunosuppressive drugs (Table 1 below). Patients infected during the first wave have higher frequency of comorbidities (49% vs 41%; p= 0.004). Hospitalizations due to COVID 19 (31% vs 20%; p <0.001) and ICU admissions (9% vs 5%; p= 0.009) were higher during the first wave. No differences in the use of mechanical ventilation (16% vs 16%; p= 0.97) nor in the mortality rate (5% vs 4%; p= 0.41) were observed. In the multivariable analysis, after adjusting for demographics, clinical features and immunosuppressive treatment, patients infected during the second wave were 40% less likely to be hospitalized (OR= 0.6, IC95% 0.4-0.8) and to be admitted to the ICU (OR= 0.6, IC95% 0.3-0.9).

Table 1.

Variable (% or Mean – SD)	First wave (n=1342)	Second wave (n=435)	p Value
Female gender	81	80	0.7
Age (years)	51.0 (14.5)	50.0 (13.3)	0.2
Disease diagnosis			
Rheumatoid arthritis	46	46	1
Ankylosing spondylitis	10	11	0.8
Systemic lupus erythematosus	17	185	0.9
Systemic Scleroderma	5	5	1
Sjögren´s syndrome	6	5	0.7
Inflammatory myopathies	3	3	0.5
Vasculitis	4	3	0.4
Disease activity			
High	4	3	0.5
Use of immune modulators			
DMARDcs	53	56	0.2
DMARDts	4	6	0.1
DMARDb	82	82	1
Use of glucocorticoids ≥10 mg	12	12	0.9
Comorbidities	49	41	**0.004**

Conclusion: The impact of COVID 19 in Argentina, in terms of mortality in patients with IMADs was still higher compared to the general population during the second wave. However, the frequency of hospitalizations and ICU admissions was lower. These findings could be explained by the introduction of the SARS COV 2 vaccination and, probably, by the cumulative knowledge and management improvement of this infection among physicians.

Pisoni[1]. *[1]CEMIC Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno, Rheumatology Section, Buenos Aires, Argentina; [2]On behalf of the SAR-COVAC Registry, SAR Research Unit, Buenos Aires, Argentina*

Background: Patients with rheumatic diseases (RD) have been excluded from SARS-CoV-2 vaccine trials, though data appear to show safety and efficacy, mostly evidence remains in mRNA vaccines. In our country, adenovirus-vector, inactivated and heterologous scheme vaccines are frequently used.

Objectives: To describe the safety of SARS-CoV-2 vaccines in patients with RD from the national registry SAR-CoVAC and to assess sociodemographic and clinical factors associated to AE and disease flares after vaccination.

Methods: Adult patients with RD who have been vaccinated for SARS-CoV-2 from de Argentine Society of Rheumatology Vaccine Registry (SAR-CoVAC) were consecutively included between June 1st and December 21st, 2021, This is a national multicentric observational registry that includes patients that have received at least one dose of any SARS-CoV-2 available vaccines in Argentina. Data is voluntarily collected by the treating physician. Naranjo scale was use to assess the association between the AE and vaccination. Homologous and heterologous schedules were defined according to whether both vaccines received were the same or different, respectively. Descriptive statics, Chi2 test, Fischer test, T test, ANOVA and multivariate regression logistic model were used.

Results: A total of 1679 patients, with 2795 SARS-CoV-2 vaccine doses were included. Vaccines more frequently used were: Gam-COVID-Vac (1227 doses, 44%), ChAdOx1 nCov-19 (872 doses, 31%), BBIBP-CorV (482 doses, 17%) and mRAN-1273 (172 doses, 6%). Altogether, 510 EA were experienced by 449 (27%) patients. Pseudo-flu syndrome was the most frequent (11%), followed by injection site reaction (7%). They were significantly more frequent after the first dose in comparison to the second one (13% vs 7% and 9% vs 5%, respectively, p<0.001 in both cases). All were mild or moderate and no patient was hospitalized due to an AE. One case of moderate anaphylaxis was reported by a patient who received Gam-COVID-Vac. No cases of vaccine-induced thrombotic thrombocytopenia were observed. There were 25 disease flares reported, 17 (68%) cases of arthritis. Among patients with two doses, those with heterologous schedule presented AE more frequent after the second dose (39% vs 17%).Total incidence of EA was 182.5 events/10 00 doses, it was significantly lower for BBIBP-CorV (105.9 events/1000 dosis, p<0.002 for all cases). The higher incidence of AE was observed for mRAN-1273 (261.6 events/1000 doses) and ChAdOx1 nCov-19 (232.8 events/1000 doses). Patients with AE were younger [mean 55 years (SD 14) vs 59 years (SD 14), p <0.010], not Caucasian ethnicity [48% vs 35%, p<0.001], had higher education level [mean 13.8 years (SD 4) vs 11.9 years (SD 5), p<0.001], were more frequently employed [54% vs 44%, p<0.001], lived mostly in urban area [99% vs 95% p <0.001, had more frequently dyslipidemia [38% vs 28% p 0.012], and less frequently arterial hypertension [49% vs 65%, p<0.001]. Systemic lupus erythematosus [11% vs 7%, p=0.039] and Sjögren syndrome [6% vs 1.8%, p<0.001] were more frequent among them, while non inflammatory diseases were less prevalent [19% vs 31%, p<0.001]. They were taking steroids [24 vs 18%, p=0.007], antimalarials [17% vs 10%, p<0.001] and methotrexate [41% vs 31%, p <0.001] more frequently. In the multivariable analysis, mRAN-1273 and ChAdOx1 nCov-19 were associated with AE, while BBIBP-CorV with lower probability of having one. (Figure 1)

Conclusion: The incidence of AE was 1825 events/1000 doses, were significantly higher for mRAN-1273 and ChAdOx1 nCov-19 and lower for BBIBP-CorV. Most common AE was pseudo-flu syndrome. Female sex, being younger, higher education level, ChAdOx1 nCov-19 and mRAN-1273 vaccines, the use of methotrexate and antimalarials were related of EA in patients with RD.

POS1202

B-CELL RECONSTITUTION IS STRONGLY ASSOCIATED WITH A POSITIVE SEROLOGIC RESPONSE TO THE COVID-19 BOOSTER VACCINE IN PREVIOUSLY SEROLOGICALLY UNRESPONSIVE RITUXIMAB TREATED RHEUMATIC DISEASE PATIENTS

K. Schultz[1], D. Jannat-Khah[1,2], R. Spiera[1,2]. *[1]Hospital for Special Surgery, Medicine, New York, United States of America; [2]Weill Cornell Medical College, Medicine, New York, United States of America*

Background: Booster doses of SARS-CoV-2 vaccines have emerged as an important strategy for containing the pandemic and may be especially important to rituximab treated patients. B-cell depletion has been associated with worse outcomes from COVID-19 infection, and many rituximab treated patients demonstrate an inadequate serologic response to the initial vaccine series (1). Strategies to optimize serologic response to COVID-19 vaccine boosters in previously serologically unresponsive patients is, therefore, of particular relevance.

Objectives: To assess factors associated with serologic response to COVID-19 booster vaccines in rituximab treated patients previously serologically unresponsive to the initial vaccine series.

Methods: A retrospective chart review of rituximab treated patients who failed to demonstrate a serologic response to the first SARS-CoV-2 vaccination series and subsequently received an mRNA vaccine booster was performed. Serologic response four weeks or more after the booster was the primary outcome. T-tests, Fisher's exact tests, and Wilcoxon rank sum tests were used for comparisons. Box and whisker plots were constructed to visualize differences between serologic response.

Results: In 31 rituximab treated patients who were seronegative following the initial vaccine series, demographic characteristics, concurrent therapies, rheumatologic diagnosis, and vaccine type were not associated with serologic positivity to the booster vaccine (Table 1). B-cell reconstitution was significantly different between those with positive (median, IQR 1.785 (0.65, 3)) and negative (median, IQR 0 (0,0)) serologic responses to the booster (p-value<0.001) as was time from last rituximab exposure (p-value = 0.030) (Figure 1). Positive predictive value of B-cell presence was 90.9% (95% CI: 70.8%, 98.9%) and negative predictive

Table 1. Bivariate comparisons between seronegative and seropositive patients to the COVID-19 booster vaccine by patient characteristics and demographics

Factor	Value	Negative	Positive	p-value[a]
N	31	10	21	
Age, median (IQR)	64 (51, 72)	63 (51, 69)	65 (51, 73)	0.75
Sex				1.00
Female	23 (74%)	7 (70%)	16 (76%)	
Male	8 (26%)	3 (30%)	5 (24%)

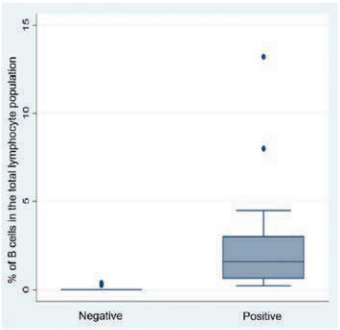
[a]P-values are from Fisher's exact test, Student's T-test and Wilcoxon rank sum tests[b]Immunosuppressants included Leflunomide, Azathioprine, Methotrexate, Mycophenolate Mofetil, and Tocilizumab IQR= Interquartile range

Figure 1: COVID-19 booster vaccine response in rituximab treated patients by B-cell status



Among N=29 people with % B-cells available, 9 were serologically negative and 20 were serologically positive. The percentage of B-cells among the negative serologic response median IQR was 0 (0, 0). Among the positive serologic vaccine response group, the median IQR was 1.785 (0.65, 3). The p-value is from the Wilcoxon rank sum test. The Y-axis is the percentage of B-cells in the total lymphocyte population as measured by flow cytometry.

value was 100% (95% CI: 59%, 100%) for serologic response to the mRNA booster. Positive predictive value of time >6 months from last rituximab to the booster was 78.3% (95% CI 56.3%, 92.5%) and the negative predictive value was 62.5% (95% CI 24.5%, 91.5%).

Conclusion: Presence of detectable B-cells and longer time from last rituximab were associated with the development of SARS-CoV-2 spike protein antibodies following the booster vaccine. These factors should be considered in timing of administration of booster vaccine doses in previously unresponsive rituximab treated patients.

Background: In acute COVID-19 infection, growing evidence hints towards a broad activation of plasma cells and the presence of pathologic autoantibodies (abs). A systematic screening for abs confirmed induction of diverse functional abs by SARS-CoV-2 infection (1, 2). Immune-mediated thrombosis, involving platelet activation, has been identified as one of the key pathogenic mechanisms in COVID-19 and is linked to morbidity and mortality (3). As natural abs against G protein-coupled receptors, functional abs against the thrombin receptor type-1 (PAR-1) might predispose for increased activation of the coagulation system present in COVID-19 infection.

Objectives: The aim of this study is to identify the diagnostic value of anti-PAR1 antibodies and their capacity to predict the outcome of COVID-19 infection.

Methods: 82 serum samples from 55 individuals with COVID-19 derived from three different hospitals in Schleswig-Holstein, Germany, and 88 single time point samples from healthy controls were subjected to ELISA-based quantification of anti-PAR-1 abs (CellTrend GmbH Luckenwalde, Germany). The levels of anti-AT1R abs were compared with clinical and laboratory parameters.

Results: COVID-19 patients revealed markedly increased levels of circulating anti-PAR1 abs in hospitalized patients particularly in those required intensive care treatment in comparison to controls ($p < 0.0001$, Figure 1a). Anti-PAR1 ab levels were highest in patients with fatal outcome ($p = 0.006$, Figure 1a). Receiver operating characteristic (ROC) analysis of PAR1 abs levels in COVID-19 patients revealed a sensitivity of 84.00% and a specificity 79.25% for patients requiring intensive care unit (ICU) treatment and a sensitivity of 87.50 % and a specificity 84.51 % to distinguish fatal vs. non-fatal disease outcome (Figure 1b). We found correlation of circulating anti-PAR1 abs with D dimers.

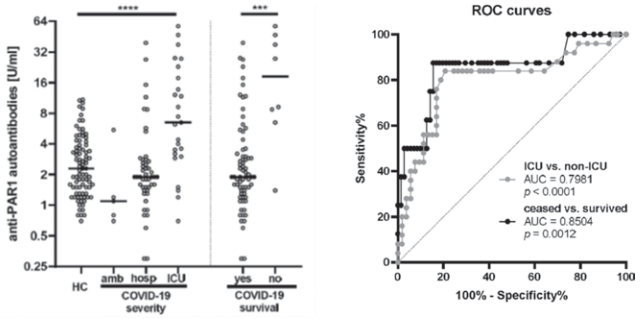

Figure 1. Levels of anti-PAR-1 abs in healthy controls (HC) versus COVID-19 positive patients with different disease severity and in non survivors (left). ROC curves are shown to discriminate patients requiring intensive care unit (ICU) or survivors in COVID-19 infection.

Conclusion: The increased anti-PAR1 abs, their prediction to identify patients requiring ICU and fatal outcome, and the correlation with markers for blood clotting suggest a role for antibodies against PAR1 in the disease development of blood clotting in COVID-19.

Luna[2], C. Echeverria[2], B. M. Virasoro[2], K. Roberts[2], C. A. Isnardi[2], E. E. Schneeberger[2], G. Pons-Estel[2], C. Pisoni[1]. *[1]CEMIC Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno, Rheumatology Section, Buenos Aires, Argentina; [2]On behalf of the SAR-COVAC registry, SAR Research Unit, Buenos Aires, Argentina*

Background: Patients with rheumatic diseases (RD) have been excluded from SARS-CoV-2 vaccine trials. Though data appear to show safety and efficacy, mostly evidence remains in mRNA vaccines. However in our country, adenovirus and inactivated vaccines, as well as heterologous schemes are frequently used.

Objectives: To describe clinical characteristics and outcomes of SARS-CoV-2 infection after vaccination in patients with RD from de the SAR-CoVAC registry and to compare them with patients who got infected before vaccination. Additionally, factors associated with COVID-19 unfavorable outcome were assessed.

Methods: Adult patients with RD who have been vaccinated for SARS-CoV-2 were consecutively included between June 1st and December 21st, 2021. Confirmed SARS-CoV-2 infection (RT-PCR o serology) was reported by the treated physician. Infection after an incomplete scheme was defined when the event was diagnosed at least 14 days after first dose; and after a complete scheme when it occurred > 14 days after second dose. Homologous scheme is defined by two same doses of vaccine and heterologous by two different doses. Patients with previous SARS-CoV-2 infection were excluded. To compare SARS-CoV-2

infection characteristics in not vaccinated patients, subjects from the SAR-COVID registry, which includes patients with RD and SARS-CoV-2 infection, were matched 2:1 by gender, age and RD.
WHO-Ordinal Scale ≥5 was used to define unfavorable infection outcome. Descriptive statics, Chi2 test, Fischer test, T test and ANOVA were used.
Results: A total of 1350 patients from the SAR COVAC registry were included, 67 (5%) presented SARS-CoV-2 infection after vaccination. The later were mostly (72%) females with a mean age of 57 (SD 15) years old. The most frequent RD were rheumatoid arthritis (41%), psoriatic arthritis (12%) and systemic lupus erythematosus (10%). At vaccination, most of them (75%) had low disease activity or remission, 19% were taking steroids, 39% methotrexate, 27% bDMARDs and 6% JAK inhibitors. A total of 11 (16%) patients had SARS-CoV-2 infection <14 days after the first vaccine dose, 39 (58%) after an incomplete scheme and 17 (25 %) following a complete one. In the incomplete scheme group, 59% received Gam-COVID-Vac, 31% ChAdOx1 nCov-19 and 10% BBIBP-CorV; and in patients with complete scheme 47%, 24% and 29%, respectively. No event was reported after a complete heterologous scheme. No significant differences regarding sociodemoghraphic characteristics, RD, disease treatment, type of vaccine and regimen was found between in those with infection and those without it. After vaccination only 8 (12%) of the patients who got infected had an unfavorable course, 88% of them following an incomplete scheme (5 received Gam-COVID-Vac, 1 ChAdOx1 nCov-19 and 1 BBIBP-CorV) and one subject after a complete homologous Gam-COVID-Vac scheme. Having an unfavorable outcome of SARS-CoV-2 infection was associated to: male gender [63% vs 24%, p=0.036], older age [mean 70 years (SD 7) vs 55 years (SD 15), p=0.005], being Caucasian [100% vs 54%, p=0.018], higher education [mean 17 years (SD 4) vs 12 years (SD 4), p=0.010], the presence of comorbidities [100% vs 39%, p=0.001, having pulmonary disease [37% vs 5%, p=0.019], dyslipidemia [63% vs 17%, p=0.011] and arterial hypertension [63% vs 24%, p=0.036], RD, treatments, disease activity and types of vaccines received were comparable between groups. When comparing patients with and without vaccination prior SARS-CoV-2 infection, those who received at least one dose of vaccine had less frequently severe COVID-19 (12% vs 24%, p=0.067) and presented lower mortality due to COVID-19 (3% vs 6%, p=0.498). However these differences did not reach statistical significance.
Conclusion: In the SAR-CoVAC registry 5% of the patients had SARS-CoV-2 infection after vaccination, most of them mild and 25% after a complete scheme. Any vaccine was associated with severe COVID-19. When comparing with non-vaccinated patients, those with at least one dose, had less frequently severe disease and died due COVID-19.

POS1205 COVID-19 IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES - DATA FROM THE ROMANIAN REGISTRY OF RHEUMATIC DISEASES

D. Minca[1], A. Minca[2], C. E. Ionescu[1], O. G. Dinache[1], C. Popescu[1], M. Agache[1], L. Enache[1], C. Mogosan[1], C. Codreanu[1]. *[1]Center of Rheumatic Diseases, Rheumatology, Bucharest, Romania; [2]University Emergency Hospital of Bucharest, Internal Medicine, Bucharest, Romania*

Background: Registries are providing real-life, long-term data relevant to safety, efficacy and long-term outcomes in patients with various rheumatic diseases. The Romanian Registry of Rheumatic Diseases (RRBR) collects efficacy and safety data, for patients with inflammatory rheumatic conditions treated with biologics and targeted synthetic DMARDs in the country. Infections are the most frequently adverse events associated with biologics exposure.
Objectives: To analyze the distribution, severity class and outcome of infection with SARS-CoV-2 in inflammatory arthritides during the last 2 years of COVID-19 pandemic.
Methods: We collected data for the past 2 years (2020 and 2021) from the RRBR, for the three main inflammatory rheumatic diseases (Rheumatoid Arthritis - RA, Spondyloarthritis - SpA and Psoriatic Arthritis - PsA): treatment exposure (drug class) at the time of COVID-19 diagnosis, severity class (mild, moderate, severe), the disease outcome (recovered, disabled, death). Finally, we compared those data to reported numbers of COVID - 19 infections in the general population, aiming to observe if there is a significant difference between the two groups.
Results: The study included 9469 patients with inflammatory rheumatic disease, in 298 (3.14%) patients a history of COVID-19 infection was recorded: 160 (53.69%) were diagnosed with RA, 116 (38.92%) with SpA and 22 (7.28%) with PsA. At the moment of COVID-19 infection, 200 patients were receiving anti-TNF inhibitors (67.11%), 27 JAK inhibitors (9.06%), 24 tocilizumab (8.05%), 23 rituximab (7.71%), 9 anti-IL17A monoclonal antibodies (3.02%) and 4 abatacept (1.34%). More than half of the cases were mild - 59.39% (177), whereas moderate forms were noted in 26.17% (78) and severe in 14.09% (42) of the total infected patients. Out of the 42 severe COVID-19 cases, 11 (26.19%) were treated with rituximab, 18 (42.85%) with TNF inhibitors, 7 (16.66%) with JAK inhibitors, 4 (9.52%) with tocilizumab, 1 (2,38%) with secukinumab and 1 (2.38%) with abatacept. Almost all cases recovered: 286 (95.97%) patients, while 12 (4.02%) deaths were recorded. The patients who died were on treatment with rituximab (5), tofacitinib (3), etanercept (2), secukinumab (1) and tocilizumab (1). Data from the National Public Health Institute showed a rate of COVID-19 infection in the general population of 9.36%, out of which 96.7% had a favorable outcome, while 3.26% deaths were reported.
Conclusion: This study confirms that patients receiving treatment with rituximab are at risk for a worse COVID-19 outcome. The increased number of severe cases and deaths related to COVID19 in patients receiving TNF inhibitors may be explained by the large use of this therapeutic option. Surprisingly, we noted 4 severe cases and one death related to COVID19, in patients treated with tocilizumab. We observed no significant differences in death rates and the outcomes of COVID-19 in patients with rheumatic diseases treated with biological therapies and the general population. The low rate of SARS-CoV-2 reported infections in the registry, compared to the general population, is most probably due to the commonly found underreporting of adverse events in registries.

POS1206 UNDERSTANDING THE LANDSCAPE OF RHEUMATOID ARTHRITIS (RA) PATIENTS TREATED WITH IL-6 INHIBITORS DURING THE COVID-19 PANDEMIC

D. Baldock[1], E. Baynton[1], A. Kamaruddin[2]. *[1]Ipsos MORI, Healthcare, London, United Kingdom; [2]Ipsos Sdn Bhd, Healthcare, Kuala Lumpur, Malaysia*

Background: Rheumatoid Arthritis (RA) is a complex autoimmune disease which affects the joints and various organs[1] and patients may experience frequent and painful flare ups. Besides conventional therapies, multiple bDMARDS are approved to treat RA, including tocilizumab and sarilumab. With IL-6 inhibitors being approved for emergency use to treat critically ill COVID-19 patients, this may influence the treatment paradigms of some RA patient cohorts.
Objectives: The objective of this study is to observe the landscape of RA patients treated with IL-6 inhibitors during the COVID-19 pandemic period, compared to the pre COVID-19 period.
Methods: A multi-centre online medical chart review study of patients with RA was conducted between January 2019 – March 2020 ("pre-COVID") and April 2020 – June 2021 ("during-COVID") among UK, FR, DE, IT & ES rheumatologists practicing across hospital and private practices. Recruited from a large access panel, physicians were screened for duration of practice in their specialty (3-30 years) and caseload (2 or more RA patients seen in an average week). Participants were asked to complete a 3-part survey online: (1) a doctor demographic questionnaire, (2) a perceptual questionnaire, and (3) patient charts for the next 5 biologic/JAKi receiving RA patients seen following receipt of the survey, which captures patient demographics and treatment history. Descriptive statistics were used to analyse the data.
Results: For the pre-COVID cohort, 1283 physicians were recruited and collectively reported 6250 RA patients, 754 of which were treated with IL-6 inhibitors for their RA. For the during-COVID cohort, 1279 physicians were recruited and collectively reported 6188 RA patients, 760 of which were treated with IL-6 inhibitors for their RA. 96% of sampled physicians cited access to IL-6 inhibitors in hospital or practice in the during-COVID period, compared to 77% in the pre-COVID period ($p<0.01$) - this may be linked to the approval of emergency use of IL-6 inhibitors to treat critically ill COVID-19 patients, hence making it more widely available during this period. A larger proportion of reported IL-6 inhibitor patients in the during-COVID cohort had stayed on this drug class for more than 6 months, compared to the pre-COVID cohort (67% vs 62%, $p<0.05$). Association with high-risk comorbidities, severity of RA at diagnosis and previous therapies received were key areas of differentiation between the two reported patient groups. For the during COVID cohort, IL-6 patients were significantly more likely to be recorded as having concomitant metabolic conditions vs the pre-COVID cohort (72% vs 48%, respectively; $p<0.01$) and respiratory conditions (4% vs 1%, respectively; $p<0.01$). Furthermore, reported IL-6 patients from the during COVID cohort were significantly more likely to have their RA classified as 'severe' (physician-defined) at the time of diagnosis vs pre-COVID reported IL-6 patients (41% vs 33%, respectively; $p<0.01$) and were significantly more likely to have switched from previous TNFi/CD20 biosimilar therapy compared to the pre-COVID cohort (16% vs 7%, respectively; $p<0.01$).

Conclusion: From the sample surveyed, it appears that high risk comorbidities, severity of RA at diagnosis and type of previous therapy are key differentiating points behind IL-6 usage in RA patients pre vs during the COVID-19 pandemic. With the increasing risk that RA patients may experience severe side effects if infected with COVID-19[2] and guidance to use IL-6 inhibitors in certain patient cohorts during this time, this may explain the patterns seen in our dataset. Further investigation using comparator cohort is warranted.

POS1207 SEROCONVERSION AFTER A THIRD COVID-19 VACCINATION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH (ULTRA-)LOW DOSE RITUXIMAB WITH A PREVIOUS INSUFFICIENT HUMORAL RESPONSE IS DEPENDENT ON RITUXIMAB DOSAGE

C. Van der Togt[1], D. Ten Cate[1], B. Van den Bemt[2,3], J. Rahamat-Langendoen[4], N. Den Broeder[1], A. Den Broeder[1,5]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [2]Sint Maartenskliniek, Pharmacy, Ubbergen, Netherlands; [3]Radboud University Medical Center, Clinical Pharmacy, Nijmegen, Netherlands; [4]Erasmus MC, Medical Microbiology, Rotterdam, Netherlands; [5]Radboud University Medical Center, Rheumatic Diseases, Nijmegen, Netherlands*

Background: Around 60% of rheumatoid arthritis (RA) patients treated with ≥1000 mg rituximab (RTX) has an insufficient deemed humoral response after two COVID-19 vaccinations.[1] Recent research shows that a third COVID-19 vaccine may actually lead to a humoral response in 27% of patients with a previous non-response.[2] After two-dose vaccination, both ultra-low dose (ULD) 200 mg RTX and a longer time between latest RTX and vaccination were positively associated with sufficient response.[3] Yet, no data is available on the effect of those variables after a third vaccination in these ULD patients with an insufficient response after two vaccinations.

Objectives: To investigate the role of dosage and relative timing of RTX and vaccination on humoral response after a third COVID-19 vaccine in RA patients treated with RTX with insufficient humoral response after two COVID-19 vaccinations.

Methods: We included RA patients treated with ≥1 RTX dose in the year previous to the first vaccine from the COVAC cohort (Netherlands Trial Register, NL9342), who had an insufficient humoral response after two COVID-19 vaccines. Humoral response was measured 2-6 weeks after the third vaccine. As there is still a lot of uncertainty about a serological correlate of protection, we dichotomized between 'sufficient' and 'insufficient' response based on the cut-off of the specific assay used. Univariable logistic regression was used to investigate the association between dosing and timing, and sufficient response.

Results: Eighty-nine patients had an antibody measurement performed within the right time-frame and could be included (Table 1). Overall, 17 patients (19%) had a sufficient antibody response. Proportion of patients with sufficient humoral response was higher when the latest dose was 200 mg compared to 500 and 1000 mg (38% versus 21% versus 13% (Figure 1); odds ratio 200 versus 1000 mg (OR) 4.25; 95% confidence interval (CI) 0.99 to 18.29 (p=0.052), and especially when the dose was already 200 mg before the first vaccination (OR 4.63; 95% CI 1.08-19.84 (p=0.039)). Time since latest RTX infusion was not significantly associated with sufficient response after third vaccination (OR 1.00; 95% CI 1.00-1.01 (p=0.15)).

Table 1. Characteristics and outcomes sorted by rituximab dose before first vaccination

	200 mg (n=13)	500 mg (n=34)	1000 mg (n=42)

Days between latest RTX and 3rd vaccine†	127 (100-160)	117 (99-153)	126 (91-150)
Latest RTX dose before 3rd vaccine			
200 mg	12 (92%)	1 (3%)	0 (0%)
500 mg	1 (8%)	31 (91%)	5 (12%)
1000 mg	0 (0%)	2 (6%)	37 (88%)
Sufficient humoral response after 3rd vaccine	5 (38%)	7 (21%)	5 (12%)

Either displayed as number (percentage), median (interquartile range)† or mean ± standard deviation‡.

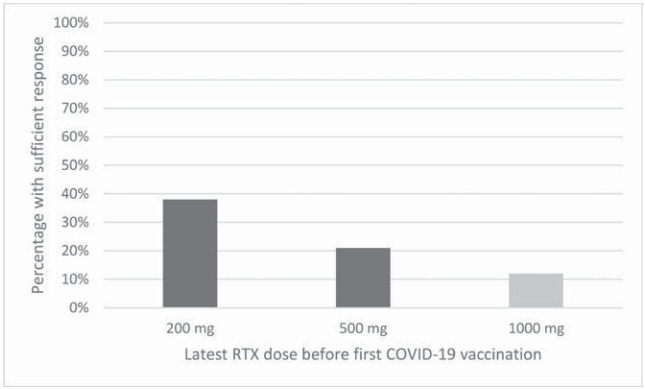

Figure 1. Humoral response rate after third COVID-19 vaccination sorted by baseline rituximab dose

Conclusion: Our study shows that a third COVID-19 vaccine can induce sufficient humoral response in a relevant proportion of (ultra-)low dose RTX treated RA patients who did not respond to the first two vaccinations, and that lower RTX dosing is associated with significant higher proportion of patients with sufficient humoral response. In contrast to the analysis after two vaccine doses, time since latest infusion was not significantly associated with response.

POS1208 EQUITY CONSIDERATIONS IN COVID-19 VACCINATION STUDIES OF INDIVIDUALS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES

H. Wang[1,2], O. Dewidar[2], S. Whittle[3,4], E. Ghogomu[2], G. Hazlewood[5], L. Mbuagbaw[6,7,8,9], J. Pardo Pardo[10], P. Robinson[11], R. Buchbinder[4,12], V. Welch[2]. *[1]University of Ottawa, Medicine, Ottawa, Canada; [2]Bruyère Research Institute, Methods Centre, Ottawa, Canada; [3]The Queen Elizabeth Hospital, Rheumatology Unit, 28 Woodville Road, Australia; [4]Cabrini Health, Monash-Cabrini Department of Musculoskeletal Health and Clinical Epidemiology, Melbourne, Australia; [5]University of Calgary, Cumming School of Medicine, Calgary, Canada; [6]McMaster University, Health Research Methods, Evidence and Impact, Hamilton, Canada; [7]St Joseph's Healthcare, Biostatistics Unit, Father Sean O'Sullivan Research Centre, Hamilton, Canada; [8]Yaoundé Central Hospital, Centre for Development of Best Practices in Health (CDBPH), Yaoundé, Cameroon; [9]Stellenbosch University, Department of Global Health, Cape Town, South Africa; [10]Cochrane Musculoskeletal Group, Department of Medicine, University of Ottawa, Ottawa, Canada; [11]The University of Queensland, School of Clinical Medicine, Herston, Australia; [12]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*

Background: Individuals with autoimmune inflammatory rheumatic diseases (AIRDs) have an increased baseline risk of severe COVID-19 infection. Intersection of inequity factors may result in more severe adverse effects through influencing opportunities for health. We sought to examine the extent to which populations experiencing inequities were considered in studies of COVID-19 vaccination in individuals with AIRDs.

Objectives: The objective of this study is to assess how health equity is considered in studies of COVID-19 vaccination studies in individuals with AIRDs.

Methods: All studies (*N*=19) from an ongoing Cochrane living systematic review on the effects of COVID-19 vaccination in people with AIRDs were included. We identified inequity factors using the PROGRESS-Plus framework which stands for Place of residence, Race/ethnicity, Occupation, Gender/sex, Religion, Education, Socioeconomic status, and Social capital. Age, multimorbidity, and

health literacy were also assessed as "Plus" factors. We applied the framework to assess equity considerations in relation to differences in COVID-19 baseline risk, description of participant characteristics, controlling for confounding factors, subgroup analysis and applicability of study findings.

RESULTS:

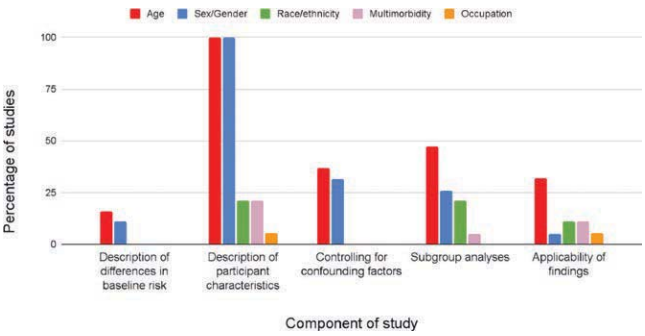

Figure 1.

All nineteen studies are cohort studies that followed individuals with AIRDs after COVID-19 vaccination. Two articles (11%) described differences in baseline risk for COVID-19 across age. All nineteen studies described participant age and sex, with race/ethnicity and multimorbidity described in four (21%) and occupation in one (5%). Seven studies (37%) controlled for age and/or sex as confounding factors. Eleven studies (58%) conducted subgroup analysis across at least one PROGRESS-Plus factor, most commonly age. Eight studies (42%) discussed at least one PROGRESS-Plus factor in interpreting the applicability of results, most commonly age (32%), then race/ethnicity and multimorbidity (11%).

Conclusion: It is unknown whether COVID-19 vaccine studies on individuals with AIRDs are applicable to populations experiencing inequities, as key inequity factors beyond age and sex have little to no reporting or analysis. Future COVID-19 vaccine studies should report social characteristics of participants consistently, facilitating informed decisions about the applicability of study results to the population of interest.

POS1209 THE IMPACT OF THE COVID-19 PANDEMIC ON WORK PRODUCTIVITY IN PATIENTS WITH SPONDYLOARTHRITIS: RESULTS FROM THE DUTCH SPA-NET REGISTRY

C. Webers[1,2], A. Van Tubergen[1,2], H. Vonkeman[3,4], A. Boonen[1,2]. *[1]Maastricht University Medical Centre, Rheumatology, Maastricht, Netherlands; [2]Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands; [3]Medisch Spectrum Twente, Department of Rheumatology and Clinical Immunology, Enschede, Netherlands; [4]University of Twente, Department of Psychology, Health & Technology, Enschede, Netherlands*

Background: Since early 2020, governments have initiated local and nationwide measures to contain the spread of the coronavirus disease 2019 (COVID-19). In the Netherlands, people were strongly recommended to work from home, and several work sectors were shut down. In addition, hospitals had to reduce regular care. These changes, together with the risk of contracting COVID-19 and becoming ill, could have affected people's employment perspectives and work productivity. It is unknown to what degree this affected persons with chronic disorders, such as spondyloarthritis (SpA).

Objectives: To investigate whether work productivity in patients with SpA changed following the onset of the pandemic and the associated government-initiated containment measures in the Netherlands.

Methods: Data from the Dutch eHealth monitoring system SpA-Net were used. Since 2016, patients in SpA-Net completed outcome measurements when they attended outpatient rheumatology visits. Employment and work productivity were assessed with the Work Productivity and Activity Impairment questionnaire (WPAI, work productivity loss range 0-100%), capturing both sick leave and reduced at-work productivity. Covariables of interest were age, gender, education (high vs. low) and disease activity (ASDAS, BASDAI, patient global). The proportions of patients employed and their work productivity losses were compared during a 1-year period before and after the onset of the pandemic (March 2020). Generalized Estimating Equations (GEE) analysis of all assessments over time explored if work productivity in employed patients had changed with the onset of the pandemic, adjusting for potential confounders. Similar analyses with disease activity as outcome were used to facilitate interpretation of work productivity results.

Results: Of 238 patients, data were available during the 1-year period both before and after onset of the pandemic. Pre-pandemic, 128 (54%) patients were employed. These employed patients had a mean age of 49.0 (SD 10.2) years, 66 (54%) were male and the mean ASDAS was 2.1 (0.9). After the onset of the pandemic, 7 (5.5%) were no longer employed. In addition, 8 out of 110 (7.3%) originally unemployed patients had become employed by this time. Work productivity loss (0-100%) was worse after the onset of the pandemic (37.0) compared to the pre-pandemic year (27.0) (p<0.01). In multivariable GEEs with work productivity loss as outcome (and stratified by education due to interaction), patients with low education had work productivity losses that were almost 10% (absolute) higher after onset of the pandemic compared to pre-pandemic (B = 9.57, 95%CI 5.63-13.51) (Table 1). This was independent of ASDAS and other confounders. In patients with high education, however, no such association between pandemic onset and work productivity was seen. Analyses adjusting for other measures of disease activity (BASDAI, patient global) showed similar results. In GEEs with disease activity as outcome, disease activity before and after pandemic onset did not differ (B = -0.05, 95%CI -0.15 to 0.06 for ASDAS, model not shown).

Conclusion: Work productivity has worsened in patients with SpA since the onset of the pandemic, especially in patients with lower educational attainment, while disease activity remained stable. Care should be taken to support patients in their work role during the pandemic, and thereafter.

POS1210 SAFETY AND IMMUNOGENICITY OF COVID-19 VACCINES IN PATIENTS WITH IMMUNE MEDIATED INFLAMMATORY DISEASE

C. Hitchon[1], R. Marrie[1], C. N. Bernstein[1], J. Kim[2], S. Obrien[3]. *[1]University of Manitoba, Internal Medicine, Winnipeg, Canada; [2]Public Health Agency of Canada, National HIV/AIDS Laboratories, Winnipeg, Canada; [3]Canadian Blood Services, Epidemiology & Surveillance Canadian – Blood Services, Ottawa, Canada*

Background: COVID-19 vaccination strategies have evolved with increasing vaccine availability and emerging vaccine safety data. While data on immunogenicity and safety of COVID vaccination strategies exists, there is limited data

for people with immune mediated inflammatory diseases (IMIDs) such as inflammatory arthritis (IA), systemic autoimmune rheumatic disease (SARD), inflammatory bowel disease (IBD) and multiple sclerosis (MS).

Objectives: In IMID patients treated with homologous or heterogeneous COVID vaccines, to compare post vaccine IMID disease activity and COVID antibody responses.

Methods: Between March 2021 and Dec 2021, patients with IA (n= 70; 77% rheumatoid arthritis), SARD (n=82; 70% lupus), IBD (n= 92; 40% crohn's), and MS (n= 71; 77% RRMS) self-reported COVID illness and exposure risks, and disease activity prior to and 1 month post both COVID-19 vaccinations (V1 and V2). Disease activity was assessed by the Systemic Lupus Activity Questionnaire (SLAQ) for SARDs, the RAPID-3 and RA flate index for IA, the IBD Symptoms Inventory-short form (IBDSI) and IBD flare index for IBD and the 25 meter walk and 9 hole peg test and Expanded Disability Status Scale (EDSS) for MS. Patient reported flare state was assessed using the relevant questions these indices (SLAQ "Have you had a flare?"; RA Flare index "Are you in a flare?"; IBD flare "My IBD is sometimes to continously active"). Disease activity and serum anti-spike, anti-receptor binding domain (RBD) and anti-nucleocapsid (NC) IgG antibody titers at 30 days post V2 were compared across vaccine courses and to age-sex matched vaccinated blood donor controls (CNTS).

Table 1.

	All IMIDs	IA	SARD	IBD	MS
Age (mean (sd) years)	**56(15)**	**63(12)**	**56(14)**	**54(16)**	**51(17)**
Female (%)	**80**	**84**	**90**	**64**	**83**
COVID risk exposure (%)					
Any	**44**	**39**	**46**	**50**	**44**
Contact	**14**	**12**	**14**	**12**	**21**
Travel	**6**	**6**	**6**	**6**	**6**
HCW/hospitalized	**15**	**15**	**16**	**20**	**9**
Other risk	**9**	**6**	**10**	**12**	**8**
V1 mRNA (%)	**74**	**80**	**68**	**82**	**64**
V2 mRNA (%)	**97**	**98**	**96**	**96**	**99**
Homologous V1 V2 (%)	**71**	**79**	**67**	**74**	**64**
Flare status post V2 (%)	**10**	**15**	**6**	**0**	**-**
Seroconversion (%)					
Anti-Spike	**89**	**90**	**86**	**93**	**84**
Anti-RBD	**91**	**92**	**86**	**96**	**88**

Results: Patients were predominantly female (79.7%), with a mean (standard deviation-sd) age of 56 (15) years; 8% had suspected or diagnosed COVID-19 illness; 1.2% positive anti-NC (Table 1). For all IMIDS, the majority received mRNA vaccines-BNT162b2 (BNT) or mRNA1273 (V1 74%; V2 97%;) the rest received ChAdOx1 viral vector vaccines; 71% received homologogous vaccines (ChAdOx1-ChAdOx n=6; BNT-BNT n=174; mRNA1271-mRNA1273 n=21; ChAdOx1-BNT n=36; ChAdOx1- mRNA1273 n=30; BNT-mRNA1273 n=15; mRNA1273-BNT n=3; other n=4). For most IMIDs, disease activity was similar before and after each vaccination. Post V2 disease activity did not differ between homologous versus heterologous vaccines nor by vaccine type (RAPID3; SLAQ, 25 meter walk and 9 hole peg test and EDSS overall and subscales, IBDSI overall and subscales all p=NS). In 254 IMIDs, most seroconverted (anti-spike 86%; anti-RBD 96%). Seroconversion rates for CNTS were 98.1% for anti-Spike and 3.5% for anti-NC. Antibody titers were higher following homologous mRNA (BNT or mRNA12723) than homologous vector vaccine (Figure 1). For IMIDs primed with ChAdOx vector vaccine, boosting with BNT or mRNA1273 generated similarly increased anti-Spike and anti-RBD titers.

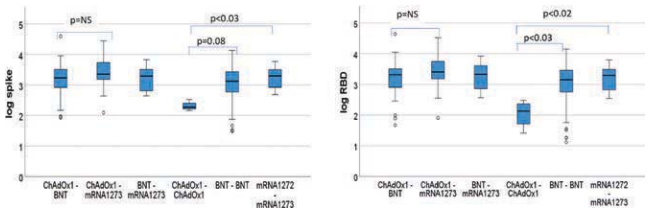

Figure 1. Post vaccine antibody titers

Conclusion: Heterologous COVID vaccination improves seroconversion rates following a viral vector vaccine and does not lead to disease flare in most IMID patients. While data is needed to assess vaccine effectiveness, duration of immunogenicity and effects of subsequent vaccination, this work supports mixing COVID vaccines for IMID patients.

POS1211 SEROLOGICAL RESPONSE TO BNT162B2 MRNA ANTI-SARS-COV-2 VACCINATION IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES: RESULTS FROM THE RHEUVAX COHORT

D. Mauro[1,2], A. Ciancio[1,2], C. DI Vico[1,2], L. Passariello[1,3], G. Rozza[1,2], M. D. Pasquale[1,2], I. Pantano[1,2], L. Bucci[1,2], C. Cannistà[1,2], S. Scriffignano[1,2], F. Riccio[1,2], M. Patrone[1,2], G. Scalise[1], M. T. Vietri[1,3], F. Ciccia[1,2]. *[1]Università degli Studi della Campania "L.Vanvitelli", Department of Precision Medicine, Naples, Italy; [2]University Hospital of Università degli Studi della Campania "L.Vanvitelli", Rheumatology Unit, Naples, Italy; [3]University Hospital of Università degli Studi della Campania "L. Vanvitelli", Unit of Clinical and Molecular Pathology, Naples, Italy*

Background: To date, globally considered, the literature suggests that AIRD may be at higher risk of infection and death due to COVID19 compared to the general population. Vaccination against SARS-CoV-2 reduces the risk of hospitalization and mortality. However, immunological alteration associated with Autoimmune Inflammatory Rheumatic Diseases (AIRD) and immunosuppressive medications may impair the response to vaccination. Emerging data suggest that immunosuppressive treatment may negatively impact the response to anti-SARS-CoV-2 vaccines in the AIRD population; data are robust for some treatments, more controversial for others. Identifying patients at higher risk of lack of protection is essential for shielding them and for adapting therapeutic protocol and vaccination timing.

Objectives: In the light of the current COVID19 epidemic and the availability of effective vaccines, this study aims to identify predictors of non-response to anti-SARS-CoV-2 vaccines in patients affected by AIRD.

Methods: An observational cross-sectional study was conducted evaluating the serological response and the persistence of antibodies at eight weeks in IRD patient cohort and non-IRD control. IRD and age and sex-matched controls volunteer among the health professionals (CTRL) who underwent vaccination with two doses of BNT162b2 were recruited for this study. Anti-Trimeric Spike protein antibodies were assayed eight ± one week after the second vaccine dose. Univariate and logistic regression analyses were performed to identify predictors of non-response and low antibody titers.

Results: Samples were obtained from 237 IRD patients (m/f 73/164, mean age 57, CI 95% [56-59]): 4 autoinflammatory diseases (AI), 62 connective tissue diseases (CTD), 86 rheumatoid arthritis (RA), 71 spondylarthritis (SpA) and 14 vasculitis (Vsc). 232 CTRL were recruited (m/f 71/161, mean age 57, CI 95% [56-58]). Globally, IRD had a lower seroconversion rate (88.6% vs 99.6%, CI 95% OR [1.61-5.73], p<0.0001) and lower antibody titer compared to controls (median (IQR) 403 (131.5-1012) vs 1160 (702.5-1675), p<0.0001). After logistic regression, age, corticosteroid (CCS), Abatacept (ABA), and Mycophenolate Mofetil (MMF) use were predictors of non-response. The antibody titers eight weeks after the second dose of vaccine were lower in AIRD compared to controls, median (IQR) 403 (131.5-1012) vs 1160 (702.5-1675), p<0.0001 with no difference between sexes and age groups. CTD, RA and SpA had lower antibodies levels. However, the logistic regression model identified treatment with MMF, ABA, CCS, Methotrexate (MTX), Rituximab (RTX), Janus Kinase inhibitors (JAKi) and TNF inhibitors (TNFi) as independent predictors of serum titer. ABA, RTX, MMF, and MTX had the strongest effect size.

Conclusion: The response to anti-SARS-CoV-2 vaccines is often impaired in AIRD patients under treatment and may pose them at higher risk of severe COVID-19. Although this work focused on serological response, most of the treatment the impaired vaccine response are known to act on T cells, possibly also influencing the cellular response. Evidence-based protocols are required to time vaccination and treatment to improve immunization of AIRD patients.

Background: There is a lack of data on Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) vaccination safety in children and young people (CYP) with rheumatic and musculoskeletal diseases (RMDs). Current vaccination guidance is based on data from adults with RMDs or CYP without RMDs.

Objectives: To describe the characteristics and outcomes of adolescents with inflammatory RMDs and adults with juvenile idiopathic arthritis (JIA) vaccinated against SARS-CoV-2.

Methods: We described patient characteristics, flares, and adverse events in adolescent cases under 18 with inflammatory RMDs and adult cases aged 18 or above with JIA submitted to the European Alliance of Associations for Rheumatology (EULAR) COVAX registry.

Results: Thirty-six adolescent cases were reported from 4 countries, the most frequent diagnosis was JIA (42%). Over half (56%) reported early reactogenic-like adverse events (AEs) experienced within 7 days of vaccination. One mild polyarthralgia flare and one serious AE (malaise) were reported. No CYP reported SARS-CoV-2 infection post-vaccination. In addition to the adolescent cases, eleven countries reported 74 adult JIA cases. Among these, 62% reported early reactogenic-like AEs and two flares were reported (mild polyarthralgia and moderate uveitis). No serious AEs of special interest were reported among adults with JIA. Three 20-30 year old females were diagnosed with SARS-CoV-2 post-vaccination; all fully recovered.

Conclusion: In this observational registry dataset, SARS-CoV-2 vaccines appeared safe in adolescents with RMDs and adults with JIA, with a low frequency of disease flares, serious AEs, and SARS-CoV-2 re-infection seen in both populations.

Table 1. Characteristics of adolescents with RMDs and adults with JIA reported to the EULAR COVAX registry

		Adolescents with RMDs (N=36)	Adults with JIA (N=74)
Sex	Female	21 (58)	54 (73)

POS1213 SAFETY AND EFFICACY ASSESSMENT OF COVID-19 IMMUNIZATIONS / VACCINATIONS IN PATIENTS OF A GERMAN GENERAL RHEUMATOLOGICAL PRACTICE

C. Pohl[1]. [1]*Internistisch-rheumatologische Hausarztpraxis Dr. med. Christoph Pohl, Internal Medicine, Rheumatology, Berlin, Germany*

Background: German Covid-19 pandemic immunization program started Dec 26th, 2020 without population representative standardized real world data efficacy study protocols(1). Safety assessment: side effect panel of the Paul-Ehrlich Institute reporting system of suspected side effects (analogue and digital): Comparison of reported side effects against 100000 immunization doses vs historical known medical events against 100000 patient years. Not much is known how long side effect reporting periode after MRNA / Vector immunization is appropiate for the different immunization drugs (Biontech/Pfizer-Comirnaty(2), AstraZeneca-Vaxzevria, Moderna-Spikevax, Johnson&Johnson–Covid-19 vaccine Janssen) because for these no pharmacokinetic and –dynamic data (2,3) are available on spike protein biodistribution and how long it lasts in the human body. EMA / WHO guidelines declare these data not as essential for approval of vaccines, only for drugs (4).

Objectives: Real world safety and efficacy of Covid-19 immunizations.

Methods: In 664 patients (612 patients with rheumatic diseases) planned standardized assessment: Safety parameters before and 3-7 days after immunization (organ, hematology, myositis, thrombosis, inflammatory, autoimmunity parameters), after 5-6 months (before booster decision) d-dimer-levels, routine lab assessment (routine surveillance of rheumatic patients under therapy) and Covid-19-antibody levels (AbL).

Results: Most patients (94.5%) developed Covid19-AbL (except a few under Abatacept and Rituximab). After 5-6 months most patients (77%) still had Covid19 sufficient AbL above 128 BAU/ml (87% above 64 BAU/ml) (1). 37% of all patients developed relevant elevated d-dimers (still 5-6 months after immunization). In most of these patients the suspicion of inflammation of the microvascular system was a reasonable explanation (large vessel or pulmonary thromboembolism was ruled out in 98 %).

Conclusion: Inflammation of the microvascular system as an underestimated side effect of MRNA / Vector immunization should be taken into account if (booster)-immunization decisions in patients with rheumatic diseases (maybe general) are to be made. Most patients with rheumatic diseases under (DMARD) therapy developed Covid-19 AbL (94.5%) (1) 5-6 months after MRNA / Vector immunization. All immunization decisions should also made dependent on AbL, because in case 5.5 % of immunized people do not react with AbL response, high numbers of breakthrough infection rates and hospitalization of immunized patients could be explained. Microvascular inflammation after MRNA / Vector immunization as a side effect in 37 % of rheumatologic patients could cause medical problems later on. Therefore also for safety reasons MRNA / Vector (booster) immunizations should also depend on the amount of already existing humoral response reflected by AbL.

Background: Mixed cryoglobulinaemic vasculitis (MCV) is an immune-complex-mediated systemic vasculitis characterized by heterogeneous clinical manifestations mainly involving skin, kidney and peripheral nervous system. Despite reassuring safety data from EULAR Coronavirus Vaccine (COVAX) physician-reported registry, a significant proportion of patients with autoimmune diseases reported unwillingness to get vaccinated against SARS-CoV-2 infection in the preliminary results of the COVAD study, due to concerns about the lack of long-term safety data, and fear of associated side effects and disease flare.

Objectives: Aims of this multicentre Italian study were to investigate the prevalence of vaccination against SARS-CoV-2 in Italian population of MCV patients, to explore the reason for the missed vaccination, and to investigate short and long-term side effects of the vaccine, including vasculitis flare.

Methods: All MCV patients referring to 12 Italian centres were investigated about vaccination and possible both short- (within 48 hours) and long-term (within 30 days) adverse events (AE), classified according to FDA Toxicity Grading Scale for preventive vaccine clinical trials, and possible disease flares. Patients with MCV related to lymphoproliferative disorders or connective tissue diseases were excluded from the study. The baseline variables were expressed as percentages or mean±standard deviation. The differences between continuous variables were analysed using the Mann–Whitney nonparametric test. The chi-squared test, or Fischer's exact when appropriate, were used for categorical variables (absolute numbers and percentages) regarding baseline characteristics.

Results: A total of 416 patients, 69.2% females and 30.8% males, with a mean age of 70.4±11.7 years, were included in the study. Only 7.7% of patients were not vaccinated, mainly for fear of adverse events (50%) or for medical decision (18.8%). Corminaty was the vaccine most frequently used (80.5%). Interestingly, 6 patients (1.44%) were with a heterologous vaccination (usually AstraZeneca-Corminaty). Considering ongoing treatment, not vaccinated subjects were more frequently treated with chronic glucocorticoid therapy and/or Rituximab (p=0.049 and p=0.043 respectively). AE were recorded in 31.7% of cases, mainly mild and self-limiting (grade 1). More severe adverse events, such as flare of vasculitis, were observed in 5.3% of cases. AE were not associated with the kind of vaccine used and with the clinical manifestations of vasculitis. Patients with active MCV showed a lower frequency of short-term (within 48 hours) adverse events, but patients affected by peripheral neuropathies or skin vasculitis frequently showed a flare of their symptoms, recorded in 40% and 25% of cases, respectively. Finally, patients under glucocorticoid treatment were more prone to develop a vasculitis flare within a month after vaccination.

Conclusion: Vaccination in MCV patients has been performed in a high percentage of patients showing a good safety. Other than patients' fear, treatments with rituximab and glucocorticoids are the main reasons for delaying vaccination, and it should be considered by the physician before starting therapy. Vasculitis flares were observed in about 5% of cases, in line with that observed in other autoimmune diseases. Specific attention should be reserved to people with purpura or peripheral neuropathy, for the increased risk of exacerbation of their symptoms.

POS1215

IMMUNE CORRELATES AND CLINICAL COURSE OF PATIENTS WITH RHEUMATOID ARTHRITIS FOLLOWING VACCINATION WITH ANTI SARS-COV-2 MRNA BASED VACCINES: RESULTS FROM A PROSPECTIVE, OBSERVATIONAL AND CONTROLLED STUDY

K. Schmiedeberg[1], I. A. Abela[2], N. B. Pikor[3], N. Vuilleumier[4], M. Schwarzmueller[2], S. Epp[2], S. Pagano[4], S. Grabherr[3], A. B. Patterson[3], M. Nussberger[1], A. Trkola[2], B. Ludewig[3], J. Von Kempis[1], A. Rubbert-Roth[1].
[1]Rheumatology Clinic, Kantonsspital St Gallen, St Gallen, Switzerland; [2]Zürich, University of Zurich, Institute of Medical Virology, Zürich, Switzerland; [3]St. Gallen, Institute of Immunobiology, St. Gallen, Switzerland; [4]Geneva, Laboratory Medicine Division, Geneva, Switzerland

Background: Vaccines are highly effective in preventing COVID-19 associated hospitalization and deaths. Strong and persistent immune responses are critical to provide protection for patients with immunomodulatory therapies.
Objectives: To assess humoral and cellular immune responses following 2 doses of an anti-SARS-CoV-2 mRNA based vaccine in rheumatoid arthritis (RA). Immune responses in patients treated with csDMARDs, bDMARDs (with the exception of rituximab) and JAK inhibitors were compared to healthy controls (HC) over 24 weeks. In addition, disease activity by CDAI and vaccine-induced side effects were prospectively monitored.
Methods: The RECOVER trial (**R**heumatoid **C**ovid-19 **V**accin**e** Immune **R**esponse) is a non-randomised, prospective observational control group trial and enrolled 77 RA patients on DMARD therapy and 21 HC. Clinical assessment and blood sampling was performed at baseline, 3 weeks after the 1st and 2 weeks after the 2nd vaccine dose and at week 12 and 24 after the 1st. Antibody response to the receptor binding domain (RBD) within the SARS-CoV-2 S1 protein was measured with the Elecsys Anti-SARS-CoV-2-S (Roche Diagnostics GmbH) test. The seroprofiling assay ABCORA, which has been suggested as a surrogate for neutralization,[1] was used to determine IgG, IgA and IgM responses to RBD, S1, S2 and N. The neutralizing activity NT50 at week 12 was assessed against Wuhan-Hu-1 pseudoviruses (HIV-based). IFN-γ ELISpots were applied to detect spike-reactive T cell responses after in vitro stimulation with a spike peptide mix.
Results: Baseline characteristics of participants are detailed in Table 1. Vaccination was well tolerated with no differences between RA patients and HC. At baseline, the majority of RA patients were in remission/LDA (57/77, 74%), this proportion decreased to 51% (39/77) after the second vaccine dose ($p = 0.005$). Treatment adjustments were required in 11/77 patients. The immunogenicity analyses were based on 73 RA patients after exclusion of 4 patients with previously unnoticed SARS-CoV-2 infection (positive for anti-nucleoprotein). In contrast to HC, anti-S titers were lower at all timepoints with significantly reduced titers observed in patients on abatacept and JAK inhibitors (Figure 1). Potent neutralizing activity (NT50 ≥ 250)) was detected in all HC at week 12, in contrast to 62% RA patients. NT50 correlated to the results based on the ABCORA assay. Peak anti-S titers (2 weeks after 2nd vaccine) were predictive of NT50 ≥ 250 at week 12 ($p < 0.0001$). In contrast to marked differences in the humoral immune responses, spike-protein specific IFN-α secreting T cells were largely unaltered by different DMARD regimen.

Table 1. Baseline characteristics

	RA patients (n = 77)	HC (n = 21)	p-value
Age (yrs), mean (± SD)	64 (13)	44 (14)	< 0.0001
Female, n (%)	46 (60)	15 (71)	NS
Vaccination type			
mRNA-1273, n (%)	12 (16)	0 (0)	0.06
BNT162b2, n (%)	65 (84)	21 (100)	
Disease activity (CDAI)			
Remission (≤ 2.8), n (%)	17/77 (22)		
Low (2.9 - 10), n (%)	40/77 (52)		
Moderate (10.1 - 22.0), n (%)	15/77 (20)		
High (22.1 - 76.0), n (%)	5/77 (7)		
DMARD therapy			
Mono csDMARDs, n (%)	22/77 (29)		
bDMARDs, n (%)	35/77 (46)		
Mono bDMARDs, n (%)	14/35 (40)		
JAKi, n (%)	20/77 (26)		
Mono JAKi, n (%)	8/20 (40)		
Prednisone, n (%)	25/77 (33)		
Mean daily dose (mg ± SD)	5.6 ± 3.6		

Conclusion: RA patients, in comparison with HC, revealed a slower kinetic and lower magnitude of humoral immune responses depending on the treatment regimen while T cell responses were largely maintained. Peak anti-S responses two weeks after the second vaccine were able to predict the development of potent neutralizing activity and should therefore be considered to individually tailor vaccination strategies.

Background: A hyperinflammatory response compatible with features of macrophage activation syndrome (MAS) contributes to this worse outcome in patients with Coronavirus Disease 2019 (COVID-19). Glucocorticoids have become the standard of care for those requiring oxygen support or mechanical ventilation. More targeted anti-inflammatory treatments with tocilizumab and anakinra have also been shown to be effective.
Objectives: More studies are being awaited to clarify the features of patients who would benefit more, and we investigated the characteristics of the surviving and dead patients who received anakinra.
Methods: The records of hospitalized adult patients between March 2020 and May 2021 in a tertiary referral center were evaluated. Diagnosis of COVID-19-related MAS was based on the expert opinion and preliminary criteria developed by our group that patients with a score of ≥45 were accepted COVID-19-related MAS.[1] Patients who received anakinra constituted the study group. Anakinra dose was determined according to the clinical and inflammatory parameters; and doses varied between daily 100-300 mg SC to 400-800 mg IV. Laboratory data of surviving and died patients were comparatively analyzed by using the ANCOVA method on the relevant days (baseline, anakinra-onset day, first response to anakinra treatment, and discharge or death). The temporal variation (drug onset day-first response day, drug onset day-discharge, or death day) was evaluated

using the ANOVA method. A 50% reduction of CRP compared to the anakinra start day was accepted as the first response to the treatment.
Results: Out of 1080 hospitalized patients, 218 (151 male, 67 female, mean age 60.0±14.1) who received anakinra were identified. Among them, 125 (57.3%) patients were followed in the ward, 21 (9.6%) did not need oxygen treatment during the hospitalization; 69 (31.6%) patients were followed at ICU, 40 of them were intubated, 30 (13.7%) died in ICU. Anakinra had been started in a mean of 4.8 days of hospitalization. Twenty had tocilizumab initially and then received anakinra because of ongoing inflammatory parameters. The majority (83.5%) received steroid treatment (79.5% methylprednisolone, 5% of dexamethasone), and 6 received one IV pulse 250 mg of methylprednisolone; 36 (16.5%) were followed before September 2020 and received anakinra without steroids because of the standard of care at that period. Only CRP was different between the alive and dead patients for the baseline parameters (p=0.05). On the first day of drug treatment, CRP and procalcitonin values were significantly higher in dead patients (Table 1). A 50% decrease in CRP level was achieved in 3.1 days in survivors and 4.7 days in dead patients. D-dimer (p=0.018), CRP (p=0.006), LDH (p=0.003), procalcitonin (p=0.005), creatinine kinase (p=0.001), and fibrinogen levels (p=0.05) were significantly different between the surviving and dead patients when the measurements between the first drug administration day and response day were compared. Neutrophil, lymphocyte count, ferritin, D-dimer, CRP, LDH, AST, procalcitonin, creatinine kinase, and fibrinogen levels were significantly different between the patients when the parameters between the first drug administration day and discharge/death day were compared. Dead patients had higher CRP values and they did not show a continuing CRP decrease with the steroids and anakinra (Figure 1).
Conclusion: Retrospective analysis of 218 patients suggests that starting anakinra earlier in hospitalized patients may provide better results, and a decrease in CRP, ferritin, D-dimer values, as well as an increase in lymphocyte count, are associated with favorable outcomes. Increasing values of D-dimer and troponin during treatment are associated with worse outcomes, possibly indicating cardiovascular and thrombotic pathologies not responding to anakinra. Changes in the CRP values are found to help monitor the response to anakinra. Other inflammatory pathways could be targeted in those who are not responding to appropriate doses of anakinra within 5 days.

Figure 1: Mean CRP changes in healthy and dead patients

Background: The impact of immunosuppressants on COVID-19 vaccination response and durability in patients with immune-mediated inflammatory diseases (IMID) is yet to be fully characterized. Humoral response may be attenuated in these patients especially those on B cell depleting therapy and higher doses of corticosteroids, but data regarding other immunosuppressants are scarce.
Objectives: We aimed to investigate antibody and T cell responses and durability to SARS-CoV-2 mRNA vaccines (BNT162b and/or mRNA 1273) in IMID patients on immunomodulatory maintenance therapy other than B-cell depleting therapy and corticosteroids.
Methods: This prospective observational cohort study examined the immunogenicity of SARS-CoV-2 mRNA vaccines in adult patients with IMIDs (psoriatic arthritis, psoriasis, inflammatory bowel disease and rheumatoid arthritis) with or without maintenance immunosuppressive therapies (anti-TNF, methotrexate/azathioprine [MTX/AZA], anti-TNF + MTX/AZA, anti IL12/23, anti-IL-17, anti-IL23) compared to healthy controls. Automated ELISA for IgGs to spike trimer, spike receptor binding domain (RBD) and the nucleocapsid (NP) and T-cell release of 9 cytokines (IFNg, IL2, IL4, IL17A, TNF) and cytotoxic molecules (sFasL, GzmA, GzmB, Perforinin) in cell culture supernatants following stimulation with spike or NP peptide arrays were conducted at 4 time points: T1=pre vaccination, T2=median 26 days after dose 1, T3=median 16 days after dose 2 and T4=median 106 days after dose 2. Neutralization assays against four SARS-CoV-2 variants (wild type, delta, beta and gamma) were conducted at T3.
Results: We followed 150 subjects: 26 healthy controls and 124 IMID patients: 9 untreated, 44 on anti-TNF, 16 on anti-TNF with MTX/AZA, 10 on anti-IL23, 28 on anti-IL12/23, 9 on anti-IL17, 8 on MTX/AZA (Table 1). Most patients mounted antibody and T cell responses with increases from dose 1 to dose 2 (100% seroconversion at T3) and some decline by T4, with variability within groups. Antibody levels and neutralization efficacy was lower in anti-TNFgroups (anti-TNF, anti-TNF + MTX/AZA) compared to controls and waned by T4 (Figure 1). T cell responses were not consistently different between groups. Pooled data showed a higher antibody response to mRNA-1273 compared to BNT162b.
Conclusion: Following 2 doses of mRNA vaccination there is 100% seroconversion in IMID patients on maintenance therapy. Antibody levels and neutralization efficacy in anti-TNF group are lower than controls, and wane substantially by 3 months after dose 2. These findings highlight the need for third dose in patients undergoing treatment with anti-TNF therapy and continued monitoring of immunity in these patient groups, taking into consideration newer variants and additional vaccine doses.

POS1218

RELAPSES OF IDIOPATHIC INFLAMMATORY MYOPATHIES AFTER VACCINATION AGAINST COVID19: A REAL-LIFE ITALIAN STUDY

E. Conticini[1], M. D'alessandro[2], S. Grazzini[1], M. Fornaro[3], D. Sabella[3], G. Lopalco[3], F. Iannone[3], A. Gattamelata[4], S. Colafrancesco[4], F. Giardina[4], R. Priori[4], C. Rizzo[5], G. Guggino[5], P. Cameli[2], D. Bennett[2], E. Bargagli[2], L. Cantarini[1], B. Frediani[1]. *[1]University of Siena, Rheumatology Unit, Siena, Italy; [2]University of Siena, Respiratory Diseases and Lung Transplantation Unit, Siena, Italy; [3]University of Bari, Rheumatology Unit, Bari, Italy; [4]Sapienza University of Rome, Rheumatology Unit, Rome, Italy; [5]University of Palermo, Rheumatology Unit, Palermo, Italy*

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) vaccination plays a crucial role as pivotal strategies to curb the coronavirus disease-19 (COVID-19) pandemic. Despite the mass-scale vaccination, literature data about the incidence of disease flares in IIM patients are still not reported as well as the immunological condition.
Objectives: The present study aimed to describe the clinical status of patients affected by IIM after vaccination against COVID19 in order to assess the number of relapses or immune-mediated reactions in a cohort of Italian patients with such disease.
Methods: We included all patients affected by IIM and followed by Myositis Clinic, Rheumatology and Respiratory Diseases Units, Siena University Hospital, Bari University Hospital, Policlinico Umberto I, Sapienza University, Rome, and Policlinico Paolo Giaccone, Palermo. Inclusion criteria were a recent (<3 months) clinical and serological assessment before the survey and a definite diagnosis of dermatomyositis, polymyositis and anti-synthetase syndrome. All patients underwent a telephone survey in order to establish their clinical status and potential relapses after vaccination.
Results: A total of 119 IIM patients (median, IQR 58 (47-66) years; 32 males) were consecutively enrolled. Fifty had a diagnosis of DM, 39 had PM and 30 had ASS. The median months of disease duration was 79.62±83.98. According to number of organs involvement, forty-two had only one, 45 had two organs involvement, 20 had three, 11 had four and one had five. The majority of them received two doses of COVID-19 vaccine, except four patients who refused the vaccination: 94 (78.9%) Cominarty, 16 (13.4%) Moderna, 5 (0.04%) AZ. Seven (0.06%) patients had flare after vaccination, the majority of them were mild except one major with three organs involved and one life-threatening with systemic involvement. In order to understand or predict the effect of demographic and clinical features on the flare development after vaccination, a logistic regression analysis was performed. The goodness-of-fit statistics showed a Chi^2 associated with the Log ratio (L.R.) of 0.045. From the probability associated with the Chi-square tests, the Type II analysis showed the variable that most influences the development of flare was the number of organs involved (p=0.047). Sixty-eight patients received the third dose of COVID-19 vaccination: 51 (75%) Cominarty and 17 (25%) Moderna. Only one (0.01%) patient (the same who had life-threatening flare with systemic involvement after two doses) had flare after third dose and eventually died.
Conclusion: Vaccines against SARS-CoV2 have provided, both in registratory studies and in preliminary real-life evidence, an overall good efficacy and safety. Nevertheless, only scanty data are available for rheumatic patients in general and the ones affected by IIM in particular. To the best of our knowledge, ours represent the largest cohort of IIM patients in which immunogenicity of anti-SARS-CoV2 vaccine was assessed. In line with real-life data from other diseases, we found a non-statistically significant risk of relapse in our patients, which occurred seldom, usually mild and in patients with a more severe and aggressive course of disease.

SARS-COV-2 COURSE AND OUTCOME IN PATIENTS WITH SYSTEMIC AUTOINFLAMMATORY DISEASES (SAID) TREATED WITH IL-1 INHIBITORS AND COLCHICINE

S. Bindoli[1], S. Della Mora[1], A. Doria[1], P. Sfriso[1]. [1]*University of Padova, Rheumatology Unit, Dept of Medicine, Padova, Italy*

Background: The spread of COVID-19 had a strong impact in north-east Italy especially during 2020 and in the first months of 2021. Patients affected by rheumatological disorders are at high risk of infections due to immunosuppressant therapies and a clear immunological imbalance. However, some anti-cytokines such as IL-1 inhibitors proved to be effective in curbing the cytokine storm, frequent feature of severe COVID-19.

Objectives: We assessed the SARS-CoV-2 clinical course in 28 patients affected by autoinflammatory diseases, referring to the Autoinflammatory Outpatient Clinic of Padova University; in particular we observed if patients undertaking IL-1 inhibitors (group-1) had a diverse outcome compared to those not on anti-IL-1 drugs (group-2).

Methods: Through telephone or e-mail consultancy, 28 patients (18 females, mean age 39.5±15), confirmed to have contracted COVID-19 between March 2020 and January 2022. Twelve patients (42.8%) were affected by periodic fevers (FMF/TRAPS), 10/28 (35.7%) had Adult-Onset Still's Disease, 3/28 (10.7%) had Undifferentiated Autoinflammatory Diseases, while 2/28 (7.1%) were affected by Behçet Disease and one patient had Schnitzler Syndrome. 12 out of 28 patients (42.8%) were undertaking IL-1 inhibitors; 8/28 (28.5%) were in therapy with colchicine; 2 patients were in therapy with methotrexate and abatacept respectively, and 6/28 (21.4%) received no therapy. All were diagnosed with COVID-19 after molecular nasopharyngeal swab performed either for the presence of symptoms or close contact with a positive subject. 5/28 patients had the infection after receiving the second vaccine shot, two after the booster dose. All the others had COVID-19 before the vaccine injection. *GraphPad5* was used for statistical analysis and Fisher's test was applied.

Results: COVID-19 clinical course was benign in 27 out of 28 patients (96.4%); a total of 29 infections were counted due to a case of re-infection; 2 patients discontinued the therapy; all the others continued their medications (92.8%). Two patients (7.1%) of the entire cohort were hospitalized, one died. Regarding the major symptoms (fever ≥ 38 C°, cough/respiratory or gastro-intestinal symptoms) no difference was noticed between group-1 and group-2 (p=0.449); despite group-1 required less symptomatic therapy than group-2, the difference was not significant (p=0.471). Table 1 summarizes the clinical features exhibited by the patients and the therapies undertaken during the infection.

Table 1. Clinical features and therapies of the examined cohort

	Total COVID-19 infections (%) 29 (100)	Group-1 (anti IL-1 drugs) 12 (41.3)	Group-2 (no anti IL-1 drugs) 17 (58.6)
COVID-19 symptomatic therapy			
Acetaminophen	4 (13.7)	0	4 (23.5)
NSAIDs	8 (27.5)	3 (25)	5 (29.4)
Other (corticosteroids, mAb°)	5 (17.2)	3 (25)	2 (11.7)
Total	17 (58.6)	6 (50)	11 (58.8)
No therapy for COVID-19	12 (41.3)	6 (50)	6 (35.2)
COVID-19 major symptoms *	10 (34.4)	3 (25)	7 (41.1)
COVID-19 minor symptoms **	16 (48.7)	8 (66.6)	8 (47)
COVID-19 asymptomatic	3 (10.3)	1 (8.3)	2 (11.7)
Discontinuation of therapy	2 (6.8)	0	2 (11.7)
Outcome			
Home	27 (93.1)	11 (91.6)	16 (94.1)
Hospitalization (and fully recovered)	1 (3.44)	1 (8.33)	0
Death	1 (3.44)	0	1 (5.8)
Infection after receiving vaccine (at least II doses)	7 (24.13)	5 (41.6)	2 (11.7)

Legend: *(Fever ≥ 38 C°, cough/pneumonia, important gastro-intestinal symptoms); **(Fever < 38 C°, anosmia, ageusia, asthenia, arthralgias); °Monoclonal antibodies

Conclusion: Despite the low sample size, our study is of interest since it proves that the inhibition of IL-1 with both anakinra or canakinumab and the employment of colchicine, an important inflammasome regulator, may curb the hyperinflammation typical of COVID-19. Given the promising results obtained with anti-IL-1 and colchicine in treating severe COVID-19, it is conceivable a "protective" role of these drugs in preventing a massive cytokine release. Unsurprisingly, none of our patients but one, had a severe course or fatal outcome after SARS-CoV-2 infection.

POS1220

HUMORAL IMMUNE RESPONSE AGAINST BNT162B2 MRNA COVID-19 VACCINE IN JAPANESE RHEUMATIC DISEASE PATIENTS RECEIVING IMMUNOSUPPRESSIVE THERAPY: A MONOCENTRIC STUDY

K. Sugihara[1], R. Wakiya[1], H. Shimada[1], T. Kameda[1], S. Nakashima[1], M. Kato[1], T. Miyagi[1], M. Mizusaki[1], R. Mino[1], H. Dobashi[1]. [1]*Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Miki, Japan*

Background: Patients with immune-mediated inflammatory diseases are inherently susceptible to infections and are at high risk of developing COVID-19. COVID-19 vaccination in patients with rheumatoid and musculoskeletal disease (RMD) is strongly recommended [1]. BNT162b2 is the most used COVID-19 vaccine in Japan. The safety and efficacy of this vaccine has been demonstrated in the general population [2], but patients receiving immunosuppressive therapy were excluded from the study. Although data on the immunogenicity of COVID-19 vaccine in the immunocompromised adult population is rapidly increasing, the immunogenicity of mRNA COVID-19 vaccine in RMD patients receiving medication has been reported in various and still inadequate ways. Furthermore, the immunogenicity of mRNA COVID-19 vaccine may vary depending on the medication. In addition, most of these data were reported from Western countries, and data on Japanese patients with RMD are limited.

Objectives: To investigate serum antibody titre against SARS-CoV-2 spike protein following BNT162b2 vaccination in Japanese RMD patients on various immunomodulatory treatment.

Methods: Two hundred and twelve RMD outpatients undergoing treatment at Kagawa University Hospital and 43 healthy volunteers, who had received two doses of BNT162b2, were included in the study. Serum sample was collected at least 14 days after the second dose. Antibody titer against SARS-CoV-2 spike protein in serum was measured by ELISA (Elecsys Anti-SARS-CoV-2 S RUO). We analyzed the relationship between clinical characteristics, including the type of disease and treatment of RMD, and antibody titer against SARS-CoV-2 spike protein.

Results: The antibody titer against SARS-CoV-2 spike protein in RMD patients was significantly lower than that in healthy subjects. In the analysis with therapeutic agents, the mean antibody titer in RMD patients treated with rituximab (RTX) was much lower than that in healthy controls. Patients treated with baricitinib, azathioprine, mycophenolate mofetil, abatacept, TNF inhibitors, cyclosporine, IL-6 inhibitors, methotrexate (MTX), or glucocorticoids (GC) had only moderately lower antibody titers. Patients treated with tacrolimus, an immunosuppressive drug commonly used for treatment in Japan, showed a slight decrease in antibody titer, but the difference was not significant compared with healthy subjects. IL-17 and IL-23 inhibitors did not impair the humoral response. In addition, the combination of MTX with various immunosuppressive agents reduced titers, although this was not statistically significant.

Conclusion: Many of the immunosuppressants impaired the immunogenicity to BNT162b2 in Japanese RMD patients. The degree of decline of antibody titers differed according to immunosuppressant. MTX potentially impairs the immunogenicity of BNT162b2 also in the case of concomitant use with other immunosuppressant.

POS1221

EFFECT OF COVID-19 ON CHILDREN WITH RHEUMATIC DISEASE

T. Limon[1], G. Kaya Aksoy[2], S. Akman[2], M. Koyun[2], G. Öngüt[3], D. Mutlu[3], E. Çomak[2], T. Tural Kara[4], Ö. Koyuncu Özyurt[3]. [1]*Akdeniz University Faculty of Medicine, Department of Pediatrics, Antalya, Turkey;* [2]*Akdeniz University Faculty of Medicine, Department of Pediatric Nephrology, Antalya, Turkey;* [3]*Akdeniz University Faculty of Medicine, Department of Microbiology, Antalya, Turkey;* [4]*Akdeniz University Faculty of Medicine, Department of Pediatric Infectious Diseases, Antalya, Turkey*

Background: Pediatric patients with a diagnosis of rheumatic disease are at increased risk for infectious diseases due to immune dysregulation arising fromthe disease itself, as well as immunoregulatory or immunosuppressive drugs they use. However, there are studies reporting that COVID-19 disease has a moderate course in children with rheumatic disease.

Objectives: This study aims to determine the seroprevalence of SARS-CoV-2 in children with rheumatic disease during the COVID-19 pandemic, to evaluate the effects of immunosuppressive drugs and biological agents on seroprevalence of COVID.

Methods: Between September 2020 and September 2021, patients aged 2-18 years with a diagnosis of and with a follow-up period of more than 6 months were included in the study. Patients were selected by "simple random sampling" method.

Anti-SARS-CoV-2 antibodies (IgG and IgA) against the S1 domain of the SARS-CoV-2 spike protein were investigated with a micro ELISA kit.

Results: 170 patients, 92 (54.1%) girls, with a mean age of 12.16±4.18 years, were included. The median age at diagnosis was 7.59 (IQR 4.33-11.30) years, and the median follow-up time after diagnosis was 3.24 (IQR 1.87-5.99) years. Primary disease distribution was presented on Figure 1. The co-morbid diseases as obesity, hypertension and chronic kidney disease was present in 4.7%, 9.4% and 5.3% of patients, respectively. The distribution of medications was as follows; colchicine 101 patients (59.4%), Disease Modifying Anti-Rheumatism Drugs 49 (28.8%), steroid 25 (14.7%), and biological agents 28 (16.5%).

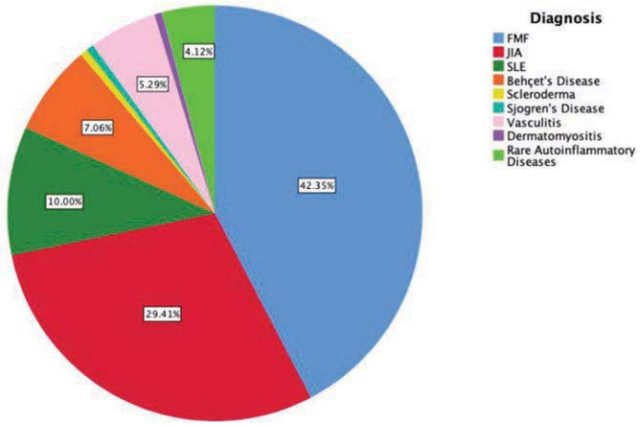

Figure 1. Distribution of patients according to primary rheumatologic diagnosis

Anti-SARS-CoV-2 Ig G antibody was positive in 40 (23.5%) of the patients. Demographic characteristics and treatment-related variables were similar between SARS-CoV-2 IgG seropositive and seronegative patients (Table 1).

Table 1. Characteristics of patients who are seropositive and seronegative for anti-SARS-CoV-2 Ig G

Variable	Anti-SARS-CoV-2 IgG negative patients (n=130)	Anti-SARS-CoV-2 IgG positive patients (n=40)	p

Diagnosis (%)			
FMF and other autoinflammatory disease	62 (%78.5)	17 (%21.5)	0.166
Juvenile idiopathic arthritis	39 (%78.0)	11 (%22.0)	
SLE ve other autoantibody related diseases	16 (%80.0)	4 (%20.0)	
Behçet's disease	8 (%66.7)	4 (%33.3)	
Vasculitis	5 (%55.6)	4 (%44.4)	
MEFV mutation			
Homozygous	30 (%75.0)	10 (%25.0)	0.991
Heterozygous	33 (%76.7)	10 (%23.3)	
No mutation	36 (%75.0)	12 (%25.0)	
Presence of colchicine usage			
Yes	76 (%75.2)	25 (%24.8)	0.396
No	54 (%78.2)	15 (%21.7)	
Median colchicine dose (mg/day)	1.09±0.44	1.13±0.42	0.842
Presence of DMARD usage			
Yes	37 (%75.5)	12 (%24.5)	0.499
No	93 (%76.9)	28 (%23.1)	
Presence of steroid usage			
Yes	17 (%68.0)	8 (%32.0)	0.202
No	113 (%77.9)	32 (%22.1)	
Median steroid dose (mg/day)	10.50±8.91	14.71±11.95	0.333
Presence of biological agent usage			
Yes	21 (%75.0)	7(%25.0)	0.505
No	109 (%76.8)	33(%23.2)	

Thirty-eight (22.4%) of the patients had close contact with an individual diagnosed with COVID-19. Thirty two (18.9%) patients underwent PCR testing for SARS-CoV-2; only 4 (2.4%) had positive. Of these 32 patients, 28.1% were positive for IgG. IgG seropositivity was observed in 3 (75.0%) of 4 patients with PCR positivity.

Conclusion: We found the SARS-CoV-2 seroprevalence of 23.5% in children with a diagnosis of rheumatic disease. It seems that primary rheumatological diagnosis does not affect COVID seropositivity in children.

POS1222 FOLIC ACID AND METHOTREXATE USE AND THEIR ASSOCIATION WITH COVID-19 DIAGNOSIS AND MORTALITY: AN ANALYSIS FROM THE UK BIOBANK

R. Topless[1], R. Green[2], S. Morgan[3], P. Robinson[4], T. Merriman[1,3], A. Gaffo[3,5]. *[1]University of Otago, Biochemistry, Dunedin, New Zealand; [2]University of California, Davis, Medicine, Davis, United States of America; [3]University of Alabama at Birmingham, Medicine, Birmingham, United States of America; [4]The University of Queensland, Medicine, Saint Lucia, Australia; [5]Birmingham VA Medical Center, Medicine, Birmingham, United States of America*

Background: Folate metabolism is implicated in SARS-CoV-2 infectivity (Ref).

Objectives: To determine if methotrexate (an antifolate) or folic acid prescription were associated with a lowered and increased risk, respectively, for COVID-19 diagnosis or mortality in a large population-based cohort (UK Biobank).

Methods: Data from 380,380 UK Biobank participants with general practice prescription data were used. Criteria for COVID-19 diagnosis were 1) a positive SARS-CoV-2 test and / or 2) ICD-10 code for confirmed COVID-19 (U07.1) or probable COVID-19 (U07.2) in hospital records, or death records. This definition identified 26,003 individuals diagnosed with COVID-19 of whom 820 were known to have died from COVID-19. Logistic regression statistical models were adjusted for age group (4 categories), sex, ethnicity, Townsend deprivation index, BMI, smoking status, presence of rheumatoid arthritis, sickle cell disease, use of anticonvulsants, statins and iron supplements.

Results: Compared with people prescribed neither folic acid nor methotrexate, people prescribed folic acid supplementation had increased risk of diagnosis of COVID-19 (OR 1.51 [1.42; 1.61]). The prescription of methotrexate with or without folic acid was not associated with COVID-19 diagnosis (P≥0.18). Compared with people prescribed neither folic acid nor methotrexate, people prescribed folic acid supplementation had an increased risk of death after a diagnosis of COVID-19 (OR 2.64 [2.15; 3.24]) in a fully adjusted model. The prescription of methotrexate in combination with folic acid was not associated with an increased risk for death after a diagnosis of COVID-19 (1.07 [0.57; 1.98]). (Table 1)

Table 1. COVID-19 diagnosis and associated death in people prescribed methotrexate and / or folic acid in the UKBB, compared to people not prescribed methotrexate or folic acid. Model 1 adjusted for age group, sex, ethnicity, Townsend deprivation index, BMI, smoking status Model 2 is model 1 plus adjustment by the presence of rheumatoid arthritis, sickle cell disease, use of statins, anticonvulsants and iron supplementation.

	Unadjusted		Model 1		Model 2	
	OR [95% CI]	*P*	OR [95% CI]	*P*	OR [95% CI]	*P*
Neither Folic acid nor Methotrexate	1.0	-	1.0	-	1.0	-
COVID-19 diagnosis						
Folic acid only	1.58 [1.49; 1.68]	<0.001	1.60 [1.50; 1.70]	<0.001	1.51 [1.42; 1.61]	<0.001
Methotrexate and Folic acid	1.09 [0.96; 1.23]	0.18	1.15 [1.02; 1.30]	0.021	1.09 [0.96; 1.23]	0.18
COVID-19 associated death						
Folic acid only	5.14 [4.23; 6.24]	<0.001	2.91 [2.38; 3.55]	<0.001	2.64 [2.15; 3.24]	<0.001
Methotrexate and folic acid	1.47 [0.81; 2.67]	0.21	1.26 [0.70; 2.30]	0.44	1.07 [0.57; 1.98]	0.84

Conclusion: We report increased risk for COVID-19 diagnosis and COVID-19-related death for people prescribed folic acid supplementation. The prescription and use of supplemental folic acid may confer risk of infection with the SARS-CoV-2 virus as well as the risk of death resulting from COVID-19. Our results also suggest that methotrexate might attenuate an increased risk for COVID-19 diagnosis and death conferred by folic acid.

POS1223 DIFFERENT ANTI-SARS-COV-2 VACCINE RESPONSE UNDER B- AND T-CELL TARGETED THERAPIES VERSUS ANTI-CYTOKINE THERAPIES IN PATIENTS WITH INFLAMMATORY ARTHRITIDES

R. Felten[1], M. Geoffroy[2], B. Loïs[2], P. M. Duret[3], M. Desmurs[4], A. Fan[5], M. Couderc[5], L. Messer[3], M. Ardizzone[4], S. Ahmed-Yahia[1], R. M. Javier[1], A. Meyer[1], E. Chatelus[1], C. Sordet[1], L. Pijnenburg[1], J. Sibilia[1], M. Soubrier[5], J. E. Gottenberg[1], J. H. Salmon[2]. *[1]Hôpitaux Universitaires de Strasbourg, Service de Rhumatologie, Centre National de Référence des Maladies Auto-immunes Systémiques Rares Est Sud-Ouest (RESO), Strasbourg, France; [2]Hôpital Maison Blanche, Centre Hospitalier Universitaire de Reims, Service de Rhumatologie, Reims, France; [3]Hospices Civils de Colmar, Hôpital Pasteur, Service Rhumatologie, COLMAR, France; [4]Hôpital Emile MULLER de Mulhouse, Service de Rhumatologie, Mulhouse, France; [5]Hôpitaux Universitaires de Clermont-Ferrand, Service de Rhumatologie, Clermont-Ferrand, France*

Background: Vaccination against SARS-CoV-2 is effective in preventing severe forms of COVID-19, but there remain concerns about a reduced vaccine response in patients suffering from inflammatory arthritides who are treated by immunosuppressive therapies.

Objectives: We analysed the impact of bDMARDs on the humoral anti-SARS-CoV-2 vaccine response of patients followed in day hospitals.

Methods: We studied the vaccine response after a complete vaccine regimen followed in day hospital in 5 French hospitals and treated with an intravenous bDMARD between September 2019 and August 2021. After obtaining their informed consent, we included patients with an anti-SARS-CoV-2 serology. They were considered non-responders if the antibody level detected was inferior to the threshold of positivity of the kit used.

Results: 205 patients were included (148 females/57 males). The median age was 64 years (Interquartile Range [IQR] 56-71). 25 were treated with tocilizumab (TCZ), 36 with abatacept (ABA), 53 with infliximab (IFX) and 91 with rituximab (RTX). When considering both patients after a complete vaccination schema (2 doses,

or 1 dose in case of prior COVID-19) and those with 1 booster dose, 34 patients (16.6%) were non-responders (2 [5.9%] treated by IFX, none treated by TCZ, 9 [26.5%] treated by ABA and 23 [67.7%] treated by RTX). In multivariate analysis, the only characteristics that significantly and independently differed between responders and non-responders were last bDMARD and corticosteroid therapy at the time of 1st vaccination (Table 1). In RTX-treated patients, the delay from last infusion to 1st vaccine dose was significantly shorter in non-responders (median 4.3 IQR [2.9-6.1] months in non-responders versus 8.4 IQR [5.7-14.5] in responders, p=0.0007). Median survival, i.e. achieving a vaccine response in 50% of RTX-treated subjects, was achieved after 277 days (95CI [209-310]) in patients vaccinated with 2 or 3 doses (Figure 1). In ABA-treated patients, the delay from last infusion to 1st vaccine dose was not different between non-responders and responders.

Table 1. Patients' characteristics and comparisons between responders and non-responders.

POS1224

RHEUMATOID ARTHRITIS DISEASE ACTIVITY ASSESSED BY PATIENT-REPORTED OUTCOMES AND FLOW CYTOMETRY BEFORE AND AFTER AN ADDITIONAL DOSE OF COVID-19 VACCINE

S. Tedeschi[1,2], J. Stratton[1], J. Ellrodt[1], M. G. Whelan[1], K. Hayashi[1], K. Yoshida[1,2], L. Chen[1], I. Adejoorin[1], K. E. Marks[1,2], A. H. Jonsson[1,2], D. Rao[1,2], D. Solomon[1,2]. *[1]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America; [2]Harvard Medical School, Department of Medicine, Boston, United States of America*

Background: The Centers for Disease Control and Prevention recommends an additional dose (AddDose) of COVID-19 vaccine for moderately/severely immunosuppressed individuals following an initial vaccine series. The American College of Rheumatology suggests that patients interrupt use (hold) certain DMARDs around the time of COVID-19 vaccination to improve immunogenicity. Whether holding DMARDs around an AddDose of COVID-19 vaccine affects RA disease activity or affects frequencies of lymphocyte populations that may be associated with RA disease activity remains unknown.

Objectives: To test whether RA disease activity and frequencies of lymphocyte populations change pre- vs. post-AddDose of COVID-19 vaccine, overall and stratified by holding vs. continuation of DMARDs around the AddDose.

Methods: Prospective observational cohort study of patients with RA who had completed an initial COVID-19 vaccine series (2 doses of mRNA vaccine or 1 dose of adenovirus vector vaccine). Subjects enrolled July-November 2021, prior to receiving an AddDose. Subjects held or continued DMARDs around the AddDose based on discussion with their rheumatologist and/or personal decision-making. RA disease activity was assessed weekly using the validated patient-reported RA Disease Activity Index-5 (RADAI-5) from enrollment through 4 weeks post-AddDose. We compared mean RADAI-5 pre- vs. post-AddDose using generalized estimating equations to account for correlated data among individual subjects. We aimed to enroll 60 subjects to achieve 91% power to detect a 15% non-inferiority margin in mean RADAI-5 post- vs. pre-AddDose. A subset of subjects with seropositive RA provided blood for flow cytometry at enrollment and week 4 post-AddDose. Frequencies of lymphocyte populations (T peripheral helper [Tph] cells, T follicular helper [Tfh] cells, age-associated B cells [ABC], and plasmablasts) were compared pre- vs. post-AddDose using Wilcoxon paired tests with Bonferroni correction.

Results: Among 71 subjects, mean age was 62 (SD 12) years, 85% were female, and 87% had seropositive RA. Methotrexate (42%) and TNF inhibitors (38%) were the most common DMARDs; 21% were taking prednisone. One subject reported COVID-19 infection prior to the AddDose. The mean RADAI-5 was 3.20 (SD 0.23) pre-AddDose compared to 3.25 (SD 0.23) after (difference of 1.6%, p=0.51). Figure 1 displays mean RADAI-5 in 35 (49%) subjects that held at least 1 DMARD and 36 (51%) subjects that continued all DMARDs around the AddDose. Mean change in RADAI-5 between pre- vs. post-AddDose did not significantly differ based on whether subjects held vs. continued DMARDs (p for interaction = 0.16). Frequencies of Tph, Tfh, ABC, and plasmablast populations did not significantly differ between the pre- and post-AddDose timepoints in subjects that held at least 1 DMARD (n=16) or subjects that continued all DMARD (n=11) (Figure 1).

Conclusion: RA disease activity, measured weekly with a validated patient-reported outcome, is stable around the time of an AddDose of COVID-19 vaccine. Lymphocyte subsets of interest in RA were also similar before and after the AddDose, supporting the observation of stable patient-reported RA disease activity. Holding DMARDs was not associated with greater RA disease activity following the AddDose.

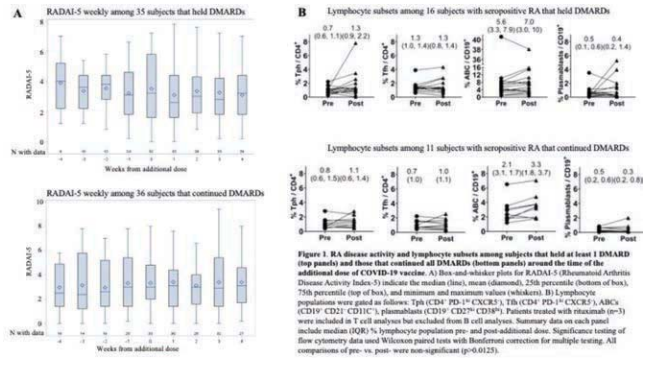

Figure 1. RA disease activity and lymphocyte subsets among subjects that held at least 1 DMARD (top panels) and those that continued all DMARDs (bottom panels) around the time of the additional dose of COVID-19 vaccine. A) Box-and-whisker plots for RADAI-5 (Rheumatoid Arthritis Disease Activity Index-5) indicate the median (line), mean (diamond), 25th percentile (bottom of box), 75th percentile (top of box), and minimum and maximum values (whiskers). B) Lymphocyte populations were gated as follows: Tph (CD4+ PD-1hi CXCR5+), Tfh (CD4+ PD-1hi CXCR5+), ABCs (CD19+ CD21- CD11C+), plasmablasts (CD19+ CD27hi CD38hi). Patients treated with rituximab (n=3) were included in T cell analyses but excluded from B cell analyses. Summary data on each panel include median (IQR) % lymphocyte population pre- and post-additional dose. Significance testing of flow cytometry data used Wilcoxon paired tests with Bonferroni correction for multiple testing. All comparisons of pre- vs. post- were non-significant (p>0.0125).

POS1225 PREDICTORS OF WEAK ANTIBODY RESPONSE POST-COVID-19 MRNA VACCINATION IN SLE

C. Parsons[1], J. Rubio[2], A. Boulougoura3, V. Kyttaris[2]. *[1]Beth Israel Deaconess Medical Center, Internal Medicine, Boston, United States of America; [2]Beth Israel Deaconess Medical Center, Rheumatology, Boston, United States of America; [2]Beth Israel Deaconess Medical Center, Rheumatology, Boston, United States of America*

Background: Throughout the COVID-19 pandemic, the BNT162b2 (manufactured by Pfizer—BioNTech) and mRNA-1273 (manufactured by Moderna Inc) vaccines have demonstrated an acceptable safety profile and a high degree of effectiveness in preventing severe COVID-19 outcomes in healthy individuals. However, it remains to be determined if similar benefits can be replicated in immunocompromised patients, who were largely excluded from Phase III clinical trials. Preliminary data on vaccine immunogenicity among lupus patients reveal blunted humoral responses, particularly in those using prednisone and/or mycophenolate (1-2).
Objectives: This study sought to measure the antibody responses following SARS-CoV-2 vaccination in patients with SLE and to identify clinical and laboratory parameters associated with low antibody responses.
Methods: We prospectively enrolled SLE patients from the Beth Israel Deaconess Medical Center Systemic Lupus Erythematosus Cohort (BIDLC). The patients received two doses of either BNT162b2 or mRNA-1273 and were tested for the SARS-CoV-2 IgG spike antibody at least 4 weeks after the second vaccine dose. Patients with evidence of prior COVID-19 infection were excluded. The primary goal of this study was to measure the prevalence of a weak IgG spike antibody response and identify predictive clinical-laboratory factors. We first measured the antibody responses in a healthy control group and defined a low antibody titer as values that fell below the 25% percentile of this reference group (<6). We then used simple logistic regression to assess for associations between different predictive variables and our predefined dichotomous outcome: <6 vs ≥6 IgG spike antibody titer. To account for potential cofounders, a multiple logistic regression model was performed. Risk ratios were calculated with the Log Binomial regression. Significance level was set at p <0.05.
Results: A total of 71 patients were included in the study. At the time of vaccination, patients were on various immune modulator and suppressive medications, including: Hydroxychloroquine 87%, Prednisone 38%, Mycophenolate 38%, Azathioprine 18% and Belimumab 7%. The proportion of patients who received BNT162b2 and mRNA-1273 were 58% and 42%, respectively. Overall, 63% of patients had a high IgG spike antibody titer (≥ 6) and 37% of patients had a low IgG spike antibody titer (<6). Univariate logistic regression demonstrated that a SLEDAI ≥6 (OR: 4.55, *p = 0.02*), the use of azathioprine (OR: 3.55, *p = 0.04*) and receiving the BNT162b2 vaccine vs. mRNA-1273 (OR: 3.80, *P = 0.01*) were independent predictors of antibody titers <6. After controlling for age, sex, race, time to spike testing and use of immunosuppressive drugs, the association between a high SLEDAI score or receiving the BNT162b2 vaccine and a weak antibody response remained significant (Figure 1). Using the Log Binomial regression, the BNT162b2 and the high SLEDAI group were found to have 2.1- and 2.4-times, respectively, higher likelihood of developing weak antibody responses.

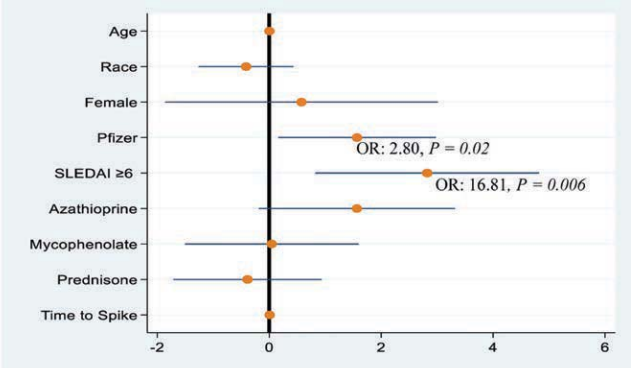

Figure 1. Logistic regression plot

Conclusion: In patients with SLE, Azathioprine use independently predicts reduced antibody titers. More importantly, we demonstrated that a pre-vaccine high disease activity score or receiving BNT162b2 (Pfizer—BioNTech) increases the risk of impaired immune response to the COVID-19 vaccine.

Background: Patients with inflammatory rheumatic diseases (IRD) have used self-isolation and social distancing during the pandemic to avoid SARS-CoV-19 infection (reference). In countries with unlimited and free access to SARS-CoV-19 testing, anxiety or other patient related factors might potentially increase test-frequency.
Objectives: In patients with IRD followed in the nationwide DANBIO registry we aimed to explore clinical factors including self-isolation associated with a) a positive SARS-CoV-19 test result ('infection'), b) higher frequency of SARS-CoV-19 testing during the first 1½ year of the pandemic.
Methods: In May-June 2020, IRD patients followed in the quality registry, DANBIO (n=36,152), were invited to participate in the voluntary online questionnaire survey 'You and your rheumatic disease during times with corona-virus'. Patient characteristics, treatment and patient reported outcomes were captured in DANBIO and from the questionnaire. Patients were considered as self-isolating if they agreed to the question: I stay at home and avoid others as much as possible.
After written consent, information on dates and SARS-CoV-19 test results (by PCR, polymerase chain reaction) during follow-up (until Nov 2021 and thus before entry of the Omicron variant) was obtained through linkage to the nationwide laboratory system.
Time to first positive PCR and associated characteristics were explored by multivariable Cox regression analyses with hazard ratios, HR, adjusted for: gender/age-group/ diagnosis/biologic therapy/working/ self-isolation/HAQ/EQ-5D. Day 0 was defined as the date of first positive test in cohort (May-07-2020).
Number of SARS-CoV-19 tests (median (IQR)), and characteristics associated with higher test frequency (upper quartile) was explored with multivariable logistic regression analyses (odds ratios, OR, adjustment like above).
Results: In 10,098 included patients, 2.8% were infected during follow-up (Table 1). Age and HAQ seemed lower in infected (Table 1, Figure 1). In multivariable Cox

regression analyses, male gender was associated with higher infection risk (HR 1.38 (1.05;1.80) whereas risk was lower in the age-group 61-80 years (0.60 (0.39;0.92) vs. below 40 years). Other factors were statistically insignificant.

Working		4616	4	96	58	42

Row percentage unless otherwise shown* At least one positive PCR before Nov 2021**May 2020AxSpA: Axial spondyloarthritis, EQ-5D: EuroQol quality of life (5D), HAQ: health assessment questionnaire, IQR: interquartile range, PsA: psoriatic arthritis, RA: rheumatoid arthritis

Median number of PCR tests was 4 (IQR 1-9). In patients with <9 tests, 2.6% were infected whereas for patients with ≥9 tests, 3.2% were infected. Patients with ≥9 tests were younger, more frequently female and working in univariate (Table 1) and adjusted analyses, whereas other characteristics were statistically insignificant (details not shown).

Conclusion: Few patients with IRD were infected during the first 1½ years of the pandemic. Gender and age were associated with infection risk and frequency of testing. Self-isolation and a range of other clinical characteristics had no impact, which to some extent may be due to behavioral differences across age-groups.

POS1227 TIME BETWEEN SECOND AND THIRD DOSES INFLUENCES RESPONSE TO COVID-19 VACCINE IN AUTO-IMMUNE DISEASE PATIENTS TREATED WITH RITUXIMAB WITHOUT RESPONSE TO TWO DOSES.

S. Bitoun[1], J. Avouac[2], J. Henry[1], R. Ghossan[2], O. Al Tabaa[2], R. Belkhir[1], G. Nocturne[1], C. Vauloup-Fellous[3], X. Mariette[1], R. Seror[1]. *[1]Hôpital Bicêtre, Assistance Publique-Hôpitaux de Paris, FHU CARE, Université Paris-Saclay, Inserm UMR 1184, Rheumatology Department, Le Kremlin Bicêtre, France; [2]Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, Université de Paris, Rheumatology Department, Paris, France; [3]Université Paris Saclay, INSERM U1193, AP-HP, Hôpital Paul Brousse, Virology, Villejuif, France*

Background: It is now well established that patients treated with rituximab (RTX) for auto-immune disease (AID) have a diminished antibody response to COVID-19 vaccines after two doses. Optimizing antibody response is a key objective in this population. To achieve this goal, a 3rd booster dose may be considered.

Objectives: Focusing on the population of AID patients treated with RTX without any antibody response after two doses we sought to explore how these patients could respond to a 3rd dose and identify factors of response.

Methods: We performed a French retrospective bicentric observational trial which is a follow up of previously published work (1). We included consecutive patients treated with RTX that were non-responders regarding their anti-Spike antibody (anti-S) status at least one month after the second dose of COVID-19 vaccination. Patients were included between March and October 2021. All patients then received a third dose according to local guidelines and had an anti-S measurement at least one month after the third dose. Some patients without response to a third dose had a fourth dose. Anti-S were measured in serum with various kits, but all results were in BAU/mL with upper quantification limit at 243. Patients with anti-S above 49 BAU/mL, which has been demonstrated to be the threshold associated with detectable neutralizing response were considered as responders (1).

Results: 60 patients treated with RTX without response to 2 doses (Anti-S Ab < 49 BAU/mL) were included in the study. 9/60 (15%) patients responded to the 3rd vaccine dose with anti-S > 49BAU/ml. Responders and non-responders had similar demographic characteristics (Table 1). There was a positive correlation between anti-S Ab levels after dose 3 and time between 2nd and 3rd doses (r=0,41 p=0,001) (Figure 1). Nevertheless, the median time between 2nd and 3rd doses was numerically but not significantly higher in responders than in non-responders (129 vs 80 days, p=0.30). There was no correlation between anti-S levels after the third dose and the time between the last RTX infusion and the third vaccine dose. There was a trend towards more patients with methotrexate co-medication in the non-responder group 31/51 (61%) vs 3/9 (33%) in the responder group (p=0,15). Seven non-responder patients after the 3rd dose received a 4th dose and 4 (57%) responded.

Table 1. Characteristics of patients without response after the second dose of vaccine treated with Rituximab for auto-immune diseases according to their seroconversion status after the third dose.

	Non responders (n=51)	Responders (n=9)	p
Age, median (min-max)	61 (17-85)	58 (36-78)	0,33
Female sex n (%)	42 (82)	6 (67)	0,36
Underlying disease n (%)			
Rheumatoid Arthritis	36 (69)	5 (56)	0,46
Other auto-immune disease	16 (31)	4 (44)	
Rituximab treatment			
Received a RTX infusion between dose 2 and 3 n (%)	14(27)	3(33)	0,70
Time between the last RTX infusion and the 3rd dose of vaccine in days median (min-max)	162 (1-687)	187 (79-959)	0,16
Previous number of RTX injections, median (min-max)	7 (0-34)	6 (1-22)	0,58
Vaccination scheme			
Interval between 2nd and 3rd vaccine dose in days, median (min-max)	80 (23-287)	129 (24-220)	0,30
Less than 3 months between 2nd and 3rd vaccine dose n (%)	27(53)	2(22)	0,14
Co-medications			
Patients on steroids n (%)	20(40)	5 (37,5)	0,99
Prednisone equivalent dose per day in mg median (min-max)	5(2-25)	5(5-10)	0,48

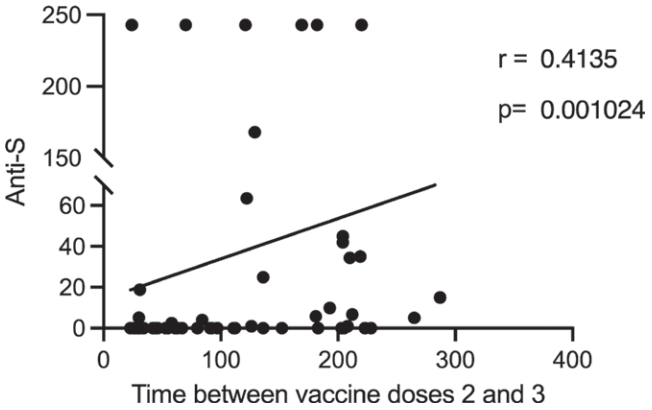

Figure 1. Correlation between anti- spike Ab levels after the third dose and time in days between doses 2 and 3.

Conclusion: A third vaccine dose of COVID-19 vaccine leads to only 15% of response in previously non-responding RTX treated AID patients. A longer time between 2nd and 3rd doses might positively influences response to a 3rd COVID-19 vaccine. Finally exploratory findings show that a fourth dose could be useful to obtain response non-responders.

POS1228 IMPACT OF COVID-19 ON THE PRESCRIPTION OF BIOLOGIC DMARDS: A POPULATION-LEVEL STUDY IN ENGLAND

M. Russell[1], S. Balachandran[1], S. Norton[1], E. Alveyn[1], D. Nagra[1], M. Adas[1], J. Galloway[1]. [1]*King's College London, Centre for Rheumatic Diseases, London, United Kingdom*

Background: There has been considerable uncertainty about the impact of biologic DMARDs (bDMARDs) on COVID-19 morbidity and vaccine efficacy, which may have influenced prescribing during the pandemic.

Objectives: To assess trends in the prescription of three commonly used bDMARDs with different modes of action - adalimumab (ADA), rituximab (RTX) and tocilizumab (TOC) - in England before and during the COVID-19 pandemic.

Methods: The National Health Service (NHS) Secondary Care Medicines dataset was utilised to analyse temporal trends in bDMARD prescriptions issued by all NHS hospital pharmacies in England. Monthly averages of prescriptions issued for ADA, RTX and TOC for combined indications, standardised using WHO Defined Daily Doses (DDD), were described from January 2019 to November 2021. Interrupted time-series analyses (ITSA) were used to estimate the effect of the pandemic on prescription trends for ADA, RTX and TOC; Newey-West standard errors with lags were used to account for autocorrelation between observation periods in these models.

Results: Temporal trends in ADA, RTX and TOC prescriptions are shown in Figure 1. A 46% decrease in RTX prescriptions was observed between March and April 2020, from 1,338,300 DDD to 718,900 DDD, respectively, coinciding with the worsening COVID-19 pandemic in England. RTX prescriptions increased after May 2020, reflected in the positive prescription trend observed in ITSA models (Table 1); however, RTX prescriptions remained below pre-pandemic levels, before decreasing again between November 2020 and February 2021. This coincided with increasing COVID-19 case numbers in England.

Table 1. Trends in prescriptions issued for ADA, RTX and TOC in England before and after the onset of the COVID-19 pandemic, assessed using interrupted time-series analyses. The absolute change in prescriptions issued in March 2020, relative to April 2020, is shown.

	Rituximab	Adalimumab	Tocilizumab
Prescription trend before March 2020	-0.23% per year (95% CI -0.97 to 0.52)	+2.94% per year (95% CI 2.14 to 3.73)	+0.04% per year (95% CI -0.07 to 1.53)
Absolute change in prescriptions in March 2020	-46.3%	+15.5%	+10.7%
Prescription trend after March 2020	+2.11% per year (95% CI 0.52 to 3.70)	+3.24% per year (95% CI 2.02 to 4.46)	+0.64% per year (95% CI 0.38 to 0.90)
Difference in trends post vs. pre-March 2020	+2.33% per year (95% CI 0.51 to 4.17) P=0.014	+0.30% per year (95% CI -1.03 to 1.63) P=0.65	+0.60% per year (95% CI 0.31 to 0.90) P<0.001

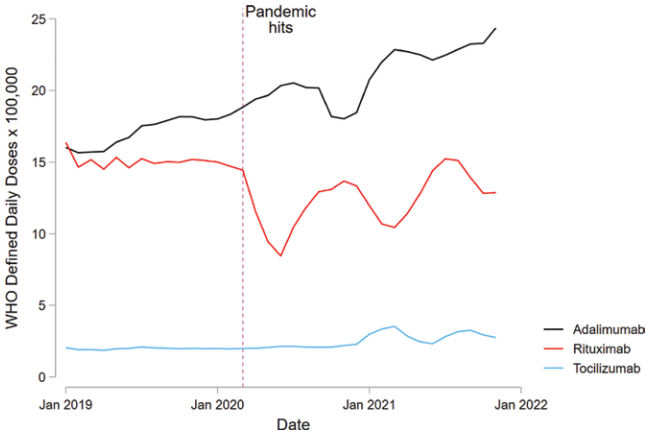

Figure 1. Temporal trends in prescriptions for ADA, RTX and TOC in England between January 2019 and November 2021. Monthly averages of prescriptions for combined disease indications are shown, standardised using WHO Defined Daily Doses.

For ADA, the pre-pandemic trend of increasing prescriptions continued during the pandemic, with no differences in prescription trends seen in ITSA models (Table 1). A 22% decrease in ADA prescriptions was observed between September and October 2020, from 2,037,800 DDD to 1,587,500 DDD, respectively, before rebounding to above pre-pandemic levels. Prescriptions for TOC increased during the pandemic, driven primarily by a 76% increase in prescriptions between December 2020 and January 2021, from 241,800 DDD to 425,000 DDD, respectively.

Conclusion: Prescriptions for RTX in England halved during the early COVID-19 pandemic, and remain below pre-pandemic levels as of November 2021. This likely reflects concerns about RTX use and increased COVID-19 mortality and reduced vaccine efficacy.[1,2] In contrast, prescriptions for ADA have continued to increase during the pandemic, while prescriptions for TOC surged in December 2020, coinciding with the more widespread use of TOC for the treatment of severe COVID-19.

POS1229 THE IMPACT OF COVID-19 ON MEDICATION NON-ADHERENCE IN A RHEUMATOID AND PSORIATIC ARTHRITIS UK COHORT

P. Curry[1], H. Chinoy[2], M. Jani[3], D. Plant[1,2], K. Hyrich[2,3], A. Morgan[4], A. G. Wilson[5], J. Isaacs[6], A. Morris[1,2], A. Barton[1,2], J. Bluett[1,2]. [1]*The University of Manchester, Versus Arthritis Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester, United Kingdom;* [2]*Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom;* [3]*The University of Manchester, Versus Arthritis Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester, United Kingdom;* [4]*Leeds Teaching Hosptials NHS Trust, School of Medicine, University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom;* [5]*University College Dublin, School of Meidicine & Medical Science, Conway Institute, Dublin, Ireland;* [6]*Newcastle upon Tyne Hospitals NHS Foundation Trust, Translational and Clinical Research Institute, Newcastle University and Musculoskeletal Directorate, Newcastle upon Tyne, United Kingdom*

Background: In March 2020, as part of the UK's COVID-19 prevention strategy, those identified as 'clinically extremely vulnerable,' were advised to shield. This included a number of patients prescribed anti-rheumatic drugs, who were asked to continue their current treatment unless they developed symptoms of infection. Suboptimal treatment adherence (16.0%-81.0%) has been reported in patients with arthritic diseases, and is associated with psychological factors, including anxiety (1). Previous literature in

non-UK cohorts has highlighted suboptimal adherence levels in immunosuppressed patients during the pandemic, although many were single centre studies (2,3).

Objectives: The aim of this multi-centre study is to investigate the impact of the COVID-19 pandemic on adherence to anti-rheumatic medications in patients with established rheumatoid (RA) and psoriatic (PsA) arthritis in the UK who had recently commenced a biologic or targeted synthetic DMARD.

Methods: Between September 2020 and May 2021, RA and PsA patients prescribed biologic or targeted synthetic anti-rheumatic drugs from two multi-centre observational studies (BRAGGSS and OUTPASS) were sent a questionnaire on medication usage, adherence, and perceptions to establish the impact of COVID-19 on these parameters. Patients were asked about compliance during the COVID-19 pandemic using a 5-point Likert scale (always, often, sometimes, rarely, and never) and the reason for non-adherence. Adherence was defined as never missing or delaying a dose, unless medically advised. Descriptive summary statistics were calculated, and logistic regression and Pearson's chi-squared tests were employed to investigate variables associated with self-reported non-adherence.

Results: In total 159 questionnaires were returned (81.1% RA and 18.9% PsA). Methotrexate (53.5%) was the most frequently prescribed agent, followed by etanercept (25.2%), sulfasalazine (22.6%), hydroxychloroquine (21.4%) and adalimumab (19.5%). Furthermore, 68.6% of patients were prescribed ≥2 drugs. During the pandemic, 42.1% of patients reported missing or delaying a treatment dose for any reason. Adherence information was available for 97.5% of patients with 25.8% reporting non-adherence which was not medically advised. Methotrexate non-adherence was 27.1%, with similar levels reported for etanercept (20.0%), sulfasalazine (27.8%), hydroxychloroquine (35.3%) and adalimumab (29.0%). No drugs had significantly different adherence compared to methotrexate. Furthermore, there was no association between disease type or perception of disease control and adherence. Of non-adherent patients, 17.5% reported increased anxiety, fear, and increased risk due to the COVID-19 pandemic as an influencing factor. Meanwhile, 37.5% of non-adherent patients listed non-COVID-19 intentional reasons and 45.0% reported non-intentional reasons, with forgetting and running out of treatment listed most frequently.

Conclusion: In a UK cohort self-reported non-adherence was reported in 25.8% of patients during the COVID-19 pandemic, despite medical advice, with reasons including increased anxiety due to COVID-19.

POS1230

INCREASED ANTIBODY RESPONSE AFTER SARS-COV-2 MRNA-BASED VACCINATION IN RITUXIMAB-TREATED PATIENTS WITH PREVIOUS COVID-19 INFECTION

J. Avouac[1], R. Ghossan[1], O. Al Tabaa[1], A. Combier[1], A. Steelandt[1], M. Thomas[1], O. Fogel[1], A. A. Mariaggi[2], J. F. Meritet[2], F. Rozenberg[2], A. Moltó[1], C. Miceli Richard[1], Y. Allanore[1]. [1]*Cochin Hospital, Rheumatology, Paris, France;* [2]*Cochin Hospital, Virology, Paris, France*

Background: Rituximab (RTX) is associated with reduced humoral response to SARS-CoV-2 mRNA-based vaccine (1, 2). A recent study has shown that, despite their immunosuppression burden, kidney transplant recipients with previous exposure to SARS-CoV-2 showed a marked increase in antibody titer, even after a single dose of vaccine (3).

Objectives: To describe the results of immunization after 1 to 3 doses of mRNA SARS-CoV-2 vaccine in RTX-treated patients with previous symptomatic COVID-19 infection.

Methods: Observational prospective usual care study including consecutive patients with inflammatory rheumatic diseases in maintenance therapy with RTX. All patients received a 1 to 3-dose regimen of mRNA-based COVID-19 vaccination (BNT162b2 Pfizer/BioNTech or mRNA-1273, Moderna). Serum IgG antibody levels against SARS-CoV-2 spike proteins were measured at the time of the new RTX infusion. The SARS-CoV-2 S1/S2 IgG immunoassay (DiaSorin) was used for the quantitative determination of antibodies to the receptor-binding domain of the viral spike (S) protein. Seropositivity was defined by anti-S antibodies >15 UA/mL.

Results: We included 69 patients (60 females, mean age 60±13 years) on maintenance therapy with RTX including 13 with previous symptomatic COVID-19, all proven by RT-PCR (10 females, mean age 58±12 years) (Table 1). SymptomaticCOVID-19 occurred between March 2020 and May 2021. The mean interval between the infection and vaccination was 8±3 months and the serological response was assessed after a mean of 74±58 days from the last dose of vaccination (3rd dose for 3 patients, 2nd dose for 6 patients and 1st dose for 4 patients). The 56 patients with no history of symptomatic COVID-19 infection all received 3 doses of vaccine and the serological response was assessed after a mean of 63±27 days from the 3rd dose of vaccination. The seropositivity rate was significantly higher in RTX-treated patients with previous symptomatic COVID-19 infection (11/13, 85% vs.15/56, 27%, p<0.001). Anti-S antibody titles were also markedly increased in patients with previous symptomatic COVID-19 infection (median 119 AU/mL, 95% CI 16-400 AU/mL vs. 3.80 AU/mL, 95% CI 3.80-4.81 AU/mL p<0.0001) (Figure 1). Antibody titles were not different according to the severity of previous COVID-19, the number of doses of vaccine, the underlying disease, and B-cell counts.

Table 1. Study population

	Patients with previous symptomatic COVID-19 (n=13)	Patients without symptomatic COVID-19 (n=56)
Age (years), mean ± SD	58±12	60±11
Females, n (%)	10 (77)	50 (89)
Underlying disease:		
Rheumatoid arthritis	10 (77)	45 (80)
Systemic sclerosis	2 (15)	5 (9)
Systemic lupus erythematosus	1 (8)	1 (2)
Sjögren syndrome	0 (0)	3 (5)
Mixed connective tissue disease	0 (0)	2 (4)
Disease duration (years), mean ± SD	17±9	20±10
Associated Methotrexate, n (%)	9 (69)	36 (64)
Current treatment with corticosteroids, n (%)	5 (38)	21 (38)
Corticosteroid dose >10 mg/day, n (%)	0 (0)	0 (0)
CD19+ (/µL) (100-600), mean ± SD	65±106	45±51
CD19 <18/µL, n (%)	7 (54)	33 (58)

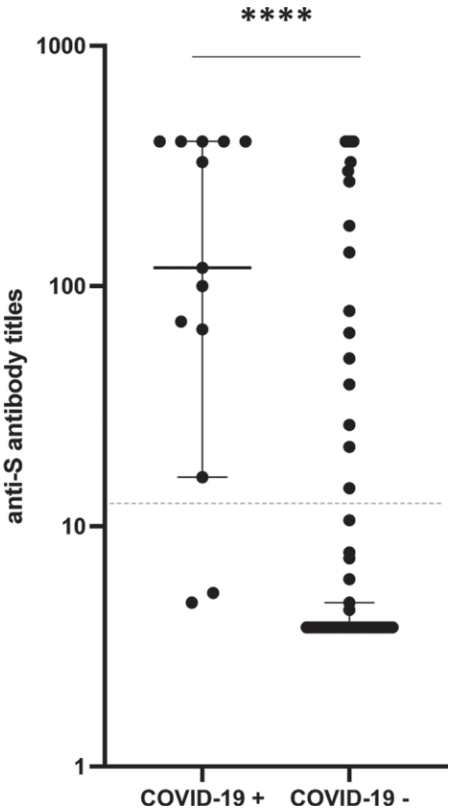

Figure 1. Distribution of SARS-CoV-2 spike antibody levels according to the history of proven symptomatic COVID-19. **** p<0.0001 by Mann Whitney test. Dotted red line corresponds to the seropositivity threshold

Conclusion: RTX-treated patients with previous proven COVID-19 showed increased seropositivity and antibody titers after SARS-CoV-2 vaccination, even after a single-dose of vaccine. This response is strikingly different from that observed for SARS-CoV-2-naïve RTX treated patients who received 3 doses of SARS-CoV-2 mRNA-based vaccination. An "antigen dose phenomenon" may account for these discrepancies. A potential clinical implication might be to increase antibody response with an additional dose of vaccine following an exposure to SARS-CoV-2 in RTX-treated patients with absent or insufficient post-vaccination antibody response.

POS1231 PREDICTORS OF MORTALITY IN SEVERE AND CRITICAL COVID-19 PATIENTS WHO RECEIVED ANAKINRA

M. Bektaş[1], M. İ. Kılıç[1]. [1]*Aksaray Trainig and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Aksaray, Turkey*

Background: Several predictive factors were described in COVID-19 during the pandemic, however there is limited data in severe/critically ill patients (pts) with COVID-19 who received biologic therapies including anakinra.

Objectives: We aimed to evaluate the predictive factors of mortality in pts with severe and critically ill COVID-19 who received anakinra.

Methods: Diagnosis of COVID-19 was confirmed by PCR and/or typical CT findings. Severe and critically ill pts according to NIH severity scale who received anakinra in the ward were evaluated retrospectively (1). Laboratory values at admission, highest levels and the last day of hospitalization were recorded. COVID hyperinflammatory syndrome score (cHIS) was calculated according to the highest levels of laboratory results (2). All pts received background steroid therapy with 80 mg methylprednisolone (or its equivalent). Anakinra was started in pts who did not respond to steroid therapy at least two days or concomitantly with steroids in pts with higher risk and/or critical illness at admission. Average starting dose of anakinra was 600 mg/day intravenously and increased gradually to 1600 mg/day if necessary.

Results: Data of 148 pts (53 % male) were analyzed. Of those 57 pts (38.5 %) severe, 91 pts (61.5 %) had critical disease. Overall, 56 pts (37.8 %) died during the follow-up and intensive care unit admission was in 60 pts (40.5 %) and intubation in 54 pts (54.5 %). Diabetes mellitus was in 28 %, hypertension in 59 %, coronary heart disease in 19 %, heart failure in 12.6 %, chronic kidney failure in 21 %, chronic obstructive pulmonary disease in 16 %, dementia in 12.8 %, malignancy in 11 % and rheumatic disease in 5.6 % of pts. Only dementia significantly differed between pts had mortality and had not (p=0.005 OR:9.8).

In univariable analysis; patient age, neutrophil to lymphocyte ratio (NLR), mean cHIS scores were higher in pts had mortality. Higher baseline, maximum and last values of CRP, LDH, ferritin, D-dimer levels were observed in pts had mortality. Mortality was also higher in pts with critically ill compared to severe disease

In multivariate analysis; higher age (p=0.01 OR:1.05 CI: 1.01-1.09), cHIS score (p=0.002 OR:2.6 CI:1.4-4.9), critical illness compared to severe disease (p=0.02 OR:14 CI:1.6-122) were associated with mortality.

In ROC analysis; cut-of values for cHIS score (3.5), NLR (7.1), CRP (160.5 mg/L), LDH (581 U/L), ferritin (771 ng/mL), D-dimer (7.56 mcg/mL) with 72/72, 69/70, 70/69, 72/75, 70/72, 70/73.4 sensitivity/specificity were calculated, respectively.

In ROC analysis; cut-of values for cHIS score (3.5), NLR (7.1), CRP (160.5 mg/L), LDH (581 U/L), ferritin (771 ng/mL), D-dimer (7.56 mcg/mL) with 72/72, 69/70, 70/69, 72/75, 70/72, 70/73.4 sensitivity/specificity were calculated, respectively.

Conclusion: In our study mortality was developed in third of anakinra receiving pts. Mortality was independently associated with advanced age, critical illness and higher cHIS score reflecting higher inflammatory burden. Furthermore, highest levels of CRP, LDH, ferritin, D-dimer and higher cHIS score predict higher mortality in pts receiving anakinra. It is important to identify the pts with higher mortality risk to improve outcome.

Background: Since the COVID-19 vaccination campaign was launched all over Europe, there has been general agreement on how benefits of SARS-CoV2 vaccines outweigh the risks in patients with rare connective tissue diseases (rCTDs). Yet, there is still limited evidence regarding safety and efficacy of such vaccines in these patients, especially in the long-term. For this reason, in the framework of ERN-ReCONNET, an observational long-term study (VACCINATE) was designed in order to explore the long-term outcome of COVID-19 vaccination in rCTDs patients. The consent form was developed thanks to the involvement of the ERN ReCONNET ePAG Advocates (European Patients Advocacy Group).

Objectives: To evaluate the safety profile of COVID-19 vaccination in rCTDs patients and the potential impact on disease activity. Primary endpoints were the prevalence of adverse events (AEs) and of disease exacerbations post-vaccination. Secondary endpoints were the proportion of serious adverse events (SAEs)

and adverse events of special interest for COVID-19 (adapted from https://bright-oncollaboration.us/wp-content/uploads/2021/01/SO2_D2.1.2_V1.2_COVID-19_AESI-update-23Dec2020-review_final.pdf)

Methods: The first ad-interim analysis of the VACCINATE study involved 9 ERN-ReCONNET Network centres. Patients over 18 years of age with a known rCTD and who received vaccine against COVID-19 were eligible for recruitment. Demographic data and diagnoses were collected at the time of enrolment, while the appearance of AEs and potential disease exacerbations were monitored after one week from each vaccination dose, and then after 4, 12 and 24 weeks from the second dose. A disease exacerbation was defined as at least one of the following: new manifestations attributable to disease activity, hospitalization, increase in PGA from previous evaluation, addition of corticosteroids or immunosuppressants.

Results: A cohort of 300 patients (261 females, mean age 52, range 18-85) was recruited. Systemic lupus erythematosus (44%) and systemic sclerosis (16%) were the most frequent diagnoses, followed by Sjogren's syndrome (SS,12%), idiopathic inflammatory myositis (IMM,10%), undifferentiated connective tissue disease (UCTD,8%), mixed connective tissue disease (MCTD,4%), Ehlers-Danlos's syndrome (EDS,4%), antiphospholipid syndrome (APS,2%). AEs appearing 7 days after the first and second doses were reported in 93 (31%) and 96 (32%) patients respectively, mainly represented by fatigue, injection site reaction, headache, fever and myalgia. Otitis, urticaria, Herpes Simplex-related rash, stomatitis, migraine with aura, vertigo, tinnitus and sleepiness were reported with very low frequency. Less than 2% of patients experienced AEs within 24 weeks from the second dose. No SAEs or AEs of special interest were observed in the study period. There were 25 disease exacerbations (8%), 7 of which severe. The highest number of exacerbations was observed after 4 weeks from the second dose (12 within week 4, 6 within week 12 and 7 within week 24). Disease exacerbation was most frequent in patients with EDS (33%) and MCTD (25%).

Conclusion: This preliminary analysis shows that COVID-19 vaccination is safe in rCTDs patients. AEs appear most often early after vaccination and are usually mild. Disease exacerbations are not frequent, but can be potentially severe and tend to occur most frequently within the first month after vaccination. Exacerbations can also occur 3-6 months after vaccination, although a causal relationship with the vaccination remains to be established. Our present data underline the importance of long-term observational studies.

Table 1. AEs and disease exacerbations per disease

Diagnosis	Patients enrolled (%) (n=300)	EAs after 1st and 2nd dose (%)	Exacerbations (%)

POS1233 DIFFICULTIES AND MENTAL IMPACT OF THE SARS-COV- 2 PANDEMIC IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A NATIONWIDE PATIENT ASSOCIATION STUDY

M. Scherlinger[1], N. Zein[2], J. E. Gottenberg[1], M. Riviere[2], J. F. Kleinmann[1], J. Sibilia[1], L. Arnaud[1]. *[1]Strasbourg University Hospital, Rheumatology Department, Strasbourg, France; [2]Association France Lupus et autres maladies auto-immunes, AFL+, Metz, France*

Background: The COVID-19 pandemic has taken a toll on the mental health of the general population. Patients with systemic lupus erythematosus (SLE) were particularly exposed due to many uncertainties linked to the virus and their immunosuppression as well as difficulties to access medical care and their treatment (eg, hydroxychloroquine) during the early pandemic.

Objectives: To evaluate the difficulties encountered by SLE patients during the early COVID-19 pandemic, and evaluate their impact on patient mental health.

Methods: We conducted a nationwide survey including SLE patients from France metropolitan and overseas territories, recruited by their treating specialist or through a patient association (AFL+). The survey was administered online or in paper form between November 2020 and April 2021, and included questions aiming at evaluating the difficulties encountered during the early COVID-19 pandemic (March to August 2020). The impact on mental health was evaluated using Hospital Anxiety and depression scale (HADS) and post-traumatic stress disorder (PTSD) Checklist for DSM-5 (PCL-5).

Results: 536 SLE patients (91.9% women) of mean age 50 (±14.1) years responded to the survey. The main reported difficulties were issues to access medical care (n = 136, 25.4%) or to obtain hydroxychloroquine treatment (n = 98/389, 25.2%), the loss of employment (n = 85/349, 24.4%) and financial difficulties (n = 75/536, 11%). Hydroxychloroquine shortage was responsible for difficulties in obtaining the drug for 25.2% (98/389) of HCQ-treated patients, and 57 had to interrupt HCQ treatment for a median of 7 days (IQR: 3-17). In the 342 patients with complete assessment, 161 (47.2%) screened positive for anxiety, 141 (41.2%) for depressive syndrome and 128 (38.7%) for PTSD. Multivariate analysis showed that female sex (OR=4.29 [95%CI: 1.39-13.24]), financial issues (OR=2.57 [1.27-5.22]), difficulties to access medical care (OR=2.15 [1.26-3.69]), or to obtain hydroxychloroquine treatment (OR=1.90 [1.06-3.40]) were independently associated with a positive screening for PTSD.

Conclusion: The COVID-19 pandemic resulted in a severe burden in SLE patients, including difficulties in access to care and treatment along with high psychological distress. Better understanding these difficulties will allow better prevention and care in times of crisis.

Table 1. Factors associated with the development of anxiety, depression or PTSD. Odds ratio (CI95%) using multivariate logistic regression are shown.

Patient and pandemic-associated factors	Odds ratio (95%CI) for anxiety	Odds ratio (95%CI) for depression	Odds ratio (95%CI) for PTSD
Female sex	2.25 (0.97-5.25), p = 0.058	ns	**4.29 (1.39-13.24) p = 0.01**
Financial difficulties	ns	**2.59 (1.31-5.11) p = 0.006**	**2.57 (1.27-5.22) p = 0.009**
Difficulties to obtain HCQ	**1.70 (0.97-2.98) p = 0.065**	**ns**	**1.90 (1.06-3.40) p = 0.03**
Difficulties to access medical care	**1.94 (1.15 3.25) p = 0.012**	**2.57 (1.53-4.33) p < 0.0001**	**2.15 (1.26-3.69) p = 0.005**

POS1234 DMARD DISRUPTION, INCREASED DISEASE ACTIVITY, AND PROLONGED SYMPTOM DURATION AFTER ACUTE COVID-19 AMONG PATIENTS WITH RHEUMATIC DISEASE: A PROSPECTIVE STUDY

M. DI Iorio[1,2], C. Cook[3], K. Vanni[4], N. Patel[2,3], K. D'silva[2,3], X. Fu[3], J. Wang[4], L. Prisco[4], E. Kowalski[4], A. Zaccardelli[4], L. Martin[4], G. Qian[4], T. Hsu[2,4], Z. Wallace[2,3,5], J. Sparks[2,4]. *[1]Brigham and Women's Hospital, Department of Medicine, Boston, United States of America; [2]Harvard Medical School, Harvard Medical School, Boston, United States of America; [3]Massachusetts General Hospital, Division of Rheumatology, Allergy, and Immunology, Boston, United States of America; [4]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, United States of America; [5]Mongan Institute, Clinical Epidemiology Program, Boston, United States of America*

Background: Systemic autoimmune rheumatic disease (SARD) patients may be at risk for disease flare and prolonged symptom duration after COVID-19, perhaps related to DMARD disruption and immune activation.

Objectives: To describe DMARD disruption and identify differences in SARD activity among patients with and without prolonged COVID-19 symptom duration.

Methods: We identified all SARD patients with confirmed COVID-19 at the Mass General Brigham healthcare system in Boston, USA; prospective recruitment is ongoing. Surveys were used to collect demographics, clinical characteristics, DMARD disruption, COVID-19 course, and SARD disease activity before and after COVID-19. The survey included validated instruments measuring disease activity, pain, fatigue, functional status, and respiratory quality of life. Prolonged symptom duration was defined as COVID-19 symptoms lasting ≥28 days. We compared differences in patient-reported measures between those with and without prolonged symptoms.

Results: We analyzed survey responses from 174 COVID-19 survivors with SARDs (mean age 52±16 years, 81% female, 80% White). The most common SARDs were RA (40%) and SLE (14%). Fifty-one percent of the 127 respondents on any DMARD reported a disruption to their regimen at COVID-19 onset (Figure 1). Among individual DMARDs, 56-77% were reported to have any change, except for hydroxychloroquine (23%) and rituximab (46%). SARD flare after COVID-19 was reported by 41% of respondents (Table 1). Patient global assessment of SARD activity was worse after COVID-19 (mean 7.6±2.3 before vs. 6.6±2.9 after COVID-19, p<0.001). Prolonged symptom duration was reported by 45% of participants. Those with prolonged symptoms had a higher initial COVID-19 symptom count (median 7 vs. 4, p<0.001) and were more likely to be hospitalized for COVID-19 (28% vs. 17%, p=0.001). Respondents experiencing prolonged symptom duration had higher disease activity on RAPID3 (p=0.007) as well as more pain (p<0.001) and fatigue (p=0.03) compared to those without prolonged symptoms.

Table 1. Acute COVID-19 course, SARD flare/activity, and patient-reported outcomes among COVID-19 survivors with SARDs.

	All COVID-19 survivors with SARDs (n=174)	Prolonged symptom duration ≥28 days (n=78)	No prolonged symptom duration/ (n=96)	p-value (prolonged vs. not)
Acute COVID-19 course				
COVID-19 symptom duration, days, median [IQR]	14 [9, 29]	46 [30, 65]	11 [7, 14]	<0.0001
Initial symptom count, median [IQR]	6 [3, 8]	7 [6, 9]	4 [2, 7]	<0.001
Hospitalized, n (%)	38 (22)	22 (28)	16 (17)	0.001
SARD flare/activity				
Self-reported SARD flare after COVID-19, n (%)	71 (41)	38 (49)	33 (34)	0.15
Disease activity by RAPID3, median [IQR]	9 [4, 14]	11.2 [6, 16]	7 [3, 13]	0.0067
RAPID3 categorical score, n (%)				0.13
Remission (0)	11 (7)	4 (5)	7 (7)	
Near remission (0.3-1.0)	23 (14)	5 (7)	18 (19)	
Low severity (1.3-2.0)	26 (15)	10 (14)	16 (17)	
Moderate severity (2.3-4.0)	55 (33)	27 (36)	28 (29)	
High severity (4.3-10.0)	54 (32)	28 (38)	26 (27)	
Patient-reported outcomes				
Pain by SF-MPQ, median [IQR]	2 [1, 2]	2 [1, 2]	1 [0, 2]	0.0008
Fatigue by FSI, median [IQR]	53 [27, 84]	66 [31, 91.5]	43 [26, 76]	0.031
mHAQ, median [IQR]	0.125 [0, 0.38]	0.25 [0, 0.75]	0.125 [0, 0.38]	0.11
Respiratory quality of life by SGRQ, global [IQR]	15 [4, 29]	16 [4, 36]	10 [4, 26]	0.49

RAPID3, Routine Assessment of Patient Index Data 3; SF-MPQ, Short-form McGill Pain Questionnaire; FSI, Fatigue Symptom Inventory; mHAQ, modified Health Assessment Questionnaire; SGRQ, Saint George's Respiratory Questionnaire.

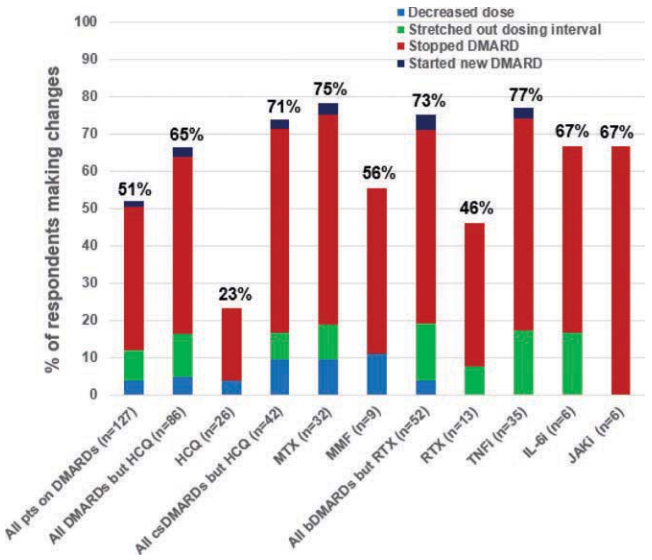

Figure 1. Frequency of baseline DMARD use and proportion with any disruption at COVID-19 onset.

Conclusion: DMARD disruption, SARD flare, and prolonged symptoms were common in this prospective study of COVID-19 survivors with SARDs. Those with prolonged COVID-19 symptom duration, defined as ≥28 days, had higher SARD activity, more pain, and more fatigue compared to those without prolonged symptoms. These findings suggest that post-acute sequelae of COVID-19 may have a large impact on underlying SARD activity and quality of life.

POS1235 WORKING FROM HOME IN PATIENTS WITH RMDS DURING THE COVID-19 PANDEMIC IN EUROPE. RESULTS FROM THE REUMAVID STUDY (PHASE 1 AND 2)

M. Garrido-Cumbrera[1,2], V. Navarro-Compán[3], L. Christen[4], J. Correa-Fernández[1], H. Marzo-Ortega[5,6]on behalf of REUMAVID working group.
[1]Health & Territory Research (HTR), Universidad de Sevilla, Seville, Spain; [2]Spanish Federation of Spondyloarthritis Patient Associations (CEADE), Patient Advocacy, Madrid, Spain; [3]Hospital Universitario La Paz, IdiPaz, Madrid, Spain; [4]Novartis Pharma AG, Patient Engagement, Basel, Switzerland; [5]NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, United Kingdom; [6]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

Background: The COVID-19 pandemic has introduced significant changes in the workplace, implementing teleworking as an effective solution to reduce contagion

Objectives: We sought to explore the impact of working from home on people with rheumatic and musculoskeletal diseases (RMDs) in Europe during the COVID-19 pandemic.

Methods: REUMAVID is an international cross-sectional study collecting data through an online survey in seven European countries led by the Health & Territory Research group of the University of Seville, together with a multidisciplinary team including patient representatives, rheumatologists, and health researchers. Data were collected in two phases, the first (P1) between April-July 2020 and the second (P2) between February-April 2021. Demographics, health behaviors, employment status, access to healthcare services, disease characteristics, WHO-5 Well-Being Index and Hospital Anxiety and Depression Scale (HADS) were collected. Workplace conditions including internet connection, computer, workstation, webcam, telephone, light, noise, calmness, and temperature were assessed (on a scale of 0 to 5, being 5 the best condition). Pearson's Chi-square test, Kruskal-Wallis and Mann-Whitney test were used to explore association with working from home.

Results: There were a total of 3,802 participants across both phases (mean age 52.6 (P1) vs. 55.0 years (P2); 80.2% female (P1) vs 83.7% (P2); 69.6% married (P1) vs 68.3% (P2), 48.6% university educated (P1) vs 47.8% (P2), 34.7% employed (P1) vs 38.1 (P2)). Most prevalent RMD was axial spondyloarthritis in P1 (37.2%), and rheumatoid arthritis in P2 (53.1%). Rates of working from home were consistent (P1: 39.8% vs P2: 39.9%).

In P2, 37.4% of those working from home had a home office, while 38.5% worked from their living room or kitchen. Work-related aspects at home were assessed, with the worst rated being the workplace (3.2) and the best being the computer (4.0). Compared to patients with good well-being and without anxiety and depression, patients with poorer well-being and at higher risk of anxiety or depression reported more frequently poorer rating of work from home issues, such as workplace (3.0 vs. 3.5; 2.9 vs. 3.6; 2.9 vs. 3.4; p<0.001), light (3.6 vs. 4.0; 3.6 vs. 4.0; 3.5 vs. 4.0; p<0.001), noise (3.3 vs. 3.8; 3.2 vs. 3.9; 3.2 vs. 3.8; p<0.001) and calmness (3.3 vs. 4.0; 3.2 vs. 3.9; 3.1 vs. 3.9; p<0.001; Table 1).

Conclusion: Patients with poorer well-being, at higher risk of anxiety or depression reported poorer ratings of workspace-related aspects. Therefore, although work from home has helped to reduce the spread of the COVID-19 pandemic, the conditions under which RMD patients work from home must be considered, as these may affect the well-being and mental health of an already vulnerable group. It is necessary to assess the conditions of home-based workspaces - especially for workers with chronic diseases such as RMD patients - to ensure that it is feasible to work from home and that employers provide the necessary equipment for healthy work.

Bellocchi[11], L. Beretta[11], D. Roccatello[5], L. Dagna[12], E. Bozzolo[12], R. Caporali[1,2]. *[1]University of Milan, Milan, Italy, Research Center for Adult and Pediatric Rheumatic Diseases, Department of Clinical Sciences and Community Health, Milan, Italy; [2]ASST Pini CTO, Lupus Clinic, Division of Clinical Rheumatology, Milan, Italy; [3]ASST Santi Paolo e Carlo, Medicina generale I, Milan, Italy; [4]University of Turin, Department of Clinical and Biological Sciences, Turin, Italy; [5]San Giovanni Bosco Hub Hospital, CMID-Nephrology and Dialysis Unit (ERK-net member), Research Center of Immunopathology Coordinating Center of the Network for Rare Diseases of Piedmont and Aosta Valley, Turin, Italy; [6]IRCCS Ospedale San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy; [7]Humanitas University, IRCCS Humanitas Research Hospital, Department of Biomedical Sciences, Milan, Italy; [8]Universita` degli Studi di Milano Bicocca and ASST-Monza, Department of Medicine and Surgery, Renal Unit, Monza, Italy; [9]University of Brescia, Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, Brescia, Italy; [10]Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico Milano, Divisione di Nefrologia e Dialisi, Milan, Italy; [11]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Referral Center for Systemic Autoimmune Diseases, Milan, Italy; [12]IRCCS Ospedale San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Vulnerable subjects, including systemic lupus erythematosus (SLE) patients have been prioritised to receive anti-SARS-CoV-2 vaccine. Questions have been raised about the effect of vaccines on immunity and their potential role as trigger for flare. Few data about the safety of these vaccines in SLE are available

Objectives: To investigate the safety of different anti-SARS-CoV-2 vaccines in SLE

Methods: Data on SLE patients who have received anti-SARS-CoV-2 vaccine (from 12/2020 to 10/2021) were collected. Patients referred to 7 SLE tertiary centres (Lupus Clinic, ASST Pini-CTO, Milan; Nephrology Unit of Ospedale Giovanni Bosco, Turin; IRCCS Humanitas Research Hospital; Renal and Rheumatology Units, San Gerardo Hospital, Monza; ASST Spedali Civili Brescia; Lupus Clinic IRCCS Ospedale S. Raffaele, Milan, Italy; IRCCS Policlinico, Milan)

Results: 452 SLE patients who had received anti-SARS-CoV-2 vaccines were included (91% BNT162b2 mRNA, 8% mRNA-1273, 1% ChAdOx1-S). 12 (3%) were off therapy, 71% were on low-medium dose prednisone, 83% on anti-malarials, 50% were treated with an immunosuppressant. 9 patients transiently discontinued therapy. 119 (26%) reported adverse symptoms after the first/second shot (12% and 21%) The most frequent were fever, local reaction, fatigue and

Table 1. distribution of demographic and SLE characteristics according to sides effects and disease flares after vaccination

arthralgias. Nineteen (4%) patients flared up after immunisation with a 7 days median time to relapse. Baseline demographics, SLE characteristics and therapy stratified by adverse events and disease flare are reported in Table 1. Anti-dsDNA positivity, moderate/high DAS before vaccine and use of Belimumab were significantly more frequent in the group of patients flared. These patients displayed a significantly higher rate of adverse events after vaccination. Flares consisted mainly musculoskeletal and constitutional manifestations (32%), involvement of renal (21%), cardio-respiratory (16%), hematological (16%) or mucocutaneous domains (10%) was less frequent

Conclusion: our reassuring data confirm that anti-SARS-CoV-2 vaccine is safe in SLE patients and should be recommended in this clinical setting, as potential benefits widely outweigh the risk of adverse events. Treatment adjustment might be considered with the aim of minimizing the risk of side effects and/or flare, while ensuring a satisfying protection against infection

POS1237 SARS-COV-2 MRNA VACCINE IMMUNOGENICITY IN CHRONIC INFLAMMATORY ARTHRITIS ON DMARD THERAPY

N. Darwish[1], S. Jhaveri[2], U. Yoganathan[1], H. Bakillah[1], K. Chun[3], T. Wasser[4], J. Freeman[1]. *[1]Arnot Ogden Medical Center, Internal Medicine, Elmira, New York, United States of America; [2]Lake Erie College of Osteopathic Medicine, Osteopathic Medicine, Elmira, United States of America; [3]Labcorp, R&D, Calabasas, California, United States of America; [4]Consult-Stat: Complete Statistical Services, Department of Statistics, Macungie, Pennsylvania, United States of America*

Background: Patients with chronic inflammatory arthritis (CIA) are at increased risk for the development and mortality from COVID-19[1]. Vaccinations are integral to the management of these conditions. Disease-modifying antirheumatic drugs (DMARDs) used to treat CIA have the potential to blunt the immune response and efficacy of vaccinations[2]. There is little data on the effect of DMARDS used for CIA on the response to novel mRNA vaccines, limiting guidelines to direct therapy.

Objectives: Assess the antibody response (ABR) to the SARS-CoV-2 mRNA vaccines in patients with CIA on treatment with either methotrexate (MTX), tumor necrosis factor inhibitors (TNFi), or both with healthy controls. Determine the effect of interrupting therapy after vaccination in patients with CIA on the ABR to the vaccine.

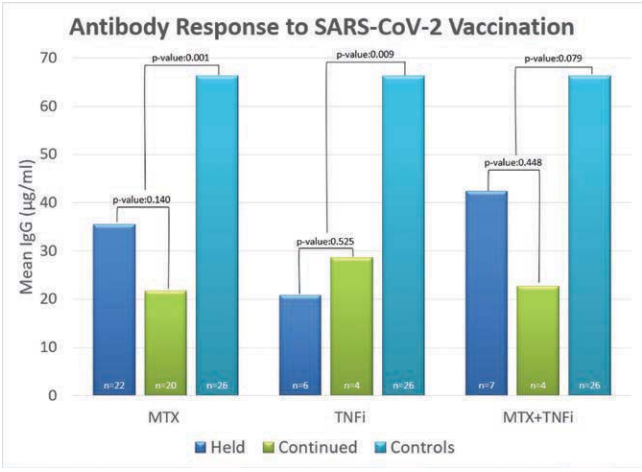
Methods: 63 patients with rheumatoid or psoriatic arthritis on MTX, TNFi or both were recruited from a community-based rheumatology practice. All subjects received two doses of a mRNA COVID vaccine. Use of hydroxychloroquine (HCQ), NSAID's, and prednisone (Pred) ≤10mg daily were allowed. Those with prior COVID infection were excluded, as determined by SARS-CoV-2 nucleocapsid assay. 26 healthy age-matched controls were obtained from banked blood from Labcorp. IRB approval was obtained, and patients were consented to participate in the study. SARS anti-receptor binding domain IgG antibodies were measured by electro chemiluminescent immunoassay 90-120 days post initial vaccine dose. Patients were divided into 3 groups based on therapy:

1. MTX monotherapy
2. TNFi with eternacept (ETN) or adalimumab (ADA)
3. A combination of MTX with either ETN or ADA

Each of the groups were subdivided into two categories:

1. Continued treatment uninterrupted at the time of each of the two vaccines.
2. Held treatment for two weeks after each vaccine. Statistical significance (p<.005) determined using one way ANOVA with Scheffe procedure and Student's T-test.

Results: The 63 patients with CIA had a significantly lower ABR to vaccine compared with healthy controls (p=0.001). Further analysis was limited by sample size: The MTX held group had a higher ABR than the MTX continued group (mean IgG=35.5 vs 21.74; p=0.14), demonstrating a trend toward increased immunogenicity. There was a similar ABR to vaccine between those on TNFi who held vs continued therapy (mean IgG 20.83 vs 28.65; p=0.525). Combination MTX +TNFi held vs continued groups demonstrated a trend toward increased immunogenicity when holding therapy post vaccine (mean IgG 42.4 vs 22.7; p=0.44). All treatment groups were comparable in Pred, HCQ, NSAID use, age, Rapid 3 score, and time between vaccination and blood draw for antibody levels (VI).



Conclusion: The ABR in patients with CIA to the mRNA vaccine appeared to be blunted by ongoing therapy with MTX. This effect was attenuated by holding MTX post-vaccine. There was no significant difference in the ABR to vaccine in patients on TNFi who held vs continued these agents after vaccine, due to small sample size. Patients with CIA on DMARD therapy had a significantly lower ABR to the vaccine compared to healthy controls. Our findings need further validation in a larger cohort. Clinicians may consider holding MTX for two weeks post vaccination to optimize the immune response to the vaccine.

Background: High disease activity, treatment with glucocorticoids (GC) and rituximab (RTX), have been related to worse outcomes of COVID-19.
Objectives: To assess the clinical characteristics and severity of the SARS-CoV-2 infection in patients with rheumatoid arthritis (RA) included in the SAR-COVID registry and to identify factors associated with poor outcomes.
Methods: SAR-COVID is a national, longitudinal and observational registry. Patients of ≥18 years old, with diagnosis of RA (ACR-EULAR criteria 2010) who had confirmed SARS-CoV-2 infection (RT-PCR or positive serology) were included between 13-8-20 and 31-7-21. Sociodemographic and clinical data, comorbidities, disease activity and treatment at the moment of the SARS-CoV-2 infection were collected. Additionally, infection symptoms, complications, medical interventions and treatments for COVID-19 were registered. Infection severity was assessed using the WHO-ordinal scale (WHO-OS)[1]. A cut-off value of ≥5 identified patients with severe COVID-19 and those who died.
Statistical analysis: Descriptive statistics. Chi^2 or Fischer test, Student T test or Mann-Whitney and Kruskal Wallis or ANOVA, as appropriate. Multiple logistic regression model.
Results: A total of 801 patients were included, with a mean age of 53.1 ± 12.9 years, most of them were female (84.5%) and the median (*m*) disease duration was 8 years (IQR 4-14). One third were in remission and 46.4% had comorbidities, being the most frequent, hypertension (26.9 %), dyslipidemia (13.5 %), obesity (13.4 %) and diabetes (8.9%). Moreover, 3.2% had interstitial lung disease (ILD) associated with RA. At SARS-CoV-2 diagnosis, 42.5% were receiving glucocorticoids (GC), 73.9% conventional (c) disease modifying antirheumatic drugs (DMARD), 24% biologic (b) DMARD and 9.1% targeted synthetic (ts) DMARD. Among bDMARD, the most frequently used were TNF inhibitors (17%), followed by abatacept (2.8%), IL-6 inhibitors (2.4%) and rituximab (RTX) (2.1%). During the SARS-CoV-2 infection, 95.8% had symptoms, 27% required hospitalization, 7.9% presented complications and 4.4% died due to COVID-19. Severe disease and death (WHO-OS≥5) was present in 7.5% of the patients. They were older (62.9±12.5 vs 52.2±12.7, p<0.001), and they had more frequently ILD (18.5% vs 2%, p<0.001), comorbidities (82.5% vs 43.7%, p<0.001), ≥2 comorbidities (60.3% vs 25.8%, p<0.001), treatment with GC (61% vs 40.7%, p=0.04) and RTX (8.3% vs 1.6%, p=0.007). Conversely, the use of cDMARD and TNF inhibitors was more frequent in patients with WHO-OS<5, nevertheless this difference was not significant. Disease activity was comparable between groups.

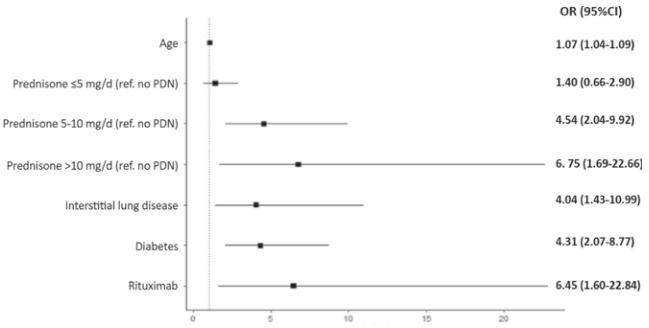

Figure 1. Factors associated with severe disease and death due to COVID-19 (WHO-OS≥5) in patients with rheumatoid arthritis. Multivariable analysis. (ref.: reference; PDN: prednisone; OR: odds ratio; CI: confidence interval)

In multivariable analysis, older age, the presence of diabetes, ILD, the use of GC and RTX were significantly associated with WHO-OS≥5 (Figure 1). Furthermore, older age (65.7±10.8 vs 52.4±12.8, p<0.001), the presence of comorbidities (87.9% vs 44.7%, p<0.001), chronic obstructive pulmonary disease (21.9% vs 5.2%, p=0.002), diabetes (30.3% vs 7.9%, p<0.001), hypertension (57.6% vs 25.6%, p<0.001), cardiovascular disease (15.6% vs 3.2%, p=0.005), cancer (9.1% vs 1.3%, p=0.001), ILD (23.3% vs 2.4%, p<0.001) and the use of GC (61.8% vs 41.4%, p=0.02) were associated with mortality. Older age [OR 1.1 IC95% 1.06-1.13] and the use of GC 5-10 mg/day [OR 4.6 IC95% 1.8-11.6] remained significantly associated with death due to COVID-19.
Conclusion: Treatment with RTX and GC, as well as older age, the presence of diabetes and ILD were associated with poor COVID-19 outcomes in this national cohort of patients with RA. Older patients and those taking GC had a higher mortality rate.

POS1239

RISK FACTORS FOR SEVERE DISEASE COURSE IN MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN (MIS-C) – A MULTICENTER, RETROSPECTIVE STUDY

K. Kaidar[1], Y. Levinsky[1], R. Tal[1], L. Harel[1], G. Amarilyo[1]. *[1]Schneider Children's Medical Center of Israel, Pediatric Rheumatology, Tel Aviv, Israel*

Background: Multisystem Inflammatory Syndrome in Children (MIS- C) associated with COVID-19, presents as a cytokine storm with features of Kawasaki disease. Many cases present with shock and require intensive care admission.
Objectives: We aimed to identify predictors for severe clinical course of MIS-C as defined by the need for ionotropic support during admission
Methods: A retrospective multinational cohort study was conducted. Patients with a diagnosis of MIS-C from 9 Israeli medical centers and one US medical center (Chicago, IL) were included. Demographic, clinical, laboratory and imaging variables during admission and hospitalization were retrieved. Univariate and multivariate regression models were used to assess odds ratio (OR) of ionotropic support need during hospitalization.
Results: Overall 100 MIS-C patients were included in the study. Sixty-five patients (65%) were hypotensive, 44% required ionotropic support, and 37% had finding of Left ventricular dysfunction. Univariate model showed that LVD was associated with the need for ionotropic support (OR 4.178 [95%CI 1.760-9.917], while conjunctivitis (OR 0.403 [95%CI 0.173-0.938]) and mucosal changes (OR 0.333 [95%CI 0.119-0.931]) were protective. Laboratory markers for severe disease course were low hemoglobin levels, leukocyte count, thrombocyte count, lymphocyte count, neutrophils count, albumin and potassium, as well as high troponin and BNP.

Table 1. and laboratory characteristics on admission of patients diagnosed with MIS-C

	w/o Hemodynamic support N=56 (56.0%)	with Hemodynamic support N=44 (44.0%)	p-value
Gastrointestinal symptoms	46 (82.1%)	41 (93.2%)	0.103
Mucosal changes	18 (32.1%)	6 (13.6%)	0.031
Rash	34 (60.7%)	20 (45.5%)	0.129
Conjunctivitis	27 (48.2%)	12 (27.3%)	0.033
Extremity changes	4 (7.1%)	6 (13.6%)	0.280
Lymphadenopathy	11 (19.6%)	11 (25.0%)	0.521
No. of days of fever at admission	4 [3-5]	5 [3-5]	0.646
Systolic BP	99 [90-108]	97 [85-102]	0.263
Diastolic BP	60 [53-67]	53 [45-59]	0.006
HR	124 [114-143]	126 [108-144]	0.957
hemoglobin admission (g/dL)	11.65 [10.83-12.67]	11.25 [10.22-12.58]	0.220
White cells admission (K/μL)	9.02 [6.63-12.01]	9.03 [5.75-16.99]	0.742
platelets admission (K/μL)	174.0 [134.50-250.0]	147.50 [121.25-146.25]	0.126
lymphocytes admission (K/μL)	0.90 [0.64-1.70]	0.70 [0.48-1.11]	0.015
ESR admission (mm/hr)	43.00 [35.5-74.50]	44.00 [28.50-66.00]	0.575
C-reactive protein admission (mg/dL)	14.05 [10.32-22.28]	19.50 [10.90-27.30]	0.117
Creatinine admission (mg/dL)	0.55 [0.40-0.70]	0.69 [0.50-0.81]	0.008

Conclusion: Patients with MIS-c that present with a Kawasaki-like phenotype are less likely to require ionotropic support, while other clinical and laboratory parameters were found as risk factors and should be monitored during MIS-C hospitalization.

POS1240 HIGH PREVALENCE OF SERUM AUTOANTIBODIES IN SEVERELY ILL COVID-19 PATIENTS HOSPITALIZED IN THE INTENSIVE CARE UNIT.

K. Bitzogli[1], E. Jahaj[2], A. D. Bakasis[1], E. Kapsogeorgou[1], A. Goules[1], I. Stergiou[1], V. Pezoulas[3], P. Skendros[4], K. Ritis[4], D. I. Fotiadis[3], A. Kotanidou[2], A. Tzioufas[1], P. Vlachoyiannopoulos[1]. *[1]National and Kapodistrian University of Athens, School of Medicine, Department of Pathophysiology, Athens, Greece; [2]National & Kapodistrian University of Athens, School of Medicine, First Department of Critical Care Medicine & Pulmonary Services, Athens, Greece; [3]University of Ioannina, Unit of Medical Technology and Intelligent Information Systems, Ioannina, Greece; [4]Democritus University of Thrace, School of Medicine, First Department of Internal Medicine, Alexandroupolis, Greece*

Background: Coronavirus Disease-19 (COVID-19) caused by the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) is characterized by a wide range of clinical manifestations [1]. Although COVID-19 was initially considered a respiratory infection, it was shortly recognized as a multisystemic disorder associated with heightened inflammatory responses, including autoimmune phenomena [1]. The presence of autoantibodies (AAbs) has been described in COVID-19 patients, highlighting the state of immune dysregulation in COVID-19 [1]. The clinical significance of AAbs, however, is still elusive.
Objectives: To assess the prevalence of AAbs in critically ill, mechanically ventilated COVID-19 patients admitted to the intensive care unit (ICU) and investigate whether AAbs influence the clinical outcome of these patients.
Methods: The current study evaluated prospectively from March 8th, 2021 to May 10th, 2021 the presence of AAbs against nuclear antigens (ANA), extractable nuclear antigens (ENA), neutrophil cytoplasmic antigens (ANCA), cyclic citrullinated peptides (anti-CCP), double stranded-DNA (anti-dsDNA), cardiolipin (anti-CL), β2-glycoprotein-I (anti-β2-GPI), thyroid peroxidase (anti-TPO), and thyroglobulin (anti-TG) in critically ill COVID-19 patients upon admission in the ICU (n=217). Samples from 60 COVID-19 patients that were available 15 days after ICU admission were further analyzed for the evaluation of de novo AAbs production. Serum samples of age and sex matched healthy individuals before the COVID-19 pandemic were used as a control group (n=117).
Results: COVID-19 patients treated in ICU had more commonly at least one AAb compared to age and sex matched controls (174/217, 80.2% vs 73/217, 62,4%, p< 0,001). More specifically, COVID-19 patients expressed more frequently ANAs (48.4% vs 21.4%, p<0.001), anti-dsDNA (5.1% vs 0%, p=0.01), anti-CCP (8.3% vs 1.7%, p=0.014) and anti-CL IgM AAbs (21.7% vs 9.4%, p=0.005) than controls. The majority of critical COVID-19 patients who were positive for AAbs (144, 82.8%) expressed reactivity in up to three autoantigens with the most prominent being ANA, anti-phospholipid, ANCA and anti-TPO AAbs. AAbs-positive patients demonstrated more robust anti-SARS-CoV-2 humoral responses compared to AAbs-negative patients [detectable anti-SARS-CoV-2 S1-protein IgG antibodies: 150 (86.2%) vs 28 (65.1%), p=0.001; adequate neutralizing activity: 159 (91.4%) vs. 33 (76.7%), p=0.007]. The two groups, however, did not differ in terms of clinicoepidemiologic characteristics or the incidence of death in the ICU. Convalescent COVID-19 patients (n=111) compared to those who died (n=106), did not differ in the prevalence of serum AAbs or antibody responses against SARS-CoV-2. Differences were only shown in clinicolaboratory parameters including patients' age, comorbidities, O2 saturation, inflammatory markers, and in-hospital prognostic scores as expected. Paired samples testing (n=60) revealed that 45 patients had at least one newly induced AAb, 28 patients lost at least one reactivity and only 6 patients didn't show any seroconversion. The most common new-onset AAb reactivity was against anti-CL (IgG isotype) (n=21) followed by ANA (n=20), anti-β2-GPI (IgG isotype) (n=11), myositis-related antigens (n=13) and ENAs (n=9); nevertheless, no associations with clinicoepidemiologic features or COVID-19 outcome were revealed.
Conclusion: Patients with severe COVID-19 express AAbs more commonly than age and sex matched controls, suggesting that SARS-COV-2 infection may induce a hitherto unknown B-cell autoreactivity. The presence of autoantibodies does not play a role in the outcome of SARS-COV-2 infection. However, further studies are needed to define their role in future development of systemic autoimmune disorders or the long-COVID syndrome.

POS1241 THE IMPACT OF TELEMEDICINE CONSULTATIONS FOR RHEUMATOID ARTHRITIS, GIANT CELL ARTERITIS, OSTEOARTHRITIS AND CRYSTAL ARTHRITIS DURING COVID19 PANDEMIC

M. Tormo-Ratera[1], M. Mirza[2], R. Luqmani[2]. *[1]Hospital Universitari de Bellvitge, Rheumatology, L'Hospitalet de Llobregat, Spain; [2]Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom*

Background: Rheumatology departments across the UK have adapted to the COVID-19 pandemic, implementing novel methods of working via remote consultations.
Objectives: We wanted to explore the rates of telemedicine consultations for patients with Rheumatoid Arthritis (RA), Giant cell arteritis (GCA), Osteoarthritis (OA), and Crystal arthritis (CA). We also wanted to check how effective the telemedicine consultations had been in terms of avoiding the need for a face-to-face appointment.
Methods: No telemedicine consultations took place before the COVID-19 pandemic in patients diagnosed with GCA, RA, CA and OA. We assessed the number of telemedicine consultations (telephone or videocall) using data from the departmental database covering September 2020 to December 2021. We analysed the rates of face-to-face versus telemedicine appointments for both new referrals and follow-up consultations. The statistical analysis was conducted using chi-square test.
Results: There were 20,648 patients assessed in our department from September 2020 to December 2021. In total 1786 face-to-face and 2079 telemedicine consultations were conducted for GCA (18%), RA (66%), OA (13%) and CA (3%). The highest percentage of telemedicine consultations versus face-to-face for new referrals were observed for OA (30% Vs 70%) followed by RA (14% Vs 86%), CA (12% Vs 88%) and GCA (2% Vs 98%) (Table 1). Combining all these conditions, 68% of clinicians felt the telemedicine appointment avoided a face-to-face appointment. However, 33% of clinicians seeing new patients with RA did not feel the telemedicine appointment avoided a face-to-face appointment.

Table 1.

Diagnoses	New referrals		Follow-up	
	Telemedicine	Face-to-face	Telemedicine	Face-to-face
RA	36 (14%)	227 (86%)	1480 (65%)	783 (35%)
CA	7 (12%)	50 (88%)	41 (61%)	26 (39%)
OA	82 (30%)	187 (70%)	115 (51%)	109 (49%)
GCA	3 (2%)	21 (98%)	315 (53%)	283 (47%)

In contrast, follow-up appointments were mainly conducted by telemedicine when compared with face-to-face; RA (65% Vs 35%), GCA (53%Vs 47%), OA (51% Vs 49%) and CA (61% Vs 39%). For the follow-ups, an overall majority of 90% of telemedicine consultations avoided the need for a face-to-face appointment, particularly observed for patients with CA and GCA (98% and 93% respectively). We noted that patients with RA were more likely than GCA to have a telemedicine follow-up (p value<0.00001).

Conclusion: Telemedicine appointments for new referrals and follow-up patients with Rheumatological diagnoses has been a new development because of COVID-19 pandemic. Our analysis shows that most of our new RA, GCA, OA, and CA referrals are still being seen face-to-face but most follow-up appointments are telemedicine consultations. In most cases, clinicians felt that telemedicine consultations avoided the need for a face-to-face appointment.

POS1242 BARICITINIB AND PULSE STEROIDS COMBINED TREATMENT IN SEVERE COVID-19 PNEUMONIA: PRELIMINARY DATA FROM A RHEUMATOLOGIC EXPERIENCE IN INTENSIVE CARE UNIT

F. Ferro[1], E. Elefante[1], N. Italiano[2], M. Moretti[2], G. La Rocca[2], R. Mozzo[3], L. De Simone[3], C. Baldini[1,2], M. Mosca[1,2]. *[1]Azienda Ospedaliero-Universitaria Pisana, Rheumatology Unit, Pisa, Italy; [2]University of Pisa, Clinical and Experimental Medicine, Pisa, Italy; [3]Azienda Ospedaliero-Universitaria Pisana, Anaesthesiology Unit, Pisa, Italy*

Background: Growing evidence from in vitro and clinical studies have highlighted important similarities between severe COVID-19 and rapidly progressive interstitial lung diseases (ILD) occurring in systemic autoimmune disorders. These data supported the use of anti-rheumatic drugs, baricitinib and glucocorticoids, for the treatment of COVID-19 pneumonia.

Objectives: To compare mortality rate and inflammatory response in critically ill COVID-19 patients treated with either a "rheumatologic approach" based on baricitinib plus pulse steroids (BPS) or with a "conventional approach" (Standard of Care, SoC).

Methods: In this retrospective study, we enrolled patients admitted to the Intensive Care Unit (ICU) with CT-proven SARS-CoV2 pneumonia, from September 2020 to April 2021. Demographic, laboratory, and clinical data were collected at the admission to ICU and after one week of treatment. SoC included dexamethasone 6 to 8 mg daily plus remdesivir (+/- antibiotics and hydroxychloroquine); BPS approach was based on baricitinib 4 mg daily for 10-14 days plus 6-methylprednisolone pulses (250-500 mg) for three consecutive days followed by rapid tapering. The primary endpoint was the intra-ICU mortality rate; the secondary endpoint was the change in inflammatory biomarkers at week 1 after treatment.

Results: We enrolled a total of 210 consecutive patients with SARS-CoV2 pneumonia (male 61.4%, mean age 66.6 ± 10.9 years); 137/210 (male 59.8%, mean age 66.3 ± 11.9 years) were treated with SoC and 73/210 (male 64.3%, mean age 67.3 ± 8.8 years) with BPS.

At admission in ICU, all patients presented lag time from the first symptom of SARS-CoV2 infection ≤ 10 days, laboratory biomarkers' alterations suggestive of hyper-inflammatory response (CRP 10.8 ± 11.9 mg/dL, ferritin 1238 ± 1005 µg/L, fibrinogen 575 ± 173 mg/dL, LDH 385 ± 152 U/L) and severe respiratory failure, requiring non-invasive or invasive ventilatory support. Lung-CT pattern showed multiple and diffuse areas of ground glass opacities, septal thickening, and/or consolidation.

No statistically significant differences were found between SoC and BPS groups in terms of demographic, laboratory, and clinical features at enrolment.

59/210 (28.1%) patients died during ICU hospitalization (mean ICU length of stay 14.6 ± 9.6 days). Mortality rate in the BPS group (13/73, 17.8%) resulted significantly lower compared to that in the SoC group (46/137, 33.6%) (p= 0.016). Furthermore, patients in the BPS group had significantly lower levels of CRP (BPS=1.9 ± 2.8 vs SoC 6.1 ± 7.3, p<0.001) and fibrinogen (BPS=335 ± 108 vs SoC 453 ± 172, p<0.001) at one week after the start of treatment.

Conclusion: Our real-life experience, in an ICU setting, showed that baricitinib and pulse steroids combination was associated with a lower mortality rate paralleled by a prompt reduction of inflammatory biomarkers. These results shed new light on the possible usefulness of baricitinib for the treatment of rapidly progressive ILD in patients with systemic autoimmunity and hyper-inflammation.

Background: Little is known about the duration of humoral antibody levels after two SARS-CoV-2 mRNA vaccinations in patients with immunosuppression. During this ongoing global epidemic, it is of essential interest to gather information about the time of protection after initial immunization in the vulnerable patients receiving either conventional synthetic disease modifying antirheumatic drugs (csDMARD) or biological/ targeted drugs (b/tsDMARDs).

Objectives: In this study we compared the antibody level development after vaccination and after six months in patients with inflammatory arthritis, inflammatory bowel disease (IBD) and healthy controls. Furthermore, we assessed factors affecting the quality and quantity of the humoral response.

Methods: We enrolled 85 healthy controls (HC), 75 patients with rheumatoid arthritis and spondyloarthritis and 41 patients suffering from IBD. Patients treated with B-cell depleting therapies were excluded from this study. Binding antibody units were measured after vaccination and 6 or more months. Neutralizing antibodies were measured after 6 months. Multivariate regression analyses analyzing factors associated with low titers after 6 months was performed.

Results: We found that patients with inflammatory arthritis or IBD showed reduced anti-SARS-CoV-2 S titers compared to HC. When we stratified for therapies, we found that patients receiving conventional synthetic disease modifying antirheumatic dugs (csDMARDs) had comparable anti-SARS-CoV-2 S titers to HC. In contrast, patients receiving biological or targeted synthetic (b/tsDMARDs) showed reduced anti-SARS-CoV-2 Igs as well as neutralizing antibody titers compared with healthy controls (HC) or patients receiving conventional synthetic (cs)DMARDs. We further show that anti-SARS-CoV-2 titers declined more rapidly in patients receiving b/tsDMARDs compared to HC, leading to a 50 percent reduction in vaccination-associated protection time in patients receiving b/tsDMARDs when compared to those receiving csDMARDs or even HC. In multivariate regression analyses, we found that in addition to the type of treatment, also age as well as corticosteroid use were associated with reduced anti-SARS-CoV-2 S titers.

Conclusion: Patients under ongoing b/tsDMARDs therapy exposed an accelerated waning of anti-SARS-CoV-2 S titers and therefore decreased immunity and protection against severe Covid-19 infections over time. These results may lead to more personalized approaches for further vaccination strategies in this group of immunosuppressed patients.

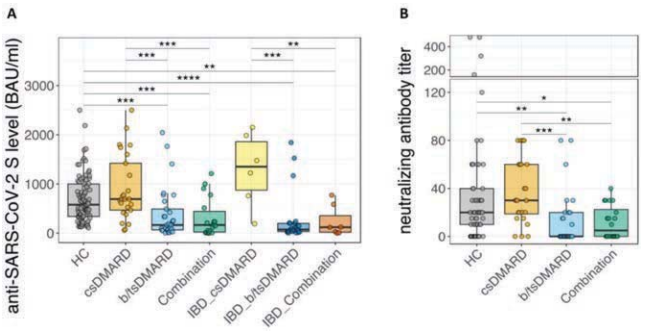

Figure 1. A, Analysis of anti-SARS-CoV-2 S titers 6 months after the second vaccination in patients with inflammatory arthritis, inflammatory bowel disease and HC (** p ≤ 0.01; *** p ≤ 0.005, **** p ≤ 0.001). **B**, Determination of neutralizing antibody activity in sera of HC and patients with inflammatory arthritis receiving the indicated therapies.

POS1244 THE EFFECT OF SECUKINUMAB ON THE HUMORAL RESPONSE FOLLOWING TWO AND THREE DOSES OF THE BNT162B2 MRNA VACCINE IN PATIENTS WITH SPONDYLOARTHRITIS

O. Elkayam[1], T. Eviatar[1], H. Peleg[2], D. Paran[1], D. Levartovsky[1], I. Kaufman[1], A. Broyde[1], O. Elalouf[1], A. Polachek[1], J. Feld[3], A. Haddad[3], T. Gazitt[3], M. Elias[3], N. Hijaze[3], M. Aassi[4], E. Quebe-Fehling[4], I. Alarcon[4], S. Pel[1], D. Zisman[3], V. Furer[1]. Background: Data on the effect of secukinumab on the humoral response to the BNT162b2 mRNA vaccine are limited.
Objectives: We aimed to assess prospectively the humoral response to the BNT162b2 mRNA vaccine in patients with spondyloarthritis (SpA) treated with secukinumab in comparison to immunocompetent controls.
Methods: Patients with psoriatic arthritis (PsA) or ankylosing spondylitis (AS) treated with secukinumab for at least 3 months and immunocompetent controls were vaccinated with two-dose regimen of the BNT162b2 mRNA vaccine. Clinical and laboratory assessments were performed at 2-8 weeks [SpA: 37 on secukinumab, (median age 53% female), 122 controls (median age 53, 51% female)], and 6 months [SpA: 27 on secukinumab, 116 controls] after the second vaccine dose. A subgroup of patients (22 SpA on secukinumab, 45 controls) were evaluated after the third vaccine dose. The seropositive response was defined as a detectable S1/S2 IgG ≥15 binding antibody units (BAU)/ml.
Results: The two-dose vaccine regimen induced a similar immunogenic response in patients and controls reflected by the seropositivity rates of 100% in both groups. After six months, the rate of seropositivity remained as high as 96% in both secukinumab-treated patients and immunocompetent controls. The decline of S1/S2 IgG titer within six months was similar in controls and secukinumab-treated patients, -66.4 (95% CI {-70.9, -39.9}) and -55 BAU/ml (95% CI {-95.42, -36.87}). Following the third vaccine, the seropositivity rate increased to 100 % in both groups. At all-time points, S1/S2 IgG titers were similar in secukinumab treated patients and immunocompetent controls (Figure 1).

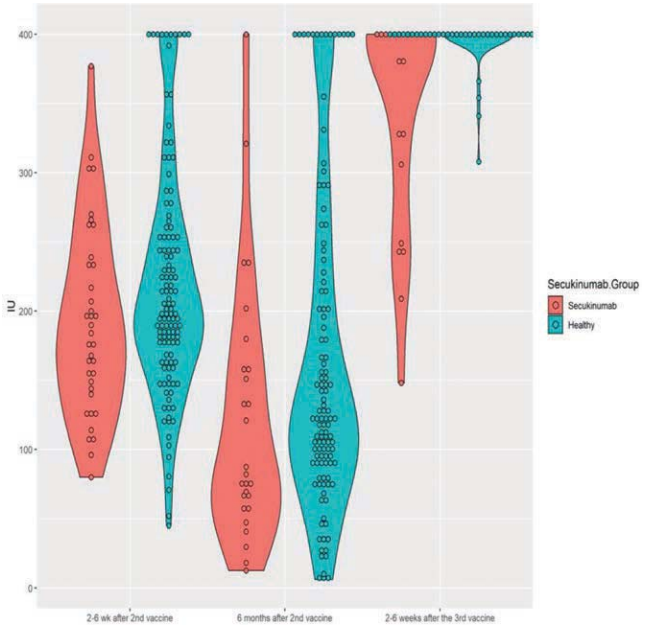

Figure 1. Kinetics of an immunogenic response (S1/S2 IgG titer) to two and three doses of the BNT162b2 mRNA vaccine in SpA patients treated with secukinumab and immunocompetent controls.

Conclusion: SpA patients treated with secukinumab consistently demonstrated an adequate humoral response to the BNT162b2 mRNA vaccination similar to immunocompetent controls, both short-term and within six months after two vaccine doses and after the third vaccine dose.

POS1245 REVERSAL OF DECLINE IN HUMORAL RESPONSE TO BNT162B2 MRNA COVID-19 VACCINE AFTER BOOSTER ADMINISTRATION IN AUTOIMMUNE INFLAMMATORY RHEUMATOID DISEASES (AIRD) PATIENTS

Y. Braun-Moscovici[1], M. Kaplan[2], M. Braun[3], R. Daood[1], D. Markovits[1], S. Giryes[1], A. Mashiah Avshalom[4], V. Shataylo[4], K. Toledano[1], Y. Tavor[1], F. Hasan[1], K. Dolnikov[1], R. Erlich[4], A. Rozin[1], H. Jiries[1], A. Balbir-Gurman[1]. [1]*Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Rheumatology Institute, Haifa, Israel;* [2]*Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion-Israeli Institute of Technology, Biochemistry Laboratory, Haifa, Israel;* [3]*Hadassah Medical Center, Hebrew University of Jerusalem, Bioinformatics, Jerusalem, Israel;* [4]*Rambam Health Care Campus, Rheumatology Institute, Haifa, Israel*

Background: Previous studies proved that mRNA vaccinations against SARS CoV2 induced significant humoral responses in AIRD patients (pts). However, the humoral response was blunted in pts treated with CD20 depleting antibodies. There are limited data regarding the long-term outcome of the humoral response and the contribution of the booster vaccine, in immunosuppressed AIRD pts.

Objectives: To assess the long-term outcome of the humoral response to mRNA vaccine against SARS CoV2, in AIRD pts treated with immunomodulating drugs, and the contribution of the booster vaccination.
Methods: Consecutive pts treated at the Rheumatology Institute at Rambam Hospital who received their first SARS-CoV-2 (Pfizer) vaccine were recruited to the study, at their routine visit. The visit included AIRD activity assessment and questioning regarding vaccine side effects. We performed serology test 4-6 weeks and 24 weeks after receiving the second dose of vaccine. Pts who received the booster (3rd vaccine) were invited for serology tests 4-8 weeks afterwards. The immunomodulating treatment was not modified, either before or after the vaccination. IgG Antibodies (Ab) against SARS COV2 virus were detected using the SARS-Cov-2 IgG II Quant (Abbott) assay based on a chemiluminescent microparticle immunoassay (CMIA) on the ARCHITECT ci8200system from Abbott. This assay is measuring IgG antibodies against the spike receptor-binding domain (S-RBD) of the virus. The test was considered positive above 50 AU/ml.
Results: 262 pts (mean age(SD) 57(13), disease duration 11.2(7.4), were recruited. The cohort included 152 pts with inflammatory joint disease, 26 pts with systemic lupus erythematosus, 62 pts with other connective tissue disease and 22 pts with vasculitis; 27 % received csDMARDs only, 35% - b/tsDMARDs only, 30% - combined therapy (csDMARDs+b/tsDMARDs) and 26% received steroids. 225 pts (86%) were seropositive for IgG Ab against SARS CoV2 virus (median 2832.5 AU/ml, IQR 58-29499). 37 (14%) pts had negative tests, 23 (62.2%) of them were rituximab treated.
The IgG levels correlated with the medication used to treat the AIRD, the patients' age but not with the type of the AIRD (Figure 1). 24 weeks afterwards, the median IgG level dropped to 282 AU/ml and 15% of the pts with previous seropositive tests became negative. The booster administration (Pfizer) significantly augmented the humoral response (median 8328 AU/ml, IQR 375-40000). De novo serologic response was observed in 10 out of 37 pts (4/23 rituximab treated pts).

Figure 1: Serology per drug

	No Rx (N=21)	DMARDs (N=71)	Other Biological Rx ± DMARDs (N=119)	B-Cell Depleting Biological Rx (N=51)
Antibody Titer	9891±2615	4947±883	4524±733	1769±719
Age (yr)	61.2	57.17	59.57	60.36

Plus–minus values are means ±SE; ***, p-value<0.005; *, p-value<0.05; NS, not significant

Figure 1.

The reported side effects of the vaccine were minor (muscle sore, headache, low grade fever). The AIRD remained stable in all pts following all three vaccinations.
Conclusion: Although the vast majority of AIRD pts developed a substantial humoral response following the administration of the second dose of the Pfizer mRNA vaccine against SARS CoV2 virus, the humoral response significantly declined 24 weeks afterwards. An enhanced response was obtained after the third booster vaccination. Only minor side effects were reported and no apparent impact on AIRD activity was noted. Notably, 62% of the non-responders were treated with B cell depleting agents.

POS1246 COVID-19 IN RITUXIMAB TREATED PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES

R. Hasseli[1], B. F. Hoyer[2], H. M. Lorenz[3], A. Pfeil[4], A. Regierer[5], J. Richter[6], T. Schmeiser[7], A. Strangfeld[5], R. Voll[8], H. Schulze-Koops[9], A. Krause[10], C. Specker[11], U. Müller-Ladner[1]on behalf of COVID-19 task force of the German Society for Rheumatology. *[1]Campus Kerckhoff, Justus-Liebig-University Giessen, Department of Rheumatology and Clinical Immunology, Giessen, Germany; [2]Clinic for Internal Medicine I, University Hospital Schleswig-Holstein, Campus Kiel, Department of Rheumatology and Clinical Immunology, Kiel, Germany; [3]University Hospital Heidelberg, Division of Rheumatology, Department of Medicine V, Heidelberg, Germany; [4]University Hospital Jena, Department of Internal Medicine III, Jena, Germany; [5]German Rheumatism Research Centre, Epidemiology Unit, Berlin, Germany; [6]Department of Rheumatology and Hiller Research Unit, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany; [7]Private Practice, Rheumatology, Cologne, Germany; [8]University Medical Center, Albert-Ludwigs University of Freiburg, Department of Rheumatology and Clinical Immunology, Freiburg, Germany; [9]University of Munich, Department of Internal Medicine IV, Division of Rheumatology and Clinical Immunology, Munich, Germany; [10]Immanuel Hospital, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [11]Kliniken Essen-Mitte, Department of Rheumatology and Clinical Immunology, Essen, Germany*

Background: At the beginning of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) disease 2019 (COVID-19) pandemic, the influence of anti-inflammatory therapy on the course of SARS-CoV-2 infection in patients with inflammatory rheumatic diseases (IRD) was unknown. In the meantime, several data indicate an association of severe courses of COVID-19 with the use of rituximab (RTX).
Objectives: To gather further knowledge about SARS-CoV-2 infections in RTX-treated IRD patients, data from the German COVID-19-IRD-registry were analysed.
Methods: Hospitalisation was used as a surrogate of COVID-19 severity. Baseline characteristics, disease features, medication and outcome of COVID-19 were compared in RTX-treated inpatients and outpatients.
Results: In total, 3592 cases were reported in the registry, which included 130 RTX patients (3.6%) for our analysis. RTX-treated inpatients were older than RTX-treated outpatients (median age 63 y vs 56 y, p=0.007). Patients with granulomatosis with polyangiitis treated with RTX (n=32) showed a significant higher COVID-19 related hospitalisation rate (33% vs 11%, p=0.005), which was not the case for patients with rheumatoid arthritis (49% vs 50%). Cardiovascular comorbidities were reported more frequently in hospitalised RTX-treated patients (20% vs. 6%, p=0.032). More than 50% of the RTX-treated inpatients developed COVID-19 related complications, e.g. acute respiratory distress syndrome. The median time period between the last RTX treatment and SARS-CoV-2 infection was shorter in inpatients than in non-hospitalised patients (3 (range 0-17) vs. 4 months (range -29), p=0.039). The COVID-19 related mortality rate was 14% (n=19) in RTX-treated IRD patients. In RTX-treated inpatients and outpatients, there were no relevant differences with respect to the use of concomitant glucocorticoids or other disease modifying anti-rheumatic drugs, disease activity, median last RTX dose or median number of immunomodulatory drugs prior to RTX treatment.
Conclusion: In addition to general risk factors, such as age and comorbidities, it is already known that IRD patients treated with RTX show a higher rate of severe COVID-19. In our registry, RTX-treated patients with granulomatosis with polyangiitis appear to be at even higher risk to develop severe COVID-19 compared to other IRD. Moreover, the shorter the time since the last RTX treatment, the higher seems to be the risk of developing severe COVID-19. This might be explained by a more profound B-cell depletion in the first weeks after RTX treatment warranting further studies.

POS1247 THE EFFECT OF IMMUNOSUPPRESSIVE AGENTS ON ANTIBODY FORMATION AFTER COVID-19 VACCINATION IN RHEUMATOID ARTHRITIS PATIENTS

E. Kang[1], Y. G. Kim[1], J. S. Oh[1], S. Hong[1], C. K. Lee[1], B. Yoo[1], S. M. Ahn[1]. *[1]Seoul, Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Rep. of (South Korea)*

Background: There is still controversy about the efficacy of COVID-19 vaccination and its extent in lowering immunogenicity of Rheumatoid Arthritis (RA) patients. The guideline in whether immunosuppressive agents need to be discontinued before the vaccination is continuously updated because it is considered to lower immunogenicity. Furthermore, there is great discussion on the effectiveness of the COVID-19 booster vaccine and interest in antibody generation in different types of vaccine, as in South Korea there are many patients who were prescribed the mRNA booster vaccine after two doses of ChAdOx1-S nCoV-19 vaccine.

Objectives: Thus, we investigated the differences of antibody production between patients who received only two doses of ChAdOx1-S nCoV-19 and those who received the mRNA booster vaccine. Also, antibody production under different types of immunosuppressive agents was analyzed.

Methods: From October 14, 2021 to January 21, 2022 at a tertiary referral center, two patient groups diagnosed with RA were studied prospectively; one group that completed 1st and 2nd doses of ChAdOx1-S nCoV-19 vaccine, second group that completed mRNA booster vaccine as well as two doses of ChAdOx1-S nCoV-19 vaccine. SARS-CoV-2 antibody testing on the semiquantitative anti-SARS-CoV-2 S enzyme immunoassay was done, and differences in antibody titers were analyzed in patients who received different immunosuppressive agents such as csDMARD, TNF inhibitor, JAK inhibitor, Tocilizumab, Abatacept and Corticosteroid. Statistical analysis with a multivariate logistic regression model was performed.

Results: In a total of 261 patients, 153 patients had completed two doses of ChAdOx1-S nCoV-19, 108 patients had completed third mRNA booster vaccine. Anti-SARS-CoV-2 RBD antibody positive rate (titer>0.8U/mL) was 97%(149/153) and 99%(107/108) respectively, and only 5 patients showed negative result. In the aspect of high antibody titer(>250U/mL), which is the upper limit of the RBD antibody immunoassay, the result showed rate of 31% (47/153) in the non-booster group and 94%(102/108) in the booster group respectively.

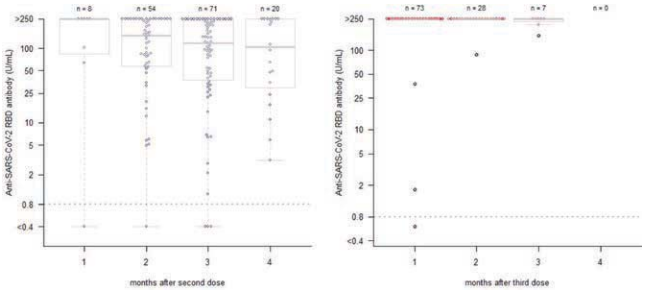

Figure 1. Anti-SARS-CoV RBD antibody titer of two groups

Among the different immunosuppressive agents and other clinical aspects, multivariate analysis revealed that corticosteroid use (OR 0.91; 95% CI: 0.86-0.98), older age(OR 4.33; 95% CI: 1.34-13.91), and male gender(OR 0.35; 95% CI 0.16-0.75) were significantly associated with low rate of high antibody titer. Furthermore, out of 14 patients who underwent antibody test twice before and after the mRNA booster vaccine, other than four patients who already showed high titer of >250U/mL before the mRNA booster vaccine, 10 patients showed an increase in titer after the booster vaccine and 7 patients were acquired high titer of >250U/mL.

Conclusion: Anti-SARS-CoV-2 RBD antibody positive rate was 97% or more regardless of the mRNA booster vaccination. However, patients who received the mRNA booster vaccine after two doses of ChAdOx1-S nCoV-19 vaccine showed high antibody titer (>250U/mL) three times more than those who did not receive the booster shot. Our findings also showed that corticosteroid use, old age, and male gender is significantly associated with low rate of acquiring high antibody titer.

POS1248 URIC ACID AND COVID-19: PATTERN OF CHANGES AND ASSOCIATION WITH PROGNOSIS

A. Sydorova[1], O. Iaremenko[2]. [1]*Medical Center «Universal Clinic «Oberig», Clinical Advisory, Kyiv, Ukraine;* [2]*Bogomolets National Medical University, Department of Internal Medicine №3, Kyiv, Ukraine*

Background: Coronavirus disease causes a proximal tubule dysfunction of kidneys, inducing uric acid loss [1]. It has been established that several changes in laboratory markers (C-reactive protein (CRP), ferritin, interleukin-6 (IL-6)) can predict the severity of Covid-19 [2]. The purpose of this retrospective study was to analyze whether uric acid could act as another predictor of severe Covid-19.

Objectives: To evaluate the relationship between the severity of Covid-19 and uric acid levels on admission to the hospital.

Methods: This retrospective study included 150 hospitalized patients with confirmed Covid-19 (mean age 60.3±14.6 years; 52% were men), the severity of which was determined by the presence and type of oxygen support: (1) without O2, (2) O2 by mask or nasal cannula, (3) continuous positive airway pressure, (4) positive bi-pressure in the airways or high-flow oxygen, (5) invasive ventilation. Among them, 90 subjects required oxygen support, and 60 people didn't. The mortality rate in our study was 9.3%. The average uric acid level was compared with patients without Covid-19 (40 subjects). The study included patients who didn't receive urate-lowering therapy. Levels of CRP, ferritin, IL-6, D-dimer were also determined on admission. The Spearman's rank coefficient was used for measuring correlation.

Results: The mean uric acid level in patients with coronavirus disease was 251.5±104.1 μmol/L; without Covid-19 it was significantly higher — 328.6±96.9 μmol/L (p<0.001). Approximately one in four (24.6%) Covid-19 patients had uric

Table 1. Analysis of immunosuppressive agents and other clinical aspects for high antibody titer(>250U/mL) after two doses of ChAdOx1-S nCoV-19

Corticosteroid	0.849	0.719-1.003	0.054			

acid levels below the lower limit of normal (208 µmol/L for men, 155 µmol/L for women). A decrease in serum uric acid levels was also observed in patients suffering from asymptomatic hyperuricemia or gout. However, there was no correlation between uric acid levels and disease severity (r=0.01, p=0.88). Also, uric acid levels did not correlate with other laboratory markers of severe Covid-19 (CRP: r=0.07, p=0.73; ferritin: r=0.15, p=0,07; IL-6: r=0.11, p=0,22; D-dimer: r=0.02, p=0,79).

Conclusion: Low uric acid levels are common in patients with Covid-19, but are not predictive of a more severe course of this disease. A correlation between uric acid and the level of other laboratory markers of severe Covid-19 was not found.

POS1249 EFFICACY AND SAFETY OF CHADOX1 NCOV-19/AZD1222 AND MRNA-1273 VACCINES: A COMPARATIVE STUDY IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES

Y. J. Chen[1], W. N. Huang[1], H. H. Chen[1], H. W. Chen[2], P. L. Cheng[2], J. P. Chen[2], C. T. Lin[1], K. T. Tang[1], W. T. Hung[1], T. Y. Hsieh[1], T. H. Hsiao[2], Y. M. Chen[1], Y. H. Chen[1]. *[1]Taichung Veterans General Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China; [2]Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China*

Background: Several studies have demonstrated immunogenicity after COVID-19 vaccination in patients with autoimmune rheumatic diseases (AIRD) [1], but the differences between mRNA-based and vector vaccines and the cellular responses to COVID-19 vaccines according to distinct immunogenicity in AIRD patients are still unclear.

Objectives: To investigate the differences in efficacy and safety between the vector vaccine ChAdOx1 nCoV-19/AZD1222 (Oxford-AstraZeneca) and mRNA-based vaccine mRNA-1273 (Moderna) in patients with AIRD, and to explore the cell-cell interactions between high and low anti-SARS-CoV-2 IgG levels in patients with rheumatic arthritis (RA) by single-cell RNA sequencing (scRNA-seq).

Methods: From September 16 to November 15, 2021, we consecutively enrolled 243 participants aged ≥20 years with AIRD who received COVID-19 vaccination, of whom 113 were immunized with AZD1222 and 130 with mRNA-1273. The level of serum IgG antibodies to the SARS-CoV-2 receptor-binding domain on the spike protein S1 subunit was quantified by electrochemiluminescence immunoassay at 4-6 weeks after vaccination. Moreover, peripheral blood mononuclear cells were isolated from two RA patient with high anti-SARS-CoV-2 IgG level and four RA patients with low level for scRNA-seq and cell-cell communication signal was analyzed by CellChat.

Results: The anti-SARS-CoV-2 IgG seropositivity rate was 78.8% (89/113) for AZD1222 and 83.1% (108/130) for mRNA-1273. The level of anti-SARS-CoV-2 IgG was higher in patients who received mRNA-1273 than in those who received AZD1222 (β: 30.15, 95% CI: 11.67-48.63, p=0.002) (Table 1). Prednisolone-equivalent dose >5 mg/day and methotrexate (MTX) use in AIRD patients, and non-anti-tumor necrosis factor (TNF)-α biologics and Janus kinase (JAK) inhibitor use in RA patients were associated with inferior immunogenicity. ScRNA-seq revealed CD16⁻monocytes were predominant in RA patients with high anti-SARS-CoV2-IgG antibody level, and enriched pathways related to antigen presentation via major histocompatibility complex class II (MHC class II) were found (Figure 1). HLA-DRA and CD4 interaction was vigorous among all identified MHC-II pathway and was enhanced in high anti-SARS-CoV2-IgG antibody group.

TNF: tumor necrosis factor, bDMARDs: biologic disease-modifying antirheumatic drugs, JAK: Janus kinase.

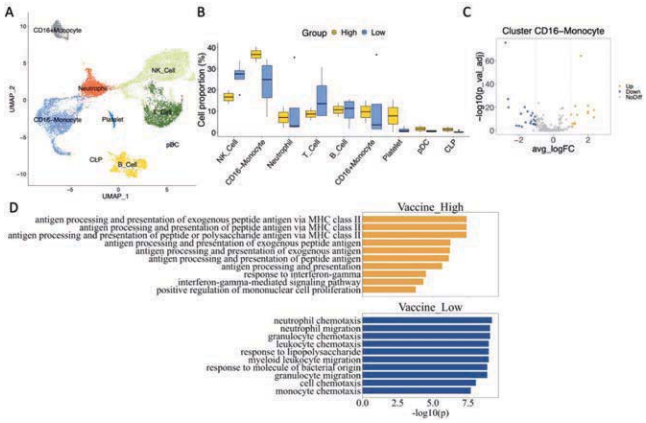

Figure 1. The comprehensive cell atlas of PBMC of RA patients with high and low anti-SARS-CoV2-IgG antibodies. A) UMAP visualization of PBMC cells from RA patients. B) The proportion of cell types between high and low antibody groups. C) Volcano plot of CD16-monocyte showed differential expressed genes. D) Pathway analysis between high and low antibody groups; PRBC: peripheral blood mononuclear cell, RA: rheumatoid arthritis, NK cell: natural killer cell, pDC: plasmacytoid dendritic cell, CLP: common lymphoid progenitor.

Conclusion: mRNA-1273 and AZD1222 vaccines exhibited differential immunogenicity in patients with AIRD. Enriched pathways related to antigen presentation via MHC class II in CD16⁻monocytes might be associated with higher anti-SARS-CoV2-IgG level in RA patients and further study is warranted.

POS1250 EVALUATION AFTER COVID-19 VACCINATION IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: A RETROSPECTIVE COHORT STUDY.

Ö. Karakaş[1], A. Erden[1], B. Armagan[1], S. C. Güven[1], E. Atalar[1], B. Polat[1], A. Omma[1], O. Küçükşahin[2]. [1]*Ankara City Hospital, Rheumatology, Ankara, Turkey;* [2]*Ankara Yıldırım Beyazıt Universıty, Rheumatology, Ankara, Turkey*

Background: Anti-phospholipid syndrome (APS) is an autoimmune disorder characterized by presence of anti-phospholipid antibodies (aPL) comprising lupus anticoagulant, anti-β2-glycoprotein I and/or anti-cardiolipin antibodies together with recurrent thrombosis and/or obstetric morbidity. In the course of COVID-19, thromboembolism may ocur due to endothelial dysfunction directly related to the viral factor and systemic inflammatory response. Concerns about COVID-19 vaccines began to arise after unexpected thromboembolic events were launched with the launch of vaccine campaigns around the world to prevent the disease.

Objectives: The purpose of the study is to contribute to the literature on this subject by evaluating the development of any side effects or activation of the disease after the COVID-19 vaccine in our APS patients.

Methods: This study was designed as a cross-sectional, retrospective cohort study. The patients who meet the Sapporo Criteria for APS which are followed up in Ankara City Hospital Rheumatology Clinic, 18 years and over and vaccinated with any of the COVID-19 vaccines, were included into the study. The files of the patients were examined in order to evaluate the side effects and APS disease activation (thrombosis, embolism or pregnancy complications) in the 3-month period after the last dose of the COVID-19 vaccines (CoronaVac and BNT162b2). Also, information of the patients was collected via telephone or reviewed at regular follow-up visits.

Results: A total of 35 patients were included into the study (Table 1). In our patients, we did not observe any new thrombotic events or pregnancy complications during the 3-months observation period after COVID-19 vaccinations. The most common side effects after vaccinations were as follows; myalgia (30%), weakness (16.7%) and fever (10%) (Table 2). No patient became pregnant or gave birth during the follow-up.

Table 1. Demographic and clinical characteristics of patients with Antiphospholipid antibody syndrome who received Covid-19 vaccine

	N=35
Age, years, meadian (min-max)	43 (28-63)
Gender, female, number (%)	33 (94.3)

POS1251 INCIDENCE AND OUTCOMES OF SARS-COV-2 INFECTION IN PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES: A POPULATION-BASED STUDY OF MORE THAN FOUR MILLION INHABITANTS IN THE LAZIO ITALIAN REGION

E. De Lorenzis[1,2,3], P. Parente[4], G. Natalello[1], S. Soldati[2], S. L. Bosello[1], A. Barbara[4], C. Sorge[2], S. Axelrod[5], L. Verardi[1], P. G. Cerasuolo[1], G. Peluso[1], A. Gemma[2], M. Davoli[2], D. Biliotti[2], V. Bruzzese[4,6], M. Goletti[4], M. DI Martino[2], M. A. D'agostino[1]. [1]*Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy, Rheumatology Department, Roma, Italy;* [2]*Local Public Health Office Roma 1, Department of Epidemiology, Roma, Italy;* [3]*University of Verona-Verona, Italy, Ph.D. Programme in Biomolecular Medicine-Cycle XXXV, Verona, Italy;* [4]*Local Public Health Office Roma 1, Health Directorate, Roma, Italy;* [5]*University of Sechenov, Institute of Leadership, Moscow, Russian Federation;* [6]*Nuovo Regina Margherita Hospital, Department of Internal Medicine, Rheumatology and Gastroenterology, Roma, Italy*

Background: The impact of the severe acute respiratory syndrome Coronavirus 2 disease (COVID-19) pandemic on people with systemic autoimmune rheumatic diseases (SARDs) remains to be fully established. It is unclear whether SARDs are an independent risk factor for COVID-19 infection and poor outcome.

Objectives: The aim of our study is to assess the incidence and prognosis of test-proven SARS-CoV-2 infection during the first COVID-19 wave in a large population of SARD patients of the Lazio Italian region.

Methods: We retrospectively evaluated in a cohort of 4.716.119 subjects aged over 18 years and affiliated to the health system of the Lazio Italian Region, the incidence and 30-day outcomes of COVID-19 infection in 40.490 SARD pts and compared to the affiliated population as incidence rate ratio adjusted for demographics and comorbidities (adjIRR). SARD diagnosis and comorbidities were derived from medical administrative records using the Chronic Related Group classification system. Data on COVID-19 infection were derived from a dedicated regional digital network.

Results: The risk of COVID-19 infection was increased in patients with Psoriatic Arthritis (adjIRR=1.21, 95% CI 1.10-1.33) and Undifferentiated Connective Tissue Disease (adjIRR=1.26, 95% CI 1.03-1.54). The risk of hospitalisation was higher in patients with Axial Spondylarthritis (adjIRR=2.16, 95% CI 1.45-3.22), and Systemic Vasculitis (adjIRR=1.81, 95% CI 1.07-3.06) while the risk of Intensive care unit admission was higher in Systemic Erythematous Lupus (adjIRR=3.67, 95% CI 1.52-8.83) and primary Sjögren Syndrome (adjIRR=4.13, 95% CI 1.71-9.96) patients. An increased COVID-19 mortality was reported in patients with Rheumatoid Arthritis (adjIRR=1.50, 95% CI 1.04-2.17), Systemic Erythematous Lupus (adjIRR=2.67, 95% CI 1.10-6.44), primary Sjögren Syndrome (adjIRR=2.51, 95% CI 1.12-5.62), and Scleroderma (adjIRR=4.60, 95% CI 2.06-10.29).

Conclusion: The incidence of severe COVID-19 is not increased in the same percentage in SARDs. Each SARD presents a peculiar pattern in terms of increased risk of COVID-19 incidence, hospitalisation, intensive care unit admission and death, that is not linked to the immunosuppressive behaviour of the disease.

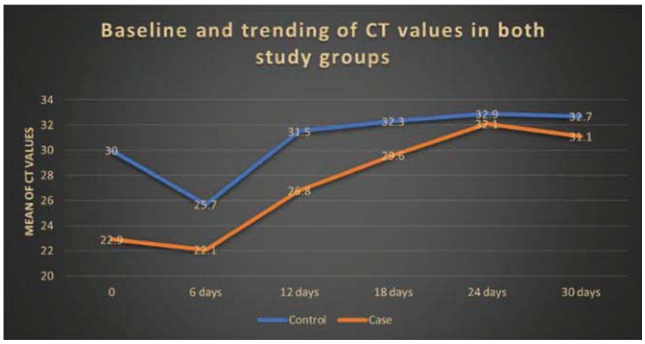
POS1252 DURABILITY OF THE HUMORAL RESPONSE TO M-RNA BASED ANTI-SARS-COV-2 VACCINES IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASE, A COMPARATIVE STUDY

O. Alsaed[1], M. Chaponda[2], E. Elsayed[1], H. Ashour[1], M. Almaslamani[2], S. Al Emadi[1]. [1]*Hamad Medical Corporation, Medicine/Rheumatology, Doha, Qatar;* [2]*Hamad Medical Corporation, Medicine/Infectious Disease, Doha, Qatar*

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) viral load and its impact on disease outcome in patients with autoimmune rheumatic disease (ARD) are lacking. Also, whether patients with ARD receiving immunomodulators have different viral loads compared to the general population is unknown.
Objectives: To compare the viral load of SARS-CoV-2 and its trending between patients without and with ARD.
Methods: Retrospectively, patients with ARD infected with SARS-CoV-2 were matched by age and sex at a ratio of 1:2 to patients without ARD and not receiving immunosuppression or immunomodulator drugs. Viral load was determined by the cycle threshold (CT) value measured by a number of platforms: (a) Automated Platforms - the Roche Cobas 6800 system using the Cobas SARS-CoV-2 Test targeting the E and orf1a/b genes (Roche, Switzerland) and the Xpert Xpress SARS-CoV-2 targeting the E and N genes (Cepheid, USA); (b) Manual platforms - EZ1 (QIAGEN, USA), QIAsymphony (QIAGEN, USA), and Bioneer ExiPrepTM 96 Virus DNA/RNA kits Catalogue No K4614 (Bioneer, South Korea) extraction with thermal cycling using TaqPath™ PCR COVID-19 Combo Kit targeting the N, S and orf1a/b genes (Thermo Fisher Scientific, USA) on ABI 7500 thermal cyclers. Independent samples t-test was used to compare the mean CT values of the study groups at baseline and at 5 subsequent intervals (1 – 5.9, 6 – 11.9, 12 – 17.9, 18 – 23.9 and 24 – 30 days).
Results: Mean age (SD) of 197 cases and 420 controls were 45.2 (11.8) and 44.1 (12.3) years, respectively. Females were predominant in both groups 60% vs. 52%, P=0.053. The most common ARD was rheumatoid arthritis in 82 cases (41.6%), followed by spondyloarthropathy in 33 (16.8%) and systemic lupus erythematosus in 31 (15.7%). Of the cases, 67% were on conventional synthetic disease modifying anti-rheumatic drugs (DMARDs), 15.2% on biological DMARDs and 4.6% patients were on rituximab. The mean CT values was significantly lower in the ARD group at baseline and persisted till day 24.

Table 1. Demographic characteristics and comparison of the mean CT values in the study groups at baseline and at different intervals with the corresponding OR (95% CI)

	Case (N=197)	Control (N=420)	OR (95% CI)
Mean (SD) age, years	45.2 (11.8)	44.1 (12.3)	1.008 (0.994–1.022)
Sex, female N (%)	120 (60.9%)	221 (52.6)	0.713 (0.505–1.006)
Mean (SD) CT values at			
Baseline	22.9 (5.5)	30 (5.2)	**0.799 (0.745–0.858)**
1 – 5.9 days	22.1 (4.6)	25.7 (6.3)	**0.901 (0.842–0.963)**
6 – 11.9 days	26.9 (4.9)	31.5 (3.9)	**0.802 (0.724–0.888)**
12 – 17.9 days	29.6 (4.1)	32.3 (3.2)	**0.827 (0.743–0.921)**
18 – 23.9 days	32.1 (4)	32.9 (2.5)	0.903 (0.728–1.119)
24 – 30 days	31.2 (1.2)	32.7 (2.6)	0.824 (0.589–1.151)



Conclusion: Compared to patients without ARD, the viral load of SARS-CoV-2 in patients with ARD is significantly higher at baseline testing and persists till day 24. This finding may indicate that patients with ARD are at higher risk of severe SARS-CoV-2 infection and prolonged potential transmission. Clinical outcome correlation is needed.

POS1253 THE COURSE OF COVID-19 IN A COHORT OF SPONDYLOARTHRITIS PATIENTS: A CASE-CONTROL PROSPECTIVE STUDY

C. Castellani[1], R. Terribili[1], L. DI Sanzo[1], E. Molteni[1], G. Sciarra[1], G. Bevignani[1], M. DI Franco[1], V. Riccieri[1], C. Alessandri[1], R. Scrivo[1], F. Conti[1]. [1]*Sapienza University of Rome, UOC Reumatologia - Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Rome, Italy*

Background: With the outbreak of the SARS-CoV-2 pandemic, the rheumatologists' attention was directed at understanding whether infected patients could have a less favorable outcome. Available data seem to indicate that the course in rheumatic patients is not dissimilar from that in the general population. However, data on the outcome of COVID-19 in patients with spondyloarthritis (SpA) are scant.
Objectives: To describe the outcome of COVID-19 in patients with SpA in terms of hospitalization, need of oxygen therapy, and symptoms compared to a control group. The variation in disease activity before and after COVID-19 was also assessed.
Methods: We enrolled adult patients with psoriatic arthritis (PsA) and ankylosing spondylitis (AS) classified according to standard criteria, that received a diagnosis of COVID-19 through molecular or rapid antigen swab tests between September 2020 and January 2022. Demographic and clinical data, including age, body mass index (BMI), smoking habit, comorbidities, rheumatic treatment at diagnosis of COVID-19, date of COVID-19 diagnosis, symptoms and additional therapy during the infection and vaccination status were collected through a questionnaire and recorded on an electronic database. Disease activity, assessed by DAPSA in PsA patients and by BASDAI and ASDAS in AS patients, was evaluated before and at the first visit after the infection. As controls, individuals with COVID-19 but with no known diagnosis of rheumatic/autoimmune disease were recruited using the "best friend" system.
Results: Sixty-two patients were enrolled [43 with PsA and 19 with AS; F:M=40:22; median age 51 years, 25th-75th percentile 39.5-61; median BMI 25.5, 25th-75th percentile 21.75-28; median disease duration 90 months, 25th-75th percentile 36-192; 6 (9.7%) smokers, 37 (59.7%) non-smokers, 19 (30.6%) past smokers; 15 (24.2%) only treated with one conventional DMARD, 27 (43.5%) with bDMARDs and 20 (32.3%) with both; 44 (71%) had received no vaccine, 18 (29%) one or more doses of vaccine]. Forty-eight controls were also recruited [F:M=29:19; median age 48 years, 25th-75th percentile 41.5-57; median BMI 23.86, 25th-75th percentile 20.69-28.03; 10 (20.83%) smokers, 28 (58.33%) non-smokers, 10 (20.83%) past smokers; 43 (89.6%) had received no vaccine, 5 (10.4%) one or more doses of vaccine]. Among patients, 10 (16.1%) were hospitalized, of whom 8 (80%) required noninvasive oxygen therapy. Among controls, 7 (14.5%) were hospitalized, of whom 5 (71.4%) required noninvasive oxygen therapy. No differences were observed compared to the control group in terms of hospitalization and need for oxygen support. Likewise, the two groups did not bear any statistically significant difference in terms of symptoms (fever, dysgeusia, dyspnoea) and cardiovascular and respiratory comorbidities. BMI and smoking habit did not influence the outcome of COVID-19 in SpA patients, while a BMI of 25 or above was associated with hospitalization in the control group (p=0.0004, RR 3.417). Baseline treatment with immunosuppressants did not influence the disease outcome. DAPSA, ASDAS, and BASDAI did not significantly change after the infection (Table 1). We did not record any COVID-19-related death in either group.

Table 1. Disease activity before and after COVID-19

	Last visit before COVID-19		**First visit after COVID-19***	
	PsA (n=43)	**AS (n=19)**	**PsA (n=43)**	**AS (n=19)**
Remission/low disease activity, n (%)	19 (44.2%)	17 (89.5%)	23 (53.5%)	14 (73.7%)
Moderate/high disease activity, n (%)	11 (25.6%)	0 (0%)	7 (16.3%)	1 (5.3%)
	NA 13 (30.2%)	NA 2 (10.5%)	NA 13 (30.2%)	NA 4 (21%)

* Reassessment of patients was performed 2 months (median) after COVID-19, 25th-75th percentile 1-4 monthsPsA, psoriatic arthritis; AS, ankylosing spondylitis; NA, not available

Conclusion: Our data show that patients with SpA do not face a worse prognosis of COVID-19 than subjects without rheumatic/autoimmune diseases and that demographic and clinical features did not influence the course of the disease.

Background: AIRD patients (pts) may be more susceptible to severe COVID19.
Objectives: To determine the risk factors for severe COVID19 and the effect of vaccinations among AIRD pts followed at dedicated rheumatology clinics.
Methods: At the onset of the pandemic, we established a national registry of AIRD pts, diagnosed with COVID19, based on voluntary reporting by the treating rheumatologist. 12 centers from Israel participated in the study. COVID19 was confirmed by a positive SARS CoV2 PCR. The indications for PCR testing were clinical symptoms or close contact with an infected person. Severe illness was defined by SpO_2 <94% in room air, respiratory rate of >30 breaths/min, PaO_2/FiO_2 <300 mm Hg, or lung infiltrates >50% on imaging. The registry included demographic data, AIRD diagnosis and duration, visceral involvement, co-morbidities, immunomodulatory treatment, date of diagnosis and severity of COVID19 disease, management, complications, duration of hospitalization, the dates of the mRNA vaccinations, lab results and outcome. We analyzed data from 1.3.2020 to 30.11.2021
Results: During the study period we experienced 4 outbreaks of COVID19 infection. Initially social distancing, followed by a lockdown were imposed. The low number of cases led to relaxation of the measures. Two more severe outbreaks followed, which triggered 2 new lockdowns. The 3rd outbreak ended almost 2 months after vaccination started (BNT162b2 mRNA COVID19 vaccine). From March 1st 2020 to April 30, 2021, 298 AIRD pts (70.8% females, mean (SD) age 53.3(15.3)) with confirmed COVID19 infection were included. 43.3%(129) had visceral involvement due to the AIRD. 58.7%(175 pts) were on conventional synthetic disease modifying drugs (csDMARDs), 44.6% (133) on biologic/targeted DMARDs and 40% (120) on prednisone. Almost 2/3 of pts had at least one comorbidity.
In a multivariate logistic regression analysis age, AIRD with pulmonary involvement, diabetes and treatment with prednisone, mycophenolate mofetil or JAK inhibitors were associated with hospitalization. Older age, renal and vascular involvement due to the AIRD, and congestive heart failure were associated with higher mortality.
The 4th outbreak occurred 6 months after the introduction of vaccines, with spreading of the delta variant: 110 AIRD pts with COVID19 were recorded. Demographic data, clinical AIRD's characteristics, immunomodulatory treatment and comorbidities were similar to the previous outbreaks. However, during the 4th outbreak, the proportion of pts with severe COVID19, the hospitalization and mortality rate were significantly lower as compared to the first 3 outbreaks (15% vs 24%, 27% vs 53%, 6.7% vs 9.1%, respectively). Among COVID19 pts, 25% received a 3rd vaccine dose (booster), 56% contracted infection more than 5 months after the 2nd vaccine dose and 24% were unvaccinated. Most of the pts who received the booster contracted the disease within a week of vaccination. The odds ratio for hospitalization in vaccinated pts compared to unvaccinated was 0.11 (0.01 – 0.63 95% CI, p=0.041) in those vaccinated within the previous 1-5 months, and 0.38 (0.21-0.67 95% CI, p=0.001) in those vaccinated more than 6 months ago. 9 pts died, 5 were more than 6 months after the 2nd mRNA vaccine, 2 were unvaccinated and 1 patient received the booster on the same day of COVID19 diagnosis.
Conclusion: Before the vaccination campaign, the hospitalization and mortality rate in our cohort were similar to the data reported by other registries. COVID19 tends to be more severe, with increased mortality in patients with active AIIRD and visceral involvement (pulmonary, cardiac, renal), advanced age and co-morbidities. The delta outbreak occured 6 months after the implementation of vaccinations and was associated with significantly lower hospitalization and mortality rates, despite the increased aggressiveness of the variant. Vaccination of AIIRD pts with 3 doses of mRNA vaccines protects from severe COVID19 disease, hospitalization, and death.

POS1255 SAFETY OF THE PFIZER/BIONTECH AND SINOVAC/CORONAVAC VACCINES AMONG PATIENTS WITH BEHCET'S SYNDROME AND FAMILIAL MEDITERRANEAN FEVER

A. Ozdede[1], S. Güner[2], G. Ozcifci[3], B. Yurttas[2], Z. Toker Dincer[2], Z. Atli[4], U. Uygunoglu[5], E. Durmaz[6], D. Ucar[7], S. Ugurlu[2], S. Saip[5], Ö. F. Tabak[8], V. Hamuryudan[2], E. Seyahi[2]. *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Division of Rheumatology, Department of Internal Medicine, İstanbul, Turkey; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Division of Rheumatology, Department of Internal Medicine, İstanbul, Turkey; [3]Columbia University Irving Medical Center, Division of Allergy, Immunology, and Rheumatology, Department of Pediatrics, New York, United States of America; [4]Sinop University, Biostatistics and Informatics, Department of Accounting and Taxation, Sinop, Turkey; [5]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, İstanbul, Turkey; [6]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Cardiology, İstanbul, Turkey; [7]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophthalmology, İstanbul, Turkey; [8]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Infectious Disease and Clinical Microbiology, İstanbul, Turkey*

Background: Since first emerged in December 2019, the COVID-19 pandemic has resulted in a death toll surpassing 5.5 million worldwide and had severe consequences on the global economy, environment, public health and social life [1, 2]. Multiple potential vaccines against COVID-19 have been developed swiftly and as shown in several phase 3 clinical trials, they demonstrated considerable efficacy without an unusual safety signal in healthy individuals.
Objectives: In this study, we aimed to evaluate vaccine reactivity and disease flare following vaccination with either Sinovac/CoronaVac or Pfizer/BioNTech among BS and FMF patients compared with patients with various diagnosis of RD and healthy controls.
Methods: Only those patients and healthy controls who rece,ved at least one single shot of either CoronoVac or BioNTech against COVID-19 were included in the study. We tried to contact all of these patients and controls consecutively by telephone and attempted to make interviews with the eligible ones.
Results: We studied the efficacy, side effects and disease flares after COVID-19 vaccination in 256 patients with Behcet's syndrome (BS), 247 with familial Mediterranean fever (FMF), 601 with rheumatic diseases (RD) and 612 healthy controls (HC). Study participants were vaccinated either with CoronaVac (BS:109, FMF: 90, RD: 343, and HC: 334) or BioNTech (BS: 147, FMF:157, RD: 258 and HC: 278). BioNTech ensured a significantly better efficacy than CoronaVac against COVID-19 in all patient groups (BS: 1.4% vs 10.1%; FMF: 3.2% vs 12.2%, RD:2.7% vs 6.4%). Those with at least one adverse event (AE) were significantly more frequent among those vaccinated with BioNTech than those with CoronaVac (BS: 86.4% vs 45%; FMF: 83.4% vs 53.3%; RD: 83.3% vs 45.5% and HC: 86.3% vs 52.1%). The majority of AEs were mild to moderate and transient and this was true for either vaccine. There were also AEs that required medical attention in all study groups following CoronaVac (BS:5.5%, FMF:3.3%, RD:2.9% and HC:3.3%) or BioNTech (BS:5.4%, FMF:1.9%, RD:4.7% and HC:4.7%). The main causes for medical assistance were disease flare, and cardiovascular events. Disease flares after vaccination were significantly more frequent among BS (41/256; 16.0%) and FMF (43/247; 17.4%) patients compared to patients with RD (36/601; 6.0%). This was true for both CoronaVac (BS: 11.0%, FMF: 24.4% and RD: 5.2%, p<0.001) and BioNTech (BS: 19.7%, FMF: 13.4% and RD: 7.0%, p=0.001)(Table 1).

Table 1. Flares among patients with Behçet's syndrome, familial Mediterranean fever, rheumatic diseases after vaccination with CoronaVac and BioNTech

CoronaVac		
Behçet's syndrome, n=109	Familial Mediterranean Fever, n=90	Rheumatic diseases, n=343
Flares, n (%)	Flares, n (%)	Flares, n (%)
12 (11.0)	22 (24.4)	18 (5.2)
BioNTech		
Behçet's syndrome, n=147	Familial Mediterranean Fever, n=157	Rheumatic diseases, n=258
Flares, n (%)	Flares, n (%)	Flares, n (%)
29 (19.7)	21 (13.4)	18 (7.0)

RA, Rheumatoid Arthritis; BS, Behçet's syndrome; FMF, Familial Mediterranean Fever

Conclusion: Our study demonstrates that BS and FMF patients vaccinated with either CoronaVac or BioNTech demonstrated almost similar AE profile and frequency compared to RD patients and HC. AEs that required physician consultation or hospitalization occurred in all study groups after either CoronaVac or BioNTech. Caution should be required when monitoring these patients after vaccination. Increased frequency of flares in BS and FMF compared to that seen in RD might reflect defects in innate immunity and deserves further investigation.

RISK FACTORS FOR SHORT-TERM ADVERSE EVENT IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES

L. Kummer[1,2], L. Wieske[2,3], E. Stalman[2], K. Van Dam[2], L. Boekel[4], G. Wolbink[4], A. Volkers[5], M. Steenhuis[1], N. Verstegen[1], T. Rispens[1], A. Ten Brinke[1], Z. Van Kempen[6], S. Tas[7], M. Van Ham[1,8], T. Kuijpers[9], F. Eftimov[2]on behalf of T2B! Immunity against SARS-CoV-2 study. *[1]Sanquin Blood Supply, Department of Immunopathology, Amsterdam, Netherlands; [2]Amsterdam UMC, locatie AMC, Neurology and Neurophysiology, Amsterdam, Netherlands; [3]St. Antonius Hospital, Clinical Neurophysiology, Nieuwegein, Netherlands; [4]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology, Amsterdam, Netherlands; [5]Amsterdam UMC, locatie AMC, Gastroenterology and Hepathology, Amsterdam, Netherlands; [6]Amsterdam UMC, locatie Vumc, Neurology, Amsterdam, Netherlands; [7]Amsterdam UMC, locatie AMC, Rheumatology and Immunology, Amsterdam, Netherlands; [8]Swammerdam Institute for Life Sciences, Life Sciences, Amsterdam, Netherlands; [9]Amsterdam UMC, locatie AMC, Pediatric Immunology, Rheumatology and Infectious Disease, Amsterdam, Netherlands*

Background: Many countries are promoting booster SARS-CoV-2 vaccination campaigns as the COVID-19 pandemic continues. Incremental short-term adverse events after two SARS-CoV-2 vaccinations have been reported in healthy individuals.[1,2] However, data on incremental short-term adverse events in patients with various immune-mediated inflammatory diseases (IMIDs) after repeated SARS-CoV-2 vaccination is scarce.

Objectives: We report risk factors for short-term adverse events in IMID patients after SARS-CoV-2 vaccination.

Methods: Self-reported daily questionnaires on adverse events in the first seven days after SARS-CoV-2 vaccination were obtained from individuals participating in an ongoing prospective multi-arm multicenter cohort study on SARS-CoV-2 vaccination in patients with various IMIDs in the Netherlands (T2B! immunity after SARS-CoV-2). Clinically relevant adverse events were defined as systemic adverse advents lasting longer than two days or hindering daily activities. Adjusted relative risks for developing clinically relevant adverse events were calculated using a logistic mixed-effects model.

Results: Data of 2081 patients and 178 healthy controls were obtained. Inflammatory bowel disease (N:480), Multiple sclerosis (N:343) and Rheumatoid arthritis (N:266) were the largest disease groups. Adjusted relative risks for relevant adverse events are presented in Figure 1. Third vaccination was not associated with increased risk on adverse events when compared to a second vaccination (aRR: 0.93 95% CI: 0.84-1.02). Patients with IMIDs were at increased risk for developing adverse events after vaccination when compared to controls (aRR: 1.16 95% CI: 1.01-1.34). Female sex (aRR 1.43 95% CI: 1.32-1.56), age below 50 (aRR 1.14 95% CI: 1.06-1.23) and a preceding SARS-CoV-2 infection (aRR: 1.14 95% CI: 1.01-1.29) were also associated with increased risk of adverse events following vaccination. Allergic reactions and hospital admission were uncommon (0.67% and 0.19% respectively); 7.4% and 6.8% of patients reported adverse events impacting daily life on day seven after second and third vaccination, respectively. Data on increase in disease activity of the IMID following vaccination are currently being investigated.

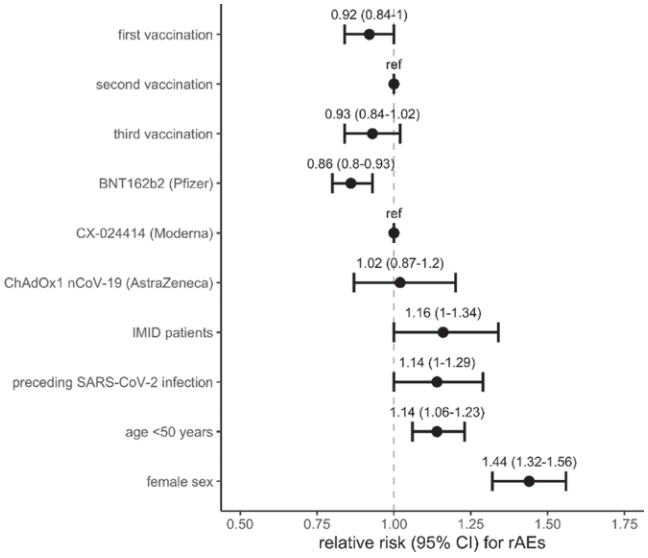

Figure 1. Risk factors for adverse events after SARS-CoV-2 vaccination in patients with immune-mediated inflammatory disease

Conclusion: A third SARS-CoV-2 vaccination was not associated with an increased risk on short-term clinically relevant adverse events when compared to a second vaccination. Although patients with IMIDs may be slightly more at risk to develop adverse events after SARS-CoV-2 vaccination, most adverse events were transient and disappeared within seven days. This message should reassure IMID patients who are hesitant on booster vaccination. Data on potential IMID flare-ups after vaccination will follow.

READING THE WAVES: IDENTIFYING DISTINCT PHENOTYPES OF MULTISYSTEM INFLAMMATORY SYNDROME IN CHILDREN IN A SINGLE CANADIAN CENTER DURING THE 2020-2021 COVID-19 PANDEMIC

T. Renson[1], P. Miettunen[2,3], S. Parsons[4], M. Dhalla[3], N. Johnson[2,3], N. Luca[2,3], H. Schmeling[2,3], R. Stevenson[3], M. Twilt[2,3], L. Hamiwka[2,5], S. Benseler[2,3].
[1]Alberta Children's Hospital, Rheumatology and Nephrology, Calgary, Canada; [2]Alberta Children's Hospital Research Institute, Cumming School of Medicine, Calgary, Canada; [3]Alberta Children's Hospital, Rheumatology, Calgary, Canada; [4]Alberta Children's Hospital, Critical Care Medicine, Calgary, Canada; [5]Alberta Children's Hospital, Nephrology, Calgary, Canada

Background: The COVID-19-associated multisystem inflammatory syndrome in children (MIS-C) is characterized by Kawasaki disease (KD)-like features and circulatory shock [1]. The genesis of SARS-CoV-2 variants triggered successive waves of mass infections followed by MIS-C outbreaks.
Objectives: To compare MIS-C phenotypes across the waves of the COVID-19 pandemic. To identify predictors of pediatric intensive care unit (PICU) admission and treatment with biologic agents.
Methods: Youth aged 0-18 years, fulfilling the WHO case definition of MIS-C, and admitted to the Alberta Children's Hospital during the COVID-19 pandemic (May 2020-December 2021) were included. Clinical, laboratory, imaging, and treatment data were captured (KD-like manifestations, signs of shock and/or hypotension, peak C-reactive protein (CRP) and ferritin, platelet count nadir, peak NT-proBNP and troponin, liver enzyme abnormalities, sodium and albumin nadir, echocardiogram findings, biologic agents).
Results: 57 consecutive MIS-C patients (median age 6 years, IQR 4-6; 72% males) were included. 31 patients (54%) required PICU admission. All received immunoglobulins, 44 (77%) received corticosteroids, 8 patients (14%) were treated with biologic agents. Patients presenting during the third (mainly driven by Alpha variant) or fourth wave (mainly driven by Delta variant) presented with higher ferritin and NT-proBNP levels, and more liver enzyme abnormalities, hypoalbuminemia and thrombocytopenia compared to those presenting during the first or second wave (Table 1, Figure 1). PICU admission was associated with the presence of shock/hypotension, higher CRP, ferritin, and NT-proBNP levels, lower albumin levels, and the presence of ventricular dysfunction on echocardiogram (Table 1). A logistic regression model combining peak NT-proBNP, troponin and ferritin levels explained 70% (Nagelkerke R^2) of the variance in PICU admission and correctly classified 91% of the cases. NT-proBNP was the sole significant contributor (p=0.017). Treatment with biologic agents was associated with higher CRP (mean 148.8 mg/l versus 251.7 mg/l; p=0.024) and ferritin (797 µg/l versus 1280 µg/l; p=0.049) levels.

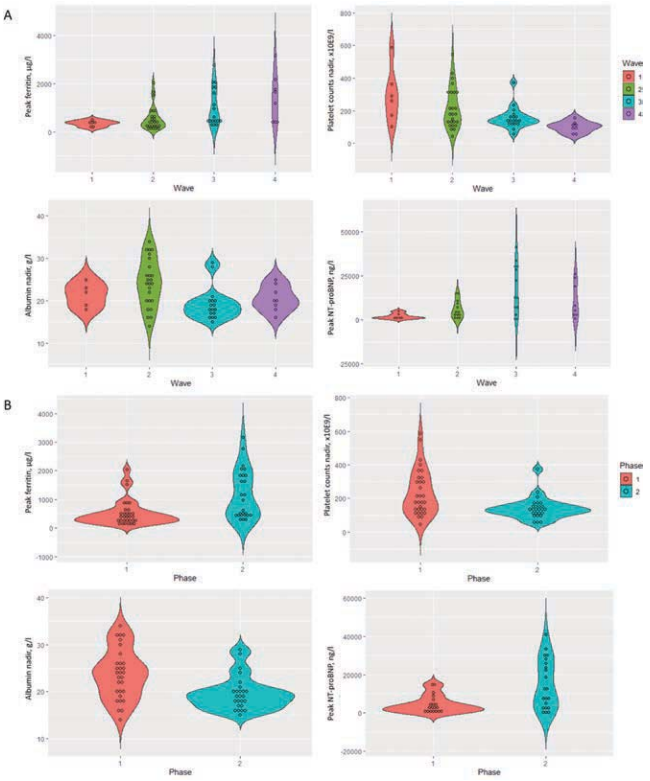

Figure 1. Violin plots depicting differences in key laboratory MIS-C features between the waves (A) and both phases (phase 1 = wave 1+2, phase 2 = wave 3+4; B) of the COVID-19 pandemic.

Table 1. Upper panel: Differences in MIS-C features of patients presenting during the first phase of the COVID-19 pandemic (first + second wave) compared to those presenting during the second phase (third + fourth wave) (*one missing value). Lower panel: Differences regarding MIS-C features between patients admitted to PICU compared to those managed on the general ward.

	Phase 1 (n = 31)	Phase 2 (n = 26)	P-value
Peak ferritin, µg/l (mean, SD)	548 (529)	1129 (724)	<0.001
Liver enzyme abnormalities (n, %)	10 (32)	18 (69)	0.008
Peak NT-proBNP, ng/l (mean, SD)	5250 (4721)	13366 (11211)	0.012
Hypoalbuminemia (n, %)	24 (80)*	25 (100)*	0.027
Thrombocytopenia (n, %)	11 (35)	18 (69)	0.017
		PICU	
	No (n = 26)	**Yes** (n = 31)	**P-value**
Shock/hypotension (n, %)	19 (73)	31 (100)	0.002
Peak CRP, mg/l (mean, SD)	140.7 (92)	203.8 (84)	0.008
Peak ferritin, µg/l (mean, SD)	612 (676)	1183 (627)	0.002
Peak NT-proBNP, ng/l (mean, SD)	3772 (5074)	15584 (9662)	<0.001
Albumin nadir, g/l (mean, SD)	24 (4)	19 (3)	0.014
Ventricular dysfunction (n, %)	2 (8)	18 (58)	<0.001

Conclusion: A shift in MIS-C phenotype was identified across the successive COVID-19 waves, including the predominance of features associated with macrophage activation syndrome in later stages. These findings may reflect the impact of distinct SARS-CoV-2 variants. NT-proBNP emerged as the most important MIS-C feature predicting PICU admission, underscoring the importance of monitoring.

LESS THAN EXPECTED IMPACT OF RHEUMATOID ARTHRITIS AND AXIAL SPONDYLOARTHRITIS DISEASE ON COVID SEVERITY

S. Keeling[1], B. Pan[1], E. Hutchings[1], S. Wichuk[2], M. Osman[1], A. Singh[1], A. Sonpar[1], I. Swartz[1], W. P. Maksymowych[1]. *[1]University of Alberta, Medicine, Edmonton, Canada; [2]University of Alberta, Radiology and Diagnostic Imaging, Edmonton, Canada*

Background: Throughout the pandemic, there has been ongoing concern that people with autoimmune diseases such as rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA) will have more severe COVID-19 disease due to immune dysfunction associated with autoimmune diseases and their treatment.
Objectives: We aimed to compare the severity of COVID-19 in patients with RA versus axSpA and characterize the predictors of COVID-19 severity during the pre-Omicron pandemic phases.
Methods: The IMPACT (**IMP**act of inflammatory **A**rthritis on **C**OVID Outcomes S**T**udy) study is a monthly survey of two established northern Alberta, Canada prospective cohorts of RA and axSpA patients from November 2020-2021 who answered Redcap surveys through de-identified email link surveying patient demographics, disease characteristics, COVID-19 symptoms, treatment of RA and axSpA, health care utilization, vaccination status and vaccine adverse events. Descriptive and univariate analyses (dependent variable = severe COVID-19) were performed followed by multivariate analyses of all significant and clinically relevant independent variables from the univariate analysis. Infection severity was defined as any patient with COVID-19 symptoms who visited a doctor, ER or required hospital admission.
Results: 773 of 2167 (36%) patients (RA n=574, axSpA n=197) registered in both cohorts answered at least one baseline survey, 28 (4%) reporting positive COVID-19 tests (24 positive once). Of 442 reporting COVID-19 symptoms during the survey, 11 (3%) were admitted for a mean of 4 days, 2 requiring ICU or blood clot treatment and 1 requiring advanced therapy. 116 (26%) visited a physician for Covid symptoms. Univariate analysis showed that the use of steroids, NSAIDs and increased disease activity were associated with having less severe infection but these associations were not significant in the multivariate analysis (Table 1). There were no significant impacts of RA vs axSpA, age, gender, treatment, disease activity, or smoking.

Table 1. Multivariate Level Mixed-Effect Logistic Regression Model: IMPACT of RA and axSpA Disease Characteristics on COVID Infection Severity Defined as Patients with COVID Symptoms Requiring Visit to Doctor, Emergency Room and/or Hospital Admission.

Variable		Coefficient (S.E)	Odds Ratio (95 % Confidence Interval)	P-value
Gender	Male	0.17 (0.34)	1.18 (0.61 – 2.31)	0.6193
	Female	Reference		
Age		-0.01 (0.01)	0.99 (0.97 – 1.01)	0.2543
Rheumatic Disease Type	RA	0.18 (0.40)	1.20 (0.58 – 2.48)	0.6213
	SpA	Reference		
Steroids	Yes	-0.40 (0.56)	0.67 (0.23 – 2.01)	0.4757
	No	Reference		
NSAIDS	Yes	-0.20 (0.26)	0.82 (0.49 – 1.37)	0.4508
	No	Reference		
Current Disease Activity		-0.04 (0.06)	0.96 (0.85 – 1.09)	0.5275
HAQ		-0.03 (0.29)	0.97 (0.55 – 1.70)	0.9041
Nicotine products	Yes	-0.67 (0.37)	0.51 (0.25 – 1.06)	0.0714
	No	Reference		
Cannabis products	Yes	-0.45 (0.31)	0.64 (0.35 – 1.18)	0.1510
	No	Reference		
DMARDs	Yes	0.26 (0.30)	1.30 (0.72 – 2.35)	0.3860
	No	Reference		
Biologic DMARD	Yes	-0.46 (0.43)	0.63 (0.27 – 1.46)	0.2813
	No	Reference		

Conclusion: Possible disease related risk factors for increased COVID-19 severity in RA and axSpA patients preceding the onset of the Omicron variant including use of steroids or DMARDs were not associated with severe infection. These findings are consistent with other international studies whereby other non-rheumatic disease comorbidities played a greater role in infection severity.

AXIAL SPONDYLOARTHRITIS, AGE AND MALE GENDER IMPACT COVID VACCINATION AES MORE THAN RHEUMATOID ARTHRITIS

S. Keeling[1], B. Pan[1], E. Hutchings[1], S. Wichuk[1], M. Osman[1], A. Singh[1], A. Sonpar[1], I. Swartz[1], W. P. Maksymowych[1]. [1]*University of Alberta, Medicine, Edmonton, Canada*

Background: Rheumatologists recommend vaccination in rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA) patients, but there are few studies on the occurrence of adverse events (AEs), particularly worsening disease related activity and unrelated immune reactions in these groups.

Objectives: To evaluate the uptake of COVID vaccination in RA and axSpA patients, compare the frequency of AEs, and identify risk factors associated with vaccine AEs in two prospective cohorts comprised of these patients.

Methods: The IMPACT study is a monthly survey of two prospective cohorts of established RA and axSpA patients in northern Alberta, Canada from November 2020-2021 who answered at least one or more Redcap surveys through de-identified email link surveying demographics, disease characteristics, COVID symptoms, treatment of RA and axSpA, health care utilization, vaccination status, vaccine AEs and use of cannabis. Univariate analyses evaluated independent variables associated with the dependent variables of (1) any AE, (2) any severe

*Severe = Any of the following: ranked moderate to severe and/or lasting more than 7 days and/or saw physician

AE, (3) any arthritis flare, and (4) any severe arthritis flare, followed by multivariate analyses of these four dependant variables using all clinically relevant variables from the univariate analysis.

Results: 773/2167 patients (RA 574, axSpA 197) responded to at least one survey. 32/663 (5%) were single vaccinated, 631 (95%) double vaccinated and 230 (54%) triple vaccinated with 80% receiving Pfizer, 24% Moderna, 28% AstraZeneca and 30% "other". 456 (69%) reported at least one AE (Figure 1) with 21 (3%) patients seeing a physician for their AE. Increased age was associated with all AEs. RA patients had lower reported AEs versus axSpA patients for all AE definitions except for severe arthritis flares. Generally, males reported worse AEs (Table 1). "Any arthritis flare" was lower in patients reporting cannabis use.

Conclusion: RA and axSpA patients showed high uptake of COVID vaccination with largely minor AEs. Older age and male gender were associated with more general and arthritis specific AEs. The association of any AE and/or arthritis-specific AEs in SpA versus RA patients is a novel finding which may correlate with the male predominance of SpA. The association of cannabis with fewer arthritis AEs may reflect the nociceptive properties of cannabis.

Background: COVID-19 vaccines have been proven to be safe and effective in the healthy population at large. However, significant gaps remain in the evidence of their safety in patients with systemic autoimmune and inflammatory disorders (SAIDs). Patients and rheumatologists have expressed concerns regarding vaccination triggered allergic reactions, thrombogenic events, and other adverse events (ADEs) contributing to vaccine hesitancy (1)

Objectives: This study aimed to assess and compare short term COVID-19 vaccination associated ADEs in patients with SAIDs and healthy controls (HC) seven days post-vaccination, as well as between patients with SAIDs receiving different vaccines.

Methods: We developed an comprehensive, patient self-reporting electronic-survey to collect respondent demographics, SAID details, COVID-19 infection history, COVID-19 vaccination details, 7-day post vaccination adverse events and patient reported outcome measures using the PROMIS tool. After pilot testing, validation, translation into 18 languages on the online platform surveymonkey.com, and vetting by international experts, the survey was circulated in early 2021 by a multicenter study group of >110 collaborators in 94 countries. ADEs were categorized as injection site pain, minor ADEs, major ADEs, and hospitalizations. We analyzed data from the baseline survey for descriptive and intergroup comparative statistics based on data distribution and variable type (data as median, IQR).

Results: 10900 respondents [42 (30-55) years, 74% females and 45% Caucasians] were analyzed. 5,867 patients (54%) with SAIDs were compared with 5033 HCs. All respondents included in the final analysis had received a single dose of the vaccine and 69% had received 2 primary doses. Pfizer (39.8%) was the most common vaccine received, followed by Oxford/AstraZeneca (13.4%), and Covishield (10.9%). Baseline demographics differed by an older SAID population (mean age 42 vs. 33 years) and a greater female predominance (M:F= 1:4.7 vs. 1:1.8) compared to HCs.

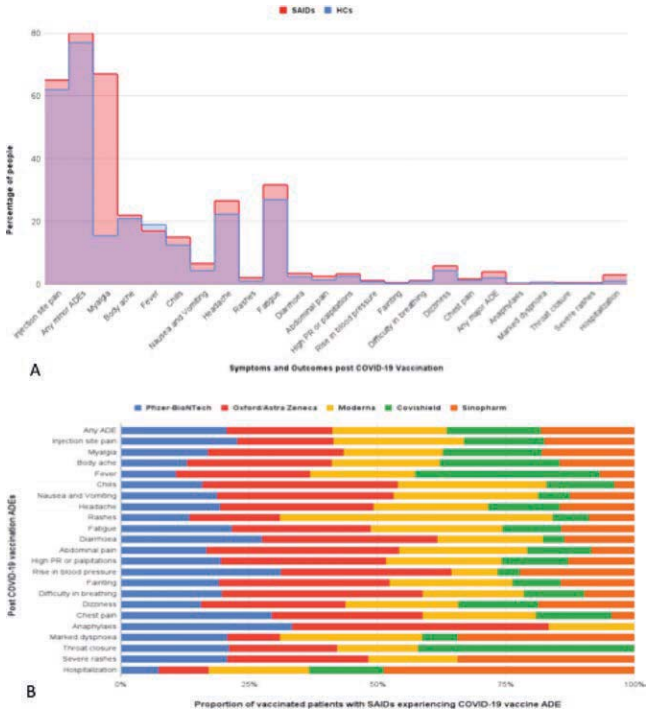

Figure 1. A. Post Vaccination ADEs in SAIDs compared to HCs. B. Proportions of post COVID-19 vaccination ADEs in SAIDs by vaccine type.

79% had minor and only 3% had major vaccine ADEs requiring urgent medical attention overall. In adjusted analysis, among minor ADEs, abdominal pain [multivariate OR 1.6 (1.14-2.3)], dizziness [multivariate OR 1.3 (1.2-1.5)], and headache [multivariate OR 1.67 (1.3-2.2)], were more frequent in SAIDs than HCs. Overall major ADEs [multivariate OR 1.9 (1.6-2.2)], and throat closure [multivariate OR 5.7 (2.9-11.3)] were more frequent in SAIDs though absolute risk was small (0-4%) and rates of hospitalization were similarly small in both groups, with a small absolute risk (0-4%). Specific minor ADEs frequencies were different among different vaccine types, however, major ADEs and hospitalizations overall were rare (0-4%) and comparable across vaccine types in patients with SAIDs (Figure 1).

Conclusion: Vaccination against COVID-19 is relatively safe and tolerable in patients with SAIDs. Certain minor vaccine ADEs are more frequent in SAIDs than HCs in this study, though are not severe and do not require urgent medical attention. SAIDs were at a higher risk of major ADEs than HCs, though absolute risk was small, and did not lead to increased hospitalizations. There are small differences in minor ADEs between vaccine types in patients with SAIDs.

POS1261 CLINICAL RESPONSE PREDICTORS OF TOCILIZUMAB THERAPY IN PATIENTS WITH SEVERE COVID-19

W. Schmidt[1,2,3], K. Pawlak-Bus[1,2], P. Leszczynski[1,2]. [1]*Jozef Strus Municipal Hospital, Department of Rheumatology and Osteoporosis, Poznan, Poland;* [2]*Poznan University of Medical Sciences, Department of Rheumatology, Rehabilitation and Internal Diseases, Poznan, Poland;* [3]*Poznan University of Medical Sciences, Doctoral School, Poznan, Poland*

Background: Aberrant immune response is hallmark of severe COVID-19, irrespectively from viral replication. Immunomodulatory therapies such as interleukin-6 (IL-6) receptor inhibitors were proven to be beneficial in reducing in-hospital mortality[1]. Yet, it remains unclear which patients can benefit most from such therapy.

Objectives: To identify predictors of clinical response to tocilizumab (TCZ) added to dexamethasone in patients hospitalized with severe COVID-19.

Methods: We prospectively assessed clinical and laboratory details of 120 patients hospitalized due to severe COVID-19 treated with TCZ (two doses of 8 mg/kg 24h apart) in our ward between 1st Feb 2021 and 31st Dec 2021. Severe COVID-19 was defined as SpO_2 <94% on room air with ground glass opacities in chest computed tomography (CT). Clinical response was defined as respiratory improvement on day 5 after TCZ infusion compared to day of treatment initiation, no further deterioration and survival. Decision of adding TCZ to dexamethasone as emergency therapy was made collectively by rheumatologists experienced in COVID-19 treatment. Laboratory and clinical parameters from hospital admission day and from TCZ institution day were analyzed. Statistical analysis was conducted with PQStat v.1.8.2 and predictors were identified in univariate logistic regression.

Results: We identified 86 (71.7%) clinical responders and 34 (28.3%) non-responders. 20 (58.8%) of the second group needed ICU admission, 18 (52.9%) died on ICU and 2 patients (5.9%) died on the ward. Responders were significantly younger (mean age 56.1 vs. 63.5 years, p=0.006), had lesser comorbidity burden (median Charleson Comorbidity Index 2 vs. 3, p=0.005), lower median lung involvement (50 vs. 70%, p<0.001), higher median baseline PaO2/FiO2 index (203 vs. 106, p<0.001) and less of them needed high-flow oxygen therapy on TCZ initiation day (12.7% vs 32.4%, p=0.025). Identified predictors of clinical response are shown in Table 1.

Conclusion: Administration of TCZ early in severe disease, with moderate IL-6 concentration and low organ damage indices is most beneficial in patients with severe COVID-19, especially in younger patients without respiratory and cardiac comorbidities.

OR – odds ratio, 95%CI – 95% confidence interval, LDH – lactate dehydrogenase, RR – respiratory rate, hs-TnI – high sensitivity troponin I, BUN – blood urea nitrogen, COPD – chronic obstructive pulmonary disease, $25(OH)D_3$ – 25-hydroxycholecalciferol, IL-6 – interleukin 6

POS1262 COVID-19 VACCINATION IN PATIENTS WITH RHEUMATIC DISEASES –RESULTS OF 2,134 CASES ANALYSIS

I. Gaydukova[1,2], V. Mazurov[1,2], O. Inamova[1,2], E. Gaydukova[3]. *[1]North-Western State Medical University n.a.Il Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E.Eichwald, St Petersburg, Russian Federation; [2]Clinical Rheumatological Hospital #25, Department of Rheumatology, St Petersburg, Russian Federation; [3]Sorbonne University, Department of Informatics, Paris, France*

Background: Decrease of COVID-19-associated morbidity and mortality among patients with rheumatic diseases (RD) is one of the main goals of current rheumatology. Vaccination may be one way to limit the incidence of COVID-19 in population of patients with RD.

Objectives: The goal of this work was to evaluate the results of vaccination in patients with RD against the new coronavirus infection COVID-19 bases on the data from real clinical practice.

Methods: We analyzed data from the St. Petersburg register of patients with RD till September 1, 2021 (totally 16,263 patients, vaccinated 2,134 patients). The data from the register were compared with population data of morbidity and mortality associated with new coronavirus infection in Russia (data from Russian Federations' Ministry of Health). Statistics was performed with SPSS2022.

Results: The rates of COVID-19 associated morbidity and mortality in rheumatological patients were comparable with morbidity and mortality in total Russian population (morbidity 26.2% and 28.5%, mortality 3.47% and 2.8%, respectively, p≥0.05).

Patients with RD demonstrate three times less frequency of vaccination against COVID-19 (13.2% of patients versus 31.8% in the population, respectively). Vaccination was prescribed by rheumatologists in 8.2% of cases, 75% of patients are self-vaccinated or were vaccinated by their general practicians.

An analysis of data from 2,134 rheumatological patients vaccinated in 2021 with Gam-COVID-Vac (Sputnik V™) showed a decrease in the incidence of new coronavirus infection from 26.2% to 0.25% in the absence of deaths among the vaccinated (mortality rate from COVID-19 in non-vaccinated patients was 2,8%, p<0.0000). From 2,134 vaccinated patients 42 had manifestation of COVID-19 in 6 months after vaccination, 39 persons of them demonstrated symptoms of COVID-19 during the first month after receiving the first dose of vaccine.

There were no serious adverse reactions to vaccination among vaccinated rheumatological patients; in 12 % of cases, slight pyrogenic post-vaccination reactions, arthralgias and myalgias were established. 11 patients showed a prolonged slight pyrogenic reaction, myalgias, arthralgias, hypercreatinophosphataemia, which resolved within 3-6 months. Relapses of the underlying RD after vaccination were recorded by patients in 12% of cases, but rheumatologists classified the presented clinical symptoms as the RD worsening in 1.57% of cases, another reports of RD relapse were classified as postvaccination reactions, as they were resolved in 1-2 weeks with the use of standard tactics recommended by Association of Russian Rheumatologists.

Conclusion: The analysis of the data from 2,134 rheumatological patients vaccinated Gam-COVID-Vac (Sputnik V™) demonstrated the efficacy and safety of vaccination against COVID-19 in middle-time perspective. No serious post-vaccination reactions or severe worsening of rheumatic diseases were recorded.

POS1263 PRE-EXPOSURE PROPHYLAXIS FOR SARS-COV-2 INFECTION WITH SUBCUTANEOUS CASIRIVIMAB/IMDEVIMAB IN PATIENTS WITH IMMUNE MEDIATED INFLAMMATORY DISEASES.

F. Fagni[1,2], K. Schmidt[1,2], D. Bohr[1,2], L. Valor[1,2], F. Hartmann[1,2], K. Tascilar[1,2], K. Manger[3], B. Manger[1,2], A. Kleyer[1,2], D. Simon[1,2], G. Schett[1,2], T. Harrer[1,2]. *[1]University Hospital Erlangen and Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [2]University Hospital Erlangen and Friedrich-Alexander University (FAU) Erlangen-Nürnberg, Deutsches Zentrum fuer Immuntherapie (DZI), Erlangen, Germany; [3]Rheumatology Practice Bamberg, Bamberg, Germany*

Background: Patients with immune-mediated inflammatory diseases (IMID), particularly if treated with B-cell depleting therapies, show reduced humoral responses to SARS-CoV-2 vaccines and increased risk of severe COVID-19 (1,2). Since pre-exposure prophylaxis (PrEP) with monoclonal antibodies against SARS-CoV-2 proved effective in preventing infection and COVID-19 (3) in the general population, PrEP could be used for passive immunization of vaccine-refractory patients with IMIDs.

Objectives: To evaluate the persistence of serum and salivary anti-SARS-CoV-2 IgG antibodies in vaccine-refractory patients with IMID after PrEP with casirivimab/imdevimab. Secondary outcomes were safety, SARS-CoV-2 infection, and adverse COVID-19 outcomes.

Methods: We performed a longitudinal analysis on anti-SARS-CoV-2 IgG titers in IMID patients who received a PrEP with 1200 mg of subcutaneous casirivimab/imdevimab due to high infection risk, as they had not developed an adequate humoral response at least 21 days after three COVID-19 vaccinations (Table 1). Serum and salivary anti-SARS-CoV-2 Spike IgG were quantified by ELISA (EUROIMMUN, Lübeck, Germany) before PrEP and after 1, 14, and 30 days. IgG levels are given as antibody ratios by dividing the optical density of the sample by that of the calibrator. A cutoff of ≥1.1 was considered positive. Safety as well as polymerase chain reaction (PCR)-confirmed SARS-CoV-2 infection and adverse COVID-19 outcomes (hospitalization, mechanical ventilation, death) after PrEP were recorded.

Table 1. Baseline characteristics.

N		26
Age, mean (SD)		54 (14)
Sex, n (%)	Female	15 (57.7)
	Male	39 (42.3)
Diagnosis, n (%)	ANCA-associated vasculitis	10 (38.5)
	Rheumatoid arthritis	6 (23.1)
	Immunoglobulin deficiency	4 (15.4)
	Systemic sclerosis	2 (7.7)
	Psoriatic arthritis	1 (3.8)
	Systemic Lupus Erythematosus	1 (3.8)
	Non-infectious Uveitis	1 (3.8)
	Multiple sclerosis	1 (3.8)
	IgG4-related disease	1 (3.8)
	Autoinflammatory syndrome	1 (3.8)
CD20-depletion	Rituximab, n (%)	22 (84.6)
Other therapies, n (%)	Methotrexate	6 (23.1)
	Immunoglobulins	4 (15.4)
	Mycophenolate	1 (3.8)
	Infliximab	1 (3.8)
CD19+ lymphocytes/mm^3, median (IQR)		0 (0-9)
Serum total IgG, median (IQR)		894 (745-987)

SD, standard deviation; IQR, interquartile range; ANCA, anti-neutrophil cytoplasmic antibodies.

Results: We obtained 92 serum and 75 saliva samples from 26 participants at four consecutive timepoints (Figure 1). Anti-SARS-CoV-2 IgG titers were observed in serum and saliva samples of all participants from day 1 and throughout 30 days after PrEP independently of diagnosis, therapy, total IgG, and peripheral CD19+ B-cells. Serum IgG increased rapidly at day 1 and plateaued from day 14 to 30 (Figure 1A), reaching similar levels as seen in healthy subjects after full vaccination (1), while saliva IgG increased steadily from administration up to day 14 and plateaued at day 30 (Figure 1B). No side effects were reported. Five patients (19.2%) had a close contact with a SARS-CoV-2-infected person, after which all but one remained asymptomatic and with a negative PCR test. The patient who tested positive developed mild COVID-19 with fever and cough.

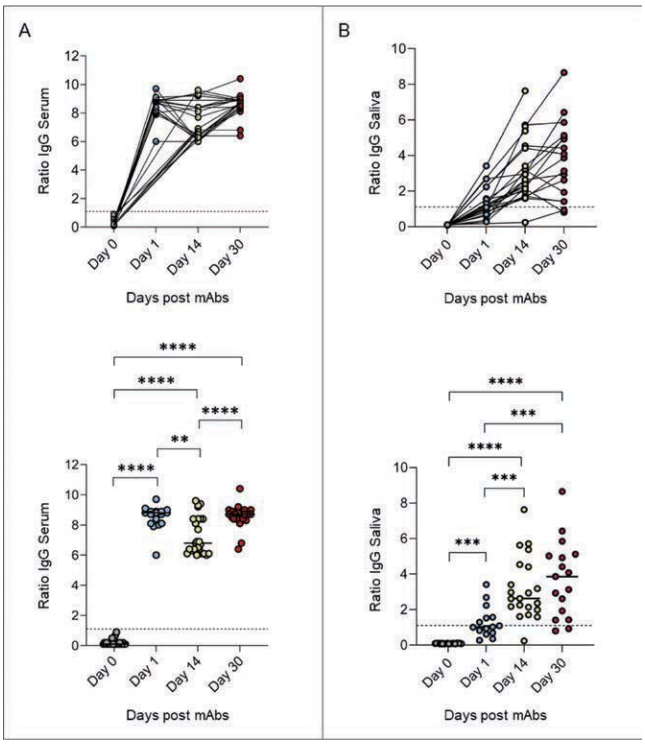

Figure 1. Temporal pattern and distribution of serum (A) and salivary (B) anti-SARS-CoV-2 IgG levels. Results from individual participants are represented as line (top) and scatter plots (bottom). Horizontal lines represent median values, the dotted horizontal line represents the positivity cutoff of 1.1. ** p =0.0082; *** p <0.001; **** p <0.0001. mAbs: monoclonal antibodies.

Conclusion: SARS-CoV-2 PrEP induces stable serum and salivary antibody levels in IMID patients who did not respond to COVID-19 vaccination, regardless of pre-existing clinical and serological features. In IMID, PrEP with casirivimab/imdevimab is safe and has the potential to prevent infection and severe COVID-19.

POS1264 LONGITUDINAL FOLLOW-UP OF HUMORAL RESPONSE AGAINST SARS-COV-2 AND VIRAL PERSISTENCE IN 96 DMARDS-TREATED PATIENTS WITH PREVIOUS COVID-19 INFECTION

O. Fogel[1], M. Beretta[2], C. Planchais[2], T. Bruneau[3], P. Goncalves[4], J. Avouac[1], F. Berenbaum[5], J. Sellam[5], C. Deprouw[5], B. Fautrel[6], J. Morel[7], B. Parfait[8], J. DI Santo[4], S. Behillil[9], S. Van Der Werf[9], H. Péré[3], H. Mouquet[2], C. Miceli Richard[1]. *[1]Cochin Hospital, Rheumatology, Paris, France; [2]Pasteur Institute & Inserm U1222, Laboratory of Humoral Immunology, Paris, France; [3]Hopital Européen Georges Pompidou, Microbiology, Paris, France; [4]Pasteur Institute & Inserm U1223, Innate Immunity, Paris, France; [5]Saint Antoine Hospital, Rheumatology, Paris, France; [6]Pitie-Salpétrière Hospital, Rheumatology, Paris, France; [7]CHU Lapeyronie, Immunorheumatology, Montpellier, France; [8]Cochin Hospital, Biological Ressource, Paris, France; [9]Pasteur Institute & UMR 2569 CNRS, Unité de Génétique Moléculaire des Virus à ARN, Paris, France*

Background: Although it prevents severe forms of the disease, vaccination does not completely protect against the occurrence of COVID19 disease. If, DMARDs used have been associated with variable humoral response to SARS-CoV-2 vaccination, the impact of their use after SARS-CoV-2 natural infection have been poorly studied.

Objectives: To characterize humoral response after SARS-CoV-2 infection and viral persistence in the nasopharyngeal sphere (NP), stools and blood of patients with rheumatic disease under DMARDs, and compared to healthy controls.

Methods: Prospective monocentric longitudinal study including patients with rheumatoid arthritis or spondyloarthritis under DMARDs and with a confirmed SARS-CoV-2 infection (positive NP PCR and/or positive serology and/or pathognomonic thoracic tomography (CT)) during the first or second wave of the COVID pandemic. Patients were followed up until one year after infection and humoral response was assessed before vaccination. Serum IgG and IgA antibodies against spike (S) and nucleocapsid (N) proteins were measured at every visit. Viral persistence was assessed at the early visit in the NP and stools using conventional RT-PCR and in the blood using a high sensitive technique (droplet digital PCR).

Results: Between June 2020 and July 2021, we include 96 patients (50 SpA and 46 RA) with a mean age of 53 +/- 14 years and 20 healthy controls (mean age 49 ± 16 years) corresponding to relatives of patients (spouses, children) living together and infected at the same time. The immune responses were analyzed according to 6 treatment groups: methotrexate (MTX)/salazopyrine (SLZ) monotherapy (n=17/2); anti-TNF monotherapy (n=24), anti-TNF + MTX (n=23); rituximab (RTX) (n=11); anti-IL17 or -23 (n=8); others (n=11). Visits were made at 1 month (29 ±13 days; n=18), 3 months (110 ±23 days; n=67), 6 months (231 ±35 days; n=48) and 12 months (368 ± 19 days; n=19) after infection. The anti-S and anti-N IgG Ab titers were not significantly different in the 6 treatment groups and the control population at 3 months. A significant decrease in anti-S IgA Ab titers was noted in the group treated with RTX (p=0.007) and with molecules targeting the IL17/23 pathway (p=0.007). A similar but non-significant trend was observed in these same treatment groups for anti-N IgA Ab (p=0.07). The titers of anti-SARS-CoV-2 antibodies at M3, was not associated with a severe COVID disease. Detection of SARS-Cov-2 RNA in stools and serum was negative for all samples taken at 1 month or 3 months. 4 patients (2 RA treated with abatacept/RTX and 2 SpA treated with anti-TNF/secukinumab) had a positive RT-PCR NP with low to very low viral load at the 1-month visit (mean Ct 36). None of these 4 patients had had a severe form of COVID19 infection.

Conclusion: DMARDs - treated patients with previous proven COVID-19 did not seem to alter IgG Ab response but RTX and anti-IL17/-IL-23 might alter IgA humoral response. This lower immune response was not associated with a more severe disease. In these patients, new infection may not be considered as a full boost for the immune system. DMARDs did not induce viral persistence in the serum, the NP or in the stool.

POS1265 DISTURBED CELLULAR IMMUNITY FOLLOWING MRNA VACCINATION AGAINST COVID-19 IN PATIENTS WITH B-CELL DEPLETING THERAPY

C. Sallegger[1], I. Hodl[1], B. Dreo[1], V. L. Ihm[1], J. Thiel[1], M. Stradner[1], J. Fessler[2], C. Consortium[3]. *[1]Medical University of Graz, Division of Rheumatology and Immunology, Graz, Austria; [2]Medical University of Graz, Division of Immunology and Pathophysiology, Graz, Austria; [3]Medical University of Graz, Departments of Rheumatology, Hematology, Neurology and Hygiene, Graz, Austria*

Background: Immunocompromised patients are considered high-risk and prioritized for vaccination against COVID-19 (1). Furthermore, vaccination-induced CD4 and CD8 T-cell responses have been suggested to have a protective role in COVID-19 (2). If T-cell responses are diminished after vaccination in immunocompromised individuals is not known to date.

Objectives: To investigate cellular immunity following mRNA vaccination against COVID-19 in healthy individuals and patients undergoing B-cell depletion therapy.

Methods: In this interim analysis of the CoVVac study (NCT04858607), we analyzed T-cell responses in autoimmune patients treated with B-cell depleting therapy (BD, n=41) and age-matched healthy controls (HCs, n=50) 3-4 weeks after the second dose of mRNA vaccination against COVID-19. Therefore, we isolated PBMCs and stimulated them with a peptide pool covering the spike protein *in vitro*. Reactive CD4 and CD8 T-cells were determined by staining for IFNg, TNFa, IL-2 and GzmB by flow cytometry. Anti-SARS-CoV-2 antibody assays targeting the receptor-binding domain (RBD) or trimeric S protein (TSP) were performed to elucidate concomitant B-cell responses.

Results: We observed significant alterations in anti-SARS-CoV-2 antibody responses in our cohort, the frequency of IFNg+ and IL-2+ CD4 and CD8 T-cells was similar in BD patients and controls. On the other hand, TNFa+ CD4 T-cells were significantly enriched in healthy controls versus BD patients (p=0.017) and correlated significantly with antibody titres (p=0.003). Similarly, GzmB+ CD8 T-cells were significantly diminished in our patient cohort (p<0.001) and also showed a significant correlation with antibody titres (p<0.001). Overall, the frequency of GzmB+ CD8 T-cells correlated very well with reactivity of T-cell subsets for other cytokines. This effect, however, is lost in the BD cohort. No difference was observed in the frequency of TNFa+ CD8 T-cells between the groups.

Only 21 (42%) healthy individuals and 14 (34%) patients showed reactive T-cells for all the cytokines tested. This observation is mainly explained by a lack of cytokine production of CD8 T-cells in 26 (52%) HCs and 27 (66%) BD patients. In turn, 22 (44%) HCs and 17 (42%) patients didn't show any IL-2 producing CD8 cells. Of note, only 2 (4%) of HCs showed no GzmB+ CD8 T-cells whereas the number increased to 15 (37%) of BD individuals (p<0.001). In contrast, 42 (84%)

HCs as well as 32 (78%) of patients showed production of all IFNg, TNFa and IL-2 in CD4 T-cells.

Conclusion: Our data suggest that most patients with B-cell depleting therapy are able to mount T-cell responses similar to those of healthy individuals while a minority of these patients did not show complete immunity against SARS CoV-2. Further analyses are needed to better understand a possible link of B-cell depletion therapy and CD8 T-cell responses.

POS1266 MULTICENTER RETROSPECTIVE STUDY EVALUATING THE SAFETY OF ANTI-SARS-COV-2 VACCINE IN A COHORT OF PATIENTS WITH SYSTEMIC VASCULITIS

E. Simoncelli[1], S. Colafrancesco[1], F. R. Spinelli[1], A. Gattamelata[1], F. Giardina[1], S. Truglia[1], C. Garufi[1], R. Izzo[1], L. Cantarini[2], B. Frediani[2], E. Conticini[2], S. Grazzini[2], R. Priori[1], F. Conti[1]. *[1]Sapienza University of Rome, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rheumatology Unit, Rome, Italy; [2]University of Siena, Department of Medicine, Surgery and Neurosciences, Rhematology Unit, Siena, Italy*

Background: Vaccinations against SARS-CoV-2 represent a fundamental tool in controlling the pandemic. To date, data on the safety of anti-SARS-CoV-2 vaccines in patients with rare rheumatic diseases, such as systemic vasculitis, are limited.

Objectives: In this study we aimed at evaluating the safety of anti-SARS-CoV-2 vaccines in a multicentric cohort of patients with systemic vasculitis.

Methods: Patients with systemic vasculitis from two Rheumatology centres who had received anti-SARS-CoV-2 vaccine were retrospectively examined. The primary outcome was to evaluate, in this multi-centric cohort, the occurence of a disease flare after the administration of the vaccine, defined as development of clinical manifestations related to vasculitis with a concomitant increase in serum inflammatory markers. As a secondary outcome we aimed at evaluating, in a monocentric cohort of patients with vasculitis, the occurrence of adverse events (AEs) following vaccine administration compared to healthy controls (HC).

Results: We examined 111 patients with systemic vasculitis (n=69 female, n=42 male), with a mean age of 64.3 (± 13) years. Sixty had ANCA-associated vasculitis (AAV), fourty-two had Giant-Cell Arterities (GCA), five had Periarteritis Nodosa, four had Takayasu's arteritis. One-hundred and five patients received a mRNA vaccine and six a viral vector one. A disease flare occurred in only 2 patients (1.8%) after the first dose of a mRNA vaccine: both had AAV (microscopic poliangioitis) and developed a pulmunary disease flare (respiratory failure requiring hospitalization and treatment with high-dose glucocorticoids). Of note, one of these patients had multiple previous comorbidities, including a severe COPD. Multivaried analysis, adjusted for age and sex, performed in a single monocentric cohort of patients with systemic vasculitis [n=60 (39 AAV, 21 GCA), 37 female, 23 male, mean age 71 (± 12.5) years] demonstrated a statistically significant higher frequency of AEs in vasculitis patients compared to HC (p=0.015) after the first dose of vaccination. No significant differences in the frequency of AEs in vasculitis patients compared to HC after the second dose were detected. All the AEs were mild in both groups (malaise was the most frequently reported); no serious AEs were reported.

Conclusion: Our data show a very low incidence of disease flares after the administration of anti-SARS-CoV-2 vaccines in patients with systemic vasculitis. Patients with systemic vasculitis seem more prone to develop mild AEs after the first dose of the vaccine. Taken together, this data suggest a good risk profile for anti-SARS-CoV-2 vaccine in patients with systemic vasculitis.

Background: Patients with autoimmune systemic diseases (ASDs) can be counted among frail populations as regards the predisposition to COVID-19 due to the frequent visceral organ involvement and comorbidities, as well as the ongoing immunomodulating treatments.
Objectives: Our long-term multicenter telephone survey prospectively investigated the prevalence, prognostic factors, and outcomes of COVID-19 in Italian ASD patients during the first 3 pandemic waves.
Methods: A large series of 3,918 ASD patients (815 M, 3103 F; mean age 59±12SD years) was consecutively recruited at the 36 referral centers of COVID-19 & ASD Italian Study Group. In particular, ASD series encompassed the following conditions: rheumatoid arthritis (n: 981), psoriatic arthritis (n: 471), ankylosing spondylitis (n: 159), systemic sclerosis (n: 1,738), systemic lupus (172), systemic vasculitis (n: 219), and a miscellany of other ASDs (n: 178). The development of COVID-19 was recorded by means of telephone survey using standardized symptom-assessment questionnaire (1).
Results: A significantly increased prevalence of COVID-19 (8.37% vs 6.49%; p<0.0001) was observed in our ASD patients, while the cumulative death rate revealed statistically comparable to the Italian general population (3.65% vs 2.95%; p: ns). In particular, among the 328 ASD patients complicated by COVID-19, 57 (17%) needed hospitalization, while mild-moderate manifestations were observed in the large majority of individuals (83%). In addition, 12/57 hospitalized patients died due to severe interstitial pneumonia and/or cardiovascular manifestations.
Interestingly, a significantly higher COVID-19-related death rate was observed in systemic sclerosis patients compared to the Italian general population (6.29% vs 2.95%; p=0.018). Other adverse prognostic factors to develop COVID-19 were the patients' older age, male gender, pre-existing ASD-related interstitial lung involvement, and chronic steroid treatment. Conversely, patients treated with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) showed a significantly lower prevalence of COVID-19 compared to those without (3.58% vs 46.99%; p=0.000), as well as the chronic administration of low dose aspirin in a subgroup of SSc patients (with 5.57% vs without 27.84%; p=0.000).
Conclusion: The cumulative impact of COVID-19 on ASD patients after the first 3 pandemic waves revealed less severe than that observed during the first phase of pandemic (1), especially with regards to the death rate that was comparable to the Italian general population in spite of the increased prevalence of complicating COVID-19 in the same ASD series.
Ongoing long-term treatments, mainly csDMARDs, might usefully contribute to generally positive outcomes of in this frail patients' population.
Of note, a significantly increased COVID-19-related mortality was recorded in only SSc patients' subgroup, possibly favored by pre-existing lung fibrosis. Among different ASD, SSc deserves special attention, since it shares the main pathological alterations with COVID-19, namely the interstitial lung involvement and the endothelial injury responsible for diffuse microangiopathy.
Besides SSc, the patients' subgroups characterized by older age, chronic steroid treatment, pre-existing interstitial lung disease, and/or impaired COVID-19 vaccine response (1-3), may deserve well-designed prevention and management strategies.

POS1268 PHASE II TRIAL OF ENPATORAN IN PATIENTS HOSPITALIZED WITH COVID-19 PNEUMONIA

J. E. Mckinnon[1], J. Santiaguel[2], C. Murta[3], D. Yu[4], M. Khursheed[5], F. Moreau[6], L. Klopp-Schulze[7], J. Shaw[8], S. Roy[9], A. Kao[10]. *[1]Henry Ford Hospital, Department of Medicine, Detroit, United States of America; [2]Quirino Memorial Medical Center, Internal Medicine, Quezon City, Philippines; [3]Santa Casa de Misericórdia, Ambulatório de Pesquisa Clínica, Belo Horizonte, Brazil; [4]EMD Serono Research & Development Institute, Inc., an affiliate of Merck KGaA, Global Clinical Development, Billerica, United States of America; [5]Merck Serono Ltd., an affiliate of Merck KGaA, Global Patient Safety, Feltham, United Kingdom; [6]EMD Serono Research & Development Institute, Inc., an affiliate of Merck KGaA, Global Biostatistics, Billerica, United States of America; [7]Merck Healthcare KGaA, Translational Medicine, Darmstadt, Germany; [8]EMD Serono, an affiliate of Merck KGaA, Translational Medicine, Billerica, United States of America; [9]Ares Trading SA, an affiliate of Merck KGaA, Global Clinical Development, Eysins, Switzerland; [10]EMD Serono Research & Development Institute, Inc., an affiliate of Merck KGaA, TIP Immunology, Billerica, United States of America*

Background: Enpatoran is a selective and potent dual toll-like receptor (TLR) 7/8 inhibitor in development for the treatment of cutaneous and systemic lupus erythematosus (CLE/SLE). Enpatoran inhibits TLR7/8 activation *in vitro* and suppresses disease activity in lupus mouse models.[1] Enpatoran was well tolerated and had linear pharmacokinetic (PK) parameters in healthy volunteers.[2] As TLR7/8 mediate immune responses to single-stranded RNA viruses, including SARS-CoV-2, it was postulated that enpatoran may prevent hyperinflammation and cytokine storm in COVID-19.
Objectives: In response to the COVID-19 pandemic, we conducted an exploratory Phase II trial to assess safety and determine whether enpatoran prevents clinical deterioration in patients (pts) hospitalized with COVID-19 pneumonia. PK and pharmacodynamics (PD) of enpatoran were also evaluated.
Methods: ANEMONE was a randomized, double-blind, placebo (PBO)-controlled study conducted in Brazil, the Philippines, and the USA (NCT04448756). Pts aged 18–75 years, hospitalized with COVID-19 pneumonia (WHO 9-point scale score =4) but not mechanically ventilated, with SpO_2 <94% and PaO_2/FiO_2 ≥150 (FiO_2 maximum 0.4) were eligible. Those with a history of uncontrolled illness, active/unstable cardiovascular disease and SARS-CoV-2 vaccination were excluded. Pts received PBO or enpatoran (50 or 100 mg twice daily [BID]) for 14 days, with monitoring to Day 28 and safety follow-up to Day 60. Primary outcomes were safety and time to recovery (WHO 9-point scale ≤3). Clinical deterioration (time to clinical status >4, WHO 9-point scale) was a secondary outcome. Exploratory endpoints were enpatoran and biomarker concentrations (cytokines, C-reactive protein [CRP], D-dimer and interferon gene signature [IFN-GS] scores) assessed over time.
Results: 149 pts received either PBO (n=49), or enpatoran 50 mg (n=54) or 100 mg (n=46) BID; 88% completed treatment and 86% received concomitant steroids. Median age was 50 years (77% <60 years old), 66% were male, and 50% had ≥1 comorbidity (40% hypertension, 24% diabetes). Overall, 59% pts reported a treatment-emergent adverse event (TEAE) with three non-treatment-related deaths; 11% reported a treatment-related TEAE. The proportion of pts in the enpatoran group reporting serious TEAEs was low (50 mg BID 9%; 100 mg BID 2%) vs PBO (18%). Gastrointestinal disorders were most common (PBO 8%; 50 mg BID 28%; 100 mg BID 9%). The primary outcome of time to recovery with enpatoran vs PBO was not met; medians were 3.4–3.9 days. A positive signal in time to clinical deterioration from Day 1 through Day 28 was observed; hazard ratios [95% CI] for enpatoran vs PBO were 0.39 [0.13, 1.15] (50 mg BID) and 0.30 [0.08, 1.08] (100 mg BID). Mean enpatoran exposure was dose-proportional, and PK properties were within expectations. The median (quartile [Q]1– Q3) interleukin 6 (IL-6), CRP and D-dimer baseline concentration across the groups were 5.7 (4.0–13.5) pg/mL, 30.04 (11.40–98.02) and 0.62 (0.39–1.01) mg/L, respectively. Baseline IFN-GS scores were similar across groups.
Conclusion: The ANEMONE trial was the first to evaluate the safety and efficacy of a TLR7/8 inhibitor in an infectious disease for preventing cytokine storm. Enpatoran up to 100 mg BID for 14 days was well tolerated by patients acutely ill with COVID-19 pneumonia. Time to recovery was not improved with enpatoran, perhaps due to the younger age of patients who had fewer comorbidities compared to those in similar COVID-19 trials. However, there was less likelihood for clinical deterioration with enpatoran than placebo. This trial provides important safety, tolerability, PK and PD data supporting continued development of enpatoran in SLE and CLE (NCT04647708, NCT05162586).

POS1269 CLINICAL COURSE AND OUTCOMES OF COVID-19 INFECTION IN PATIENTS WITH SJOGREN'S SYNDROME TREATED WITH RITUXIMAB.

A. Torgashina[1], E. Sokol[1], B. Chalcev[1], J. Khvan[1], O. Golovina[2], S. Glukhova[3]. *[1]V.A. Nasonova Research Institute of Rheumatology, Rare Rheumatic Didease and Sjogren`s Syndrome, Moscow, Russian Federation; [2]Heart and Joint Center, Rheumatology, Moscow, Russian Federation; [3]V.A. Nasonova Research Institute of Rheumatology, Educational-Methodical Department, Moscow, Russian Federation*

Background: Data from multiple rheumatological cohorts have shown that treatment with rituximab (RTM) is associated with higher COVID-19 morbidity and mortality. Information about the course of COVID-19 in patients (pts) with Sjogren's syndrome (SjS) is still lacking.
Objectives: To compare clinical course of COVID-19 in pts with SjS treated with anti-CD20 monoclonal antibody (RTM) and treated with synthetic disease-modifying antirheumatic drugs and low doses of glucocorticoids.
Methods: Single center observational study. Pts with SjS were screened for SARS-CoV-2 infection anamnesis via telephone interview. Diagnosis of SjS was based on ECR/EULAR 2016 criteria. COVID-19 diagnosis was based on positive PCR test and typical clinical features (CT signs, fever and anosmia). RTM was administered as two infusions of 1000 mg each 2 weeks apart, and then 500 mg every 6 months.
Results: 387 pts with SjS were interviewed, 142 of them with confirmed SARS-CoV-2 were included in the study and divided into 2 groups. The first group (gr) consisted of 86 pts (79 women and 7 men) receiving RTM (gr R), median age was 56 years (33-66,5 years), and median rituximab treatment duration was 36 months (12-42 months). Pts in the control gr (gr C), 56 pts did not receive RTM (55 women and 1 man), their median age was 50 years (35-69 years). Median time from last RTM administration to COVID-19 symptoms onset was 4 months (2-6 months). Ten pts had concomitant RA, 4 pts - SLE, 5 pts - Systemic sclerosis. Fifteen pts had MALT-lymphoma anamnesis. Additionally, 15 pts (10.5%) had pulmonary involvement secondary to rheumatic disease. In total 37 pts had chronic ischemic heart disease and/or severe arterial hypertension, diabetes mellitus type 2.
In gr R 31 pts (36%), and in gr C 13 (23%) required hospitalization due to marked shortness of breath and long febrile period (p=0,1). Anti-IL6 treatment or/and Jak inhibitors were prescribed to 17 of 31 pts (54.8%) in gr R and to 5 of 13 (38%) in gr C (p=0,1). The risk of hospitalization was slightly higher in pts with comorbidity (p=0.06) and with a history of lymphoma (p=0.056) and didn't correlate with the following parameters: age, the duration of RTM therapy, lung damage. A high rate of hospitalization correlated with a shorter period between the administration of the RTM and the development of COVID-19 (R=0,387, Spearman`s Rank Correlation). Anti-SARS-CoV-2 IgG were measured in 66 pts, 47 (71%) of them were positive. Positive Anti-SARS-CoV-2 IgG were significantly more often detected in gr C (84% vs. 57,6%). No correlation was found between the formation of antibodies and the duration of RTM therapy or the time from the last RTM administration.
Conclusion: According to our data anti-CD20 therapy doesn't predispose SjS pts to severe course of COVID-19. Lymphoma anamnesis, cardiovascular diseases and diabetes have greater impact on COVID-19 severity. Obviously, anti-CD20 therapy negatively affected the formation of specific anti-SARS-CoV-2 humoral immunity.

POS1270 COVID19 VACCINATION IN PATIENTS WITH AXIAL AND PERIPHERAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS: ADVERSE EVENTS AND IMPACT ON DISEASE ACTIVITY

V. Martire[1,2], C. Airoldi[2], M. Benegas[2], D. Vila[2], M. J. Gamba[2], G. P. Pendon[2], R. Perez Alamino[2], R. Nieto[2], M. Cosatti[2], P. Gonzalez[2], F. Sommerfleck[2], P. Giorgis[2], E. I. R. Saturansky[2], A. Ezquer[2], W. Patiño Grageda[2], L. Casalla[2], J. Flore Trejo[2], P. Farfan[2], N. Capozzi[2], M. S. Gálvez Elkin[2]on behalf of GESAR EspAax ARe. *[1]San Roque Hospital, Rheumatology, La Plata, Argentina; [2]Argentinian Spondyloarthritis Study Group-GESAR EspAax-ARe, Rheumatology, La Plata, Argentina*

Background: There is scarce evidence on the rate of adverse events and the consequences on disease activity after vaccination against covid19
Objectives: To evaluate adverse events to vaccination and disease flares after vaccination in patients with axial spondyloarthritis (axSpA), peripheral spondyloarthritis (pSpA) and psoriatic arthritis (PsA) and to evaluate factors associated with adverse event.
Methods: Cross-sectional, observational, descriptive study. Consecutive patients with diagnosis of ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA) according to ASAS 2009 criteria; pSpA according to ASAS 2011 criteria and PsA according to CASPAR criteria were included. Demographic data, disease clinimetry, treatments, vaccination received and post-vaccination adverse events were recorded. We evaluated, according to medical criteria, whether the patient presented a flare disease after vaccination and whether it was mild, moderate or severe. We also evaluated the factors associated with the presence of at least one mild adverse event. Statistical analysis: descriptive statistics were performed, qualitative variables were expressed as frequency and percentage (%), numerical variables as mean and standard deviation (SD) or median and percentile25-75. Binary logistic regression was performed using the presence of at least one mild adverse event to vaccination as the dependent variable.
Results: 210 patients were included with a mean age of 45 (SD 15) years. The diagnoses were: AS 50 (23.8%), nr-axSpA 10 (4.8), pSpA 9 (4.3%), PsA 141 (67%) and time of disease evolution in months 109 (SD 96). Regarding comorbidities, the following frequencies were reported: arterial hypertension 60 (30%), diabetes mellitus 25 (12%), heart failure 4 (2%), asthma/EPOC 15 (7%), inflammatory bowel disease 2 (1%), acute anterior uveitis 20 (9.5%), psoriasis 128 (61%). Sixteen percent (n=33) of the patients had SARS-CoV-2 infection prior to vaccination. Regarding treatments, those used were: antiTNF 88 (42%), Tofacitinib 6 (2.9%), Ustekinumab 2 (1%), Secukinumab 35 (17%), Ixekizumab 2 (1%), methotrexate 98 (47%), leflunomide 7 (3. 3), sulfasalazine 7 (3.3), apremilast 1 (0.5%), continuous NSAIDs 26 (12.4%) and NSAIDs on demand 103 (49%). Vaccines received were: Sputnik V 109 (51.9%), Oxford Vaccine, AstraZeneca 63 (30%), Janssen 1 (0.5%), BioNTech Vaccine, Pfizer 1 (0.5%), Sinopharm 33 (15.7%), Moderna 0%, Novavax 0% and others; 3 (1.4%). Thirty-eight percent (n=80) of patients reported having mild post-vaccination symptoms, of which 3.75% did not resolve, 41% resolved with medication and 39% resolved ad integrum without medication. The presence of mild adverse event to the vaccine was associated with lower use of methotrexate (31% vs 56 %, p<0.001), and lower age (54 (SD 14) vs 47 (SD 12), p<0.001), and lower BMI (25 (24-30.5) vs 28 (25-31), p<0.001); while no association was found with sex, diagnosis, comorbidities, treatments, desease activity or vaccines. In the logistic regression analysis all the variables remained independently associated with a lower probability of presenting a mild adverse event: methotrexate: OR: 0.30, 95%CI 0.15-0.58, p<0.001, age: OR: 0.97, 95%CI 0.95-0.99, p: 0.03, BMI: OR: 0.92, 95%CI 0.95-0.99, p: 0.02. Sixty-one percent (n=129) of patients received the 2nd dose of vaccination, which 27% (n=35) presented mild adverse event and only 1 (0.8%) patient suffered post vaccination disease flare.
Conclusion: Vaccination against COVID19 appears to be safe in this population, with only mild adverse events and low frequency of flare disease. Mild adverse events were associated with less use of methotrexate, younger age and lower BMI.

POS1271 THE COURSE AND OUTCOMES OF COVID-19 IN PATIENTS WITH TAKAYASU ARTERITIS: CASE SERIES OF 15 PATIENTS FROM A TERTIARY SINGLE CENTER

G. Sevik[1], S. Kutluğ Ağaçkıran[1], K. Abacar[1], A. Aliyeva[1], H. Direskeneli[1], F. Alibaz-Oner[1]. *[1]Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: The Coronavirus disease 2019 (COVID-19) has affected more than two hundred million individuals and many risk factors for increased mortality and morbidity in COVID-19 have defined. There are many studies evaluating the effect of immunosuppressants used in inflammatory rheumatic diseases in the course of COVID-19. (1,2) However, fewer data are available on the course of COVID-19 in patients with Takayasu arteritis (TAK).
Objectives: In this study, we aimed to evaluate the characteristics and outcomes of TAK patients with COVID-19.
Methods: A phone survey was conducted among TAK patients that are followed up in our clinic between February 2021 and March 2021. All patients were asked whether they were diagnosed as COVID-19 during the pandemic. The patients who had a history of confirmed COVID-19 were asked about the symptoms, hospitalization status and the treatment received for COVID-19. Information about their chronic diseases were obtained from the patient files.
Results: Among 118 TAK patients, 15 had COVID-19 infection during the first year of pandemic, 13 of them were female and mean age was 42,5 ± 12,0 years. None of the patients had been vaccinated before the diagnosis of COVID-19. Nine of the patients were taking prednisone therapy and 3 of them were taking moderate to high doses of glucocorticoids during the infection period. Twelve patients were taking conventionally synthetic disease-modifying antirheumatic drugs (csDMARDs), 7 patients were taking biological disease-modifying antirheumatic drugs (bDMARDs), and 5 patients were taking a combination of csDMARD and bDMARD therapy when they were diagnosed with COVID-19. Two patients were hospitalized; one of them required nasal oxygen support and discharged after 5 days. The other patient was 61 years old and had multipl comorbidities and had admitted to intensive care unit for 5 days. One patient who had a mild COVID-19 disease had pulmonary thromboembolism 2 weeks after the infection and his symptoms resolved after starting anticoagulation therapy. All of the patients fully recovered and had no mortality related to COVID-19.

Conclusion: To our knowledge, this is the largest cohort reporting the course of COVID-19 in TAK patients. Our data suggest that there is no increased risk for morbidity or mortality related to COVID-19 in TAK patients.

Background: SARS-COV-2 infection, which has become a pandemic worldwide, has led to various results, from mild clinical findings to severe respiratory failure. Multisystem inflammatory syndrome (MIS-C) in children is a rare but severe condition characterized by fever, inflammation, and multi-organ failure, caused by an overreaction of the immune system after SARS-CoV-2 infection.

Objectives: This study aims to report the clinical and laboratory findings, diagnostic methods, treatment regimens, and short-term follow-up results of patients diagnosed with MIS-C.

Methods: This is a retrospective observational study from a tertiary pediatric rheumatology center including patients (aged 1 month to 21 years) diagnosed with MIS-C between April 2020-December 2021. Demographic, clinical, laboratory results, and follow-up data were collected through the electronic patient record system and analyzed.

Results: Of the 110 patients included in the study, 67.2% (n=74) were male. Fever was a common finding in all. Macrophage activation syndrome (MAS) was dominant in 28.2% (n=31), while Kawasaki-like disease was observed in 40% of the patients. Gastrointestinal symptoms were found in 64.5% of the cases, rash in 40%, conjunctivitis in 35.5%, lymphadenopathy in 30%, hypotension in 27.3%, cardiac decompensation in 16.4%, bradycardia in 8.2%, neurological findings in 4.5%, and/or coronary artery pathology in 3.6% respectively. Included in the study, 63.6% had lymphopenia, 48.2% had hypoalbuminemia, and 39.1% had hyponatremia. Thirty-eight patients (34.5%) were followed up in the intensive care unit; 19 of them had MAS. Concomitant chronic disease was present in 21.8% of the patients. The mean hospital stay was 12±7.8 days. Hypotension and MAS were the most common indications for admission to the intensive care unit. Intravenous immunoglobulin treatment was applied to 87.2% of the cases, the steroid was given to 70.9%, and anakinra treatment was given to 27.3%, respectively. In the outpatient follow-up, it was determined that the coronary abnormalities had regressed entirely. While 97.3% of the cases recovered without sequelae, three died. Three patients who died had the comorbid disease. While there was no significant difference in terms of Kawasaki-like disease and gender in those followed up in the intensive care unit (p=0.25, p=0.81), D-dimer was higher, and the mean age was greater (p=0.08, p=0.02). No statistical correlation was found between those with Kawasaki-like disease regarding age and gender (p=0.058 p=0.068).

Conclusion: Multisystem inflammatory syndrome in children may lead to severe cardiac findings and intensive care requirements at admission and hospital follow-up. The majority of MIS-C-related findings resolve completely until discharge or in short-term follow-up. Although the pathogenesis and treatment plan of the disease has been largely clarified, follow-up studies are needed in terms of long-term prognosis and relapse probabilities.

POS1273 EVALUATION OF THE SAFETY PROFILE OF COVID-19 VACCINES IN CHILD PATIENTS USING BIOLOGICAL THERAPY

B. Sözeri[1], R. E. Yigit[1]. *[1]University of Health Sciences, Umraniye Education and Research Hospital, Pediatric Rheumatology, Istanbul, Turkey*

Background: Coronavirus vaccines have been widely applied all over the world after the coronavirus pandemic. There are inactivated vaccines and mRNA vaccines in our country. There is no clear guideline for the vaccination programs of patients receiving immunosuppressive therapy, especially childhood.

Objectives: For this reason, we wanted to evaluate the frequency of side effects developed after covid-19 vaccine in pediatric patients diagnosed with rheumatic disease using biological therapy and nonbiologic disease modifiying drugs

Methods: A total of 226 patients over the age of 12, who were followed up in the pediatric rheumatology clinic of the University of Health Sciences, Umraniye Training and Research Hospital, using biological therapy and were vaccinated against Covid-19, were included in the study. The standard questionnaire forms were filled in face-to-face after each administration for both vaccines. The patient, who had any serious side effects, was followed up in the hospital.

Results: Of the 226 patients included in the study, 97 were male and 128 were female. Their mean age was 16.4+2.4. It was determined that 88.4% (n=200) of the patients had mRNA vaccine and 11.6% (n=26) had inactivated vaccine. 105 of the patients were using biologic drugs during vaccination. Of these, 63 (27.9%) patients were treated with anti-TNF drugs (46 adalimumab, 10 etanercept, 6 infliximab), 32 patients were anti-il-1 (30 canakinumab, 2 anakirna), 4 patients were anti-il-6, 3 patients were anti-il-17, 3 patient was receiving abatacept and 1 patient was receiving rituximab. 121 patients were using DMARDs. Of these, 61 were using colchicine. 26.5% (n=60) of the patients had covid infection before vaccination. Side effects were observed in 180 of our patients. No side effects were observed in 46 patients. Pain at the injection site was the most common among them, 72.6% (n=164). Headache was seen in 16.8% (n=38) of the patients, myalgia in 18.1% (n=41), fever in 16.4% (n=37) and arthralgia in 6.6% (n=15). The frequency of serious adverse events was determined as 0.9%(n=2). Both patients were followed up in the ward. When the patients were compared in terms of covid infection and gender, there was no significant difference in the frequency of side effects. When the vaccines were compared, the incidence of side effects in the mRNA vaccine was statistically significantly higher (p=0.001). Pain at the injection site was significantly less frequent in the inactivated vaccine (p=0.004). In terms of drug distribution, there was no significant difference in the frequency of side effects between patients using biologic drugs and DMARDs. p=0.004) There was no statistically significant difference in the frequency of side effects when the patients using dmard were compared as colcicine and other dmards.

Conclusion: In our study, we have shown that the use of vaccines in individuals with adolescent rheumatological diseases is safe and that the biological treatments used by the patients do not cause an increase in the risk of vaccine side effects. In addition; We have shown in our study that the side-effect profile of the inactivated vaccine used in our country is milder than the mRNA vaccine, and that it affects daily life less. Another result of our study was that anti-TNF drugs could cause a decrease in pain sensation due to the relationship of anti-TNF with pain pathways.

Background: To prevent COVID-19 disease SARS-CoV 2 vaccines put into use worldwide with emergency use authorizations despite ongoing safety concerns. Since pyrin mediated inflammasome response is dysregulated in FMF, exposure to SARS-CoV 2 proteins via vaccination may potentially trigger inflammation, leading to attacks and/or increased rate of adverse events (AE).

Objectives: Aim of this study to investigate frequency of adverse events and attacks related to vaccination in recipients of CoronaVac and BNT162b2 comparatively in our FMF patients.

Methods: Data regarding, number of vaccine doses, types of vaccines (CoronaVac or BNT162b2), presence of AEs and/or FMF attacks after any vaccine dose within a month, history of COVID-19 infection before or after vaccination, adherence to FMF treatment during vaccination were collected from hospital database or via telephone.

Results: A total of 161 vaccinated FMF patients were included. Mean ± SD age was 40.5 ± 11.7 years. 57.1% was female. 10.6% of the patients had chronic kidney disease and 9.3% had amyloidosis. Most common MEFV mutations were M694V heterozygous (27%) and M694V homozygous (21.6%). 93.2% of the patients were under colchicine, 21.8% under anti-interleukin 1 agents, 2.5% under TNF-a inhibitors. 96.3% of the patients adhered to FMF treatment during vaccination. Vaccination properties and data regarding adverse events are presented in Table 1. 57.8% of patients reported to suffer from an AE/attack after a vaccine dose. Number of patients with AE after BNT162b2 was significantly higher (p<0.001). None of the patients had severe AEs. 39 patients had COVID-19 infection prior to primary vaccination. 61.5% of these suffered from an adverse reaction/attack after vaccination, in comparison to 56.6% of the patients without

prior COVID-19 infection (p=0.584). When patients with and without AEs/attacks were compared, no significant differences were observed regarding age, gender, body mass index, comorbidities, FMF treatments and total vaccine doses.

Table 1. Adverse events and FMF attacks in a total of 161 vaccine recipients

	BNT162b2	CoronaVac	p
Total vaccine doses, n	213	140	
Patients ever vaccinated with BNT162b2 and CoronaVac, n (%)	117 (72.7)	67 (41.6)	
Dose per patient, median (min-max)	2 (1-4)	2 (1-4)	
Patients with primary vaccination completed with BNT162b2 or CoronaVac, n (%)*	88 (54.7)	57 (35.4)	
Patients with a booster with BNT162b2 or CoronaVac, n (%)	23 (14.2)	14 (8.6)	
Patients vaccinated with BNT162b2 or CoronaVac alone, n(%)	94 (58.4)	44 (27.3)	
Patients with an adverse event after any vaccine dose of n (%)¶	64/117 (54.7)	20/67 (29.9)	**<0.001**
Adverse events, n (%)¶			
Fever	13 (11.1)	6 (9.0)	0.644
Malaise	21 (17.9)	4 (6.0)	**0.023**
Local pain/arm pain	17 (14.5)	4 (6.0)	0.079
Arthralgia	19 (16.2)	4 (6.0)	**0.043**
Myalgia	6 (5.1)	0 (0.0)	0.059
Headache	11 (9.4)	0 (0.0)	**0.010**
Nausea	6 (5.1)	1 (1.5)	0.215
Vomiting	4 (3.4)	1 (1.5)	0.439
Others	22 (18.9)	7 (10.4)	
Patients with FMF attack within one month after any vaccine dose, n (%)¶	26 (22.2)	13 (19.4)	0.653
Time from vaccine dose to FMF attack, days, median (IQR)	7.0 (12.5)	10.0 (13.5)	0.758

*9.9 % of the patients had only single dose of either vaccine, ¶Over 117 ever vaccinated with BNT162b2 and 67 ever with CoronaVac

Conclusion: We observed considerable number of FMF patients suffered from vaccine related AEs/attacks, particularly with BNT162b2. However, no serious AE was detected. Demographics, clinical characteristics and prior history of vaccination did not significantly affect AE/attack occurrence.

POS1275 A RETROSPECTIVE STUDY ON UVEITIS FLARES FOLLOWING COVID19 VACCINATION: SHARING EXPERIENCE FROM A TEACHING HOSPITAL COMBINED RHEUMATOLOGY AND UVEITIS CLINIC

A. Birchall[1], S. Byravan[2], P. Kumar[3], A. Moorthy[4]. *[1]Leicester Medical School, College of Life Sciences, Leicester, United Kingdom; [2]University Hospitals of Leicester, Rheumatology, Leicester, United Kingdom; [3]University Hospitals of Leicester, Ophthalmology, Leicester, United Kingdom; [4]University Hospitals of Leicester, Rheumatology, Leicester, United Kingdom*

Background: Uveitis is a sight threatening disease caused by inflammation of the uveal tract of the eye. Uveitis is a manifestation of many autoimmune conditions and is associated with seronegative axial spondyloarthritis, reactive arthritis, Behçet's disease, inflammatory bowel disease, and psoriatic arthritis. Acute anterior uveitis is the most common presentation and is most commonly idiopathic or associated with the HLA-B27 gene (around 20% of cases). Studies have shown that anterior uveitis frequently recurs in patients after it has previously remitted. (1) Patients suffering from autoimmune conditions are frequently prescribed immunosuppressant drugs to control their illness, thus leaving them more susceptible to bacterial and viral illnesses including severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) Previous studies have shown that some patients suffer exacerbation of their autoimmune condition after coronavirus vaccination, including uveitis(2). We aim to evaluate our cohort of patients suffering from autoimmune conditions treated at Leicester Uveitis Service at Leicester Royal Infirmary and explore any proposed link.

Objectives: To assess if COVID19 vaccination is associated with uveitis flares in immunosuppressed patients.

Methods: A retrospective study, to determine if patients diagnosed with autoimmune conditions suffered from uveitis following COVID-19 vaccination. A data collection sheet was used to document demographic and clinical data: age, sex, ethnicity, autoimmune condition, dates of COVID-19 vaccination(s), type of vaccine, medication at the time of vaccine, symptoms of autoimmune recurrence, date of uveitis onset and number of days between uveitis onset and latest vaccine. We used an already existing uveitis database with an active register of 2346 patients, of which 246 were on immunomodulation.

Results: After reviewing the first 50 patients on immunosuppression for uveitis, we found a total of 4 patients had a uveitis flare despite tight control previously; 3 are female and 1 male, their median age was 39.5 years. They experienced a recurrence of uveitis in the last 6 months. Of these 4 patients 3 were on synthetic DMARDS (2 mycophenolate mofetil, 1 azathioprine), 1 was on steroids and 1 was on a biological DMARD (adalimumab). 2 of the patients suffered from posterior uveitis and 2 from anterior uveitis. All the 50 patients had been vaccinated against COVID19 however there was no clear record of booster dose.

Conclusion: Our study showed that of 50 immunosuppressed patients, 4 had a uveitis flare following vaccination. Clinicians need to be aware of uvetis flares in rheumatology patients following vaccination. This is a small retrospective analysis of our cohort however a large observational study on flare of uveitis following COVID-19 primary vaccination and booster vaccination would be useful to get meaningful data.

POS1276 HUMORAL IMMUNE RESPONSE TO SARS-COV-2 VACCINE IN RITUXIMAB-TREATED PATIENTS

E. Flores-Fernández[1], I. Vázquez-Gómez[1], C. Valera-Ribera[1], P. Andújar-Brazal[1], E. Valls-Pascual[1], J. M. Nogueira Coito[2], À. Martínez-Ferrer[1], D. Ybáñez-García[1], J. J. Alegre-Sancho[1]. *[1]Doctor Peset University Hospital, Rheumatology, València, Spain; [2]Doctor Peset University Hospital, Microbiology, València, Spain*

Background: Vaccination against SARS-CoV-2 has shown efficacy and safety in patients with chronic inflammatory rheumatic disease, similar to the general population. However, in patients treated with rituximab (RTX) it is known that usually have a lower vaccination response rate (1-2), and recent studies suggest that it also happens with the new SARS-CoV 2 vaccine (3), which entails an increased risk of hospitalization and mortality in this specific group of patients.

Objectives: To describe humoral immune response to SARS-CoV-2 vaccine in rituximab-treated patients after one and six months from the vaccination, and study if there is any other factor associated with a lower response rate.

Methods: Prospective analysis of a cohort of patients treated with RTX who received the SARS-CoV-2 vaccine between the months of April and October 2021. Demographic and medical data were collected through electronic medical records. Blood tests and serologies with levels of antibodies against SARS-CoV-2 were performed one and six months after having received the vaccine against SARS-CoV-2. The administration of a booster dose of the vaccine was recorded. A descriptive and statistical analysis of the data was carried out using the SPSS program.

Results: From a cohort of 41 patients, of whom 81,4% were women with a mean age of 56 (13,4 SD) years, vaccine response rate was only 36,7% after a 6-month follow-up. The 88,4% of them received a booster dose of the vaccine, but this failed to produce a vaccine response in any of the patients who had not developed it with the previous ones. One patient became infected after receiving one dose of the vaccine and failed to develop a serological response either.

Hypogammaglobulinemia was associated with a statistically significant lower probability of vaccine response (p=0,04). A trend of lower vaccination response rate was observed in patients who had received the last cycle of RTX in the 6 months prior to vaccination (p=0,058). In addition, the antibody levels developed one month after vaccination were statistically significantly correlated with the time between the last RTX cycle and vaccination (p=0,014) and also with CD19 B cells levels prior to vaccination (p<0,001); however, there was no correlation with the antibody levels detected at the 6-months serology. No statistically significant differences were found in relation to the number of previous cycles of RTX, concomitant treatment with synthetic disease-modifying drugs (DMARDs) or corticosteroids.

Conclusion: In our sample, after a 6-month follow-up only 36,9% achieved a vaccine response against SARS-CoV-2, which did not improve despite the administration of a booster dose. Hypogammaglobulinemia, the time between the last RTX cycle and vaccination (at least 6 months), and previous CD19 B cells levels significantly influenced in the development of a humoral response to the vaccine.

POS1277 LONGTERM IMMUNOGENICITY AND TOLERABILITY OF A 3RD DOSE OF AN MRNA ANTI-SARS-COV-2 VACCINE IN RA PATIENTS WITH AN INADEQUATE RESPONSE TO A PREVIOUS STANDARD TWO DOSE REGIMEN

K. Schmiedeberg[1], I. A. Abela[2], N. Vuilleumier[3], S. Pagano[3], J. Von Kempis[1], A. Rubbert-Roth[1]. *[1]Rheumatology Clinic, Kantonsspital St.Gallen, St.Gallen, Switzerland; [2]Zürich, Institute of Medical Virology, University of Zurich, Zürich, Switzerland; [3]Geneva, Laboratory Medicine Division, Geneva, Switzerland*

Background: Lower seroconversion rates have been reported in patients with rheumatic diseases receiving immunomodulatory therapies following a standard mRNA-based vaccine regimen. Data with regard to immunogenicity and safety of a 3rd vaccine dose in this patient population is limited[1].
Objectives: We aim to study immunogenicity, vaccine associated side effects and the occurrence of flares in RA patients unresponsive to a standard vaccine regimen eligible for a 3rd vaccine dose.
Methods: RA patients who had a low or absent anti-S1 response after 12 (Cohort A) or 24 weeks (Cohort B) following a standard vaccination regimen received a 3rd vaccine dose. Temporary discontinuation of DMARD therapy was recommended. Serum samples were collected before, 2, 12, and 24 weeks after the 3rd vaccine dose. Quantitative measurement of anti-S was performed using the Roche Elecsys Anti-SARS-CoV-2 spike subunit assay. Neutralizing activity (NT50) against Wuhan WT and αasβ-, γ-, and δ- variants was assessed by using a HIV-based pseudovirus system.
Results: Baseline characteristics are shown in Table 1. 45/47 patients temporarily discontinued DMARD therapy: Mtx and JAKi were paused one 1 week before/restarted 2 weeks after the 3rd vaccine dose, bDMARDs were paused 2 weeks before/restarted 2 weeks after the 3rd dose. Local pain and/or systemic vaccine associated side effects following the 3rd vaccine dose were reported in 12/17 (71%) in Cohort A, and 10/29 (35%) patients in Cohort B (p = 0.018). Flares were defined as loss of low disease activity (LDA), subsequent to the 3rd vaccine dose and occurred in 17/47 (36%) patients (p = 0.0332) with comparable frequencies in both cohorts (41% Cohort A, 33% Cohort B (NS)).

Table 1. Baseline characteristics of RA patients in Cohort A and Cohort B

	RA patients (n = 17) Cohort A	RA patients (n = 30) Cohort B	p-value
Age (yrs), mean (± SD)	69 (8)	63.9 (8)	NS
Female sex, n (%)	9 (53)	13 (43)	NS
Vaccination type/schedule			
mRNA-1273/BNT162b2, n=	3/14	5/25	NS
RA disease characteristics			
ACPA ± RF, n (%)	13 (77)	12 (40)	0.02*
Disease activity (CDAI)			
Remission (≤ 2.8), n (%)	3 (18)	6 (20)	NS
LDA (2.9 - 10), n (%)	11 (64)	18 (60)	NS
Moderate CDAI (10.1 - 22.0), n (%)	2 (12)	3 (10)	NS
High CDAI (22.1 - 76.0), n (%)	1 (6)	3 (10)	NS
DMARD therapy			NS
Monotherapy of csDMARDs, n (%)	2/17 (12)	10/30 (33)	NS
bDMARDs ± csDMARDs, n (%)	8/17 (47)	14/30 (47)	NS
JAKi ± csDMARDs, n (%)	7/17 (41)	6/30 (20)	NS
Prednisone, n (%)	5/17 (29)	11/30 (37)	NS
Mean daily dose prednisone (mg ± SD)	4.1 ± 1.6	4.1 ± 1.5	NS

Low or absent anti-S titers were confirmed before the third vaccination (Cohort A: median 19.5 U/ml, IQR 0.47-57; cohort B: median 65.9 U/ml, IQR 22-154) (p = 0.0018). Two weeks after the 3rd dose, a rapid and significant increase in anti-S were observed in 12/17 (82%) and 25/28 (89%) patients (Cohort A: median 2500 U/ml, IQR 798-2500; Cohort B: median 2500 U/ml, IQR 2500-2500) (NS). High levels of anti-S were maintained in the majority of patients 55% (11/20) until week 12 in both cohorts (Figure 1). NT50 against Wuhan-WT and other variants was assessed in 21 patients 2 weeks after the 3rd vaccine dose revealing a low or absent NT50 against delta in 38% of patients despite a median anti-S response of 2500 U/ml (IQR 798-2500). 14/21 patients had peak anti-S titres of 2500 U/ml, of those 12/14 developed a strong NT50 response against the delta variant.

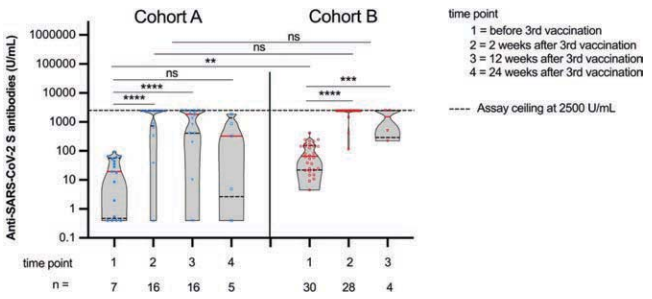

Figure 1.

Conclusion: Our data demonstrate that a 3rd vaccine dose, maybe complimented by temporary discontinuation of DMARD therapy, may lead to a rapid increase in anti-S antibodies when using a homologous vaccine and profound neutralizing activity in the majority of RA patients previously unresponsive to a standard two dose regimen. This seems to be independent of the interval to the previous standard vaccine regimen. As flares occurred in 36% of all patients, the necessity and length of DMARD discontinuation should be explored in more detail to balance between sustained control of disease activity and optimized vaccine induced immune responses.

POS1278 EXCELLENT PROGNOSIS OF RHEUMATIC MANIFESTATIONS FOLLOWING COVID-19 VACCINATION: 7 MONTHS FOLLOW-UP DATA

M. Gasparotto[1], S. Bindoli[1], R. Padoan[1], E. Zanatta[1], P. Sfriso[1], A. Doria[1], L. Iaccarino[1]. *[1]Padua University Hospital, Rheumatology, Padova, Italy*

Background: It is well established that severe forms of SARS-CoV2 infection can induce a massive cytokine storm, which may disrupt the immune system stability and conceivably stimulate the development of reactive manifestations through a molecular mimicry process. Likewise, anti-COVID-19 vaccines, which have so far proved an excellent tolerability and safety profile, are able boost the immune response via different biologic technologies and adjuvant combinations possibly facilitating, in predisposed subjects, the onset of inflammatory or even autoimmune manifestations.
Objectives: We report a case series of suspected rheumatic adverse events following immunization (AEFI) associated with anti-COVID-19 vaccine. We focused our attention on the prognosis of these patients by analysing their available follow-up data.
Methods: We included patients evaluated at first-aid rheumatologic consultancy and at rheumatologic outpatient and inpatient clinic at Padua University Hospital between May and September 2021 presenting with new-onset rheumatic manifestation or a flare of an underlying rheumatic disease within 30 days after receiving an anti-COVID-19 vaccine dose. Inclusion and exclusion criteria were in accordance with the World Health Organization guidelines for AEFI surveillance. All patients were re-evaluated in January 2022: telemedicine or face-to-face visit. Response to therapy was classified as complete, good or absent according to the clinician's judgment based on clinical examination, patient's reporting and analysis of laboratory data.
Results: We identified 30 cases of suspected rheumatic AEFI reported in Table 1. Comprehensively the most common manifestations were inflammatory arthritis (40.0%), rheumatic polymyalgia (26.7%) and adult-onset Still disease (13.3%). Among patients with an underlying rheumatic disease we recorded an AOSD flare, a rheumatoid arthritis flare with involvement of hands proximal interphalangeal joints, one case of wrist arthritis in a patient with psoriatic arthritis, one of aortitis in a patient with large vessels vasculitis, one case of polyarthritis in undifferentiated connective tissue disease and a nephritis flare in a patient with systemic lupus erythematosus.
Treatment for the suspected AEFI was based on systemic glucocorticoids (GC) alone (63.3%), systemic GC plus IL-1R antagonists (13.3%), non-steroidal

autoinflammatory drugs (13.3%), intra-articular GC (6.6%), colchicine (3.3%) and non-steroidal anti-inflammatory drugs (13.3%).

At last follow-up contact (7.8±1.5 months) 26 patients (89.6%) were classified as complete responders. Eleven of them (42.3%) withdrew therapy without experiencing recurrence of disease manifestation. One patient with lupus nephritis had a proteinuric flare after the first BNT162b dose; he showed an initial good response to increased glucocorticoid therapy but had a new 24h proteinuria increase at second follow-up visit three months later requiring implementation of immunosuppressive therapy. Another patient with AOSD was in remission at last FU visit in December 2021 but required hospitalization in January 2022 for disease relapse due to a suspected gastrointestinal infection. Finally, one patient hospitalized for a seronegative polyarthritis after the first BNT162b dose achieved complete remission at last available contact (one month after hospital discharge) but was then lost in follow-up.

Conclusion: After a mean follow-up of 7.8±1.5 months nearly all of patients showed a complete/good response to standard therapy and about half of them withdrew the treatment without losing the remission status

POS1279 FAVOURABLE COURSE OF COVID-19 IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER USING BIOLOGIC AGENTS

N. Aliyeva[1], S. Sarı[1], S. Amikishiyev[1], B. Ç. Yalçın Dulundu[1], V. Suleymanova[2], P. Telli[2], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], A. Gül[1]on behalf of The team of Istanbul Faculty of Medicine, Istanbul University. *[1]Istanbul Faculty of Medicine, Istanbul University, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul Faculty of Medicine, Istanbul University, Department of Internal Medicine, Istanbul, Turkey*

Background: Serious infections are more frequently seen in patients with inflammatory rheumatic diseases, being treated with immunosuppressive or biologic disease-modifying antirheumatic drugs (b-DMARDs). Potential harmful effects of immunosuppressive drugs as well as b-DMARDs were a major concern during the early phases of the Coronavirus disease 2019 (COVID-19) pandemic, and preliminary data documented the worse outcome of COVID-19 associated with B cell depleting treatments (1). On the other hand, limited information has been shared about the course of COVID-19 in patients with monogenic autoinflammatory disorders using IL-1 inhibitors.

Objectives: We herein aimed to evaluate the course of COVID-19 in adult patients with the most common form of inflammasomopathy, Familial Mediterranean Fever (FMF), who were on biologic agents.

Methods: In this cross-sectionally study, FMF patients were evaluated by screening their clinical and electronic records in our database in October 2021. The FMF patients with a record of PCR-confirmed COVID-19 were investigated in more detail in our hospital. Characteristics of FMF findings as well as clinical and laboratory findings associated with COVID-19 were recorded from the outpatient follow-up cards.

Results: We identified 184 FMF patients using biologic agents, and their baseline characteristics are summarized in Table 1. Among them, 36 had PCR-confirmed COVID-19; 32 of them were currently on b-DMARD along with colchicine (31 anti-IL-1, 1 anti-TNF), and 4 of them had a previous history of b-DMARD treatment. Data about the course of COVID-19 could be reached in 34 patients. Four (11%) patients had an asymptomatic course. Remaining patients with symptomatic COVID-19 had the following symptoms: cough (50%), headache (47.2%), fever (44.4%), loss of taste and smell (41.6%), myalgia (0.6%), dyspnoea (27.8%), diarrhea (25%) abdominal pain (5.6%). Thorax computed tomography was performed in 10 patients, and findings of pneumonia were documented in 6 (16.7%). The mean values of the laboratory parameters were as follows: C-reactive protein 99.48 ± 112.66 mg/L; ferritin 316 ± 208.3; D-Dimer 2445 ± 3917, Lactate Dehydrogenase 253 ± 61, troponin T 26 ± 20, procalcitonin 0.348 ± 0.53. Lymphopenia

Table 1: Baseline clinical, laboratory, and treatment characteristics of FMF patients

Features	
Female/Male [n (%)]	21 (58.3%) /15(41.7%)
Age, years, mean (SD)	40.0 (11.5)
MEFV gene mutation [n (%)]	
- **M694V homozygous**	20 (55.6%)
- **M680I homozygous**	1 (2.8%)
- **M694V heterozygous**	1 (2.8%)
- **M694V/M680I heterozygous**	4 (11.1%)
- **M694V/V726A heterozygous**	2 (5.6%)
- **NA**	8 (22.2%)
Attack properties [n (%)]	
- **Fever**	30 (83.3%)
- **Peritonitis**	30 (83.3%)
- **Pleuritis**	14 (38.9%)
- **Arthritis**	26 (72.2%)
- **NA**	2 (5.6%)
Amyloidosis [n (%)]	16 (44.4%)
- **Renal**	14 (38.9%)
- **Gastrointestinal system**	5 (13.9%)
Renal Transplantation history [n (%)]	8 (22.2%)
Colchicine use	36 (100%)
Patients on biologic treatment [n (%)]	32 (88.9 %)
- **Anakinra**	22 (61.1%)

was detected in 5 (13.9%) patients; mean lymphocyte count was 1080 ± 363. Data about the treatment could be reached in 34 patients. Antiviral therapy was prescribed in 25 (69.4%) patients (favipiravir, n=22; and oseltamivir, n=3). Antibiotics were given to 6 (16.7%) patients, and 6 (16.7%) received hydroxychloroquine. Parenteral steroids were administered to 2 patients during the hospitalization. Six (16.7%) patients required hospitalization, and 2 (5.6%) required oxygen support, non-invasive mechanical ventilation, and one of them followed in the intensive care unit. Twenty-two patients were on anakinra treatment, and none of them required additional dose. Only 1 patient, a 61-year-old male patient with a history of lung lobectomy and renal transplantation, received tocilizumab due to macrophage activation syndrome, and he later died of sepsis. This patient was on anakinra until 2 years before, and it was discontinued due to an allergic reaction. Only 4 patients had a history of vaccination before COVID-19, and none of them developed pneumonia and required hospitalization. Six patients had FMF attacks after recovering from COVID-19. None of the patients developed thromboembolism and secondary bacterial infections.

Conclusion: This survey identified 36 biologic b-DMARD receiving FMF patients, who had COVID-19. All but 1 patient had complete recovery, and b-DMARD usage did not negatively affect the COVID-19 course. None of the patients currently on anti-IL-1 or anti-TNF had a worse outcome. Based on these observations, it can be suggested that refractory FMF patients can continue their b-DMARD treatments when they had COVID-19.

POS1280

EFFECTS OF ANTI-SARS-COV-2 VACCINATION ON SAFETY AND DISEASE EXACERBATION IN BEHCET'S DISEASE PATIENTS: A SINGLE CENTRE STUDY

H. Apaydın[1], A. Erden[2], B. Armagan[1], S. C. Güven[1], H. E. Konak[1], Y. Afşin[3], M. Kaygısız[3], B. Polat[1], A. Omma[4], O. Küçükşahin[2]. [1]*Ankara City Hospital, Rheumatology, Ankara, Turkey;* [2]*Ankara Yıldırım Beyazıt University, Rheumatology, Ankara, Turkey;* [3]*Ankara City Hospital, Internal Medicine, Ankara, Turkey;* [4]*4University of Health Sciences, Rheumatology, Ankara, Turkey*

Background: Pandemic of coronavirus disease 2019 (COVID-19), caused by severe acute respiratory syndrome – coronavirus 2 (SARS-CoV-2), has become a major global health issue since December 2019. Patients affected by systemic rheumatic disorders represent a high-risk group for severe COVID-19. During the COVID-19 pandemic, vaccination has become one of the cornerstones of the fight against this disease. The EULAR and the ACR recommend vaccination in all patients with rheumatological diseases. There is a paucity of data regarding the safety of COVID-19 vaccines in patients with rheumatic and musculoskeletal diseases such as Behçet's disease (BD).

Objectives: In this study, we evaluated the safety and tolerance of COVID-19 vaccines, post-vaccine BD exacerbation and discontinuation of BD therapy in BD patients by retrospectively examining our BD cohort, from the patients' perspective.

Methods: We retrospectively evaluated 450 BD patients followed in our clinic using hospital records and formed a retrospective cohort of patients who met the International Study Group (ISG) criteria. COVID-19 vaccination status, vaccine type (inactivated or mRNA), post-vaccine side effects and exacerbations, drug compliance, change in treatment after exacerbation, and post-vaccine COVID-19 occurrence were evaluated by interviewing patients over the phone or face to face. Patient demographics, comorbid diseases, and active BD treatments were collected from our hospital records. Disease activity was measured using the BSAS and the BDCAF form.

Results: Our cohort consisted of a total of 450 BD patients. Two hundred and eighty seven patients had at least 1 dose of the COVID-19 vaccine. Of the total number of COVID-19 vaccines (n= 639), 379 (59%) were Pfizer-BionTech vaccines and 257 (41%) were Sinovac vaccines. The side-effects after first, second, third and fourth vaccine dose were 151 (52.6%), 135 (47%), 29 (10.1%) and 3 (1%), respectively. Behçet flare after first, second, third and fourth vaccine dose were 151 (52.6%), 135 (47%), 16 (22.9%) and 3 (33.3%), respectively. The most common side effects were arm pain, joint pains or arthritis, malaise, while the most common BD exacerbations were arthralgia or arthritis, oral aphthae, papulopustular eruption Pfizer-BionTech and Sinovac vaccines were compared in terms of side effects, there was a significant difference after the 1st (p<0.001) and 2nd doses (p<0.001), but no significant difference was found at the 3rd dose (p= 0.353) (Table 1). When Pfizer-BionTech and Sinovac vaccines were compared in terms of BD exacerbations, no significant difference was found after the 1st (p= 0.417), 2nd (p= 0.465) and 3rd doses (p= 0.565). Only 4 patients (1.3%) developed exacerbation with organ involvement after COVID-19 vaccine. Anterior uveitis developed in 2 patients, panuveitis in 1 patient, panuveitis and deep vein thrombosis in one patient.

Table 1. Side effects and Behçet's flare according to COVID vaccines

Side effects according to COVID vaccines

COVID vaccine, n/ N	Side effects after first dose of vaccine	p	Side effects after second dose of vaccine	p	Side effects after third dose of vaccine	p	Side effects after fourth dose of vaccine	p
Sinovac Biontech	**47 (39.5)** **104 (61.9)**	**<0.001**	**34 (30.1)** **101 (63.1)**	**<0.001**	**9 (36)** **20 (47.6)**	**0.353**	**None** 3 (33.3)	-
Behçet flare according to COVID vaccines								
COVID vaccine, n/N	Flare after first dose of vaccine	p	Flare after second dose of vaccine	p	Flare after third dose of vaccine	p	Flare after fourth dose of vaccine	p
Sinovac Biontech	**13 (11.0%)** **24 (14.3%)**	**0.417**	**18 (15.9%)** **31 (19.4%)**	**0.465**	**5 (20.0%)** **11 (26.2 %)**	**0.565**	**None** 3 (33.3)	-

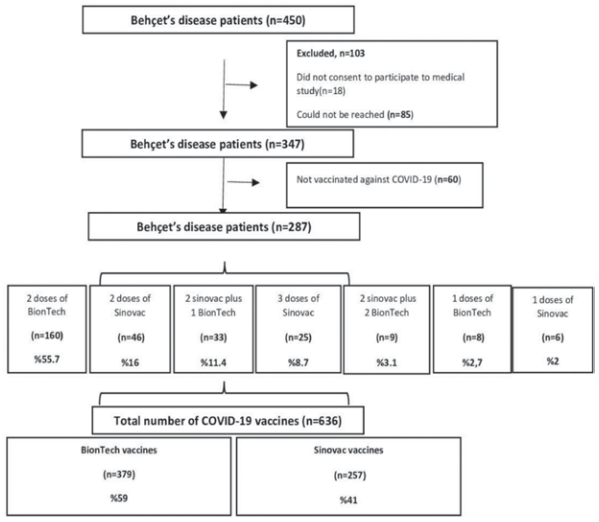

Figure 1. Flow chart of the study

Conclusion: In conclusion, our study shows that the COVID-19 vaccine is well tolerated in BD patients, and that post-vaccine Behçet's exacerbation predominantly includes mucocutaneous and articuler findings, and exacerbations with organ involvement are rare. According to the COVID-19 vaccines, although the side effects were more in the Pfizer-BioNTech group compared to the Sinovac group, there was no difference between Behçet's flare compared to the COVID-19 vaccines.

POS1281 DIFFERENT HUMORAL BUT SIMILAR CELLULAR RESPONSES OF PATIENTS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES UNDER DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS AFTER COVID-19 VACCINATION

I. Andreica[1], A. Blazquez-Navarro[2], J. Sokolar[1], M. Anft[3,4], U. Kiltz[1], S. Pfaender[5], E. Vidal Blanco[5], T. Westhoff[3,4], N. Babel[2,3], U. Stervbo[3,4], X. Baraliakos[1].
[1]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Rheumatology, Herne, Germany; [2]Charite Universitätsmedizin Berlin, Berlin Center for Advanced Therapies, Berlin, Germany; [3]Marienhospital Herne - Klinik Mitte Medizinische Klinik I - Gastroenterologie, Nieren- und Hochdruckkrankheiten, Center for Translational Medicine and Immune Diagnostics Laboratory, Medical Department I, Herne, Germany; [4]Ruhr-Universität Bochum, Medical Department I, Bochum, Germany; [5]Ruhr-University Bochum, Department of Molecular and Medical Virology, Bochum, Germany

Background: The interplay between humoral and cellular response after vaccination against SARS-CoV-2 in patients (pts.) with autoimmune inflammatory rheumatic diseases (AIRD) remains unknown.
Objectives: To investigate the impact of different immunosuppressive therapies on the development of humoral and cellular immune responses to full 2-dose SARS-CoV-2 vaccination in AIRD pts. with stable low disease activity.
Methods: The immune reactivity to COVID-19 vaccination was investigated in a prospectively recruited AIRD cohort with rheumatoid arthritis, axial spondyloarthritis or psoriatic arthritis which received a therapy with IL-17i, TNFi, JAKi or MTX (alone or in combination). Almost all patients received mRNA-based vaccine, only 4 patients had a heterologous scheme. Anti-spike(S) antibodies(ab.) and sera neutralizing capacity (neutralization dilution 50; ND50) were measured 4 weeks after the first (prime+4w) and 4 weeks after the second vaccination (boost+4w). Vaccine-specific cellular immunity was evaluated by quantifying expression of activation markers on T cells as well as their production of key cytokines, at prime+4w and boost+4w.
Results: Overall, a total of 92 pts. were included in the final cohort. 31 (33.7%) pts. were on TNFi, 24 (26.1%) on IL-17i, 24 (26.1%) on JAKi, each group encompassing pts. receiving drug inhibitors alone or in combination with MTX.13 (14.1%) were treated with MTX alone. The median time between the vaccination and blood sampling was 31 [IQR: 28-34] days after prime+4w and 28 [IRQ: 28-28] days after boost+4w. Although at prime+4w only 34/90 (37.8%) of pts. presented neutralizing ab., the majority (86/91, 94.5%), developed them at boost+4w. The highest neutralization titer developed the pts. on IL-17i both at prime+4w (74 [IQR: 13-91]) and boost+4w (798 [IQR: 511-1344]), while no statistically significant differences were found in the neutralization titer at boost+4w for the TNFi, JAKi, and MTX groups: 207 ND50 [IQR: 120-576], 319 [IQR: 133-461] and 749 [IQR: 264-1920], respectively. 81/90 (90.0%) pts. developed IgG ab. against SARS-CoV-2 S-protein at prime+4w and 91/92 (98.9%) at boost+4w. Pts. receiving IL-17i developed higher ab. titers (8295 U/mL [IQR: 4586-11,237]) compared to the other three groups: JAKi (4405 U/mL [IQR: 1436-7265], TNFi (2313 [IQR: 1156-3630] U/mL) and MTX (2010 U/mL [IQR: 693-9254]). Neutralization capacity correlated well with the titer of anti-S ab. at both timepoints. Co-administration of biologic/tsDMARDs and MTX led to lower titers compared to biologic/tsDMARDs monotherapy. All therapies left frequencies of $CD154^+CD137^+$ $CD4^+$ T cells and $CD137^+$ $CD8^+$ T cells at prime+4w and boost+4w unchanged. Polyfunctionality and T cell cytokine profiles across therapies did not significantly vary at boost+4w.
Conclusion: Even after insufficient seroconversion for neutralizing capacity and ab. response against SARS-CoV-2 S-proteins between pts. of different mod of action agents, particularly for MTX and JAKi after first vaccination, a second vaccination covered almost all pts. regardless of DMARDs therapy, with better outcomes in those on IL-17i. T cell immunity revealed similar frequencies of activated T cells in all modes of action after the second vaccination.

Table 1. Demographics and therapy

	All	IL-17i	IL-17i+MTX	TNFi	TNFi+MTX	JAKi	JAKi+MTX	MTX
Patients (n)	92	19	5	27	4	18	6	13

POS1282 PEDIATRIC INFLAMMATORY MULTISYSTEM SYNDROME TEMPORALLY-ASSOCIATED WITH SARS-COV-2 – A PORTUGUESE SINGLE CENTRE CASE SERIES

B. Santos[1], I. Cardoso[2], S. Miranda[3], F. Aguiar[4,5], M. Rodrigues[4,5], I. Brito[4,5].
[1]Centro Hospitalar Baixo Vouga, Aveiro, Rheumatology Department, Aveiro, Portugal; [2]Centro Hospitalar de Vila Nova de Gaia/Espinho - Unidade 2, Paediatrics Department, Vila Nova de Gaia, Portugal; [3]Hospital de Braga, Paediatrics Department, Braga, Portugal; [4]São João Universitary Hospital Center, Paediatrics and Young Adult Rheumatology Unity, Porto, Portugal; [5]Faculdade de Medicina da Universidade do Porto - FMUP, Rheumatology Department, Porto, Portugal

Background: Across the globe, coronavirus disease 2019 (COVID-19) caused by SARS-CoV-2 appears to affect paediatric population in a milder and non-threatening way, when compared to adults. However, since April 2020 case reports of previously healthy children presenting with unremitting fever, biologic inflammatory syndrome and cardiac dysfunction have been emerging. This syndrome, which has been termed Pediatric Inflammatory Multisystem Syndrome Temporally Associated with SARS-CoV-2 infection (PIMS-TS), represents a rare complication of COVID-19 in children[1].
Objectives: To describe the clinical, laboratory and imaging characteristics, course, management and outcomes of hospitalized children diagnosed with PIMS-TS in a Portuguese tertiary care hospital.
Methods: A retrospective study including children (< 18 years) that attended our hospital from April 2020 to December 2021 was performed. All the children included fulfilled the case definition of PIMS-TS published by the Centre for Disease Control and Prevention. Sociodemographic and clinical data, laboratory markers and imaging findings were collected.
Results: A total of 19 children met the criteria for PIMS-TS, 68% male with a mean age at diagnosis of 8 years old (IQR 5.8-15). They were all caucasian, except for a mixed-race patient, and all previously healthy, except one patient who was obese. Twelve had recent infection by SARS-CoV-2 detected by reverse transcriptase (RT) PCR and 18 had positive IgG serology.
All had fever at diagnosis, with a median duration of 6 days (IQR 5-6) and 89.5% had mucocutaneous, gastrointestinal and hematological attainment,

respectively. Other affected systems were respiratory (73.7%), cardiovascular (63%), lymphoid organs (52.6%), musculoskeletal (47%), genito-urinary (31.6%) and neurological (26.3%). Laboratory findings can be found in Table 1. Thirty-six percent were admitted in intensive care unit for a median duration of 8 days (IQR 4-9). 42.1% needed respiratory support, 87.5% with supplemental oxygen therapy, 62.5% with mechanical ventilation and 12.5% with non-invasive ventilation. All patients received intravenous (IV) immunoglobulin, 52.6% IV corticosteroid (CS) pulses and 78.9% IV and oral CS. Other treatments included acetylsalicylic acid (n=18), heparin (n=8) and antibiotic therapy (n=19) - Table 3. Seventeen fully recovered and 2 had sequalae: one of them with coronary artery aneurysms and other exertional dyspnea.

Table 1 – Laboratory results at presentation.

Hematology [a]		
	Reference range	
Total white blood cells count, x10⁹/L	4.0-11.0	10.19 (7.37-14.85)
Neutrophil count, x10⁹/L	1.5-7	10.38 (5.71-11.79)
Lymphocyte count, x10⁹/L	1.5-4	0.94 (0.67-1.45)
Hemoglobin, g/dL	12-16	11 (9.4-12.1)
Platelet count, x10⁹/L	150-400	156 (104-248)
Inflammatory markers [a]		
	Reference range	
C-reactive protein, mg/L	0-3	218.5 (132-262)
Procalcitonin, ng/mL	0-0.05	2.72 (0.00-8.18)
Ferritin, ug/L	6-140	598 (226-769)
Cardiac markers [a]		
Troponin, ng/L	0-34	118 (34-1021)
CK-MB, ng/mL	0.00-6.4	0.7 (0.3-8.1)
Pro-BNP, pg/mL	0-100	238.4 (67.5-525)

Abbreviations: PIMS-TS, pediatric inflammatory multisystem syndrome temporally associated with SARS-CoV-2.
[a] Data showed as median and inter Quartile Range (P25, P75)
[b] Data showed as frequency and percentage

Conclusion: In this case series, there was a broad spectrum of clinical symptoms and disease severity, ranging from fever and systemic inflammation to critical care admission with myocardial injury, shock, and development of coronary artery aneurysms.

Despite short-term morbidity, there were no mortality cases, with most of them recovering without sequelae. All physicians providing clinical care to children should consider this rare but severe delayed syndrome in paediatric population.

POS1283 THE COURSE OF NOVEL CORONAVIRUS DISEASE 2019 (COVID-19) IN PATIENTS WITH IGG4-RELATED DISEASE TREATED WITH RITUXIMAB

E. Sokol[1], A. Torgashina[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Rare Rheumatic Diseases and Sjogren's Syndrome, Moscow, Russian Federation*

Background: The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) disease 2019 (COVID-19) raised many questions and concerns about the safety of different immunosuppressive agents in patients (pts) with rheumatic diseases during the pandemic. There is some data that anti-B-cell depletion strategies could lead to more severe disease course. Rituximab (RTM) is one of the most effective, safe and well tolerated agents in IgG4-related disease (IgG4-RD) treatment. Information about the course of COVID-19 in pts with IgG4-RD is lacking.

Objectives: To examine clinical course of COVID-19 in pts with IgG4-RD treated with anti-CD20 monoclonal antibody (RTM).

Methods: Single center observational study. We searched in our clinical base from 2019 to 2021 years for pts with IgG4-RD, treated with RTM within this period. Diagnosis of IgG4-RD was based on comprehensive diagnostic criteria (H. Umehara, 2011). COVID-19 infection was registered when PCR test results were positive. RTM was administered in two 1000 mg infusions 14 days apart for the 1st course, then 500 mg every 6 months. We used mean ± standard deviation and median values with interquartile range of 25 - 75 percentile to characterize quantitative data.

Results: Fifteen pts, 6 women and 9 men, mean age 53.2 ± 12 years, receiving RTM monotherapy were included. The majority of patients (80%) had multiple organ involvement, mean number 2,3 (from 1 to 5): dacryadenitis – 11 pts, sialadenitis – 10 pts, AIP 1 – 4 pts, lung disease – 3 pts, sclerosing cholangiris – 2 pts, kidney disease – 2 pts, retroperitoneal fibrosis – 1 pt, aortitis – 1 pt, prostatitis – 1 pt. Median duration of IgG4-RD before COVID-19 onset was 48 [27;72] months, median duration of RTM treatment was 22 [11,5;30,5] months and median time from the last dose of RTM was 2 [1;4,5] months. Three pts had arterial hypertension or coronary heart disease anamnesis, 4 pts had asthma, 2 pts were overweight and 1 had class 3 obesity. No pts were vaccinated against SARS-CoV-2. Six patients (40%) required hospitalization and 4 of them received IL-6 inhibitors, only 1 required mechanical lung ventilation, 6 patients (40%) had only minor symptoms and didn't require any specific treatment, glucocorticoids were administered to 8 patients. All patients, except one, were older than 50, but they didn't have severe comorbidities. One patient, a 46 year-old man with a long anamnesis of IgG4-related dacryo- and sialadenitis, bronchial asthma, arterial hypertension class 3 and class 3 obesity, died. Due to small number of studied pts no statistical correlations could be established.

Conclusion: The proportion of hospitalized pts with IgG4-RD and RTM treatment was surprisingly high. The worst course was in patient with severe comorbidity. It appears that RTM can have negative impact on susceptibility to COVID-19 and its disease course.

POS1284 PAINFUL CERVICAL INVOLVEMENT AND FEBRILE TORTICOLLIS: A FREQUENT SYMPTOM OF PIMS

A. Schvartz[1], R. Kechiche[1], F. Bajolle[2], S. Poignant[3], R. Basmaci[4], C. Pajot[5], I. Melki[6], L. Morin[7], C. Adamsbaum[8], N. Matsa[9], M. Hofer[10], I. Koné-Paut[1,9], C. Galeotti[1,9]on behalf of French Covid-19 Paediatric Inflammation Consortium. [1]*CHU Bicêtre, Pediatric Rheumatology, Le Kremlin Bicêtre, France;* [2]*Necker-Enfants Malades University Hospital, AP-HP, M3C, Paris, France;* [3]*Hôpital Femme-Enfant-Adolescent Chu De Nantes, Pédiatrie Générale, Nantes, France;* [4]*Louis-Mourier Hospital, Service de Pédiatrie-Urgences, Colombes, France;* [5]*Hospital Center University De Toulouse, Department of Pediatric Nephrology, Internal Medicine and Hypertension, Toulouse, France;* [6]*Robert-Debré Hospital, APHP, General Pediatrics, Infectious Disease and Internal Medicine Department, Paris, France;* [7]*CHU Bicêtre, Pediatric and Neonatal Intensive Care Unit, Le Kremlin Bicêtre, France;* [8]*CHU Bicêtre, Pediatric Radiology, Le Kremlin Bicêtre, France;* [9]*Centre de Référence des Maladies Auto-Inflammatoires rares et des Amyloses, CEREMAIA, Le Kremlin-Bicêtre, France;* [10]*Lausanne University Hospital, Department of Paediatric Rheumatology of Suisse Romande, Lausanne, Switzerland*

Background: Pediatric Inflammatory Multisystemic Syndrome associated to SARS-CoV2 (PIMS) happens 4 to 6 weeks after SARS-CoV2 infection[1-2]. Its early diagnostic recognition as well as its early management is important to avoid cardiac complications related to this pathology.

Objectives: To highlight a frequent symptom in PIMS and improve its therapeutic care.

Methods: The JIR Cohort database, an international registry collecting data on patients with pediatric inflammatory diseases, was consulted to include patients between 03/15/20 and 12/31/2021.

Results: Of the 140 patients in whom a diagnosis of PIMS was retained, we present a series of 38 patients (27%) who presented at diagnosis or during evolution, febrile torticollis or painful cervical involvement. These patients were on average 8.2 years old (0.6-15.2). The proportion of boys was 14 out of 38 (37%). Twenty-four patients out of 33 (73%) were hospitalized in intensive care. Ten patients out of 38 (26%) underwent cervical imaging, 5 (50%) had abnormalities such as collection or infiltration of the soft tissues. At the therapeutic level, 27/38 patients (71%) received corticosteroid therapy, 33/38 (87%) immunoglobulins, and 26/38 (68%) antibiotic therapy.

Conclusion: PIMS is a pathology with significant clinical heterogeneity and severe consequences in case of delay in therapeutic management. In this epidemic context, it is important to consider PIMS in any patient with febrile torticollis, especially if he does not respond to antibiotics.

Valim[1,3]on behalf of Core Group Vaccine COVID-19 Study of the Brazilian Society of Rheumatology. *[1]Hospital Universitário Cassiano Antônio de Moraes, Reumatologia, Vitória, Brazil; [2]Fundação Oswaldo Cruz, Fundação Oswaldo Cruz, Vitória, Brazil; [3]Core Group Vaccine COVID-19 Study of the Brazilian Society of Rheumatology, Core Group Vaccine COVID-19 Study of the Brazilian Society of Rheumatology, São Paulo, Brazil; [4]Universidade Federal de São Paulo, Reumatologia, São Paulo, Brazil; [5]Universidade Federal do Espírito Santo, Educação Integrada em Saúde, Vitória, Brazil; [6]Universidade Federal do Espírito Santo, Medicina, Vitória, Brazil; [7]Secretaria de Saúde do Estado do Espírito Santo, Secretaria de Saúde do Estado do Espírito Santo, Vitória, Brazil*

Background: Patients with autoimmune inflammatory diseases (AID) have been prioritized for urgent vaccination to mitigate COVID-19 risk. However, few studies in the literature assessed the immunogenicity and safety of the COVID-19 vaccine in patients with AID.

Objectives: In this context, the present study aims to evaluate the immunogenicity and safety of the vaccine against COVID-19 in patients with AID.

Methods: These data are from "Safety and efficacy on COVID-19 Vaccine in Rheumatic Disease" - SAFER study, a Brazilian multicentric prospective phase IV study to evaluate COVID-19 Vaccine in AID, in the real-life, in Brazil. Immunogenicity and adverse events (AE) from a single center were assessed, after 2 doses of ChAdOx1 (Oxford/AstraZeneca), 8 weeks of interval, in patients with AID and healthy controls (HC). Inclusion criteria were age ≥ 18 years and fulfilling criteria according to international classification for AID. Exclusion criteria: pregnancy, previous severe AE to any vaccine, other immunosuppression causes. Stratification of post-vaccination AE was performed using a diary, filled out daily and returned at the end of 28 days for each dose. Participants were followed up through blood collection for measurement of IgG antibodies against SARS-CoV-2 spike receptor-binding domain by chemiluminescence (SARS-CoV-2 IgG II Quant assay, Abbott Laboratories, Abbott Park, IL, USA) at baseline and 28 days after the second dose. The seropositivity was defined for titers ≥50 AU/mL. Quantitative analyses were presented as observed frequency, percentage, central tendency, and variability measurements. The sample's normal distribution was verified through the Shapiro-Wilk test. The Kruskal-Wallis test and the post-hoc Dwass-Steel-Critchlow-Fligner pairwise comparisons test were used to compare the IgG-S titers between the groups through the evaluation period. Categorical data were addressed using the Fisher´s exact or Chi-squared (χ^2) test. An alpha level of 5% significance was used in all analyses.

Results: A total of 377 volunteers with AID and 50 HC were included in the study. Patients with spondyloarthritis (N=64), systemic lupus erythematosus (N=63), rheumatoid arthritis (N=61), primary Sjögren's syndrome (N=61), vasculitis (N=31), systemic sclerosis (N=14), inflammatory myopathy (N=9), Crohn´s disease (N=49), ulcerative colitis (N=11) and other systemics AID (N=12) were evaluated. Both groups had female predominance (73.5% vs. 74.0%, p=0.937) and were homogeneous for age (43.5 vs. 41.7,p=0.308). The seroconversion among those not reactive (IgG-S negative at baseline) (46 HC and 191 AID), 28 days after second dose was 97.1% for spondyloarthritis (p=0.425), systemic lupus erythematosus 88.2% (0.006), rheumatoid arthritis 93.5% (0.158), primary Sjögren's syndrome 92.6% (0.133), systemic sclerosis or inflammatory myopathy 47.1% (0.001), inflammatory bowel disease 100% (0.999) and vasculitis 80% (0.006), while in healthy control was 100%. In comparison with HC, there was a statistically significant difference in IgG-S titles only in systemic sclerosis or inflammatory myopathy (1.694 AU/ml vs. 3.719 AU/ml; p=0.006). Both groups only presented mild AE. Pain at the injection (85.7% vs. 78.4%, p=0.239), headache (67.3% vs. 53.8, p=0.074) and fatigue (59.2% Vs. 46.2%, p=0.089) were more common in HC than AID. Overall, reactions like arthralgia (52.6 vs. 22.4%, p<0.001), hematoma (14.1 vs. 4.1%, p=0.05), cutaneous rash (9.5 vs. 0%, p=0.024) were more frequent in AID. Most participants related that they felt safer after receiving a COVID-19 vaccination, and 52.4% did not reported a worse patient global assessment (PGA) index.

Conclusion: In conclusion, our data indicated that ChAdOx1 vaccine is safe and induced high titers and seroconversion rate in AID. More severe AID, such as vasculitis, systemic lupus erythematosous, and systemic sclerosis and myositis showed a lower seroconversion rate. Further analysis will explore the association between immunossupressant and reactivity, and booster dose.

POS1286 SEVERITY OF COVID-19 IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING BIOLOGICAL DMARDS

R. Samigullina[1], A. Dadalova[1], E. Vasilenko[1], V. Mazurov[1]. *[1]North-Western State Medical University named after I.I. Mechnikov, Department of Therapy, Rheumatology, Examination of Temporary Disability and Quality of Medical Care named after E.E.Eichwald, St. Petersburg, Russian Federation*

Background: The safety of biological DMARDs for rheumatic diseases in the context of the covid 19 pandemic is one of the key aspects of modern rheumatology

Objectives: assess the severity of the course of COVID-19 infection in patients with rheumatoid arthritis receiving various biological disease-modifying antirheumatic drugs.

Methods: to assess the severity of the course of SARS-CoV-2, discharged epicrisis from hospitals or the conclusion of computed tomography were used.

Since March 2020 to November 2021, among the 1389 patients with rheumatic diseases observed at the of the anticytokine therapy center of the North-Western State Medical University Named after I.I. Mechnikov 105 cases of COVID-19 infection of patients with rheumatoid arthritis were registered, of which 53 patients received outpatient treatment, and 52 patients received inpatient treatment. In 76% of cases, patients received biological DMARDs in combination with synthetic DMARDs.

Results: In patients treated on an outpatient basis, only 17% (9 patients) underwent chest X-ray examination, according to which grade 2 CT was observed in three patients. Among hospitalized patients, multispiral computed tomography was performed in all cases (n=8; 15.3%) of this group of interstitial lung lesions consistent with CT-1. At the same time, CT-2 was determined in 25 (48,1%), CT-3 - in 16 (30.8%), CT-4 - in 3 (5.8%) (2 lethal cases) patients. The most severe cases of COVID-19 (CT-3 and CT-4) were observed most often in patients (12 and 3, respectively) treated with rituximab (Table 1).

Table 1. The volume of lung damage in patients with RA with COVID-19 who received biological DMARDs before infection

	CT-1 (<25%)	CT-2 (25-50%)	CT-3 (50-75)	CT-4
TNF-alpha inhibitors (n=4)	2	2		
Abatacept (n=5)	1	2	2	
Rituximab (n=37)	3	19	12	3
Tocilizumab (n=1)			1	
Tofacitinib (n=5)	2	2	1	
Total	8 (15,3%)	25 (48,1%)	16 (30,8%)	3 (5,8%)

Conclusion: Previous rituximab therapy in patients with rheumatoid arthritis is the most unfavorable prognostic factor during COVID-19 infection.

Pain in rheumatic diseases, including fibromyalgia_

POS1287 INFLUENCES ON FIBROMYALGIA AND AUTOANTIBODIES DIRECTED TO NEURO- AND VASOREGULATORY MOLECULES NEED TO BE CONSIDERED IN BIOMARKER RESEARCH

F. Lübber[1], J. Strobach[1], H. Heidecke[2], T. Lange[1], G. Riemekasten[1]. [1]*University of Lübeck, University Clinic of Schleswig-Holstein, Rheumatology and Clinical Immunology, Lübeck, Germany;* [2]*CellTrend GmbH, Autoantibogy Tests, Luckenwalde, Germany*

Background: Fibromyalgia syndrome (FMS) is often present in autoimmune diseases but can also occur in its primary form. Biomarkers for FMS are currently missing. Systemic chronic inflammation, dysautonomia and metabolic dysfunction have been suggested to contribute to the disease. Recent studies indicate that FMS involves autoantibodies (abs), which bind to neurons, macrophages and endothelial cells.

Objectives: In the present study, we aimed to delineate changes in natural abs directed to neuro- and vasoregulatory molecules and potentially confounding factors, which could influence these abs and disease state.

Methods: Sera from 91 patients with primary FMS (pFMS), 24 patients with secondary FMS (sFMS) and 31 healthy controls (HC) were analysed for the presence of 27 different natural abs directed to e.g., cholinergic, opioid, cannabinoid, endothelin or complement receptors or angiotensin system molecules by individual ELISAs (CellTrend GmbH, Luckenwalde, Germany). All participants were characterized by several questionnaires to obtain demographic data and measures of disease state (using the Widespread Pain Index (WPI) and Symptom Severity Score (SSS)). Linear regression on log-transformed ab levels adjusted for potential confounders was used to compare ab levels between groups. Random forest analysis was applied to differentiate between pFMS and HC by measuring the Area Under the Curve Receiver operating characteristics (AUC-ROC).

Results: Compared to HC, patients with pFMS showed increased levels of abs directed to ACE II, the angiotensin receptor type-2 (AT2R), the cannabinoid receptor type 1 and 2 (Can1-R, Can2-R), the endothelin receptor type-B (ETBR), the opioid receptor κ (Op-k-R) and lower levels against the complement receptor 5a (C5a-R) and the muscarinergic acetylcholine receptor type 3 (M3)(Figure 1). After adjustment for age (linear and squared) and sex, differences in the ab levels remain significant for abs against ACE II, AT2R, ETBR and the Op-k-R. However, none of which remained significant after further adjustment for Body Mass Index (BMI). Random forest analysis of unadjusted ab levels revealed an AUC-ROC of 0.94 for pFMS compared to HC with an average accuracy of 0.85 and a kappa of 0.55. Again, after adjusting the ab levels for age, sex and the BMI, AUC-ROC to discriminate HC from pFMS patients decreased to 0.73 (accuracy = 0.79, kappa = 0.33).

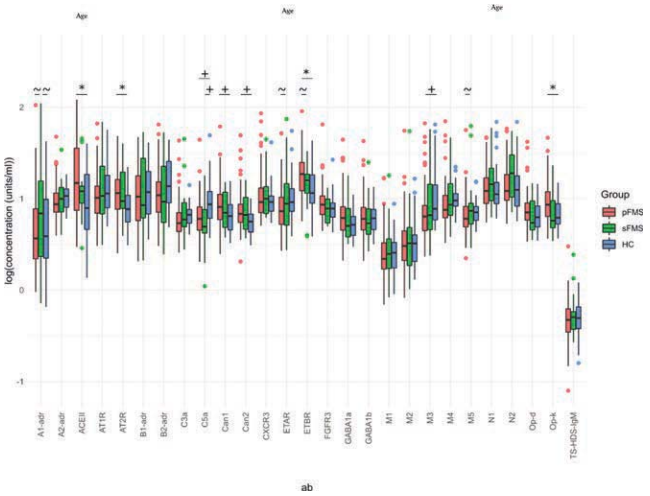

Figure 1. Boxplots of logarithmized abs levels between groups. *: p < .05 in unadjusted analysis and after adjusting for age and sex, ~: p < .05 only significant after adjusting for age and sex, +: p < .05 only in unadjusted analysis (all FDR-corrected within group comparisons across abs). Unadjusted Adjusted for age, sex and BMI

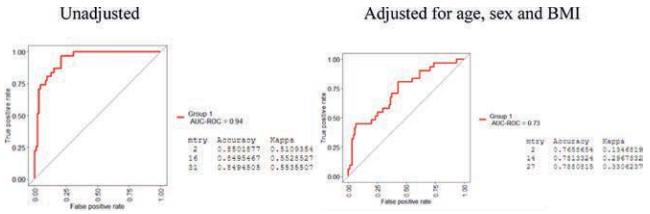

Figure 2. AUC ROC as detected by random forest analysis in pFMS patients versus HC for unadjusted ab levels as well as for ab levels adjusted for age, sex, and BMI.

Conclusion: Abs might be potential biomarkers for pFMS. However, these results highlight the important role of correct covariate adjustment for research on biomarkers supposed to classify FMS or other diseases. In FMS, increase in BMI might be a cause or a consequence of FMS and it is also unknown how BMI and abs influence each other. Thus, BMI might or might not be a confounder so that adjusting for BMI might be correct or incorrect. However, these abs could provide a link to understand how acquired conditions interact with the immune system.

Background: Because of the subjective character of symptoms, absence of a diagnostic test, modest response to treatments, and at times, patient reports of important functional disability, fibromyalgia remains a challenge for the treating health care professionals in the standard clinical practice.

Objectives: To develop an up to date consensus, evidence-based clinical practice guidelines for treat to target management of fibromyalgia.

Methods: 15 key clinical questions were identified by a scientific committee according to the Patient/ Population, Intervention, Comparison, and Outcomes (PICO) approach. A literature review team performed a systematic review to summarize evidence advocating the benefits and harms of available pharmacologic and nonpharmacologic therapies for fibromyalgia. Subsequently, recommendations were formulated. The level of evidence was determined for each section using the Oxford Centre for Evidence-based Medicine (CEBM) system. A 3-round Delphi process was conducted with 16 experts. All rounds were conducted online. A consensus was achieved on the direction and the strength of the recommendations.

Results: An online questionnaire were sent to expert panel who participated in the three rounds (response rate 100%). At the end of round 3, a total of fifteen recommendation items, categorized into 10 sections to address the main fibromyalgia categories, were obtained. Agreement with the recommendations (rank 7-9) ranged from 85-100%. Consensus was reached (i.e.≥80%of respondents strongly agreed or agreed) on the wording of all the 15 clinical standards identified by the scientific committee. Algorithm for the management of fibromyalgia have been suggested.

Conclusion: These recommendations provide an updated consensus on both the non-pharmacological as well as the pharmacological treatment of fibromyalgia. The provide strategies to reach optimal treat to target outcomes in common clinical scenarios, based on a combination of evidence and expert opinion. Best treatment decisions should be tailored to each individual patient situation.

Spine, mechanical musculoskeletal problems, local soft tissue disorders

POS1289 ANALYSIS OF INFECTIOUS SPONDYLODISCITIS: FIVE-YEARS DATA

B. A. Hiba[1], B. A. Kaouther[1], S. Miladi[1], F. Alia[1], S. Meriem[1], L. Souabni[1], K. Ouenniche[1], K. Selma[1], C. Selma[1], L. Ahmad[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Spondylodiscitis (SD) is an infection of the vertebral body or disc and may also extend to the epidural space, posterior elements, and paraspinal soft tissues. It is a cause of morbidity and mortality. However, the diagnosis is often delayed because of the non-specific clinical features.
Objectives: In this study, we aimed to describe the clinical and diagnostic features of infectious SD
Methods: We conducted a retrospective study including 40 cases of infectious SD, performed over a period of five years (2014-2019). Epidemiological, clinical characteristics, laboratory results and imaging findings were uniformly collected.
Results: : Of the 40 patients, 37.3% were male. The mean age was 53.3 ± 13.9 years [28-83] and the median Charlson Comorbidity Index was 1. Advanced age, tuberculosis and brucellar contagion were the predominant risk factors. The median duration from onset to diagnosis was 41 days [8-300]. Low back pain (LBP) was the most common symptom (98%). Lumbar spine was the most frequent location (71%). Seven patients had contiguous multiple levels (>2 vertebral bodies). Neurologic symptoms (radicular pain, spinal chord compression, neurologic loss) were observed in 15 patients. The median erythrocyte sedimentation rate was 54 mm/1st h [13-223], the median CRP was 26.3 mg/L [7-387]. Leukopenia (<4000 WBCs/mm3) was found in three patients (9.8%). Magnetic resonance imaging confirmed the diagnosis in all cases, and revealed spinal epiduritis in 17 patients (34.8%), paravertebral abscesses in 11 (20.3%) and spinal cord compression in 4 (7.8%). Pathogens were isolated in 19 cases. Computed tomography-guided percutaneous disc biopsy (PDB) was performed in 16 (53.5%) and was conclusive in (11/15) cases (66.8%). Mycobacterium tuberculosis (MT) was the most common pathogene (46.4%) followed by Brucella (21.4%), Pyogenes (17.8%) and Gram-negative bacteria (14.2%). One patient had both MT and Staphylococcus haemolyticus.Paravertebral abscess formation (19.6%) occurred most frequently in patients with tuberculous SD (P= 0.02). Leucocytosis (>10,000 WBCs/mm3) was significantly higher in patients with Pyogenes SD (p=0.002) than in patients with other types of SD. All patients were treated with antibiotics and only one patient underwent surgical act. The outcome was favourable in 27 cases (86.8%).
Conclusion: Spondylodiscitis should be considered for all patients presenting with chronic backpain especially when associated with laboratory examination abnormalities. In our study, tuberculous spondylodiscitis was the most frequent, which highlights the fact that osteoarticular tuberculosis remains endemic in developing countries, where it still constitutes a major public health problem

POS1290 EFFICACY AND SAFETY OF SODIUM THIOSULFATE IN CALCIFIC TENDINITIS OF THE ROTATOR CUFF – AN INTERIM ANALYSIS OF A RANDOMIZED CLINICAL TRIAL

H. Parente[1], S. Azevedo[1], E. Costa[1,2], F. Guimarães[1], C. Dantas Soares[1], M. Pontes Ferreira[1], D. Faria[1], D. Peixoto[1], J. Tavares-Costa[1], C. Afonso[1], F. Teixeira[1]. [1]*Centro Hospitalar do Alto Minho, Rheumatology, Ponte de Lima, Portugal;* [2]*Braga Public Hospital, Rheumatology, Braga, Portugal*

Background: Calcific tendinitis of the rotator cuff is one of the most common causes of shoulder pain. (1) Ultrasound guided percutaneous lavage (UGPL) is indicated when conservative treatments have failed. (2) Recent reports have shown the interest of topical sodium thiosulfate (STS) in the treatment of other diseases characterizes by ectopic calcifications (3, 4, 5).
Objectives: To assess the efficacy and safety of UGPL with STS versus with saline solution (standard of care - SOC) in calcific tendinitis.
Methods: Double-blinded randomized clinical trial including adult patients with calcific tendinitis, shoulder pain for more than 3 months and at least one positive shoulder impingement test. Only dense type A calcifications (according to the Molé Classification) > 5 mm in diameter were included. Patients were randomized in two groups: STS and saline solution lavage. Informed consents were collected. Both groups were reevaluated at week 1, month 1 and month 3 after UGPL. Pain Visual Analogue Scale (VAS) at rest and during activities, shoulder range of motion and strength, impingement tests, Disabilities of the Arm, Shoulder and Hand (DASH), DASH-Work, EuroQol five-dimensional (EQ5D) and University of California at Los Angeles (UCLA) scores, ultrasound (US) and radiographic evaluations were performed on all follow up visits.
SPSS was used for statistical analysis and significance level was defined as 2-sided p<0.05.
Results: Twenty-six patients were included, where 76.9% (20) were women, with a mean age of 51.2 (SD=9.0) years old. The mean duration of pain before the procedure was 12.7 months (SD=11.3) (minimum of 3 months and a maximum of 48 months).
Fifteen patients (57.7%) were randomized to the control group (SOC) and performed a saline UGPL; the other 11 patients (42.3%) were randomized to the treatment group (STS). Demographic and baseline clinical characteristics are shown in Table 1. Since patient inclusion is dynamic, our sample met 23 patients at week 1 (SOC group = 13 and STS group = 10), 19 patients at month 1 (SOC group = 10 and STS group = 9) and 16 patients at month 3 (SOC group = 8 and STS group = 8).

Table 1. Demographic and baseline clinical characteristics.

	STS lavage (n=11)	Saline solution lavage (n=15)	p-value
Age (years), M (SD)	52.3 (10.6)	50.3 (8.0)	NS
Sex, female % (n/N)	72.7% (8/11)	80% (12/15)	NS
Dominant side, right % (n/N)	100% (11/11)	93.3% (14/15)	NS

VAS EQ5D (0–100), M (SD)	54 (15.9)	58 (20.0)	NS
UCLA score, M (SD)	18.7 (4.1)	14.7 (3.3)	0.014
Bursitis, yes % (n/N)	72.7% (8/11)	66.7% (10/15)	NS
Calcification morphology, % (n/N)			
Acr-shaped	18.2% (2/11)	40% (6/15)	0.039
Fragmented	18.2% (2/11)	26.7% (4/15)	
Nodular and dense, well-defined	63.6% (7/11)	33.3% (5/15)	
Calcification size, median (IQR)	12.6 (5.7)	10.5 (6.3)	NS

SD: Standard deviation; M: Mean; NS: non-significant; IQR: interquartile range

Overall, there were no differences between control (SOC) and treatment group (STS). Both procedures were effective improving pain at rest (p=0.024), EQ5D (p=0.019), DASH-Work (p=0.032) and UCLA scores (p=0.009) and calcification size measured by US (p=0.031) at month 3.
No adverse effects or complications were reported on both groups.
Conclusion: Although well tolerated with no side effects, STS UGPL has failed to show increased benefit for calcific tendinopathy local treatment. Further studies using STS will be needed to ascertain its interest in this disease. This on-going work will be reevaluated with a larger sample.

POS1291 DEGENERATIVE DISC DISEASE IN YOUNG: IMMUNOHISTOCHEMICAL EXPRESSION OF INFLAMMATORY BIOMARKERS AND ANGIOGENIC FACTORS

N. Pravdyuk[1], N. Shostak[1], A. Novikova[1], A. Buianova[1], O. Patsap[2], A. Raksha[1], I. Senko[3], R. Tairova[4], A. Aksyonova[1], A. Muradyants[1], K. Davygora[1]. [1]*Pirogov Russian National Research Medical University, Acad. A.I. Nesterov Department of Faculty Therapy, Moscow, Russian Federation;* [2]*Federal Center of Brain Research and Neurotechnologies of FMBA of Russia, Department of Patology, Moscow, Russian Federation;* [3]*Federal Center of Brain Research and Neurotechnologies of FMBA of Russia, Department of Neurosurgery, Moscow, Russian Federation;* [4]*Federal Center of Brain Research and Neurotechnologies of FMBA of Russia, Department of Neurology, Moscow, Russian Federation*

Background: Low back pain (BP), associated with the degenerative disc disease (DDD), poses a heavy social and economic burden, emerging among young adults. The pathophysiological basis of accelerated degeneration of the intervertebral disc (IVD) and its contribution to the formation of spine osteoarthritis are at the active study stage.

Objectives: To assess infammation and angiogenesis biomarkers in IVD among young patients with chronic LBP, associated with DDD.
Methods: Human IVD tissue from 25 patients was obtained from discectomy surgery to relieve LBP (men – 13, women – 12, age: 36,7 ±3,77) and from autopsy in healthy control group (n=5, age: 37,8±2,52). The grade of DDD was verified by magnetic resonance (MRI) by the classification of C.W. Pfirrmann. Four-micron serial sections of the tissue blocks were stained with hematoxylin and eosin (H-E), than examined by immunohistochemistry staining on the automated VENTANA BenchMark ULTRA platform. Anti-IL-1β, anti-IL-6, and anti-IL-17 were used to study the expression of inflammatory cytokines; anti-VEGF-A and anti-CD31 were used as markers of angiogenesis. All slides were visualized using a Axio Imager.Z2 microscope with EC Plan-Neofluar 40X objective.
Results: In 64% of patients IVD hernias were localized at the level of L5-S1, in 36% - L4-L5. The average Pfirrmann DD stage at the operated level was 4.43±0.57. 72% of patients had Modic changes (MC). 52% of patients had a combination of hernia with endplate erosion (EP) and MC. There were identified evidence of DD on H-E-stained sections, including clusters of cells of the nucleus pulposus (NP), inflammatory cell infiltration and blood vessels in the absence of them in the fissures of the NP and annulus fibrosus (AF). Immunostaining was mainly limited to the cytoplasm of native NP chondrocyte-like cells and AF fibroblast-like cells. IL-1β expression was considerably higher in degenerate samples than in controls for both NP ($p < 0,05$) and AF ($p < 0,01$). Staining for IL-17 was more pronounced in the cytoplasm of chondrocyte-like cells of degenerative NP compared to the control ($p < 0,01$), and statistically lower in AF cells ($p < 0,05$). The number of IL-6 immunopositive cells was similar in NP and AF degenerate tissue, but a greater proportion of IL-6 immunopositive cells was seen in NP tissue ($p<0,05$). The percentage of cells immunopositive for VEGF-A and CD-31 was significantly increased in NP DD cell clusters compared to controls ($p < 0,001$) (88% and 36%, respectively) and was weakly expressed in the extracellular matrix ($p < 0,05$). This suggests that the PU cells trigger angiogenesis. Blood vessels in native sections were confirmed by CD31 detection in 64% of patient specimens versus 10% of control cartilage specimens ($p < 0,001$). The number of CD31 immunopositive cells had a tendency for decrease in severe DD ($p=0,05$), which indicates the extinction of vascularization in the terminal stage of DD. Fissures in the disc did not stained for CD31, which excludes the ingrowth of vessels directly in the area of mechanical damage and proves the immunogenic cause of vascularization. This is confirmed by the synergistic high level of expression of IL-1 and -17 in perivascular, endotheliocytes and intravascular pathological samples versus weak expression in the disc matrix ($p<0.01$).The high level of expression of all interleukins was in the hyaline cartilage of EP patients versus the absence in the controls ($p<0.001$). It indicates their association with aseptic inflammation of EP with the formation of EP erosions and reactive spondylitis (MC) development, detected by MRI in young adults with DD.
Conclusion: Local immune inflammation is a component of the degenerative cascade in IVD, it initiates angiogenesis in cartilage and EP, as well as the development of reactive osteitis of adjacent vertebrae with the formation of inflammatory-erosive lesions of the vertebral-motor segment in chronic back pain. The results obtained will help to identify molecular targets and form a new direction of anti-inflammatory therapy of LBP among young people.

POS1292 ULTRASONOGRAPHIC GUIDED INTRA ARTICULAR STEROID AND HYALURONIC ACID IN ADHESIVE CAPSULITIS WITH AND WITHOUT SUPRASCAPULAR NERVE BLOCK

E. Mohamed[1], A. Metwaly[1], A. Moshrif[2], M. Elwan[1]. *[1]AL AZAHR University Hospital, Rheumatology, Assiut, Egypt; [2]AL AZAHR University Hospital, Rheumatology, Assiut, Egypt*

Background: Adhesive capsulitis (AC), often known as frozen shoulder, is a common musculoskeletal condition characterised by shoulder pain and reduced active and passive mobility. Intra-articular injections is an effective treatment option and provide faster pain relief in patients with AC
Objectives: Compare the effictiveness of intra articular injection (IAI) of steroid and HA with or without Suprascapular nerve block (SSNB) in the management of AC.
Methods: Randomized control trial involved 80 patients (62 women and 18 men) clinically diagnosed as having adhesive capsulitis divided into 2 main groups; intra articular injection with SSNB (40 cases) and without SSNB (40 cases), each group divided into 2 subgroups; Twenty patients were treated with ultrasound guided intra articular injection of steroid (4ml of 2% lidocaine and 2ml of 40mg/ml triamcinolone) and another twenty patients were treated with ultrasound guided intra articular injection of hyaluronic acid (4ml of 2% lidocaine and 2ml hyaluronic acid).
Results: Intra articular shoulder injection with SSNB has higher significant visual analogue scale (VAS) score at baseline and lower significant VAS score at 1st and 3rd week ($p < 0.001$). However, there was no significance between both groups regarding disability score at 3rd weak ($p=0.316$). In contrast, there was a high significance between them considering disability score at baseline, 1st, 6th weak ($p<0.001$ and 0.008, respectively).
Conclusion: In patients with adhesive capsulitis, both a combination an IAI alone or with SSNB dramatically improved pain and functional results. The use of an SSNB in conjunction with an IAI especially with steroid enhanced therapeutic effectiveness.

Paediatric rheumatology

POS1293 TEN-YEAR EFFICACY DATA FROM THE CLIPPER STUDIES: OPEN-LABEL, LONG-TERM ETANERCEPT TREATMENT IN CHILDREN AND YOUNG ADULTS WITH EXTENDED OLIGOARTICULAR, ENTHESITIS-RELATED, OR PSORIATIC JUVENILE IDIOPATHIC ARTHRITIS

J. Vojinovic[1], J. Dehoorne[1], V. Panaviene[1], G. Susic[1], G. Horneff[1], V. Stanevicha[1], K. Kobusinska[1], Z. Žuber[1], B. Dobrzyniecka[1], J. Akikusa[1], T. Avcin[1], A. Martini[1], C. Borlenghi[2], E. Arthur[3], S.Y. Tatulych[4], C. Zang[5], V. Tsekouras[6], B. Vlahos[7], N. Ruperto[1]. *[1]Paediatric Rheumatology International Trials Organisation (PRINTO), Paediatric and Rheumatology, Genoa, Italy; [2]Pfizer, I&I Medical Affairs, Buenos Aires, Argentina; [3]Pfizer, Clinical Development and Operations, Peapack, United States of America; [4]Pfizer, Clinical Development, Groton, United States of America; [5]Pfizer, Global Biometrics and Data Management, Collegeville, United States of America; [6]Pfizer, I&I Medical Affairs, Strovolos, Cyprus; [7]Pfizer, Global Product Development, Collegeville, United States of America*

Background: CLIPPER2 was an 8-year, open-label extension of the phase 3b, 2-year CLIPPER study of the safety and efficacy of etanercept (ETN) in patients (pts) with juvenile idiopathic arthritis (JIA), categorized as extended oligoarticular JIA (eoJIA), enthesitis-related arthritis (ERA), or psoriatic arthritis (PsA).
Objectives: Evaluation of the efficacy of ETN and its effect on health outcomes over 10 years of follow-up were secondary objectives and are reported here.
Methods: Pts (n=127) with eoJIA (n=60; 2-17 years of age), ERA (n=38; 12-17), or PsA (n=29; 12-17) who received ≥1 ETN dose (0.8mg/kg once weekly [max, 50 mg]) in CLIPPER were eligible to enter CLIPPER2. The study design has been reported previously.[1] Efficacy endpoints included proportions of pts achieving JIA American College of Rheumatology (ACR) 30/50/70/90/100 criteria, Juvenile Arthritis Disease Activity Score (JADAS) inactive disease and clinical remission criteria, and sustained clinical remission (ACR criteria) or JADAS ≤1 for 12 continuous months (mths). Exploratory efficacy endpoints included time to flare following ETN withdrawal (based on ≥30% worsening in ≥3/6 ACR Pedi components, with ≥30% improvement in <2/6 remaining components and ≥2 active joints), and time to re-treatment with ETN.
Observed Cases were used (i.e., there was no imputation for missing data) for pts who were in the Active Treatment Period.
Results: A total of 109/127 (86%) CLIPPER participants entered CLIPPER2 (n=55 eoJIA, n=31 ERA, n=23 PsA), with 99 (78%) pts continuing in the Active Treatment Period. Overall, 84 (66%) pts completed 120 mths of follow-up; 27 (21%) while actively taking ETN. Thirty (24%) pts entered the Withdrawal Period from the Active Treatment Period (i.e., they discontinued ETN, either by meeting the Wallace definition for clinically inactive disease for at least 6 months on ETN, or by having had a good clinical response and being deemed to benefit from withdrawal in the investigator's judgment). Of the pts in the Active Treatment Period, over 90% achieved JIA ACR 50 response at all study time points. Sustained JADAS and ACR remission was achieved by 42 (33%) pts and 17 (13%) pts, respectively. The mean improvements from baseline in JADAS disease activity at mth 24 of CLIPPER were largely maintained through CLIPPER2 A total of 109/127 (86%) CLIPPER participants entered CLIPPER2 (n=55 eoJIA, n=31 ERA, n=23 PsA), with 99 (78%) pts continuing in the Active Treatment Period. Overall, 84 (66%) pts completed 120 mths of follow-up; 27 (21%) while actively taking ETN. Thirty (24%) pts entered the Withdrawal Period from the Active

Treatment Period (i.e., they discontinued ETN, either by meeting the Wallace definition for clinically inactive disease for at least 6 months on ETN, or by having had a good clinical response and being deemed to benefit from withdrawal in the investigator's judgment). Of the pts in the Active Treatment Period, over 90% achieved JIA ACR 50 response at all study time points. Sustained JADAS and ACR remission was achieved by 42 (33%) pts and 17 (13%) pts, respectively. The mean improvements from baseline in JADAS disease activity at mth 24 of CLIPPER were largely maintained through CLIPPER2.

Conclusion: The low numbers of evaluable pts notwithstanding, efficacy results were consistent with the profile of ETN, and treatment responses were considered clinically meaningful and durable with long-term treatment.

POS1294 SAFETY AND EFFICACY OF ADALIMUMAB BIOSIMILAR (AMGEVITA) IN PAEDIATRIC RHEUMATOLOGY PATIENTS

C. Chen[1], K. L. Teh[2], T. Arkachaisri[2], L. Das[2], Y. X. Book[3], S. F. Hoh[4], X. Gao[4]. *[1]KK Women's and Children's Hospital, Pharmacy, Singapore, Singapore; [2]KK Women's and Children's Hospital, Paed Med: Rheumatology and Immunology, Singapore, Singapore; [3]KK Women's and Children's Hospital, KK Research Centre, Singapore, Singapore; [4]KK Women's and Children's Hospital, Nursing, Singapore, Singapore*

Background: The approval of biosimilars requires pharmacokinetic studies to prove that there are no clinically significant differences to the originator molecule. These studies are also used to extrapolate additional indications and for different populations including paediatrics. Literature is lacking for the efficacy and safety of biosimilars for paediatric rheumatology conditions. Amgevita, a biosimilar of adalimumab, was approved for use in Singapore on 31 July 2019. It was used in KK Women's and Children's hospital (KKH), Singapore from 1 September 2020.

Objectives: To report the safety and efficacy of adalimumab biosimilar in children at our centre.

Methods: This is an ongoing prospective, IRB-approved, observation study in a paediatric rheumatology clinic sited within KKH, a tertiary children's hospital. Patients were reviewed in clinic to determine the need to initiate adalimumab (Amgevita), and completed pre-biologic screening to assess suitability to start. Patients were included if they received minimum 1 dose of adalimumab biosimilar. Safety parameters tracked: allergy, including urticaria, anaphylaxis, severe injection site reactions, rate of new onset infections requiring hospitalization and reactivation of latent infections (e.g., tuberculosis or herpes zoster). Adverse reactions were graded according to CTCAE v5.0. Efficacy parameters were tracked for patients with juvenile idiopathic arthritis (JIA) included JADAS27, JADAS71 and JSpADA.

Results: From 1 September 2020 to 31 October 2021, a total of 187 of 20mg syringes and 1403 pre-filled 40mg pens were dispensed to 117 paediatric rheumatology patients. Mean age was 14.9 years, 53.9% were male, 70.9% were Chinese and ethesitis-related arthritis (46.1%) was the most common indication. There were 68 (58.1%) biologic naïve patients. Two patients experienced injection-site urticaria which prompted discontinuation (grade 2). One patient reported initial injection site soreness which resolved spontaneously (grade 1). One patient developed latent tuberculosis requiring inpatient management and temporary interruption in adalimumab therapy (grade 3). No other adverse events were reported. Efficacy data was available for 96 patients. Median scores at baseline and at 3-months and 6-months are presented in Table 1.

Table 1. Summary of paediatric patients initiated on adalimumab biosimilar (Amgevita)

Diagnosis, n (%)						
Enthesitis related arthritis			54 (46.1)			
Of which HLA-B27 positive			44 (81.5)			
Polyarthritis			21 (17.9)			
Extended or persistent oligoarthritis			15 (12.8)			
Undifferentiated JIA			6 (5.1)			
Psoriatic arthritis			1 (0.8)			
Other indications			21 (17.9)			
Concomitant DMARDs, n (%)	Methotrexate			50 (42.7)		
	Sulfasalazine			37 (31.6)		
*Efficacy, Median (range)	Biologic naïve			Not biologic naïve		
Month number	**0**	**3**	**6**	**0**	**3**	**6**
JADAS27	2 (0-21.6)	0 (0-8.5)	0 (0-6.05)	2 (0-10.6)	0 (0-8.4)	0 (0-12.2)
JADAS71	2 (0-27.8)	0 (0-12.0)	0 (0-6.08)	2 (0-10.6)	0 (0-8.4)	0 (0-12.2)
JSpADA	0.25 (0-3.5)	0 (0-1.0)	0 (0-1.0)	0.5 (0-1.5)	0 (0-0.5)	0 (0-2.0)

DMARDs: Disease modifying anti-rheumatic drugs; JADAS: Juvenile Arthritis Disease Activity Score; JSpADA: Juvenile spondyloarthritis disease activity. *Efficacy data only for patients with juvenile idiopathic arthritis

Conclusion: We report our 14-month experience of using adalimumab biosimilar in a pediatric rheumatology population. Majority of the patients did not report major adverse reactions. Majority of JIA patients responded well when initiated on adalimumab (Amgevita). Rheumatologists should continually monitor patients for latent infections after prescribing biologics including biosimilars.

POS1295 SYSTEMIC AND AUTO-INFLAMMATORY DISEASES OF PEDIATRIC ONSET: THE EXPERIENCE OF THE FRENCH OVERSEAS DEPARTMENTS OF AMERICA

A. Felix[1], F. Delion[2], E. Coignard[3], E. Martin[4], M. Mohamed Sahnoun[5], C. Hospice[1], E. Cuadro Alvarez[4], N. Elenga[4], M. Dramé[6], B. Bader-Meunier[7], C. Deligny8, Y. Hatchuel[1]. *[1]Martinique University Hospital, Department of Pediatrics, Fort-De-France, Martinique; [2]Guadeloupe University Hospital, Department of Pediatrics, Pointe-à-Pitre, Guadeloupe; [3]Martinique University Hospital, Department of Internal Medicine, Fort-De-France, Martinique; [4]Andrée Rosemon Hospital, Department of Pediatrics, Cayenne, French Guiana; [5]Centre*

Hospitalier de l'ouest Guyanais, Department of Pediatrics, Saint-Laurent-Du-Maroni, French Guiana; [6]Martinique University Hospital, CIC Antilles-Guyane, Fort-De-France, Martinique; [7]Necker Hospital, Department of Pediatric Rheumatology, Paris, France; [3]Martinique University Hospital, Department of Internal Medicine, Fort-De-France, Martinique

Background: Systemic diseases of pediatric onset are more frequent in Afro-Caribbean population, especially Pediatric systemic lupus (pSLE).

Objectives: Our work is a retrospective study of patients followed in French overseas departments of America for systemic disease or auto-inflammatory syndrome of pediatric onset. It describes their clinical and biological specificities at diagnosis, during childhood and early adulthood.

Methods: Our retrospective study was conducted between 01/01/2000 and 01/09/2021. Listings of adult patients with pediatric onset and pediatric patients were obtained in each center through computerized hospital archives, list of patients followed by referent pediatricians and adult specialists in internal medicine and the French National Registry for rare disease. Data were then gathered by going through their medical files. The spectrum of diseases studied included pSLE, Sjogren syndrome, antiphospholipid syndrome (APS), connectivitis, systemic scleroderma, dermatomyositis, Systemic juvenile idiopathic arthritis (sJIA), unclassified auto-inflammatory syndrome.

Results: 2148 patients were identified on a 21 year-period, and 135 patients were included. Most patients diagnosed with a systemic pathology (102) suffered from pSLE (53%), followed by dermatomyositis (17%). Average follow up was 8.3 years (0.3 - 25 years), median age at last follow up was 21.2 (14 - 36.7). We found an increase in the number of new diagnoses throughout the years. For pSLE, sex repartition was 4/1 girl/boy and did not vary according to age (p= 0,31). At onset, patients had 10 Sclicc criteria (4-12) and median EULAR/ACR 2019 score was 38 (12 - 54). The combination of typical skin involvement, arthritis and fever was found for 87%. At onset, a third of patients had renal involvement, 15% had Neurolupus and 41% cardiac involvement. All patients had a positive ANA and Anti-DNA antibodies, followed by anti-Ssa/Ssb antibodies (78%), Anti-Sm (78%) and anti RNP (52%). During childhood, 54% had renal involvement and 26% suffered from Neurolupus. Patients suffered in median from 3 flares and 26% suffered from more than 5 flares during childhood. Pre-pubertal patients (26%) had worst outcomes, 93% had renal and / or neurological involvement, they had more flares (median at 5 p = 0,02) and needed an average of 4 background therapies (p = 0,04). Boys seemed to have better disease control at transition to adult care but gender was not an independent predictor of severity during childhood (p = 0,21). 17 patients had dermatomyositis, 29% of them had respiratory involvement during childhood. 33 patients had auto-inflammatory syndromes mostly sJIA (67%), 50% of them had hemophagocytic syndrome during childhood and their disease was controlled by steroids for 64%, 36% needed biotherapy. The overall mortality was 3%.

Conclusion: This is a large cohort of patients of Afro-Caribbean origin with a higher frequency of pSLE. Although the outcomes for these patients were similar to western countries, they had loud symptoms at onset, not corelated to delay at diagnosis. Compared to ethnic studies of North America or Africa, the French health care system being universal and free, the bias related to socio-economic status was lower. This work will continue with the exploration by transcriptomic and genetic tests for early and severe forms to identify the extra-environmental causes. The environmental factors specific to these regions should be explored in additional prospective studies.

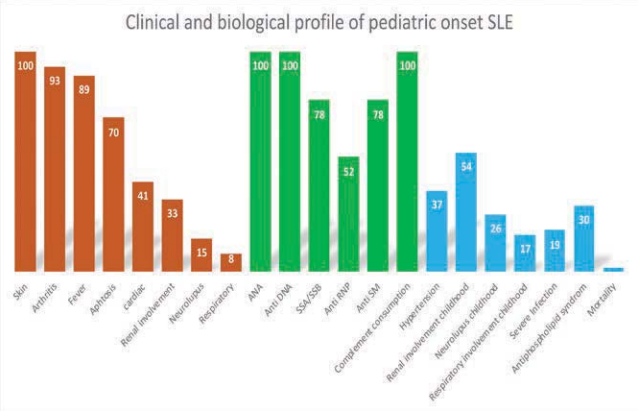

Figure 1. Clinical and biological characteristics of patients with pediatric onset systemic lupus. Orange: clinical signs at onset, Green: immunological profile, Blue: evolutive profile and proportion of organ involvement during childhood. ANA: anti-nuclear antibody.

POS1296 T-CELL RESPONSE MEASURED BY INTERFERON-Γ RELEASE ASSAY AS A NOVEL TOOL FOR BETTER UNDERSTANDING OF SARS-COV-2 IMMUNITY: THE PRELIMINARY RESULTS OF A PROSPECTIVE STUDY IN PEDIATRIC PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS.

K. Kapten[1], K. Orczyk[1], E. Smolewska[2]. *[1]Central Teaching Hospital of Medical University of Lodz, Department of Pediatric Cardiology and Rheumatology, Łódź, Poland; [2]Medical University of Lodz, Department of Pediatric Cardiology and Rheumatology, Łódź, Poland*

Background: While serological assays detecting antibodies in blood serum remain the standard exam for evaluating immunity against SARS-CoV-2 infection, the latest publications reveal certain limitations to this broadly used method. Recent studies showing the decline of antibodies titers in time, together with scientific reports which detect SARS-CoV-2-specific T-cells in seronegative individuals, evoke questions with regard to the reliability of the sole assessment of the humoral response to SARS-CoV-2. A novel T-cell-based Interferon-γ Release Assay (IGRA) is proposed to adapt our approach to the individual immunity to the new coronavirus.

Objectives: The objectives of this study were to assess T-cells and antibodies responses to the SARS-CoV-2 virus among pediatric patients at different stages of juvenile idiopathic arthritis (JIA) undergoing diverse treatment regimes. In addition, the authors aimed to evaluate humoral and cellular responses to the Covid-19 mRNA vaccine in the cohort of immunocompromised patients.

Methods: This prospective study included 30 pediatric patients between the ages 2-16 at different stages of JIA. The cohort group consisted of vaccinated and unvaccinated individuals and children with both positive and negative history of past Covid-19 infection. SARS-CoV-2 T-cell response was measured using a specific quantitative IGRA in whole blood, followed by anti-SARS-CoV-2 ELISA test measuring the presence and quantity of IgG, IgM and IgA antibodies in serum.

Results: The magnitude of the SARS-CoV-2 specific T-cell response measured by the IGRA test correlated significantly with the levels of IgG ($p<0.00005$, $R=0.653$) and IgA antibodies ($p<0.00001$, $R=0.675$) in serum, while no correlation with IgM antibodies level in serum was found. All vaccinated patients developed a cellular response to the vaccine ($p=0.0108$), regardless of the number of administered doses. The T-cells response in children undergoing biological treatment (specifically: etanercept, adalimumab or tocilizumab) was recognizably weaker compared to the group not receiving such treatment. Nevertheless, the difference did not reach statistical significance ($p=0.0715$). Similar dependencies were found in children treated with hydroxychloroquine (n=6), however, due to the small study group, a statistical significance could not have been reached.

Conclusion: Suppression of cellular response observed in different drug protocols may prove to become a protective factor against SARS-CoV-2 infection. Additionally, the authors postulate that the strong correlation found between T-cell response and IgA antibodies titer can be related to SARS-CoV-2 strong affinity with mucosal membranes. Thus, the sole testing of IgG and IgM antibodies levels in serum with regard to Covid-19 may not be the most precise diagnostic method. The presented study group needs to be expanded with more patients, mainly children receiving biological agents or hydroxychloroquine to validate the demonstrated preliminary results.

POS1297 SACROILIITIS AT DIAGNOSIS ASSOCIATED WITH LESS DISEASE FLARE AFTER STOPPING MEDICATION - OUTCOMES AND PREDICTORS OF A SOUTHEAST ASIAN ENTHESITIS RELATED ARTHRITIS (ERA) LONGITUDINAL COHORT

K. L. Teh[1], L. Das[1], Y. X. Book[1], T. Arkachaisri[1,2]. *[1]KK Women's and Children's Hospital, Rheumatology and Immunology, Singapore, Singapore; [2]Duke-NUS Medical School, Rheumatology and Immunology, Singapore, Singapore*

Background: ERA is a subtype of Juvenile Idiopathic Arthritis (JIA) characterized by involvement of entheses and axial skeleton. Outcomes have been shown to be poorer compared with oligoarticular and polyarticular JIA[1].

Objectives: To assess short-and long-term outcomes and predictors of ERA in a large monocentric cohort in Singapore.

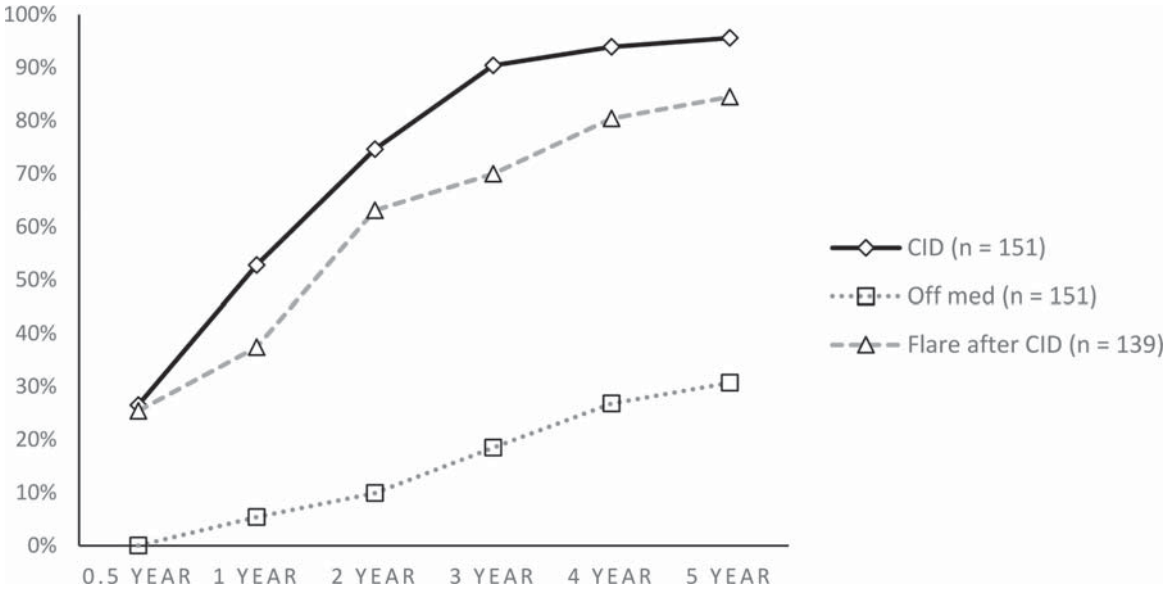

Figure 1. Probability of attaining outcomes over time

Methods: Children diagnosed with ERA according to ILAR criteria from 2002 to 2021 at KK Women's and Children's Hospital, Singapore, were recruited. Outcome statuses were defined according to the criteria for clinical inactive disease (CID) and complete remission (CR) proposed by Wallace et al.[2], with additional criteria of no enthesitis and no active sacroiliitis on MRI. Nonparametric descriptive statistics were used. Univariate and multivariate analysis were performed using logistic regression analyses. The significant level was set at < 0.05.

Results: A cohort of 151 ERA patients (male 86%; Chinese 81%) were included. Median age at onset was 11.9 years (IQR 9.4-13.9) and disease duration was 5.3 years (IQR 2.9-8.4). HLA-B27 was positive in 83% of the patients. At diagnosis, 39% of the patients had sacroiliitis, 46% had hip arthritis, 36% had knee arthritis and 25% had enthesitis. Methotrexate was used in 77% of the patients, while biologics was started in 72% of the patients.

CID was achieved in 92% of the patients, of which 27% achieved CID in 6 months or less. Sacroiliitis at diagnosis is an unfavourable predictor of CID at 6 months but not a significant predictor of ever achieving CID. Older age at diagnosis is also an unfavourable predictor of CID ever.

Medication was totally discontinued in one third of the patients. Half of them went on to have complete remission (CR) off medication. Favourable predictor includes male gender, while positive HLA-B27 and ANA were unfavourable predictors.

Two thirds of the patients with CID had at least one disease flare (23% flared after off medication, 13% flared after CR). Both intra-articular joint injection and anti-TNF use were associated with flare after CID, while anti-TNF use was associated with flare after off medication. Sacroiliitis at diagnosis is a protective predictor of flare after stopping medication.

Conclusion: Despite a high proportion of ERA patients achieving CID, only one third could stop medication completely with high rates of disease flare even after attaining CR. Unfavourable predictors include older age at onset as well as HLA-B27 and ANA positivity. While sacroiliitis at diagnosis is a negative predictor of CID at 6 months, it is protective predictor of flare after discontinuing medication.

Table 1. Predictors of outcomes

Clinical parameters	Univariate analysis			Multivariate analysis		
	OR	95% CI	p	OR	95% CI	p
CID at 6 months						
Sacroiliitis at diagnosis	0.187	0.048-0.724	0.015	0.023	0.003-0.177	<0.001
CID ever						
Age at onset	0.790	0.626-0.998	0.048	0.777	0.605-0.997	0.047
Off medication ever						
Male	5.029	1.121-22.566	0.035	7.703	1.622-36.575	0.010
HLA-B27	0.374	0.158-0.886	0.025	0.290	0.110-0.764	0.012
ANA	0.104	0.013-0.803	0.030	0.077	0.010-0.613	0.015
Flare after CID						
Intra-articular injection	2.585	1.116-5.988	0.027	3.205	1.299-7.909	0.011
Anti-TNF	3.683	1.697-7.993	0.001	4.328	1.905-9.832	<0.001
Flare after discontinue medication						
Sacroiliitis at diagnosis	0.222	0.060-0.821	0.024	0.079	0.009-0.722	0.025

POS1298

RELATIONSHIP BETWEEN DISEASE ACTIVITY BY JADAS-27, SDAI, AND DAS-28 AND SUBSEQUENT CHANGES IN PHYSICAL FUNCTION IN ADULT PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

T. Miyamae[1,2], E. Inoue[2,3], E. Tanaka[2,4], T. Kawabe[1,2], K. Ikari[5,6], M. Harigai[2,4].

[1]Tokyo Women's Medical University Hospital, Department of Pediatric Rheumatology, Institute of Rheumatology, Tokyo, Japan; [2]Tokyo Women's Medical University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan; [3]Showa University, Research Administration Center, Tokyo, Japan; [4]Tokyo Women's Medical University Hospital, Department of Rheumatology, Institute of Rheumatology, Tokyo, Japan; [5]Tokyo Women's Medical University School of Medicine, Division of Multidisciplinary Management of Rheumatic Diseases, Tokyo, Japan; [6]Tokyo Women's Medical University Hospital, Department of Orthopedic Surgery, Institute of Rheumatology, Tokyo, Japan

Background: Juvenile Arthritis Disease Activity Score (JADAS) has been developed as a composite disease activity score specific to Juvenile idiopathic arthritis (JIA). Evaluation of disease activity with a composite measure associated with subsequent changes in structural damage of joints and physical function is necessary for the proper management of Rheumatoid Arthritis (RA) with treat-to-target strategy, and this concept should be considered for patients with JIA in transition and adulthood as well. However, the usefulness of JADAS-27 and other composite measures for RA in these patients has been scarecely investigated. Additionally, JADAS-27 is unfamiliar to non-pediatric rheumatologists.

Objectives: We aimed to investigate an optimal composite score for disease activity in adult JIA from the viewpoint of the subsequent changes in physical function.

Methods: Patients diagnosed with JIA with the following conditions were enrolled: 1) disease onset at age < 18 years; 2) registered in the IORRA database for the first time between 2000 and 2020; and 3) ≥18 years old at the time of IORRA registration. The baseline of each patient was their initial entry into the IORRA database. The Simplified Disease Activity Index (SDAI), Disease Activity Score using 28 joints (DAS28), and JADAS-27 were compared. The patients were stratified into four disease activity categories: remission/inactive disease, low disease activity, moderate disease activity, and high disease activity according to mean disease activity scores in each index during the first year from baseline, and mean changes in J-HAQ (mean ΔJ-HAQ) during 2 years from baseline in each disease activity group were estimated using the linear mixed effect model

to account for correlations of repeated measures without filling in the missing data after adjusting for sex, age, and disease duration.

Results: We included 294 eligible individuals (median age at onset, 14.0 years; rheumatoid factor positive in 64.7%). The median age at baseline and disease duration was 33.8 (24.1–47.7) years and 21.0 (11.0–34.0) years, respectively. The J-HAQ was completed in all 294 patients, and 171 (58.1%) had a score of less than 0.5 at baseline, which is defined as functional remission. During the 2-year observation period, the median J-HAQ of all patients remained unchanged. There was a trend toward improvement in disease activity over time in all three composite scores. Some differeces were obsered across the three indeces: a higher proportion of patients with high disease activity and a lower proportion of patients in remission/inactive disease were observed with JADAS-27 versus SDAI and DAS28. A significant increasing trend of the estimated mean ΔJ-HAQ at 2 years after baseline was observed along with an increase in the mean disease activity during the first year measured using DAS28 (p = 0.01) and SDAI (p = 0.018), but not using JADAS-27 as shown in Table 1.

Table 1. Association of the mean disease activity categories during the first year after baseline and mean changes in J-HAQ during the two years after baseline

(n = 294)	SDAI	DAS28	JADAS-27
Remission/inactive disease	0.019 [–0.190, 0.228]	0.053 [0.024, 0.130]	0.081 [–0.072, 0.234]
LDA	0.091 [–0.150, 0.332]	0.102 [–0.013, 0.217]	0.054 [–0.102, 0.210]
MDA or HDA	0.155 [–0.286, 0.596]	0.136 [0.030, 0.242]	0.087 [0.022, 0.152]
p-value for trend	0.019	0.010	0.115

(Data are expressed as J-HAQ [95% confidence interval]. P-value less than 0.05 indicate a significant trend of the mean ΔJ-HAQ during the two years after baseline. LDA low disease activity; MDA moderate disease activity; HDA high disease activity)

Conclusion: Disease activity measured using SDAI and DAS28, but not using JADAS27, was significantly associated with subsequent changes in physical function in transitional and adult patients with JIA. This study support the use of SDAI and DAS28, but not JADAS27, in assessing disease activity in these patients to adjust treatments for preventing future deterioration of physical function.

Helmus[1].
[1]Hamburg Centre for Pediatric and Adolescent Rheumatology, Schön Klinik Hamburg Eilbek, Hamburg, Germany; [2]jSSc Collaborative Group, Hamburg Centre for Pediatric and Adolescent Rheumatology, Hamburg, Germany

Background: Juvenile systemic scleroderma (jSSc) is an orphan disease with a prevalence of 3 in 1,000,000 children. Currently no medications are licensed for the treatment of jSSc. Due to its rarity, only recently have the first management and treatment guidelines been published, the jSSc SHARE (Single Hub and Access point for paediatric Rheumatology in Europe) recommendations, reflecting consensus opinion upon pediatric rheumatologists (1).

Objectives: To better understand treatment practices internationally for jSSc, both at baseline and over 24 months observation period and to compare if real world therapies are congruent with the recent SHARE recommendations.

Methods: The juvenile systemic sclerosis inceptions cohort (jSScC) is a multinational cohort that prospectively collects clinical data, including medications at baseline and subsequent visits. The jSScC enrollment criteria include age of onset of the first non-Raynaud symptom younger than 16 years and age younger than 18 years at cohort entrance. The frequency of medications (general category and specific medication) was calculated across the cohort at timepoint 0 (enrollment), 12 months and 24 months.

Results: We extracted data from the jSScC of patients who were followed for 12 or 24 months. 109 patients were followed at time point 0 (T0) and 12 months (T12), and data was available for 77 of them up at 24 months (T24). The mean age of the patients was 13.2 years at the timepoint 0. 77% were female and 75% had diffuse subtype. Disease duration at baseline visit was 3.1 years. The medications the patients were on recorded by the physician were captured at T0, T12 and T24 listed in Table 1.

Table 1.

MEDICATIONS	Time point 0 N=109	T12 months N=109	T24 months N=77
Any Medication	92% (100)	97% (106)	97% (75)
Vascular medications			
Endothelial receptor antagonist	16% (17)	24% (26)	21% (16)
PDE-5-Blocker	5% (5)	8% (9)	9% (7)
Immunomodulators			
Corticosteroids	52% (57)	44% (48)	44% (21)
All csDMARDs:	81% (88)	93% (101)	92% (71)
csDMARDs monotherapy	61% (67)	66% (72)	60% (46)
csDMARDs combination therapy	17% (18)	15% (16)	14% (11)
Methotrexate	51% (56)	50% (55)	39% (30)
Mycophenolate Mofetil	26% (28)	44% (48)	47% (36)
Hydroxychloriquine	11% (12)	15% (16)	21% (16)
Cyclophosphamide	12% (13)	2% (2)	1% (1)
Azathioprine	2% (2)	2% (2)	3% (2)
All bDMARDs:	5% (5)	14% (15)	18% (14)
bDMARDs monotherapy	2%(2)	2%(2)	1% (1)
bDMARDs combined with csDMARDs	3% (3)	12% (13)	17% (13)
Tocilizumab	2% (2)	10% (11)	14% (11)
Rituximab	2% (2)	4% (4)	4% (3)
Adalimumab	1% (1)	0% (0)	0% (0)
Autologous Stem cell transplantation	0% (0)	1% (1)	0% (0)

csDMARDs: Conventional synthetic disease-modifying antirheumatic drugs b DMARDs: Biological disease-modifying antirheumatic drugs

Conclusion: At baseline half of the patients were on corticosteroids. This is more frequent than typical adult SSc practice but coincides with jSSc SHARE treatment recommendations (#1). After 12 months observation in the cohort over 90% of patients received a DMARD therapy. Methotrexate and mycophenolate mofetil were the most commonly prescribed DMARDs, which also reflects the SHARE treatment recommendations (#2, #3). At 12 months the use of glucocorticoid decreased and the use of bDMARDs increased. In general, biological DMARDs are typically considered in severe or refractory (SHARE recommendation #7), reflecting the lower percentage compared to csDMARDs. Autologous stem cell transplantation was observed in one patient at 12 months, reflecting an option in jSSc with progressive and refractory disease (SHARE recommendation #8). Endothelial receptor antagonists, such as bosentan, were used over time in approximately 20% of the patients, reflecting SHARE recommendation #6 for pulmonary hypertension and/or digital tip ulcers. This is the first evaluation looking at clinical medication practice pattern in jSSc, and its comparison to recently published consensus guidelines.

POS1300

PAIN AND ITS ASSOCIATION WITH HEALTH-RELATED QUALITY OF LIFE, SLEEP, PHYSICAL ACTIVITY, AND SEDENTARY BEHAVIOR IN 10-YEAR-OLD CHILDREN FROM A SWEDISH BIRTH COHORT

J. S. Malmborg[1], J. Roswall[2,3], G. Almquist-Tangen[2,4], J. Dahlgren[2], B. Alm[2], S. Bergman[1,5]. *[1]Spenshult Research and Development Centre, Halmstad, Sweden; [2]The Sahlgrenska Academy, University of Gothenburg, Department of Pediatrics, Institute of Clinical Sciences, Gothenburg, Sweden; [3]Halland Hospital, Department of Pediatrics, Halmstad, Sweden; [4]Region Halland, Child Health Care Unit, Halmstad, Sweden; [5]The Sahlgrenska Academy, University of Gothenburg, Primary Health Care, School of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden*

Background: Pain in children may be underreported and undertreated today, but due to methodological variations, pain prevalence is difficult to determine. Moreover, it is unclear to what extent pediatric pain is associated with health-related quality of life (HRQoL) and other lifestyle habits. There is a need for an increased understanding of pain in children.
Objectives: To study pain prevalence and cross-sectional associations between pain, HRQoL, sleep, physical activity, and sedentary behavior in 10-year-old children from a Swedish birth cohort.
Methods: The Swedish birth cohort the "Halland Health and Growth Study" (H^2GS) recruited 2860 children at birth (2007–2009). At 10 years of age the children answered questionnaires regarding pain (mannequin with 20 regions, frequency never–daily for each region) and HRQoL (Kidscreen-27, 27 questions, 5 domains scored worst–best). Parents estimated their child's sleep (6–8, 9, or 10–12 hours/night), physical activity time, and sedentary time (hours/weekdays and hours/weekends respectively). Children were categorized into the groups of "infrequent pain" (never–monthly pain) or "frequent pain" (weekly–almost daily pain) from the highest reported pain frequency from at least one body region. Differences in pain prevalence between boys and girls were analyzed with chi^2-test. Logistic regression analyses were performed to study associations between frequent pain (dependent variable) and HRQoL, sleep, physical activity, and sedentary behavior (independent variables). Each variable was adjusted for sex.
Results: 733 children (351 boys and 382 girls) answered pain and HRQoL questions at 10 years of age. Frequent pain was reported by 37% (boys 35% vs. girls 39%, p=0.267). The number of frequent pain regions ranged from 1–13 in boys and 1–20 in girls. Higher HRQoL in the domains physical wellbeing (OR 0.965; 95%CI 0.948–0.983; p<0.001), psychological wellbeing (OR 0.971; 95%CI 0.955–0.987; p<0.001), autonomy and parents (OR 0.971; 95%CI 0.954–0.988; p=0.001), peers and social support (OR 0.977; 95%CI 0.961–0.994; p=0.007), and school environment (OR 0.972; 95%CI 0.956–0.989; p=0.002) was associated with less risk of belonging to the frequent pain group. More sedentary time in weekdays (OR 1.107; 95%CI 1.028–1.192; p=0.007) and weekends (OR 1.122; 95%CI 1.037–1.215; p=0.004) was associated with having frequent pain, but no associations were found between frequent pain and the amount of physical activity or sleep.
Conclusion: The high prevalence of frequent pain in 10-year-old children must receive attention by the school and health-care services. The association between frequent pain and low HRQoL is troublesome. Improving HRQoL and reducing sedentary time is beneficial for children's health, but further studies are needed to follow associations over time.

POS1301

OCCURRENCE OF ARTHRITIS IS IN 37% OF THE PATIENTS WITHOUT OVERLYING SKIN INVOLVEMENT IN JUVENILE LOCALIZED SCLERODERMA. SUMMARY OF THE EXTRACUTANEOUS INVOLVEMENT IN A MONOCENTRIC COHORT.

A. Petersen[1], I. Foeldvari[2]. *[1]Asklepios Campus Hamburg, Semmelweis-Universität, Budapest, Hungary; [2]Hamburg Centre for Pediatric and Adolescence Rheumatology, An der Schön Klinik Hamburg Eilbek, Hamburg, Germany*

Background: Localized scleroderma in childhood (locSSc) occurs with a prevalence of 3.2 to 3.6 per 10 000 children[1]. There are not many publications assessing in detail the extracutaneous manifestations (EM) of locSSc. It is very important to assess the EM too, because the EM can lead to significant damage and morbidity too.
Objectives: To assess the occurrence of extracutaneous manifestations in locSSc in our cohort and the correlation of the occurring EM to the subtype of locSSc and the localisation of the skin involvement.
Methods: Retrospective chart review of all consecutive patients, who were followed at our centre from January 2000 to July 2020 with the diagnosis of locSSc. The subtype was classified according Laxer et al[2]. The patients were under the age of 18 years at the time point of the first visit. Demographic and clinical data were extracted.
Results: 73 patients could be identified, 71% of them were female. Mean age at disease onset was 8 years (4-14 years). The mean time of follow up was 5 years. The subtype distribution was 42 (57%) linear, 24 (33%) mixed, 6 (8%) circumscribed morphea and 1 (1%) pansclerotic morphea. 9 (21%) of the 42 patients with linear subtype had coup de sabre and 4 (10%) of them had Parry Romberg. Fifty six (76%) patients had EM, 40 (53%) of them had 1 form of EM, 10 (13%) of them 2 forms of EM and 6 (8%) patients 3 forms of EM. 53(73%) of the 76 patients had arthritis. Twenty (37%) of the 53 arthritis involvement occurred on a localisation without overlaying skin involvement. Most frequent localisation of arthritis without overlaying skin involvement was in the hip joints (18%). Of the 53 patients with articular involvement had 31 (58%) linear, 17 (32%) mixed, 4 (7.5) circumscribed morphea and 1 (2%) pansclerotic subtype. 14 (19%) of the 73 had length discrepancy of the extremities and 13 (93%) of them had linear subtype. Neurologic symptoms presenting as headache occurred in 8 (11%) patients, 6 (75%) of them had Parry Romberg subtype and 2 (25%) of them coup de sabre. "White" anterior uveitis was screened according to published recommendations[3,4] and it occurred in 3 patients, only one of them had coup the sabre the other two linear and mixed subtype without involvement of the face.
Conclusion: EM is very common and it occurs in 76% of the patients. Thirty seven percent of the articular involvement occurred in joints without overlaying skin involvement, which suggest the importance of the whole body joint count as in juvenile idiopathic arthritis. Only 1 of 3 patients with uveitis had skin involvement in the face, which emphasize the recommended uveitis screening.

Schonenberg[3], V. Smith[3], N. Helmus[1]. *[1]Hamburg Centre for Pediatric and Adolescent Rheumatology, Schön Klinik Hamburg Eilbek, Hamburg, Germany, Hamburg, Germany; [2]German Rheumatism Research Center, German Rheumatism Research Center, Berlin, Germany; [3]jSSc Collaborative Group, Hamburg Centre for Pediatric and Adolescent Rheumatology, Hamburg, Germany*

Background: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children (1). The Juvenile Systemic Scleroderma Inception cohort (jSScC) is the largest cohort of jSSc patients in the world. The jSScC collects longitudinal data prospectively in jSSc, allowing the evaluation of the development of organ involvement and patients and physician reported outcomes in jSSc over time.
Objectives: To review the changes in the clinical characteristics and patient and physician reported outcomes over 12 months observation period from the time of inclusion into the cohort.
Methods: The jSScC cohort enrolls jSSc patients who developed the first non-Raynaud´s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion (2, 3). We reviewed jSScC patient clinical data and patient and physician reported outcomes, who had 12 months follow up from the time of inclusion until 1st of December 2021.
Results: We could extract data of 113 patients. The female/male ratio was 3.5:1. Median age of onset of Raynaud´s was 10.1 years and the median age of onset of non-Raynaud´s was 10.8 years. Eighty-eight percent of the patients were treated with disease modifying anti-rheumatic drugs (DMARDs) at time of inclusion in the cohort (T0) and 93% after 12 months (T12). Median disease

duration was 2.5 years at T0. Antibody profile stayed unchanged. Only 3 clinical parameters changed and improved significantly, the median modified Rodnan skin score improved from 13 to 8 (p=0.002), the number of patients with swollen joints decreased from 17% to 8% (p=0.043) and number of patients with joints with pain on motion decreased from 20% to 12% (p=0.048). All other organ involvement did not show any statistically significant change from T0 to T12.

All collected patient reported outcomes improved significantly from T0 to T12: the patient reported disease activity (VAS 0 – 100) from 40 to 20 (p=0.011), the patient reported disease damage (VAS 0 – 100) from 40 to 20 (p=0.001), patient reported ulceration activity (VAS 0 – 100) from 10 to 0 (p=0.02) and the CHAQ score from 0.3 to 0.1 (p=0.002). Two of the three physician reported outcomes improved significantly, the physician global disease activity (VAS 0 – 100) from 30 to 20 (p=0.011) and physician reported global disease damage (VAS 0 – 100) from 30 to 25 (p=0.028).

Conclusion: Skin and musculoskeletal clinical features improved over 12 months, with almost all patients on DMARDs, supporting likely response of these features to therapy. It was promising that internal organ involvement, like cardiac and lung, although potentially stable, did not significantly worsen or increase. The most striking observation in the positive direction is improvement across several patient and physician reported outcome measures over the 12 month time period in this large international cohort.

POS1303 METHOTREXATE RESPONSE IN PEDIATRIC NON-INFECTIOUS UVEITIS

S. Angeles-Han[1,2], A. Cassedy[3], T. Hennard[4], M. Altaye[3], H. Brunner[4], E. Dosunmu[2], A. Grom[4], M. Henrickson[4], J. Huggins[4], S. Lopper[2], D. J. Lovell[4], R. Sisk[5,6], T. Ting[4], A. Kaufman[2,6], V. Utz[2]. *[1]Cincinnati Children's Hospital Medical Center, Pediatric Rheumatology, Cincinnati, United States of America; [2]Cincinnati Children's Hospital Medical Center, Pediatric Ophthalmology, Cincinnati, United States of America; [3]Cincinnati Children's Hospital Medical Center, Biostatistics & Epidemiology, Cincinnati, United States of America; [4]Cincinnati Children's Hospital Medical Center, Pediatric Rheumatology, Cincinnati, United States of America; [5]Cincinnati Children's Hospital Medical Center, Medical Staff Services, Cincinnati, United States of America; [6]Cincinnati Eye Institute, Ophthalmology, Cincinnati, United States of America*

Background: Children with chronic non-infectious uveitis (NIU) are at risk for sight-threatening complications. Methotrexate (MTX) is the preferred first-line systemic treatment. Initial therapeutic response takes 3-6 months to achieve NIU control, leading to prolonged glucocorticoid use. Moreover, at least 50-70% of children fail to fully respond and may accrue ocular damage while awaiting MTX response.

Objectives: To identify features of children with NIU that are associated with MTX failure.

Methods: We included children who started MTX monotherapy for NIU. We collected demographics, NIU features (type, location, & complications), ANA status, and clinical examination. We characterized children as MTX responders or non-responders. MTX responders are those whose NIU was controlled, defined by: 1) inactive graded by SUN criteria, 2) absence of new or worsening complications, and 3) requirement for ≤2 drops of prednisolone acetate and no oral glucocorticoids.

Results: Of 47 NIU children, 68% were MTX non-responders (Table 1), having a longer duration of NIU (Odds Ratio [OR]=1.28, [CI=1.03-1.8], p =0.023) and developing more ocular complications (OR=1.95 [CI=1.23-3.38], p=0.017), (ROC Area Under the Curve = 0.85). MTX non-responders were more likely to have anterior and/or posterior synechiae (p = 0.001), cataracts (p=0.015), and ocular hypertension (p=0.039). Treatment included adalimumab: 27, infliximab: 14, tocilizumab: 5, golimumab: 4, etanercept: 3, and abatacept: 2.

Table 1. Comparison of children with NIU based on MTX response.

	Responders n=15	Non-responders n=32
Caucasian	14 (93)	27 (84)
Hispanic or Latino	0 (0)	3 (9)
Female	12 (80)	23 (72)
Age of NIU onset, yrs, median (IQR)	4.3 (2.9 – 12.3)	4.6 (2.8 - 7.0)
Duration of NIU, yrs, median, (IQR)	4.1 (2.6 – 5.3)	8.2 (4.7 - 11.3)
JIA-NIU	10 (67)	25 (78)
Idiopathic CAU	2 (13)	3 (9)
Other	3 (20)	4 (12)
Bilateral disease	12 (80)	23 (72)
Anterior	12 (86)	29 (91)
Presenting BCVA (LogMAR) worst eye, median (IQR)	0.2 (0.1 – 0.3)	0.1 (0.0 - 0.2)
Average # of total complications/person, median (IQR)	1 (0 – 2)	2.5 (1.0 – 5.5)
ANA positive	10 (67)	26 (81)
Earliest ESR	8 (6– 18)	12 (8 - 18)
Earliest Vitamin D	32 (26 – 35)	31 (23 - 35)
Time on MTX, months, median (IQR)	35 (19 - 64)	19 (7 - 74)
Time from systemic or NIU onset to MTX, yrs, median (IQR)	0.3 (0.1 – 0.5)	0.2 (0.0 - 0.8)
MTX PO	6 (40)	19 (59)
MTX SC	13 (87)	31 (97)

We performed a sub analysis of children with idiopathic chronic anterior NIU (CAU) and JIA-associated NIU that included children who failed MTX due to intolerance/toxicity (Figure 1). Using Cox proportional hazard regression, 8 idiopathic CAU failed MTX earlier than 38 JIA-associated NIU (HR 2.77, [CI-=1.06-7.27], p=0.039). Results were similar with the inclusion of other types of NIU (p=0.088) (e.g., HLA-B27, non-anterior idiopathic or with systemic disease).

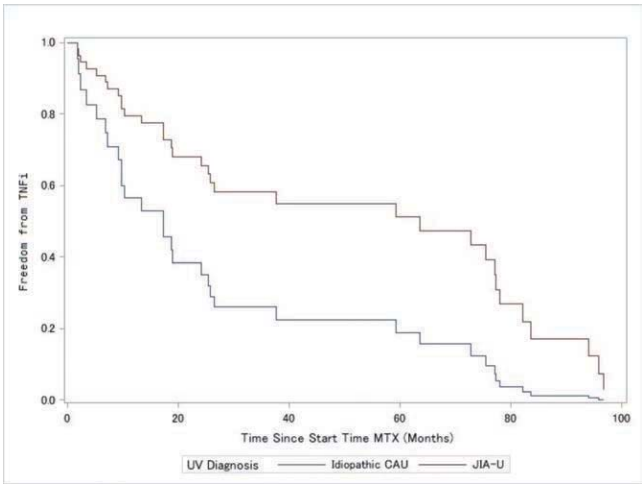

Figure 1. Kaplan-Meier curve showing freedom from TNFi (mos) stratified by diagnosis

Conclusion: Two out of three children with NIU fail initial MTX monotherapy, exposing them to increased accrual of ocular complications prior to biologic starts. The risk for delay in starting tumor necrosis factor α inhibitors (TNFi) seems higher with CAU. Future studies will examine risk factors that predict MTX response in NIU.

POS1304 CORRELATION OF SKIN SCORES (LOSCAT) WITH PATIENT REPORTED OUTCOMES IN JUVENILE LOCALISED SCLERODERMA

C. Pain[1], A. Murray[2], G. Dinsdale[3], A. Marsden[4], J. Manning[3], A. Herrick[2]. *[1]Alder Hey Children's Hospital NHS Foundation Trust, Paediatric Rheumatology, Liverpool, United Kingdom; [2]University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom; [3]Salford Royal NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom; [4]University of Manchester, Division of Population Health, Health Services Research and Primary Care, Manchester, United Kingdom*

Background: Juvenile localised scleroderma (JLS) or morphea is a rare condition, causing inflammation and fibrosis in skin and underlying tissues. A validated skin score (Localized Scleroderma Cutaneous Assessment Tool, LoSCAT) has been developed [1]. This tool has both activity (mLoSSi) and damage indices (LoSDI). Several patient-reported outcomes (PRO) have been studied in JLS including visual analogue scales (VAS), functional and health-related quality of life measures.
Objectives: To assess the associations between different PROs and the activity and damage indices of the LoSCAT.
Methods: Participants aged 4 to 17 were recruited from 3 tertiary paediatric rheumatology centres in the UK and attended 4 visits at 3 monthly intervals as part of a program of research on JLS. Patient-reported VAS (6 different scales), the Children's Dermatology Life Quality Index (CDLQI) and Childhood Health Assessment Questionnaires (CHAQ) were completed at each visit. LoSCAT was completed by the two same clinicians throughout the study (both trained in skin score techniques). Pearson correlation coefficients were calculated between each PRO and each component of the LoSCAT.
Results: 24 participants completed all 4 visits and 1 attended 3 visits. 20 participants were female (80%) and 5 were male (20%). Mean age at diagnosis was 7.6 years with mean disease duration of 4.9 years. Subtype of disease was linear head in 5/25 (20%), linear limb 12/25 (48%), generalised morphoea 1/25 (4%), mixed 5/25 (20%) and superficial plaque in 2/25 (8%). Table 1 shows the correlations with figures in bold highlighting positive correlations which were statistically significant ($p<0.05$) and medium-sized ($r>0.3$).

Table 1. Correlation between patient reported outcomes and LoSCAT

PRO	Total skin activity (mLoSSi)		Total skin damage (LoSDI)	
	r (95% CI)	p-value	r (95% CI)	p-value
CDLQI	**0.61 (0.02, 1.20)**	**0.044**	**0.42 (0.01, 0.83)**	**0.044**
CHAQ	**0.30 (0.03, 0.57)**	**0.027**	**0.20 (-0.14, 0.54)**	**0.244**
VAS 1: How much IMPACT has your disease had on your life in the PAST MONTH?	**0.49 (0.00, 0.98)**	**0.050**	**0.38 (0.06, 0.71)**	**0.021**
VAS 2: How much has your condition (localized scleroderma) affected you OVERALL in the PAST MONTH?	**0.59 (0.09, 1.09)**	**0.022**	**0.42 (0.13, 0.72)**	**0.005**
VAS 3: Have your lesions felt itchy and/or scratchy in PAST MONTH?	0.40 (-0.01, 0.81)	0.056	0.31 (0.03, 0.59)	0.028
VAS 4: Have you felt numbness, tingling, and/or other "funny" feeling in or around your lesion in PAST MONTH?	**0.55 (0.04, 1.05)**	0.033	0.33 (-0.04, 0.71)	0.084
VAS 5: How much WORRY do you have about LONG--TERM problems from your disease?	0.40 (-0.01, 0.81)	0.053	**0.32 (0.00, 0.63)**	**0.047**
VAS 6: How much WORRY do you have about problems from MEDICATIONS used to treat your condition?	**0.41 (0.00, 0.82)**	0.050	0.29 (-0.09, 0.66)	0.131

The VAS of symptoms of numbness/tingling showed a strong positive correlation with mLoSSi but a weak and/or non-significant correlation with LoSDI. VAS itchy/scratchy did not show a strong correlation with mLoSSi but showed a moderate correlation with LoSDI. Patient global VAS correlated with both mLoSSi and LoSDI, as did CDLQI. CHAQ correlated with activity only.
Conclusion: Symptoms within lesions are often interpreted as indicating disease activity. A previous study in adults and children showed itch positively correlated with mLoSSi suggesting it may be a marker of active disease [2]. However, in our study numbness/tingling correlated with disease activity whereas itch did not. Further work is required to understand whether itch correlates to both activity and damage and whether numbness/tingling is a better indicator of activity than itch. Limitations of our study include a heterogenous group of participants with longstanding high-burden disease.

POS1305 PEDIATRIC SAPHO SYNDROME: SINGLE ENTITY OR COMBINATION OF DIFFERENT DISEASES?

C. Matucci-Cerinic[1,2], G. Viglizzo[3], R. Caorsi[4,5], S. Volpi[2,4], C. Malattia[2,5], M. Gattorno[4,5]. *[1]IRCCS Istituto Giannina Gaslini, Center for Autoinflammatory Diseases and Immunodeficencies, Genoa, Italy; [2]University of Genoa, DINOGMI, Genoa, Italy; [3]IRCCS Istituto Giannina Gaslini, Division of Dermatology, Genoa, Italy; [1]IRCCS Istituto Giannina Gaslini, Center for Autoinflammatory Diseases and Immunodeficencies, Genoa, Italy; [5]IRCCS Istituto Giannina Gaslini, Division of Pediatrics and Rheumatology, Genoa, Italy*

Background: SAPHO is a heterogeneous autoinflammatory disease, characterized by bone and joint involvement and by a wide variety of dermatologic manifestations, including palmo-plantar pustulosis (PPP), acne, hidradenitis suppurativa (HS), pyoderma gangrenosum (PG), psoriasis, Snedd-Wilkinson disease and Sweet syndrome. In children, the osteo-articular manifestations are characterized by chronic recurrent multifocal osteomyelitis (CRMO), involving the metaepiphysis of the long bones and the axial skeleton, as in the adult form. The SAPHO treatment still today is a challenge, and no therapeutic guidelines are available in children: NSAIDs are frequently used as first line treatment for CRMO lesions, followed by bisphosphonates, methotrexate and biologic therapies. In the literature there are many case reports but only a few case series[1-3], of which this is the largest in Europe (29 cases reported in China[4]).
Objectives: to report the clinical and radiological features and the response to therapy of SAPHO children.
Methods: the clinical data (serological, imaging and therapy) of 13 SAPHO patients, followed between 2001 and 2021 at the Unit for Autoinflammatory diseases at the Gaslini Hospital were reviewed.
Results: 7/13 patients were male. At disease onset, acne-HS was present as the only manifestation in 8/13 patients while PPP was concomitant or subsequent to bone manifestations. The skin involvement was characterised by acne (comedonic in 3 cases, nodulo-cystic in 4 cases), PPP (5), HS (3), PG (1). Multifocal inflammatory bone lesions with axial or long bone involvement were both present in 92% of patients, whereas sternoclavicolar involvement was observed in 85% of patients.
At disease onset all patients were treated with NSAIDS but only 4, with also PPP, achieved remission. In 7/13 patients, Methotrexate or salazopirin were used, and in 2/13 with severe painful bone lesions bisphosphonates were successfully employed. In the 5 PPP patients, the cutaneous involvement was mild and did not need treatment. In 9/13 patients, the skin manifestations required a therapeutic upgrade with biologics: Etanercept in 5 with partial result, Adalimumab in 6 had an optimal response, in 1 a partial response, even if requiring an increased dose (80mg per week) and 1 was swapped to dapsone. Anakinra (3), ustekinumab and secukinumab (2) were not efficacious. It is to note that the 3 patients with comedonic acne were refractory to all treatments and needed multiple therapy cycling to achieve a partial remission only.
Conclusion: Our patients were characterised by well known SAPHO clinical manifestations. Despite the optimal therapeutic response of CRMO, comedonic acne was refractory to any treatment while PPP and nodulo-cystic acne achieved remission. This may suggest that the skin involvement in SAPHO may identify clinical phenotypes with a different response to treatments.

POS1306 EXTREME PERIODIC FEVER, APHTHOUS STOMATITIS, PHARYNGITIS AND CERVICAL ADENITIS (PFAPA) ARE A SUBSET OF PFAPA PATIENTS WITH FLARES THAT OCCUR MORE THAN TWICE A MONTH.

M. Broide[1], Y. Levinsky[1], G. Amarilyo[1], R. Tal[1], L. Harel[1], Y. Butbul[2], S. Abu Ahmad[2], S. Shoham[1]. *[1]Schneider Children's Medical Center in*

Israel, Rheumatology, Petah Tikva, Israel; [2]Rambam Health Care Campus, Rheumatology, Haifa, Israel

Background: The febrile episodes of periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome occur, by definition, every 2 to 8 weeks. However, a subset of our patients appears to experience attacks at an even higher rate of more than twice a month, and was therefore named extreme PFAPA, or ePFAPA group.
Objectives: To characterize this group both demographically and clinically in order to compare them to the non-extreme PFAPA (nPFAPA) group.
Methods: We retrospectively reviewed the medical records of patients with PFAPA that were treated in the Schneider Children's Medical Center of Israel from 3/2014 to 4/2021. Patients with concomitant familial Mediterranean fever were excluded. Thereafter the ePFAPA and nPFAPA groups were compared using Wilcoxon rank sum, Pearson's chi-squared and Fisher's exact tests.
Results: 47 patients (12.9%) out a total of 365 PFAPA patients were included in the ePFAPA group. Compared to the nPFAPA group, ePFAPA patients had earlier disease onset (age 1.7 vs 2.96 years, P<0.001) and diagnosis (age 2.94 vs 5.02 years, P<0.001). Moreover, after initiation of an abortive treatment with corticosteroids, ePFAPA patients had higher increased flares frequency (72% vs 40%, P<0.001) and were treated with colchicine prophylaxis more often (67% vs 26%, P<0.001). Other clinical and demographic aspects were not significantly different between the two groups.
Conclusion: EPFAPA patients are a subset of patients who have earlier onset and diagnosis of PFAPA, and also increased flares frequently after abortive therapy with steroids. Current study is underway to describe the long-term outcome of this group.

Background: Antiphospholipid syndrome (APS) is an autoimmune disease characterized by thrombotic events (TEs) and/or pregnancy morbidity, in association with two consecutive positive determinations (at least 12 weeks apart) of antiphospholipid antibodies (aPLs). Several manifestations which are not considered clinical criteria of APS have been identified, including hematologic disorders. [1]
Objectives: To identify the different variables associated with the development of hematological manifestations in the presence of aPLs in a pediatric cohort.
Methods: Multicentric historical cohort of children ≤ 18 years from three Spanish and one Italian tertiary referral hospitals with at least 2 positive determinations (≥12 weeks apart) of IgG/IgM anticardiolipin (aCL), IgG/IgM anti β2-glycoprotein I (aβ2GP) and/or LA. Demographic, clinical and analytical data were collected. A bivariate and multivariate analysis were carried out. Multicollinearity was also explored to build the model.
Results: 131 children were included. Demographic, clinical, analytical data; and results of bivariant analysis are shown in Table 1.

Table 1. ***Demographic characteristics; non-thrombotic clinical manifestations; immunologic laboratory findings; and bivariate analysis according to each specific entity and the occurrence of "hematological" manifestations. The multivariate analysis identified as independent risk factors to develop a hematological manifestation, children with: SLE diagnosis [OR 1.2, 95 CI (0.5-5.8), p= 0.015], cutaneous manifestations [OR 1.01, 95 CI (0.6 -2.8), p= 0.091], LA + [OR 0.8, 95 CI (0.4 -3.6), p= 0.058], and IgG aβ2GP + [OR 0.9, 95 CI (0.4 - 3.9), p= 0.048]. Sex, age, familiar history of AIDs or IgM B2GP+ did not show a higher risk.

Conclusion: Non-criteria manifestations, specially hematologic disorders, are the most frequent events in the presence of aPLs in our cohort. Cutaneous manifestations, a positive personal history of SLE, LA positivity and IgG aβ2GP positivity were associated with a higher risk of developing hematological manifestations. Therefore, their inclusion as APS classification criteria should be considered.

POS1308 SINGLE CENTER REAL-LIFE PRACTICE OF BIOLOGICAL THERAPY IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH JUVENILE ONSET

M. Kaleda[1], I. Nikishina[1], E. Fedorov[1], S. Salugina[1], A. Shapovalenko[1], T. Pachkoria[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Pediatric Department, Moscow, Russian Federation*

Background: In recent years the use of Biologics (B) at the management of systemic lupus erythematosus including with juvenile onset (jSLE) has increased. Belimumab (BEL) became the first approved B for SLE. The use of rituximab (RTM), despite the status "of label," remains relevant in a number of patients (pts) with poor response to standard therapy and the presence of life-threatening conditions. However, use of B in real clinical practice has increase slowly, in part, due to uncertainty over which pts should be treated with B and in what stage of the disease, in part, due to uncertainty over safety.

Objectives: To analyze in retrospective study the efficacy and safety of B in pts with jSLE.

Methods: The study included all pts with jSLE in our pediatric rheumatologic department, who received B.

Results: Among 160 pts with jSLE, 52 (32.5%) received B: 43 – RTM, 12 – BEL, 1 – abatacept (ABA). 4 pts received 2B in sequence (2 – RTM-BEL; 1 - BEL-RTM; 1 – RTM-ABA). The proportion of pts with jSLE was 47% among all those who received RTM in our center. The median age at onset – 12.2 y.o. [IQR 9.9; 14.6], median disease duration at start of RTM – 2.5 years [IQR 0.9; 4.5]. The girls and boys ratio = 6.2:1. The median of activity by SLEDAI at start of RTM was – 16 [12; 22]. 58% of pts underwent more than one course of RTM, with a maximum of 6 courses. The median time between each course was 182 [96–315] days. RTM was effective in 40 (93%) pts with the achievement of the inactive status of the disease and reduction of GC-therapy. Various adverse events (AE) were observed in 46.5% of pts as recurrent uncomplicated upper respiratory tract infections being the most common (23.2%). RTM was discontinued in 9 pts: 1 - the flare of Ro-associated vasculitis, 1 - inefficiency, 7 - serious AEs. Serious AEs included: pneumonia – in 1 (2.3%), serious infusion reaction – 1 (2.3%), toxic epidermolysis – 1 (2.3%), MAS – 2 (4.6%), death (inefficiency for treatment of MAS in SLE) – 2 (4.6%). Among pts receiving BEL the median age at onset was 12.7 y.o. [IQR 10.0; 15.0], median disease duration at start of BEL – 1.5 years [IQR 1.0; 2.1]. The girls and boys ratio = 1.4:1. The median of activity by SLEDAI at start of BEL was – 10 [9; 14]. 6 pts receive BEL more than 1 year with the achievement of the inactive status of the disease and reduction of GC-therapy. AEs were registrated in 3 pts (25%): neutropenia (III degree) – in 1, SAEs – in 2 pts (toxic epidermolysis after 1st infusion, flare of SLE after 6 months of therapy, with discontinuation of BEL in both pts). One patient, boy, 4 y.o. at onset, received ABA (RTM was discontinue after MAS). Disease duration at start of ABA – 7.5 years, the activity by SLEDAI – 10. Treatment with ABA allowed to decrease the activity of jSLE (now SLEDAI=2). Now boy receives ABA during 51 months with good safety, continues GC 5 mg per day, hydroxychloroquine 100 mg per day, MMF 750 mg per day.

Conclusion: Our study has shown that B is effective in jSLE and has an acceptable safety profile if possible adverse reactions are carefully monitored. In the presence of severe organ lesions, to improve the long-term prognosis, the appointment of B at an early stage of the disease can be discussed. The overall picture that emerges is one of optimism that advances in therapy of jSLE will be realised through the targeted use of an increasing different B.

POS1309 THE IMPACT OF PSORIASIS ON PATIENT-REPORTED OUTCOMES IN JUVENILE PSORIATIC ARTHRITIS

J. M. J. Low[1], K. Hyrich[2], N. Geifman[3], S. Shoop-Worrall[4]on behalf of CAPS. [1]*The University of Manchester, UK, Manchester Medical School, Manchester, United Kingdom;* [2]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom;* [3]*The University of Surrey, School of Health Sciences, Faculty of Health and Medical Sciences, Surrey, United Kingdom;* [4]*The University of Manchester, Centre for Health Informatics, Manchester, United Kingdom*

Background: Children with juvenile psoriatic arthritis (JPsA) are treated similarly to patients in other categories of juvenile idiopathic arthritis (JIA) despite distinctive clinical features, including either a personal or family history of psoriasis. It remains unknown whether the unique features in JPsA lead patients to experience the impact of disease differently from other JIA patients, and how the presence of psoriasis within JPsA affects patient outcomes. These gaps in our knowledge suggest there may be unmet treatment needs in these children and young people.

Objectives: To compare patient-reported outcomes in patients with JPsA and other JIA categories. Additionally, this study explores whether the presence or absence of psoriasis in patients with JPsA is associated with different outcomes.

Methods: Children and young people with JIA were selected if recruited to the Childhood Arthritis Prospective Study (CAPS), a UK multicentre inception cohort of JIA, between January 2001 and March 2018. Detailed demographic information, clinical data and patient-reported outcomes were collected at initial presentation to paediatric rheumatology. Patient-reported outcomes included well-being as measured on the parental global evaluation (10cm), functional ability (Childhood Health Assessment Questionnaire: CHAQ), pain (10cm), health-related quality of life (Child Health Questionnaire, CHQ psychosocial score), depressive symptoms (Mood and Feelings Questionnaire, MFQ) and parent psychosocial health (General Health Questionnaire: GHQ). The CHQ and MFQ questionnaires were completed in a subset of children recruited until 2015 and aged above 5 and 7 years old, respectively.

Patient-reported outcomes in patients with JPsA versus other JIA categories, and in patients with and without psoriasis within JPsA, were tested via multivariable linear regression, adjusted for age at first presentation, gender, disease duration, ethnicity, and number of active joints.

Results: A total of 1653 patients had JIA; the majority (64.7%) were female and median age at onset was 6.5 years (IQR 2.7 - 10.8). A total of 111 (6.7%) were categorised with JPsA, of which 62 (55.9%) were female with median age at onset of 10.2 (IQR 4.3 - 12.5). In those with JPsA, 35% had psoriasis at diagnosis. There were no significant differences between JPsA and non-JPsA in terms of parental global evaluation of wellbeing (p=0.21), CHAQ (p=0.19), pain (p=0.38), CHQ psychosocial (p=0.18), GHQ (p=0.31) or MFQ (p=0.34).

Within JPsA, depressive symptom score on the MFQ was higher in patients with psoriasis compared to those without (coefficient=9.8, 95% CI=0.5 to 19.0, p-value=0.04). However, there were no significant differences in parental global evaluation (p=0.4), CHAQ (p=0.3), pain (p=0. 3), CHQ psychosocial score (p=0.5) or GHQ (p=0.7) between those with and without psoriasis in JPsA (Table 1).

Table 1. Patient-reported outcomes in children and young people with JPsA with and without psoriasis

Patient-reported outcome at JPsA diagnosis	Outcome	Coefficient	95% confidence interval	p-value
	Reference – JPsA without psoriasis	Reference	Reference	Reference
	JPsA with psoriasis			
Wellbeing: Parent global (0-10cm)		0.5	-0.8, 1.8	0.45
Function: CHAQ (0-3)		0.2	-0.2, 0.6	0.28
Pain (0-10cm)		0.8	-0.8, 2.4	0.34
Psychosocial health: CHQ (0-100)		-2.4	-10.1, 5.3	0.52
Parent psychosocial: GHQ (0-84)		-1.3	-8.7, 6.1	0.72
Depressive symptoms: MFQ (0-66)		9.8	0.5, 19.0	0.04

Conclusion: Despite the differences in clinical features present in JPsA compared to the other JIA subtypes, there were no statistically significant differences in patient-reported outcomes overall at diagnosis. However, within the JPsA group, even when adjusting for age, children with psoriasis at time of arthritis diagnosis reported higher depressive symptom scores compared to those without psoriasis. When treating children with JPsA, attention to diagnosing and treating both arthritis and psoriasis may help mood. If poor mood persists in this subtype, then further allied health care may be required.

POS1310 LONG - TERM OUTCOMES IN ADULT PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS

E. Kiseleva[1], E. Koltsova[1], E. Volnukhin[1], N. Savenkova[1], A. Klimets[1], E. Rozochkina[1], A. Kovshik[1], G. Lukina[1]. [1]*A.S. Loginov Moscow Clinical Scientific Center, Rheumatology, Moscow, Russian Federation*

Background: Systemic juvenile idiopathic arthritis (sJIA) debuts in childhood and persists throughout the patient's lifetime. Currently there is not enough information about the course and therapeutic approaches in patients who have reached the age of 18 and moved from pediatric service to adult healthcare system.
Objectives: Evaluate long - term outcomes in patients with sJIA over 18 years of age.
Methods: Thirty - two patients with sJIA have been analyzed after their transition to adult rheumatological chain. The following parameters have been estimated: clinical manifestations, disease duration, radiological changes, medication intake, disease activity, number of arthroplasties, pregnancy, level of education. Disease activity has been assessed using a standardized DAS28 index (remission - less than 2.6, low activity - from 2.6 to 3.2, moderate activity - from 3.2 inclusive to 5.1, high activity - more than 5.1) and counting systemic manifestations.
Results: Among patients included in the study, there were 11 men (34.38%) and 21 women (65.62%); the average age at the time of inclusion was 23.68 (±5.93). In 13 (40.63%) patients the onset of the disease occurred before the age of 5, in 7 (21.87%) - from 6 to 10 years and in 12 (37.50%) - after 11 years. In 9 (28.13%) patients the duration of the disease was less than 10 years, in 23 (71.87%) patients – more than 11 years. The onset of the disease was accompanied by the following symptoms: fever - 28 (87.50%) patients, arthritis - 21 (65.63%), rash - 17 (53.13), arthralgia - 6 (18.75%), pericarditis - 4 (12.50%), sore throat - 4 (12.50%), lymphadenopathy - 3 (9.38%), hepatomegaly - 2 (6.25%). Among patients with arthritis 11 (52.38%) had oligoarthritis, 10 (47.62%) had polyarthritis. 2 patients (6.25%) were diagnosed with uveitis. According to the X-ray examination (Steinbrocker's classification of radiographic changes): 5 (15.63%) patients had the I stage, 13 (40.62%) - the II stage, 4 (12.50%) - the III stage, 6 (18. 75%) - the IV stage and 4 (12.50%) had no radiological changes. Three (9.38%) were diagnosed with aseptic necrosis and these patients underwent arthroplasty. Four (12,50%) patients had pregnancy.
Education: 17 (53.13%) people study at higher educational institutions. Two (6.25%) have a higher educational level.
Disease activity: 24 (75%) patients are currently in low activity or disease remission, 8 (25%) are in moderate activity. Twenty (62.50%) patients receive therapy with disease - modifying antirheumatic drugs (DMARDs), 14 of them take methotrexate at an average dose of 12.68 (±3.98) mg. 6 (18.75%) patients take glucocorticoids at a dose of 1 to 8 mg per day. Non - steroidal anti - inflammatory drugs (NSAIDs) are received by 2 (6.25%) patients. Biological disease - modifying antirheumatic drugs (bDMARDs) are used by 27 (84.38%) patients, 18 (66.67%) of whom are on therapy with tocilizumab.
Among the patients with low activity and disease remission: 15 out of 24 (62.50%) are treated with tocilizumab, 3 (12.50%) – with canakinumab, 3 (12.50%) – with etanercept, and 1 (4.17%) – with adalimumab; 2 (8.33%) patients don't take bDMARDs.
Conclusion: The use of bDMARDs helps successfully control the disease in patients with sJIA, maintain long - term remission and improve long - term outcomes in adult patients with sJIA.

POS1311 HETEROZYGOUS IFIH-1 AND DDX58 VARIANTS DETECTED IN CHILDREN WITH IMMUNO-MEDIATED DISEASES

R. Raupov[1,2], E. Suspitsin[3,4], R. Mulkidzhan[4], M. Kostik[1,5]. [1]*Saint-Petersburg State Pediatric Medical University, Pediatrics, Saint-Petersburg, Russian Federation;* [2]*City Hospital №40, Medical Rehabilitation of Children, Saint-Petersburg, Russian Federation;* [3]*Saint-Petersburg State Pediatric Medical University, Medical Genetics, Saint-Petersburg, Russian Federation;* [4]*N.N.Petrov Institute of Oncology, Molecular diagnostics, Saint-Petersburg, Russian Federation;* [5]*Almazov National Medical Research Centre, Laboratory of Autoimmune and Autoinflammatory Diseases, Saint-Petersburg, Russian Federation*

Background: IFIH1 gene codes for the MDA5 protein participating in interferon I signaling pathway, which is important in the innate immune response [1]. IFIH1 polymorphisms are associated with a spectrum of autoimmune disease [2]. Rare IFIH1 gene defects have been found in patients with Aicardi- Goutières syndrome-7, Singleton-Merten syndrome, and MDA-5 immunodeficiency. All these conditions are characterized by upregulation of interferon signaling [3]. DDX58 encodes RIG-I receptor that is responsible for the recognizing of single- and double-stranded viral RNA. Mutation of DDX58 was described in Singleton-Merten syndrome [4].
Objectives: to describe clinical characteristics of patients with rare IFIH1 and DDX58 variants detected by clinical exome sequencing.
Methods: 8 patients (5 girls and 3 boys) having rare IFIH1 and DDX58 variants (MAF less than 0.005) were found in heterozygous state among the patients who underwent genetic testing in our hospital in 2019-2021. Clinical manifestations, laboratory parameters, IFN I score values and treatment options were analyzed.
Results: 3 patients (#3, #6, #7) had undifferentiated systemic autoinflammatory syndromes, while others were presented with SLE, SLE-like disease, JDM and PFAPA syndrome. All of them had elevated IFN-I score and skin rash. IFIH-1 variants were in 5 patients (#1-5); 3 patients carried the same c.1879G>T polymorphic variant. Patient #6-8 have VUS DDX58 variants. All the alleles were in heterozygous state. Detailed information is presented in Table 1.

Table 1.

#	Genetic variants	MAF	IFN-score	Diagnosis	Manifestation	Treatment
1	IFIH1 c.1879G>T (p.E627X)	0.003	11.3	SLE	Fever, photosensitivity, pancytopenia, thrombosis	CS, RTX, MMF
2	IFIH1 c.1879G>T (p.E627X)	0.003	2.95	PFAPA	Fever, pharyngitis, stomatitis, adenitis	CS in flares
3	IFIH1 c.1558A>G p.T520A	0.00009	5.52	uSAID	Fever, pancytopenia, petechias, panniculitis, hepatomegaly, inflammation	CS, CsA, TOC, TOF
4	IFIH1: c.1784G>A (p.R595H)	0.0001	29.0	JDM	Gottron's papules, periorbital erythema, muscle weakness, osteoarthritis	CS, CYC, IVIG, MTX
5	IFIH1 c.1879G>T (p.E627X)	0.003	20.2	SLE-like disease	Face erythema, skin thickening	topical tacrolimus
6	DDX58 c1061A>G (p.N354S)	0.00007	2.13	uSAID	Recurrent pericarditis	CS
7	DDX58 c109G>A (p.E37K)	0.000008	n/a	uSAID	Fever, livedo racemose, inflammation	NSAIDS
8	DDX58 c.2587_2590dup (p.Cys864fs)	0.0006	21.0	SLE	Skin, mucous, joints, kidney involvement, pancytopenia	CS, RTX

Abbreviations: MAF- minor allele frequency; SLE- systemic lupus erythematosus; uSAID- undifferentiated systemic autoinflammatory syndrome; JDM- juvenile dermatomyositis; CS- corticosteroids; RTX- rituximab; CYC- cyclophosphamide; MTX- methotrexate; IVIG- intravenous immunoglobulin; MMF- mycophenolate mofetil; CsA- cyclosporine A; TOF- tofacitinib.

Conclusion: while rare IFIH1 and DDX58 variants have been repeatedly detected in children with clinically heterogeneous immune-mediated diseases, it is unclear whether these alleles have casual role. Functional testing and collection of patients with the same gene variants are required.

POS1312 ANALYSIS OF INTERFERON TYPE I SIGNATURE IN JUVENILE DERMATOMYOSITIS

R. Raupov[1,2], E. Suspitsin[3,4], R. Mulkidzhan[4], M. Kostik[1,5]. [1]*Saint-Petersburg State Pediatric Medical University, Pediatrics, Saint-Petersburg, Russian Federation;* [2]*City Hospital №40, Medical Rehabilitation of Children, Saint-Petersburg, Russian Federation;* [3]*Saint-Petersburg State Pediatric Medical University, Medical Genetics, Saint-Petersburg, Russian Federation;* [4]*N.N.Petrov Institute of Oncology, Molecular Diagnostics, Saint-Petersburg, Russian Federation;* [5]*Almazov National Medical Research Centre, Laboratory of Autoimmune and Autoinflammatory Diseases, Saint-Petersburg, Russian Federation*

Background: the crucial role of hyperactivation IFN I signaling pathway has been proved in the pathogenesis of dermatomyositis. IFN I genes and chemokines activity vary according to subtype of inflammatory myopathies. IFN type 1 signature could be measured using different genes in the blood, skin and muscle tissue [1].
Objectives: to evaluate IFN-score in children with dermatomyositis and compare with disease activity
Methods: 15 patients (5 boys and 10 girls) were enrolled in the study. Clinical and laboratory parameters, disease activity (CMAS-childhood myositis assessment tool, aCAT- abbreviated cutaneous assessment tool) and treatment were assessed. Patients were compared accordingly to IFN-score elevation. IFN I-score was assessed by RT-PCR quantitation of 5 IFN I-regulated transcripts (IFI44L, IFI44, IFIT3, LY6E, MXA1); median relative expression of ≥ 2 was considered as a cut-off. IFN I-score was evaluated in dynamics in 9 patients.
Results: median age of patients was 6.2 (3.6; 7.6) years. Skin and muscle involvement were in all patients, arthritis in 5 (33%) patients, calcinosis in 3 (20%), lipodystrophy in 2 (13%) and lung involvement in 5 patients (33%), and 9 patients (60%) had positive myositis-related antibodies. Ten patients (67%) had an active disease, while elevated IFN-signature was detected in 12 (80%) patients.
Cumulative IFN I-score and its' five components were higher in active patients, compare to inactive (13.6 vs 1.4, p=0.006).
Patients with increased IFN I-score had lower CMAS score and higher aCAT score compare to patients with normal levels of IFN I-score. IFN-I score correlated with aCAT, arthritis and lung involvement.
Conclusion: IFN-I score may be considered as disease activity biomarker in juvenile dermatomyositis with predominantly skin activity process.

POS1313 HIP INVOLVEMENT IS A MORE FREQUENT COMPLICATION IN ENTHESITIS-RELATED ARTHRITIS COMPARING TO THE ADULT SPONDYLARTHRITIS

C. Ines[1], H. Ferjani[1], L. Ben Ammar[1], D. Ben Nessib[1], W. Triki[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]on behalf of Rheumatologie Charles Nicole Hospital, Tunis.
[1]*Med Kassab Institute of Orthopeadics, Rheumatology, Manouba, Tunisia*

Background: The hip disease develops in 30% to 50% of children with juvenile idiopathic arthritis (JIA) and is associated with poor outcomes and functional impairment. The coxitis in enthesitis-related arthritis (ERA or juvenile-onset spondyloarthritis) patients was frequent but weakly studied.
Objectives: To assess the occurrence of coxitis in patients with ERA and compare it to that of older patients with spondyloarthritis (SpA).
Methods: We conducted a retrospective comparative study including patients with ERA and adult spondyloarthritis patients.
The first group included patients under 16 years old fulfilling the International League of Associations for Rheumatology (ILAR). The second group of patients fulfilled the Assessment of SpondyloArthritis International Society (ASAS) 2009 criteria.
We studied the socio-demographic characteristics of both groups, the hip involvement occurrence, and the treatment modalities.
Quality of life was appraised by the Study 36-item Short-Form Health Survey (SF-36) and the Ankylosing spondylitis quality of life test (ASQOL).
Results: Forty ERA (mean age= 25,3 ± 10,15) patients and 134 SpA (mean age=37,96±11,77) patients were enrolled. Seventeen ERA patients (42,5%) had coxitis at recruitment compared to 28 SpA patients (20,9%), p=0,06. More than half of the ERA patients were positive to HLAb27, compared to the SpA group (44,7%) without reaching a significant threshold, p=0,07. The mean delay of coxitis onset in ERA patients was 4,66 ± 8,46 years, and was 5,65 ± 6,85 years in SpA patients, with no significant difference between the two groups (p=0,527). There was no difference between the two groups for the coxitis being unilateral or bilateral (p=0,272 and 0,169 respectively). Regarding the treatment approach, local therapy was proposed to 11 patients in the ERA group and 13 patients in the SpA group (p=0,07), with synoviorthesis being the most common therapy. Total hip replacement was done in 8 ERA patients (of which seven were bilateral) and in 17 SpA patients (of which ten were bilateral), without reaching the significant threshold (p=0,858). There was no significant difference between the two groups on the period when the total hip replacement was done (p=0,925). Quality of life assessed by the ASQOL and the SF-36 was comparable between the two groups (p=0,666 and 0,326; respectively).
Conclusion: Our study shows the high prevalence of hip involvement in the juvenile group of SpA. This complication occurs within the five years of disease outcomes and constitutes a turning point in their lives.

POS1314 VALIDATION OF A PEDIATRIC-SPECIFIC ULTRASOUND SCORING SYSTEM FOR THE EVALUATION OF WRIST, FINGER, AND ANKLE SYNOVITIS

P. Vega Fernandez[1], T. Hennard[1], K. Rogers[1], A. B. Meyers[2], A. Cassedy[1], T. Ting[1]. [1]*Cincinnati Children's Hospital Medical Center, Department of Pediatrics, Cincinnait, United States of America;* [2]*University of Cincinnati, Radiology, Cincinnati, United States of America*

Background: Juvenile Idiopathic Arthritis (JIA) is the most common chronic rheumatic disease in children. Clinical evaluation of arthritis is a subjective measurement. Musculoskeletal ultrasound (MSUS) is increasingly being utilized in children. In order to provide objective assessments of arthritis, reliable and validated MSUS scoring systems are needed. Recently, a joint-specific scoring system for the assessment of arthritis of the pediatric ankle, wrist and finger joints were proposed[1, 2].
Objectives: This study aims to further validate the MSUS scoring system for the assessment of finger, wrist, and ankle arthritis
Methods: JIA patients with finger, wrist, and ankle arthritis as per expert clinician evaluation are eligible for this study. A comprehensive wrist, ankle, and finger (2-5th metacarpal and 2-5th proximal interphalangeal joints) MSUS examination by an American College of Rheumatology MSUS certified pediatric rheumatologist is performed an all enroll subjects. MSUS are scored using the semiquantitative (grade 0 to 3) scoring systems previously proposed. A subset of participants receives an MRI with contrast of the targeted joint immediately after MSUS performance. MRI findings are read for presence of synovitis, tendonitis and enthesitis by a pediatric radiologist with expertise on musculoskeletal imaging. For the analysis of the current report, MRIs were classified as having presence or absence of findings of JIA disease based on the pediatric radiologist expert opinion. MSUS were classified as normal (grade 0 and 1) or abnormal (grade 2 and 3). Cohen's Kappa Coefficient was used to assess the level of agreement between MSUS (normal and abnormal) and MRI with contrast (absence or presence of disease) for each targeted joint. Tetrachoric Correlation was used to assess the strength of the association. Fisher's Exact test was used to determine statistical significance at $p < 0.05$ level.
Results: A total of 52 children aged 2 – 18 years old have been enrolled in this study. To date 20 MSUS of the finger(s), 33 MSUS of the wrist, and 43 MSUS of the ankle joints have been collected. Three MRI of the 2-5 fingers (12 fingers total), 6 MRI of the wrist, and 5 MRI of ankle have been obtained through the study. Preliminary results of this effort reveal that for the ankle joint there is moderate agreement (Kappa coefficient 0.53 (confidence interval (CI)=0.14-0.92)) between MRI and US and a strong positive tetrachoric correlation (0.79) ($p = 0.03$). While the Kappa coefficient for comparing MRI and US finding on wrist joint indicated moderate agreement (Kappa 0.62 [0.15-1.00]) with a strong tetrachoric correlation (0.83) the Fisher's exact test indicated a trend rather than statistically significant results ($p = 0.07$). The Kappa coefficient for MCPs and PIPs joints indicated strong agreement between MRI and US (Kappa 0.83 [CI=0.52-1.00] and 0.80 [CI=0.43-1.00] respectively) and were supported by an almost perfect Tetrachoric Correlation of 0.99 ($p < 0.01$). We anticipate to complete enrollment of subjects by the summer of 2022. Analysis of collected data is underway.
Conclusion: The strong to moderate association of MSUS with contrast-enhanced MRI, suggest that MSUS can provide an objective and accurate assessment of ankle, wrist and finger arthritis at the bedside. Further refinement and validation of these pediatric-specific MSUS scoring systems may support the use of MSUS as a clinical tool and outcome measure in JIA.

POS1315

PREVALENCE OF SARCOPENIA IN YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS

M. Dzhus[1], M. Kulyk[1], T. Karasevska[1]. [1]*Bogomolets National Medical University, Internal Medicine Department №2, Kyiv, Ukraine*

Background: In the 2019 sarcopenia consensus update (EWGSOP2 [1]) experts emphasize low muscle strength as a key characteristic of sarcopenia, adding low muscle mass to confirm the diagnosis of sarcopenia. Thus, the presence of the first criterion indicates probable sarcopenia, the presence of the first and second criteria confirms the diagnosis of sarcopenia, and the presence of all three criteria indicates severe sarcopenia. There are no available data about severe sarcopenia in young adults with juvenile idiopathic arthritis (JIA).
Objectives: This study aims to assess the prevalence of severe sarcopenia in young patients with JIA.
Methods: To confirm the diagnosis of severe sarcopenia we used dual X-ray absorptiometry (DXA) to assess low muscle mass (cut off points for ASM/height2 <7 kg/m2 for men and <5,67 kg/m2 for women); dynamometry - to determine the low muscle strength (grip strength <27 kg for men, <16 kg for women); gait speed and short physical performance battery (SPPB) to assess physical function (cut off points <8 m/sec and score ≤8, respectively). Patients were divided into two groups according to the presence or absence of all three criteria for severe sarcopenia.
Results: We studied 40 young adults with JIA, including 23 female patients and 17 male patients. The mean age of the patients was 24,4±5 years; the mean age at the onset of the disease was 10,1±4,4 years. Patients were divided into 2 groups according to all three criteria for severe sarcopenia. The first group (I group) included 25 patients with reduced muscle mass, strength, and physical function, and the second group (II group) included 15 patients without criteria of severe sarcopenia. In the I and the II groups mean ASM/height2 was 5,1±0,8 kg/m2 vs 7,7±1,01 kg/m2; p=0,01; handgrip strength 14,8 ±4,8 kg vs 27,1±8,3 kg; p=0,01; gait speed 0,6±0,1 m/sec vs 1,4±0,6 m/sec; p=0,01; SPPB score 6,5±1,5 vs 10,9±1,3; p=0,01. The research found out: the height and weight of patients in the group with severe sarcopenia were lower than in the group without severe sarcopenia (height 1,67±0,07 m vs 1,75±0,08 m; p=0,01; weight 56,1±9,2 kg, 72,0±12,8 kg; p=0,01, respectively). The age of patients was not significantly different between the two groups, but the duration of the disease was longer in the I group 16,4±8,2 vs 9,2±5,3; p=0,01. The data of DXA differed between groups: the patients of I group had statistically reduced total BMD 1,07±0,1 g/cm2 vs 1,15±0,14 g/cm2; ultra-distal radius BMD 0,35±0,1 g/cm2 vs 0,51±0,12 g/cm2; femoral neck BMD 0,85±0,1 g/cm2 vs 1,04±0,2 g/cm2; p=0,01, respectively. Comparing the two groups, we found important differences: the level of ESR was higher in the I group 25,05±18,3 vs 11,5±10,02; p=0,01; the index of disease activity either (DAS28 4,0±1,5 vs 2,7±1,2; JADAS27 15,8±9,2 vs 8,3±4,8; p=0,01, respectively). Articular and extraarticular damage index were higher in I group: JADI-A 5,08±7,3 vs 0,5±0,7; p =0,01; JADI-E 1,7±1,8 vs 0,3±0,6, p=0,02.
Conclusion: The study confirms the presence of severe sarcopenia despite the young age of patients with JIA. Severe sarcopenia occurs in patients with a higher level of inflammatory activity, articular and extraarticular damage, reduced bone mineral density, and longer duration of the disease. Further study of the factors influencing the development of sarcopenia in this category of young patients is required.

POS1316

PERFORMANCE OF THE KOBAYASHI SCORE AND MODIFIED KOBAYASHI SCORE IN PREDICTING RESISTANCE TO INTRAVENOUS IMMUNOGLOBULIN IN PATIENTS WITH PEDIATRIC INFLAMMATORY MULTISYSTEM SYNDROME ASSOCIATED WITH SARS-COV-2.

N. Cybulska[1], K. Jozkow[1], K. Orczyk[1], A. Stasiak[1], E. Smolewska[1]. [1]*Medical University of Lodz, Poland, Department of Pediatric Cardiology and Rheumatology, Lodz, Poland*

Background: Pediatric Inflammatory Multisystem Syndrome Associated With SARS-CoV-2 (PIMS) is a new insidious disease which in several points may mimic Kawasaki disease. Patients diagnosed with one of the aforementioned conditions are initially treated with intravenous immunoglobulin (IVIG). However, up to 20% of children diagnosed with Kawasaki disease appear to be resistant to such therapy. Similarly, substantial portion of PIMS patients requires second line treatment including systemic glucocorticoids. There are several calculative models, including the Kobayashi Score, which are utilized to predict patients' response to such treatment. To our best knowledge, the scoring systems derived from Kawasaki disease have not yet been assessed whether they can fulfil similar role in PIMS patients.
Objectives: There were two essential questions to be addressed in the study: (1) Can the Kobayashi Score be utilized in making clinical decisions regarding concomitant treatment in PIMS patients? (2) Is there any modification that may increase the accuracy of the original score?
Methods: First step of the study involved 19 patients diagnosed with PIMS between July 2020 and June 2021. The statistical analysis including each parameter of the Kobayashi Score has been performed in order to determine potential alterations of the score. Then, the numerous variants of modified score have been compared in terms of their positive and negative predictive values in order to determine new PIMS IVIG Resistance Score (PIRS). In the next phase of the study, both scores have been validated in the second cohort involving 16 patients diagnosed with PIMS between July and December 2021. The final assessment has been performed in the unified study group (35 PIMS patients).
Results: The Kobayashi Score (see Table 1) significantly differentiated PIMS patients in terms of good response or resistance to IVIG (p=0.03967). However, the score returned a few false positive (3 out of 9) and false negative (2 out of 10) results. After step-by-step verification of clinical and laboratory parameters, authors developed a tentative PIRS (see Table 1) including the following criteria: hyponatremia, days of fever and platelet count (derived from the Kobayashi Score but with different cut-off levels) supplemented with procalcitonin level and percentage of lymphocytes. In the validatory phase of the study, both scores had equal accuracy to predict treatment response. The analysis of receiver operating characteristic curve in the unified study group has shown better performance of PIRS (Youden index 0,72) than the Kobayashi Score (Youden index 0,49).

Table 1. List of criteria included in both scores assessed in the study.

Criteria	The Kobayashi Score		PIMS IVIG Resistance Score (PIRS)	
Sodium	≤133 mmol/L	2 points	≤137 mmol/L	1 point
Days of illness at initial treatment	≤4	2 points	≤4	2 points
Aspartate aminotransferase	≥100 IU/L	2 points	-	-
Percentage of neutrophils	≥80%	2 points	-	-
Percentage of lymphocytes	-	-	≤16%	1 point
C-reactive protein	≥100 mg/L	1 point	-	-
Procalcitonin	-	-	≥3.5 ng/mL	1 point
Age	≤12 months	1 point	-	-
Platelet count	≤300 G/L	1 point	≤200 G/L	2 points
Increased risk of resistance to IVIG	**≥4 points**		**≥4 points**	

Conclusion: The Kobayashi Score is worth being considered to estimate the risk of resistance to IVIG in PIMS patients. Nonetheless, it is not free from false positive and false negative results. The postulated modified score called PIRS can become a promising alternative but it requires further validation in larger cohorts of patients.

POS1317

HOW CAN WE ASSESS CARDIOVASCULAR RISK IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS? PRELIMINARY RESULTS REGARDING MEASUREMENTS OF CAROTID INTIMA-MEDIA THICKNESS DURING THE COVID-19 PANDEMIC.

M. Gruca[1], K. Orczyk[1], J. Zamojska[1], K. Niewiadomska-Jarosik[1], J. Stanczyk[1], E. Smolewska[1]. [1]*Medical University of Lodz, Poland, Department of Pediatric Cardiology and Rheumatology, Lodz, Poland*

Background: There is growing body of evidence that adults who were diagnosed as children with juvenile idiopathic arthritis (JIA) have significantly increased risk of developing cardiovascular disease. Risk factors including prolonged sedentary screen time, insufficient physical activity and unhealthy diet are even more essential in the era of the COVID-19 pandemic. However, there is lack of simple and reliable prognostic marker identifying children at higher risk of early development of cardiovascular disease. Non-invasive tests utilized in adults to screen for early phase of atherosclerosis involve examination of the carotid intima-media thickness (cIMT). Only a few research projects have evaluated performance of cIMT measurement in JIA patients and the results remain inconclusive.
Objectives: The aim of this study was to evaluate the usefulness of cIMT testing as a screening method to determine cardiovascular risk in JIA patients. The secondary objective was to assess the frequency of risk factors related to the patients' lifestyle during the COVID-19 pandemic.
Methods: The study involved forty-five patients at mean age 13.4±3.2 years who were already diagnosed with JIA and thirty-seven age- and sex-matched healthy controls. Children were enrolled in the study between March 2020 and

September 2021. Study database included demographic data, conventional risk factors for developing cardiovascular disease (e.g. abnormal body mass index and exposure to secondhand smoking), inflammatory markers and disease activity score. Measurements of cIMT were performed by a qualified physician according to the standardized protocol using high resolution ultrasonography.

Results: Measurement of cIMT revealed values above 94th percentile in four children (three males and one female) who were all diagnosed with JIA. The quantity of abnormal results was not enough to verify the hypothesis of increased cardiovascular risk in JIA patients, though (p=0.06296). However, children diagnosed with JIA are more likely to have abnormal body mass index than their healthy peers (51.1% vs. 21.6%, p=0.00614). Children who doubled their sedentary screen time during the COVID-19 pandemic skipped the sufficient physical activity (p=0.03352). Correlation between elevated ESR and higher cIMT values in right carotid artery was marginally significant (r=0.292, p=0.051443). Regardless of JIA, exposure to secondhand smoking was proved as a significant risk factor of atherosclerosis (18.2% vs. 2.8%, p=0.02771).

Conclusion: Screening measurements of cIMT should be considered in the follow-up of JIA patients with higher disease activity with concurrent elevated ESR. Defining other indications for performing such examination requires further investigation involving larger study group. Healthy lifestyle, including reducing secondhand smoke exposure, needs to be promoted with utmost importance during the COVID-19 pandemic, especially in children with chronic diseases like JIA.

POS1318 JUVENILE IDIOPATHIC ARTHRITIS DISEASE ACTIVITY IN TRANSITIONAL CARE

K. Carpio[1], C. Burgeois Avella[1], J. C. Lopez Robledillo[2], D. Clemente[3], L. Trives Folguera[1], F. Montero[1], I. Monteagudo[1], J. M. Alvaro-Gracia[1], J. C. Nieto González[1]. *[1]Hospital General Universitario Gregorio Marañon, Rheumatology Department, Madrid, Spain; [2]Hospital Infantil Universitario Niño Jesus, Pediatric Rheumatology Unit, Madrid, Spain; [2]Hospital Infantil Universitario Niño Jesus, Pediatric Rheumatology Unit, Madrid, Spain*

Background: Juvenile Idiopathic Arthritis (JIA) is a group of heterogeneous arthritis with onset earlier than 16 years old. According to previous studies, these patients experience an improvement of their disease activity, functionality and even remission probability as they become young adults.[1] Transitional care units aim to coordinate an uninterrupted follow-up in patients with chronic diseases in order to accomplished the objective of improving the ability of manage their own disease.[2] Our transitional care unit attend patients from 18 to 25 years old who have been previously diagnosed with any pediatric rheumatic disease

Objectives: Our primary objective was to describe the disease activity of JIA patients at the transference to our unit and the remission maintenance during follow-up.

Methods: We conducted an observational retrospective longitudinal study from a cohort of patients with JIA who have been transferred to our transitional care unit. We selected patients with at least one clinical visit and active follow-up. We collected demographic data, JIA classification, previous treatments and the treatment at time of transfer, articular and ocular flares, remission defined by Wallace criteria[3] and changes in treatment during follow-up.

We calculated the percentage of patients who had active disease activity at the transference to the Unit and the proportion of patients who had an inflammatory flare (ocular or articular) during the follow-up.

Results: From December 2016 to December 2021 we received 184 patients in our Transitional Care Unit, from them 127 had a JIA and 1 had asymptomatic chronic uveitis. Demographics of JIA patients is shown in Table 1. From 127 JIA patients, 34 (26,8%) were active at the transference and 53 (41,8%) had at least one flare during the follow-up.

Table 1. Demographic data from JIA included in the study, divided according to disease activity at the transference to our transitional care unit.

	Total (n: 127)	Actives (n:34)	Not actives (n:93)
Sex (female) n (%)	84 (66.1)	24 (70.6)	60 (64.5)
Age median (IR)	8.64 (3-13)	9.1 (3-13)	8.4 (3-12.9)
Previous joint injections n(%)	43 (33.9)	16 (47.1)	27 (29)
sDMARD prior transference n (%)	98 (76.6)	26 (76.5)	72 (77.4)
bDMARD prior transference n (%)	79 (61.7)	20 (58.8)	59 (63.4)
Uveitis n (%)	23 (18.1)	8 (23.5)	15 (16.1)
JIA subcategory n (%)			
oligo persist	43 (33.9)	12 (35.3)	31 (33.3)
oligo extend	16 (12.6)	3 (8.8)	13 (14)
poly RF -	25 (19.7)	6 (17.6)	19 (20.4)
poly RF +	3 (2.4)	1 (2.9)	2 (2.2)
ERA	24 (18.9)	8 (23.5)	16 (17.2)
systemic	9 (7.1)	2 (5.9)	7 (7.5)
psoriatic	7 (5.5)	2 (5.9)	5 (5.4)

We calculated the percentage of patients who had active disease at the transference to the Unit and the percentage of patients who had an inflammatory flare during the follow-up. Figures 1 and 2 showed the proportion of flares depending on the inflammatory status at transference to the Transitional care unit and the use of biological therapy before transition.

Conclusion: JIA patients remain active in one quarter of the cases at the transference to the Transitional care unit and flares are twice frequent when they were active at the transference.

POS1319

RISK OF CORONARY ARTERY INVOLVEMENT IN KAWASAKI DISEASE.

S. Kurbanova[1], M. Kantemirova[1], Y. Y. Novikova[1], D. Ovsyannikov[1]. [1]*RUDN University, Department of Pediatrics, Moscow, Russian Federation*

Background: Kawasaki disease (KD) is a nonspecific systemic vasculitic disease that frequently occurs among children, and coronary artery lesion (CAL) is the most serious complication

Objectives: We aimed to study the risk factors for CAL in children with KD

Methods: There were examined 188 patients (boys:girls – 2:1, median age Me = 24 months [11;38]) with KD hospitalized in Morozovskaya Children's City Clinical Hospital in 2014-2019. 19 (10,1%) of them were <6 months, 29 (15,4%) - 6-<12 months, 117 (62,3%) - 12 months-<5 years, 23 (12,2%) - ≥5 years. Univariate and multivariate logistic regression analyses were conducted to explore the relationships between CAL and gender, age, clinical diagnosis, laboratory biomarkers, initiation time of IVIG administration.

Results: The enrolled 188 KD children were divided into a CAL group (n = 61) and an NCAL group (n =127) according to cardiac color Doppler ultrasonography. The incidence rate of CAL in the acute period was 26 %. The two groups had significantly different gender (p=0,0184), initiation time of IVIG administration (p=0,0209;)increase in platelets more than 700 000 at 2 weeks (p=0,0089), higher levels of NT-proBNP (p=0.002) and proANP (p=0,0005). Patients with CAL were found to have higher levels of NT-proBNP and proANP, suggesting a prognostic role. The NT-proBNP level was significantly higher in patients with CAL, and a cutoff value of 984 pg/mL yielded a sensitivity and specificity of 79 and 84.8 %, respectively. The area under the curve of the NT-proBNP for predicting CAA was 0.794 (95 % CI 0.620-0.967). The proANP level was significantly higher in patients with CAL, and a cutoff value of 1.015 nmol/L yielded a sensitivity and specificity of 87.5 and 75.8 %, respectively. The area under the curve of the proANP for predicting CAA was 0.805 (95 % CI 0.656-0.954).

Conclusion: Male gender, delayed use of IVIG, high platelets, NT-proBNP, proANP were independent risk factors for KD complicated with CAL. Current evidence suggests that NT-proBNP and proANP may be used as a diagnostic tool for KD complicated with CAL

POS1320

SAFETY AND EFFICACY OF RITUXIMAB IN PATIENTS WITH JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS: THE PRELIMINARY DATA OF RETROSPECTIVE COHORT STUDY

E. Kalashnikova[1], R. Raupov[1,2], N. Lybimova[3], E. Kuchinskaya[3], O. Kalashnikova[1], V. Chasnyk[1], T. Kornishina[1], L. Snegireva[1], E. Gaidar[1], V. Masalova[1], E. Isupova[1], M. Kaneva[1], M. Dubko[1], T. Likhacheva[1], L. Sorokina[1], M. Kostik[1,3]. [1]*Saint-Petersburg State Pediatric Medical University, Pediatrics, Saint Petersburg, Russian Federation;* [2]*City Hospital №40, Medical Rehabilitation of Children, Saint Petersburg, Russian Federation;* [3]*Almazov National Medical Research Centre, Laboratory of Autoimmune and Autoinflammatory Diseases, Saint Petersburg, Russian Federation*

Background: juvenile systemic lupus erythematosus (jSLE) is the most frequent pediatric connective tissue disease with multiorgan involvement and different outcomes and prognosis. Corticosteroids remain the base treatment option and steroid-sparing treatment is strongly required to avoid steroid toxicity. Rituximab (RTX) is one of biologics, which efficacy was proved in case reports and case series of SLE, but no data from big randomized trials, confirming the efficacy have existed.

Objectives: to evaluate safety and efficiency of RTX in jSLE.

Methods: in the retrospective observation study the information of 48 jSLE patients (12 boys, 36 girls) who received at least one RTX dose before 18 years, included. Diagnosis was made using SLICC criteria. The main indications for RTX were high disease activity with lupus nephritis (LN), CNS and hematology disturbances (hemolytic anemia, thrombocytopenia) and avoiding steroid toxicity. RTX was prescribed in dosage 375 mg/m^2 every week (2-4 infusions) with repeated courses every 6-12 months according disease activity, the degree of B-cell depletion and hypoIgG-emia. The dynamics of clinical, laboratory data, activity of the disease by SLEDAI, GCS doses were assessed in the onset and during RTX trial.

Results: The main patient's characteristics were: onset age 13.0 (11.5; 15.0) years, inclusion age 18.0 (16.0; 20.0) years, LN 25 (52%)/III+IV class 9/11 (82%), CNS involvement 26 (54%). Pre-RTX non-biologic conventional treatment includes: cyclophosphamide 24 (50%), MMF 14 (29%), azathyoprine 7 (15%), methotrexate 6 (13%), cyclosporine A 2 (4%). Observation period ranged from 6 months to 6 years with median time 0.75 (0.2; 2.75) years. Initial pre-RTX treatment (GCS, hydroxychloroquine, non-biologic DMARDS) partially reduced SLE activity (SLEDAI, ANA titer, anti-dsDNA level), and median GCS dose by 25% from the initial dose, without changes in proteinuria, hematuria, C3, C4, WBC, hemoglobin, PLT and ESR levels. Administration of the RTX realized in prominent reducing of SLEDAI, anti-dsDNA level, proteinuria, hematuria, C4, ESR, number of patients with anemia, thrombocytopenia, and median GCS dose by 90% from the initial. The hemoglobin level and WBC have increased. 19 patients received IVIG for treatment of MAS (n=3), infection (n=5) and as replacement treatment in cases where IgG<4.5 g/l (n=11). 3 deaths were observed due to catastrophic SLE with MAS, accompanied severe infection (invasive aspergillosis, n=2). 6 patients realized SAE: pneumonia (n=3), transient agranulocytosis (n=1) after 3rd RTX infusion and meningitis, caused by Lysteria monocytogenis, after 1st RTX infusion (further RTX treatment continued without adverse events), patella osteomyelitis (n=1). 10 patients received antibiotics for respiratory infections. On pre-RTX 13 had antibiotics (p=1.0).

Table 1. Dynamics of SLE features pre-RTX and during RTX trial

Parameter	SLE onset	RTX (baseline)	p	Last visit	p*
SLEDAI	16 (11.0; 23.5)	13.5 (6.5; 21.5)	0.0002	4 (0; 8.0)	0.00002
Patients with elevated anti-dsDNA n, (%)	33 (69)	20 (42)	0.008	11 (23)	0.034
Anti-dsDNA, U/ml (n.v.<25)	112 (1; 200)	24.7 (1; 130)	0.059	0 (0; 27)	0.008

FEATURES OF MACROPHAGE ACTIVATION SYNDROME IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS IN THE ERA OF BIOLOGIC THERAPY

I. Kriulin[1,2], E. Alexeeva[1,2], T. Dvoryakovskaya[1,2], R. Denisova[2], K. Isaeva[2], A. Chomakhidze[2], A. Mamutova[2], O. Lomakina[2], A. Fetisova[2], M. Gautier[2], K. Chibisova[2], E. Krekhova[1,2], I. Tsulukiya[2]. [1]*Sechenov University, Pediatrics, Moscow, Russian Federation;* [2]*National Medical Research Center of Children's Health, Rheumatology, Moscow, Russian Federation*

Background: Macrophage activation syndrome (MAS) is a severe hyperinflammatory response that develops against the background of juvenile idiopathic arthritis (JIA). It is known that the clinical feature of MAS on biologic therapy has other clinical manifestations, different from biologically naive patients.

Objectives: To study the clinical and laboratory features of macrophage activation syndrome in patients with juvenile idiopathic arthritis with systemic onset (sJIA) on the biologic therapy.

Methods: The study included 100 patients with MAS (114 cases of MAS) who observed in the rheumatological department of the National Medical Research Center for Children's health of Ministry of health. All patients met the criteria for the diagnosis of sJIA and MAS. There were children in our study who did not receive biologic therapy – 84 (74%) cases, and children who had MAS in the biologic therapy – 30 cases (26%). The drugs are distributed as follows: tocilizumab - 7 cases (6%), kanakinumab - 20 cases (17%), etanercept – 2 cases (2%), adalimumab – 1 case (1%). For pairwise intergroup comparisons of quantitative variables, the nonparametric Mann-Whitney test was used.

Results: In comparative analysis of biologic-naive and on biologic patients, the greatest differences were obtained for the following clinical manifestations: rash, lymphadenopathy, myalgia (p<0.05). Fever was the most common symptom in both groups and was present in almost all patients (99%). All patients had

elevated level of ferritin in the blood serum (773 ng/ml to 130149 ng/ml). Laboratory picture of MAS in the group of on biologic patients differed significantly from the group of patients naive for biologic therapy (Table 1). The most significant differences were found among the following laboratory parameters: hemoglobin level, the number of erythrocytes and platelets, erythrocyte sedimentation rate (ESR), levels of C-raective protein (CRP), ferritin, lactatedehydrogenase (LDH), albumin.

Table 1. Laboratory data of patients with MAS.

		n	Reference values	Median	Minimum	Maximum	Mann-Whitney Criterion (p)
Biologic-naive cases of MAS (n= 84)	Hemoglobin, g/l	84	120-145	96,50	61,00	145,00	0,008
	Red blood cells, 10^{12}/l	84	4,5-5,3	3,78	2,13	5,01	0,001
	Platelets, 10^9/l	84	150-440	149,00	41,00	523,00	0,025
	White blood cells, 10^9/l	84	4,5-11,5	4,42	0,69	25,84	0,074
	ESR, mm/h	84	2-20	45,00	2,00	111,00	0,001
	CRP, mg/l	84	0-5	111,56	7,54	368,31	0,006
	Ferritin, ng/ml	84	14-124	4195,21	702,38	130149,20	0,022
	LDH, U/l	84	91-295	413,50	162,00	5245,00	0,059
	Albumin, g/l	84	38-54	29,00	16,10	63,00	0,001
On biologic cases of MAS (n = 30)	Hemoglobin, g/l	30	120-145	104,50	67,00	163,00	0,008
	Red blood cells, 10^{12}/l	30	4,5-5,3	4,17	3,10	6,15	0,001
	Platelets, 10^9/l	30	150-440	101,50	4,00	362,00	0,025
	White blood cells, 10^9/l	30	4,5-11,5	3,22	0,70	15,58	0,074
	ESR, mm/h	30	2-20	17,50	2,00	98,00	0,001
	CRP, mg/l	30	0-5	55,77	1,86	407,12	0,006
	Ferritin, ng/ml	30	14-124	2319,59	773,90	121396,00	0,022
	LDH, U/l	30	91-295	600,00	10,60	2148,57	0,059
	Albumin, g/l	30	38-54	32,80	20,30	51,90	0,001

Conclusion: On biologic patients may also develop MAS, which is often difficult to diagnose due to the poor clinical picture and low laboratory activity. In this case, hyperferritinemia remains as a highly specific marker of MAS.

POS1322 DISCONTINUATION OF LONG-TERM ADALIMUMAB TREATMENT IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS-ASSOCIATED UVEITIS

I. Tsulukiya[1], E. Alexeeva[1,2], T. Dvoryakovskaya[1,2], R. Denisova[1], A. Mamutova[1], K. Isaeva[1], A. Chomakhidze[1], O. Lomakina[1], A. Fetisova[1], M. Gautier[1], K. Chibisova[1], I. Kriulin[1,2], E. Krekhova[1,2], M. Botova[1]. [1]*National Medical Research Center of Children's Health, Rheumatology, Moscow, Russian Federation;* [2]*Sechenov University, Pediatrics, Moscow, Russian Federation*

Background: Uveitis is the most common extra-articular manifestation of JIA which may lead to sight-threatening ocular complications. Topical corticosteroids are still used in the initial treatment for JIA-associated uveitis. The goal of treatment in these patients should be topical corticosteroid-free remission and prevention of recurrences. The most commonly used corticosteroid-sparing immunomodulatory are TNF-α inhibitors (TNFi), especially adalimumab.
Currently, limited data are available about when or how to stop adalimumab when remission of JIA-associated uveitis is presumed.

Objectives: To evaluate rates of relapse after discontinuation adalimumab in patients with JIA-associated uveitis.

Methods: Medical records of 33 patients with JIA-associated uveitis who were successfully treated with adalimumab to a state of topical corticosteroid-free remission and discontinued adalimumab due to a long-term remission were analyzed retrospectively.
Remission of uveitis was defined as <1+ cells in the anterior chamber and <1 + vitreous haze grading; relapse was defined as ≥1 cell in the anterior chamber or ≥1 vitreous haze grading [1].

Results: Corticosteroid-sparing control of inflammation was achieved in all patients. Adalimumab was discontinued after 50 (range 12–120) months after initiation of adalimumab. Duration of remission prior to discontinuing adalimumab was 42 (range 6 – 114) months. The mean duration of remission after adalimumab discontinuation was 14 (range 1–59) months. 13 (40%) of patients had flares after less than 12 months after discontinuing adalimumab, 5 (15%) had flares after 12 – 24 months, 15 (45%) had not flared due to 24 months after discontinuation adalimumab and had had a long-term non-biological remission. Disease was successfully controlled in 11(33%) patients with non-biological DMARDs, 22 (66%) patients restarted biological therapy after flares, due to lack of improvement after non-biological DMARDs. All patients in whom biological therapy was reinitiated responded satisfactorily. None of the flared patients didn't require restarting corticosteroids.

Conclusion: Corticosteroid-sparing control of inflammation was achieved in all patients. Data from our experience with adalimumab in patients with JIA-associated uveitis suggest that 45 % of patients can be successfully withdrawn from biologics for at least 24 months without disease recurrence.

and Adolescents Medicine, Cologne, Germany; [9]St. Josef-Stift Sendenhorst, Clinic of Paediatric and Adolescent Rheumatology, Northwest German Center for Rheumatology, Sendenhorst, Germany; [10]Martin Luther University of Halle-Wittenberg, Medical Faculty, Halle, Germany; [11]German Center for Paediatric and Adolescent Rheumatology, Center for Pain Treatment in Young People, Garmisch-Partenkirchen, Germany; [12]Technical University of Munich, Department of Sport and Health Sciences, Munich, Germany; [13]University Medicine Charité Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany

Background: Although regular physical activity (PA) is known to have many health-related benefits for children and adolescents with chronic conditions, JIA has been associated with reduced physical activity (PA) and increased time spent sedentary [1]. Sedentary behaviour is an important consideration alongside PA when examining the contribution of both behaviours to the health of young patients. Because young people show more complex but less structured movement behaviour than adults, capturing their many spontaneous and impulsive movements is a great challenge for PA assessment.
Objectives: Since accurate, objective measures of PA related to potential factors promoting PA have been scarce, this study aimed i) to objectively assess moderate to vigorous PA (MVPA) as well as sedentary behaviour and ii) to identify facilitators for PA in patients with JIA.
Methods: Within the framework of the ActiMON study as part of the TARISMA research network, data were collected at several German paediatric rheumatology centres. Objectively assessed PA of adolescent patients with JIA was recorded exclusively during school months in the period June - December 2021 using the accelerometer ActiGraph wGT3X-BT laterally on the right hip. In accordance with the International Children's Accelerometry Database criteria [2], ActiGraphs were worn on seven consecutive days during all waking hours, including at least 4 valid weekdays and 1 weekend day (wear time >8 hours) in the evaluation. Self-reported PA-related data were measured using a physical activity questionnaire (PAQ), while clinical parameters were used from the National Paediatric Rheumatologic Database (NPRD). Achievement of the WHO recommendation of at least 60 minutes MVPA per day and compliance with the national recommendation of no more than 120 minutes of daily screen time were determined among 12- to 18-year-olds.
Results: Data of 41 patients (mean age 14.6 ± 1.9 years, female 73%, patients' disease duration 7.9 ± 4.6 years, polyarthritis 40%, cJADAS-10 2.3 ± 2.4) were available for evaluation. Almost 71% of participating patients met the WHO-recommended minimum level of MVPA, while the average daily step count achieved was 7804. Almost 80% of the patients rated their motor and coordination skills as being good. The most frequently mentioned reasons for doing sports (multiple answers possible) included feeling good (78%), giving energy (70%), pleasure (65%) and enjoyment (60%). Patients whose parents are active in sports and support their child in finding a suitable offer were more likely to fulfil the WHO recommendation than patients without family support. The average daily time spent sedentary was 10.5 ± 1.9 hours. About half of the patients reported spending more than 4 hours a day with screen-based media, especially video games.
Conclusion: These preliminary results suggest that while a large proportion of patients achieve the WHO recommended minimum level of PA, they exhibit very pronounced sedentary behaviour with increased screen use. In addition to controlled disease activity as a well-known prerequisite for achieving PA recommendations, these results also point to the importance of family support and emotional well-being. With ongoing recruitment, further potential facilitators and barriers to PA should be identified in more in-depth analyses.

POS1324

THE IMPORTANCE OF MRI IMAGING FOR THE MANAGEMENT AND UNDERSTANDING OF THE DISEASE ORIGIN IN FIBRODYSPLASIA OSSIFICANS PROGRESSIVA

I. Nikishina[1], S. Arsenyeva[1], V. Matkava[1], M. Kaleda[1], T. Pachkoria[1], A. Arefieva[1]. [1]*V.A. Nasonova Research Institute of Rheumatology, Paediatric, Moscow, Russian Federation*

Background: Fibrodysplasia ossificans progressive (FOP) is ultra-rare autosomal dominant inherited genetic disorder which is caused by mutation in ACVR1 gene and provokes severe heterotopic ossification (HO) as a «second skeleton disease». Our long-term experience of the largest group of FOP patients in single Russian center makes possible to interpretate clinical findings and imaging as the evidences that FOP may belong to special kind of axial spondyloarthritis. Because of new bones formation process X-Ray and CT scans recognize as the main imaging methods for the FOP. But MRI method may present important information for the understanding of the disease origin in FOP.
Objectives: To analyze the MRI findings in FOP patients in relation to clinical manifestations, and therapy options.
Methods: The study was based on retrospective and prospective observation and included 40 pts (21 males; 19 females). Diagnosis of FOP was established on typical clinical features and detecting mutation. X-ray, CT and MRI were performed in most patients excluding the severe disabled status of FOP. Some patients failed to perform MRI due to the presence of severe skeletal deformities or artificial metal constructions (because of previous orthopedic operations). Blood assessment has never shown specific elevated markers.
Results: Among of all 40 FOP patients MRI of sacroiliac joints was performed in 14 patients. Chronic sacroiliitis was detected in 10/14 pts, including active sacroiliitis in STIR regimen in 6/14 pts by. Also 7/14 pts have MRI evidence of severe coxitis (see Figure 1). This imagines findings and other features of axial involvement (X ray imagines of ankylosis of the facet joints and vertebral bodies by the type of syndesmophytes) allowed us to establish alternative diagnosis of juvenile spondyloarthritis (JAS) in 7 pts and juvenile idiopathic arthritis (JIA) in 5 cases. It was needed for the legal possibility to administer tofacitinib (TOFA) in 12 pts (the youngest pt of 2 y.o, the oldest – 19 y.o) with strong uncontrolled progression of FOP. The dosage of TOFA was up to 5 mg twice a day. We noticed that all 12 pts have severe coxitis with synovia proliferation (with MRI and ultrasound evidence). Duration of TOFA therapy is from 2 to 25 months. Drug tolerance was good in all pts, no AE were registered. New nodes formation immediately stopped in most pts, significant improvement of motions was observed in 10 (83%) pts. Also, we noticed fast regression of sacroiliitis and coxitis activity by MRI in 5 (42%) pts under TOFA therapy. All other patients didn`t have repeated MRI examination yet. So MRI seems to be important method to confirm the anti-inflammatory effects for sacroiliitis and coxitis signs in patients with FOP. It seems to expect that inflammation control may prevent the sacroiliac and hip ankyloses. In spite of the absence of new HO in our 16 y.o. pt, we found continuous intraskeletal ossification between C3-C4, C5-C7 vertebral bodies, facet joints that leads to subtotal stenosis of spinal canal without any neurological symptoms. Because of «protection effect» of external heterotopic ossification severe neurological damage was not developed.

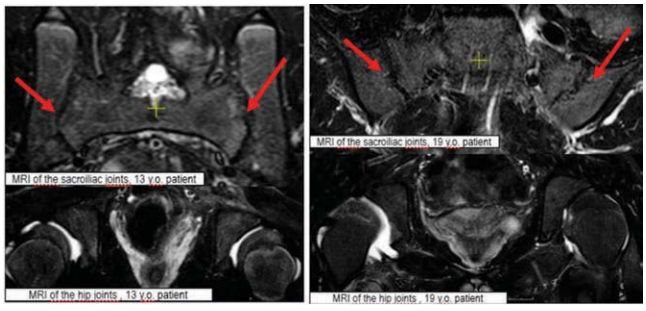

Figure 1. Two different patients with severe FOP and similar evidences of sacroiliitis and bilateral hips synovitis by MRI

Conclusion: According to MRI findings, hip damage was characterized for all ages of FOP patients. Sacroiliitis we found mostly in patients older 10 y.o. Based on our experience of JAK-inhibitor therapy we can suggest about positive effect and advantages of TOFA over other therapy approaches. Dynamics of MRI imaging may be good option for the confirmation of therapeutic anti-inflammatory effects.

POS1325 CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS (CRMO): NEW INSIGHTS INTO EXTRA-OSSEOUS MANIFESTATIONS.

M. Robert[1], C. Guillemin[1], L. Rossi-Semerano[1], C. Galeotti[1], I. Koné-Paut[1], P. Dusser[1]. [1]*Kremlin-Bicètre, Service de Rhumatologie Pédiatrique, Le Kremlin-Bicêtre, France*

Background: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare inflammatory disease of the skeleton characterized by chronic and recurrent episodes of osteo-articular inflammation. The median age of onset is 10 years old. Clinical manifestations include musculoskeletal symptoms that are well described (pain, tenderness, swelling). Sometimes, skin lesions or digestive manifestations occur. Whole body magnetic resonance imaging (MRI) is the gold standard for assessing the multifocal pattern of the CRMO. Treatment is still empirical and mainly relies on non-steroidal anti-inflammatory drugs (NSAIDs). Bisphosphonates and biologics are used as second-line treatments. To date, the focus has been set on bone involvement and very few data are available on extra-osseous manifestations in CRMO.

Objectives: This study aims to further describe these extra-osseous clinical manifestations in CRMO.

Methods: A historical cohort was designed using 61 CRMO patients at the Pediatric Rheumatology Department in a tertiary university hospital in Paris (Hôpital Bicêtre, France). All patients underwent a MRI that confirmed the diagnosis according to the criteria of Jansson. Skeletal involvement was characterized with 1/axial, 2/ peripheral, 3/ axial and peripheral lesions. Extra-osseous manifestations were divided into 1/ skin lesions, 2/ gastro-intestinal manifestations, 3/ enthesitis and 4/ others. Pain was evaluated thanks to the Visual Analog Scale (VAS, from 0 to 10). Treatments used were recorded. The study complied with ethical requirements.

Results: Forty one patients were included in the study, with 31 females (75.6%). The mean ± SD age at onset was 79.1 ± 59.8 months, with a delay at diagnosis beyond six months (6.71 ± 6.96). Twenty-one patients had a familial history of inflammatory diseases (51.2%), with a majority of psoriasis or ankylosing spondylitis (n=13/21, 61.9%). At diagnosis, the level of pain was 5.71 ± 3.24. Eleven patients (42.3%) had blood inflammation. Bone lesions were reviewed thanks to whole body MRI: four patients had isolated axial involvement (10.0%), nine had peripheral involvement (22.5%) and 27 patients harbored both types of lesions (67.5%). The mean number of lesions was 6.65 ± 4.23. After 12 months of follow-up, all parameters regarding disease's activity decreased (pain, blood inflammation, number of lesions). Regarding extra-osseous symptoms, fever occurred in seven patients (17.1%). Twenty-four patients had skin manifestations (58.5%) with palmoplantar lesions (n=3, 12.5%), acne (n=6, 25.0%), psoriasis (n=5, 20.8%) and aphthous (n=10, 41.7%). Four patients (9.76%) had gastro-intestinal symptoms and seven (17.1%) had enthesitis. One patient had uveitis. Almost all patients received NSAIDs (n=39/41, 95.1%) and half of the cohort were treated with bisphosphonates (n=21/41, 51.2%). Nine patients (22.0%) received biologics with a majority of TNF inhibitors. All patients that received TNF inhibitors had either a cutaneous involvement or digestive symptoms or enthesitis (Figure 1).

Conclusion: Extra-osseous manifestations have to be carefully searched in CRMO, especially in the presence of familial history of inflammatory diseases. While the severity of bone involvement can lead to use bisphosphonates, the introduction of biologics seems to rely on extra-osseous symptoms. These conclusions are drawn on a retrospective study and need to be confirmed in larger cohort.

Background: Paediatric inflammatory multisystem Syndrome (PIMS) is a new systemic inflammatory disease linked to SARS-CoV2 that affects children. It was first reported in may 2020 [1-2].

Objectives: The objectives of this study were to describe patients with PIMS through the international JIR cohort registry and to compare the different profiles and treatments of these patients over the different waves.

Methods: Study patients with international PIMS criteria were included from March 2020 to June 2021. Patients were identified in the JIR cohort, an international registry collecting demographic, clinical and paraclinical data on patients with pediatric inflammatory diseases. Two groups were distinguished: from March 2020 to July 2020 for patients in the first wave, from July 2020 to June 2021 for patients in the 2nd and 3rd waves. These two groups were compared using a Fischer test for categorical data and a Mann-Whitney test for quantitative data

Results: 136 patients meeting the PIMS criteria were included (64 patients in the 1st wave, 72 patients after). Patients had less frequent myocarditis (51 patients in wave 1 vs. 36 patients after, p=0,0003) and respiratory distress (34 patients vs 10 patients, p<0,0001). Corticosteroids were used more frequently in the second wave (32 patients in wave 1 vs. 67 patients after July 2020, p<0,0001). Intravenous immunoglobulins were used as much over the waves (58 patients in wave 1 vs 68 patients after, p=0.5). Antibiotics were less used since the second wave (53 patients received antibiotics before July 2020 vs 11 after, p<0,0001). The duration of hospitalization decreased significantly (p<0,0001) with a median duration of 9 days during the first wave (interquartile range, 7-12) and 7 days (interquartile range, 5-10) after the first wave.

Conclusion: There was a decrease in the number of complications of PIMS, particularly cardiac and respiratory complications, and a decrease in the length of hospitalization over time. The treatment of PIMS has also evolved, with a clear increase in the use of corticosteroids and a decrease in the use of antibiotics.

POS1327 AMYLOID STORM DEVELOPS IN PATIENTS WITH AA AMYLOIDOSIS AND ASSOCIATED WITH HIGHER AMYLOID BURDEN AND INCREASED MORTALITY

M. Bektaş[1], S. Sarı[1], N. Koca[1], E. Oguz[1], B. Ince[1], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], A. Gül[1]. [1]*Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Amyloid storm is an emerging condition which was described recently also associated with poor prognosis in patients (pts) with AA amyloidosis (AA-a).
Objectives: We herein aimed to evaluate the amyloid storm and its associated factors in pts with AA-a.
Methods: We retrospectively evaluated AA-a pts who followed in our tertiary referral amyloidosis center. Diagnosis of AA-a was made by Congo red straning and immunohistochemistry. Amyloid storm was defined as follows; developing within two weeks, increase in creatinine and proteinuria levels at least two times from baseline or reach the CRP levels more than 10 times [1].
Results: Data of 175 pts with AA-a were evaluated and after exclusion of 11 pts who had missing data, 164 pts were included into the analysis. We identified 9 pts (5.5%; of 4 male) who developed amyloid storm. Five pts were FMF-associated AA-a (FMF-AA) and 4 pts were non-FMF-AA (two pts had ankylosing spondylitis, one patient idiopathic and one patient non-FMF periodic fever syndrome) (p=0.1). Median±interquartile range (IQR) patient age, diagnosis age of FMF and amyloidosis were lower in pts had amyloid storm than had not, but they were not statistically different (p=0.2, p=0.3 and p=0.2 respectively). All pts were M694V homozygous among FMF-AA. Etiology of amyloid storm was infection in 5 pts (56%), treatment non-adherence in 3 pts (33%) and surgery in one patient (11%). Overall, 3 pts with amyloid storm died (33%), but mortality was 10% (n=16) in the remaining pts with AA-a. One patient died during the amyloid storm, and others died within one year after the diagnosis of amyloid storm (median 5 months). In univariable analysis, involvement of ≥3 organs, bone marrow involvement and current proteinuria levels (p=0.4, p=0.05 and p=0.04, respectively) were higher; median number of organ involvement and mortality (p=0.09 and p=0.07) were tended to be higher in pts with amyloid storm than those without it. End stage renal disease (ESRD) development was also higher in pts who had amyloid storm (67%; n=6) than in pts who had not (46 % n=71) but did not reach statistical significance (p=0.3). Median±IQR CRP (48 ±77 vs 9 ±17 p=0.08), creatinine (4.8 ±5 vs1.2 ±0.6 p=0.01) and proteinuria (11 ±12 vs 0.85 ±2.3 p=0.02) levels were higher during the amyloid storm than their previous records. In multivariable analysis, amyloid storm was associated with higher mortality (p=0.045 OR 4.6; 95 % CI 1.03-20). In survival analysis, development of amyloid storm tended to be higher in pts with non-FMF-AA compared to FMF-AA (Log-rank p=0.057). Mortality rate was higher in pts who had amyloid storm than those without it (Log-rank p=0.038).

Table 1. Comparison of clinical and laboratory features of pts with and without amyloid storm

Variables	Amyloid storm (n=9)	Control (n=155)	p value

POS1328 DO IL-1 ANTAGONISTS DEFINITELY PROTECT FROM THE DEVELOPMENT OF NEW DAMAGE: A SINGLE-CENTER STUDY

D. Yildirim[1], R. C. Kardaş[1], B. Ozkiziltas[1], I. Vasi[1], H. Küçük[1], M. A. Ozturk[1], S. Haznedaroglu[1], B. Goker[1], A. Tufan[1]. [1]*Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*

Background: Ongoing inflammatory episodes of familial Mediterranean fever (FMF) disease can cause damage in nearly all organ systems. Colchicine and interleukin1β blocking agents are successfully used to control the disease activity [1]. Although the effect of IL-1 blockers are known for controlling disease activity and amyloidosis [2], it is unclear whether they prevent organ damage
Objectives: In our study, we assessed the organ damage in patients with FMF treated with colchicine and IL-1 antagonists (IL-1A). It was evaluated whether new damage occurred after IL-1 antagonist treatment.
Methods: A total of 111 patients fulfilling Tel-Hashomer criteria and treated with IL-1A due to colchicine resistance were included in the study. All patients were also treated with colchicine with a maximum-tolerable dose. Patients were grouped according to their recent damage status (no damage, pre-existing damage, and damage developed under IL-1A treatment). The degree of damage was determined using Autoinflammatory Disease Damage Index (ADDI) and modified form of ADDI (mADDI) [3, 4].
Results: 44 patients (42,3%) had damage according to the modified ADDI (mADDI) index; three patients experienced new damage under IL-1 antagonist treatment while four patients showed progression of damage and mADDI score. In patients with a positive mADDI score, the most common damage was amyloidosis (n=28, 63%), the second most frequent was musculoskeletal findings (N=14, 31%), and the third was infertility (N=2, 0,04%). The most common domains of FMF-related damage with IL-1 antagonist treatment were musculoskeletal (n=4), renal (n=2) and reproductive system (n=2)
Conclusion: Our study was the first study to evaluate the progression of damage in patients with FMF and treated- with IL-1 antagonists. Although it is known that IL-1A is effective in colchicine-resistant patients, physicians should be aware that damage can still develop under IL-1A treatment.

POS1329 SECONDARY HAEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: A SINGLE-CENTRE EXPERIENCE

R. Thomas[1], H. Quah[1], R. Stratton[1], A. Singh[1]. [1]*Royal Free Hospital, Rheumatology, London, United Kingdom*

Background: Haemophagocytic lymphohistiocytosis (HLH) is a life-threatening hyperinflammatory syndrome characterised by fever, organomegaly, cytopaenias, activated macrophages in haematopoietic organs and elevated ferritin. Primary HLH is caused by inherited defects in cytolytic pathway proteins and manifests in infancy[1]. Secondary HLH (sHLH) develops in individuals with a genetic susceptibility to hyperinflammation triggered by strongly immunogenic stimulus such as autoimmune conditions, haematological malignancy, organ transplantation or infection[2].
We present a cohort of patients with sHLH and detail their characteristics.
Objectives: To evaluate the characteristics and aetiology of sHLH patients at our Centre.
Methods: A single-centre retrospective observational study of all cases of sHLH between January 2018 and July 2021. Patients were identified from referrals and included if there was a diagnosis of HLH made by a rheumatologist with an H-score of 169 or greater. P-values were calculated using the Mann-Whitney test, unpaired t-test or Fisher exact as appropriate.
Results: 30 patients (10 female) with sHLH were identified with a median age of 46, a mean H-score of 238 (range 186-317). 15 (50%) had pre-existing immunosuppression, which did not influence mortality (p=0.26). The following primary drivers were identified: lymphoma (n=8), non-HIV viral infections (n=9), first presentation of HIV/AIDS with opportunistic infections (n=4), Adult-onset Still's disease (n=4), miliary tuberculosis (n=1), *M. falciparum* infection (n=1), meningococcal meningitis (n=1), checkpoint inhibitor therapy-related (n=1), and no diagnosis (n=1) - Table 1.
Non-HIV viral infections were the most common cause overall. 6 of 9 were caused by Herpes virus family and all were primary infections. Two followed yellow fever viraemia following live vaccination and both patients died.
Mortality varied with aetiology. All four patients with AOSD survived, while 7 of 8 with lymphoma died, as per previous reports[3]. There was a strong association between lymphoma and mortality vs non-lymphoma sHLH (p=0.0025). Four patients post-solid organ transplantation were identified (three liver, one kidney), three with post-transplant lymphoproliferative disorder and one with CMV viraemia (50% mortality).
There was no significant difference between age, ferritin or H-score between surviving and deceased patients (Figure 1), but H-score trended higher in the deceased (p=0.059). Number of treatments given for HLH was higher in the deceased group vs survival (mean 3.41 deceased, mean 2.44 in survived). Anakinra was used in all 30 patients as treatment, including as monotherapy in one patient with HSV viraemia who survived.

Table 1. **[§] = Mann Whitney U test, [τ] = unpaired t-test, [φ] = Fisher exact**

	Total (n=30)	Survived (n=18)	Died (n=12)	p-value
Demographics				
Male	20	10	10	0.78[§]
Female	10	8	2	
Mean age	43	41	47	0.348[§]
Median H-score	240	230	254	0.059 [τ]
Ferritin (ng/ml)	40277	34690	48404	0.0949
Trilineage cytopenia, n (%)	9 (33%)	5 (31%)	4 (36%)	0.28[§]
Subgroup (not mutually exclusive)				1 yr survival
Lymphoma	8	1	7	12.5% (p=0.0025 [φ])
HIV/AIDS	4	4	0	100%
AOSD	4	4	0	100%
Transplant recipient	4	1	3	25%
Other viral infection	9	5	4	44%
HSV	*3*	*3*	*0*	*100%*
CMV	*1*	*1*	*0*	*100%*
EBV	*1*	*0*	*1*	*0%*
Yellow fever	*2*	*0*	*2*	*0%*
Influenza A	*1*	*1*	*0*	*100%*
Tuberculosis	3	2	1	66%
with HIV	*2*	*2*	*0*	*100%*

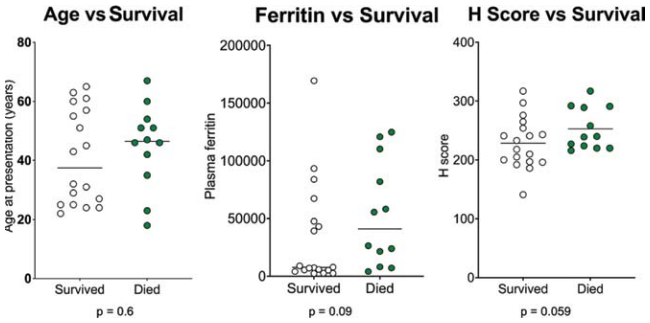

Figure 1.

Conclusion: Ferritin, H-score at diagnosis or age do not appear to correlate with mortality in sHLH. Lymphoma is associated with a significantly worse outcome. Poor response to treatment and increasing numbers of treatment options is associated with increased mortality. Causes are varied and often co-exist.

Fukuoka, Japan; [10]Med.Corp.Souseikai, Nephrology, Fukuoka, Japan; [11]Graduate School of Medical Sciences, Kanazawa University, Rheumatology, Kanazawa, Japan

Background: Although hypocomplementemia has been frequently reported in IgG4-related kidney disease (IgG4-RKD), few studies have investigated differences in the clinicopathological features of IgG4-RKD with and without hypocomplementemia in a relatively small cohort1,2).
Objectives: To compare the clinicopathological features of Japanese patients with and without hypocomplementemia in IgG4-RKD.
Methods: We retrospectively examined the clinicopathological features of 60 patients with definitively diagnosed IgG4-RKD, collected from the institutions associated with the Japan IgG4-RKD working group between December 2010 and May 2019, with reference to the presence of hypocomplementemia.
Results: Among the patients included, 42 (70%) had hypocomplementemia. In the latter group, serum levels of IgG and non-IgG4 IgG, calculated as total IgG minus IgG4, were significantly higher (mean IgG level, 3832 vs 2626 mg/dl, p=0.005, mean non-IgG4 IgG level, 2775 vs 1627 mg/ml, p =0.000). Renal function at diagnosis tended to be lower (mean eGFR level 42.4 vs 53.6 ml/min), although not to a significant degree (p=0.07). There were no significant inter-group differences in the levels of serum IgG4 and IgE, or in the number of extra-renal involved organs. Renal pathology specimens were obtained from 53 patients, 70% of whom had hypocomplementemia. In the hypocomplementemia group, light microscopy demonstrated a significantly broader extent of interstitial inflammatory cell infiltration (p=0.035), and immunofluorescence revealed a higher frequency of IgG or complement deposition on the renal tubular basement membrane (TBM) (p=0.048). C1q deposition on the TBM was evident only in the hypocomplementemia group. There was no significant inter-group difference in the presence of storiform fibrosis, the degree of interstitial fibrosis, the number of infiltrating IgG4-positive cells, or the frequency of membranous glomerulonephritis.
Conclusion: Hypocomplementemia in IgG4-RKD is associated with elevated levels of IgG subclasses other than IgG4, and may be related to progression of renal inflammation.

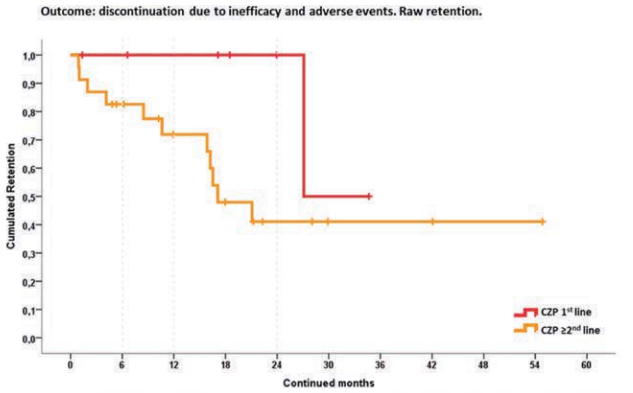
Jovani[12]on behalf of Biotherapies in Uveitis (BioÚvea) Study Group. *[1]Clínic Hospital of Barcelona, Clínic Institute of Ophthalmology (ICOF), Barcelona, Spain; [2]Hospital Virgen de la Salud, Rheumatology Department, Toledo, Spain; [3]Hospital Universitario de Donostia, Ophthalmology Department, Donostia, Spain; [4]Hospital Universitario de la Princesa, Ophthalmology Department, Madrid, Spain; [5]Hospital Galdakao-Usansolo, Ophthalmology Department, Galdakao, Bilbao, Spain; [6]Complejo Hospitalario de Navarra, Internal Medicine Department, Pamplona, Spain; [7]Complejo Hospitalario de Navarra, Ophthalmology Department, Pamplona, Spain; [8]Hospital de Bellvitge, Ophthalmology Department., L'Hospitalet de Llobregat, Barcelona, Spain; [9]Hospital General de Valencia, Ophthalmology Department, Valencia, Spain; [10]Hospital de Merida, Rheumatology Department, Merida, Spain; [11]Hospital Insular de Gran Canaria, Ophthalmology Department, Las Palmas, Spain; [12]Hospital General Universitario de Alicante, Rheumatology Department, Alicante, Spain*

Background: A personalized disease-specific treatment for non-infectious uveitis (NIU) is challenging. Around 50% of adults with NIU who required classic DMARDs or adalimumab in clinical trials, failed at 6 months during open label phase [1,2]. Therefore, to investigate treatment alternatives for NIU are most needed.
Objectives: To study Certolizumab pegol (CZP) retention rate (RR) at 24 months in NIU and susceptibility factors for discontinuation.
Methods: Adults with NIU who received CZP for this indication were included. Data were gathered from the BioÚvea Spanish registry, detailed elsewhere[3]. Demographics, clinical, and therapeutic data was recorded from Nov 2016 to Nov 2017. The primary endpoint assessed was CZP RR at 24 months. Causes and susceptibility factors for definitive discontinuation of CZP were analyzed as well. CZP RR was calculated with the Kaplan-Meier method, Log-rank test was used for the univariate, and the Cox proportional hazard model was implemented for the multivariate analysis.
Results: Thirty patients with a median of 41 (IQR 16) years, 18 (60%) females, were included. NIUs were bilateral in 19 (63%) patients and were active at CZP onset in 20 (71%). Half of the patients suffered from non-anterior NIUs, and etiologically 2 (7%) were unclassifiable, 7 (23%) had ocular syndromes, and 21 (70%) were associated to systemic disorders. Seven (23%) patients were bionaïve, whereas 23 (77%) started CZP as a 2nd (5, 17%) or ≥ 3rd (18, 60%) biologic. With a median follow-up of 21.2 (Range 0.2 to 54.8) months, 12 (40%) patients discontinued CZP, 6 (20%) due to adverse events and 6 (20%) due to lack of efficacy. The overall CZP RR at 24 months was 53.6%, with a median Retention Time (RT) of 27.1 months. In the multivariate analysis, CZP started as a first biologic (HR 0.053, 95%CI 0.003 to 0.809; p = 0.035), and male gender (HR 0.1, 95%CI 0.015 to 0.694; p = 0.02) were protective factors for discontinuation. CZP RR at 24 months as a 1st line biologic was 100% with a median RT of 27.1 months. Conversely, CZP RR at 24 months as a ≥2nd line was 41.1% with a median RT of 17.1 months. When given as a 1st biologic, one (14%) patient discontinued CZP due to loss of efficacy at 27.1 months. Conversely, discontinuation of CZP when administered in ≥2nd line was more frequent, either due to lack or loss of efficacy in 5 (22%) patients or adverse events (AEs) in 6 (26%) (Figure 1).



CZP 1st line *vs.* ≥2nd line					6 m		12 m		24 m		36 m

Lack/loss efficacy	5				1		2		2		0	
AE	6				3		0		3		0	

Figure 1. Retention rate of Certolizumab pegol in bio-naïve and bio-experienced patients with non-infectious uveitis.Abbreviations: DRT, Drug Retention Time; LTFU, lost to follow-up; DRR, Drug Retention Rate; PAR, Patients at Risk; AE, adverse event.

Conclusion: CZP in NIU showed an excellent retention rate at 24 months in bio-naïve patients. However, it was more than halved when CZP was started as a ≥2nd biologic. Discontinuation of CZP in bio-experienced patients was due to lack or loss of efficacy in 22% and to adverse events in an additional 26% of patients.

POS1332 TOWARD SAFER GLUCOCORTICOID THERAPY OF POLYMYALGIA RHEUMATICA

X. Pan[1], Q. Hou[1], J. Xu[1], Y. MA[1], J. LI[1], M. LI[1], J. Su[1], X. Shi[1], W. Bracken[2], D. Katz[2]. *[1]WuXi AppTec, N/A, Nantong, China; [2]Sparrow Pharmaceuticals, N/A, Portland, United States of America*

Background: SPI-62 is a potent 11β-hydroxysteroid dehydrogenase type 1 (HSD-1) inhibitor entering Phase 2 development as adjunctive therapy to prednisolone in polymyalgia rheumatica, as well as for treatment of Cushing's syndrome and autonomous cortisol secretion. HSD-1, an intracellular enzyme, activates glucocorticoids in target tissues in which glucocorticoid medicines are associated with morbidity including liver, adipose, muscle, and skin. In Phase 1 clinical trials SPI-62 was generally well tolerated and associated with maximal liver and brain HSD-1 inhibition.

Objectives: To demonstrate mitigation by SPI-62 of corticosterone (CORT) adverse effects in mouse.

Methods: C57BL/6 male mice (age 7 weeks; n=14 per group) were administered CORT (100 g/mL in drinking water) and SPI-62 (by gavage in 0.5% HPMC; 0, 1, or 10 mg/kg/day or 10 mg/kg twice daily) for 35 days. A control group received no CORT or SPI-62. Body weight was assessed daily and food consumption twice weekly. Whole body muscle and fat amounts were measured at Days 0, 14, and 28 using an EchoMRI-130H body composition analyzer. Blood samples for fasting glucose and insulin were obtained at Days 1 (pre-dose), 15, 29, and 35. An open field test was conducted on Day 22. A grip strength test was performed on Day 28. After sacrifice on Day 36, gonadal, subcutaneous, retroperitoneal, and mesenteric fat, quadriceps, and tibialis anterior were dissected and weighed, and skin was formalin fixed and paraffin embedded.

Results: One control mouse died due to accidental gavage injury. Two mice who received CORT + 0.5% HPMC died on Days 11 and 19. CORT resulted in increased food consumption which was normalized by SPI-62 in a dose-dependent manner. CORT-treated mice showed reduced body weight gain for 2 weeks then accelerated body weight gain. SPI-62 prevented body weight gain acceleration in a dose-dependent manner. CORT effects on dermal thickness and structure were less prominent in mice who also received SPI-62. No effect of CORT or SPI-62 was observed in the open field test. SPI-62 prevented CORT adverse effects of insulin resistance, increased adiposity, skeletal myoatrophy, and grip strength reduction (Table 1).

Table 1. Observed percentage difference of treatment group mean, compared to control group mean, in CORT-treated mice

SPI-62 treatment	none	1 mg/kg 1x/day	10 mg/kg 1x/day	10 mg/kg 2x/day
HOMA-IR Day 15	+422	+428	+104	+8
HOMA-IR Day 29	+788	+472	+204	+14
HOMA-IR Day 35	+3620	+1270	+324	+92
Body fat content Day 14*	+110	+72	-13	-7
Body fat content Day 28*	+166	+102	+63	-12
Gonadal fat weight*	+151	+74	+39	-1
Subcutaneous fat weight*	+471	+121	+83	+7
Retroperitoneal fat weight*	+227	+89	+36	+25
Mesenteric fat weight*	+240	+133	+124	+71
Body muscle content Day 14*	-10	-7	0	+1
Body muscle content Day 28*	-15	-8	-6	+3
Quadriceps weight*	-54	-43	-24	-16
Tibialis anterior weight*	-35	-29	-5	+5
Grip strength	-12	+16	+15	+26

*Normalized by body weight.

Conclusion: SPI-62 prevented several CORT adverse effects in mouse, demonstrating that blockade of local intracellular glucocorticoid activation by a HSD-1 inhibitor in target tissues can mitigate glucocorticoid toxicity. These results suggest that SPI-62 has potential to similarly mitigate adverse effects of glucocorticoid medications in human. A placebo-controlled Phase 2 clinical trial has been initiated to compare prednisolone effects with and without SPI-62. Up to 48 patients diagnosed with polymyalgia rheumatica, on stable prednisolone 10 mg daily for at least 2 weeks, and with stable disease inactivity based on acute phase biomarkers will continue prednisolone 10 mg daily for 4 weeks, during which they will receive SPI-62 or placebo for 2 weeks each. Acute phase and other immune function biomarkers, symptom measures, and biomarkers of prednisolone adverse effects will be assessed at baseline and after each 2-week period. After analysis of data from a first cohort of 12 patients the prednisolone dose might be adjusted, in blinded fashion, during the SPI-62 period to maintain equipotency on acute phase biomarker suppression.

POS1333 STUDY OF THE RELATIONSHIP BETWEEN THE TREATMENT TYPE AND THE THERAPEUTIC RESPONSE ACCORDING TO THE SAPHO SYNDROME CLINICAL FORM IN ADULTS FROM A RETROSPECTIVELY ANALYSED MULTICENTER COHORT

P. Brevet[1], P. Michelin[2], C. Marcelli[3], D. Alcaix[4], T. Lequerre[5], O. Vittecoq[6]. *[1]Rouen University Hospital, Rheumatology, Rouen, France; [2]Rouen University Hospital, Radiology, Rouen, France; [3]Caen University Hospital, Rheumatology, Caen, France; [4]Le Havre Hospital, Rheumatology, Le Havre, France; [5]Rouen University Hospital, Rheumatology, Rouen, France; [6]Rouen University Hopital, Rheumatology, Rouen, France*

Background: SAPHO syndrome (Synovitis, Acne, Palmoplantar Pustulosis, Hyperostosis and Osteitis) is a radio-clinical entity associating joint, bone and inflammatory skin disorders. The clinical presentation is very heterogeneous making the diagnosis difficult. The therapeutic strategy in SAPHO syndrome is poorly defined. The first-line treatment remains NSAIDs on demand, which are effective in treating painful flare-ups but rapidly become insufficient in 60% of cases during the course of the disease. TNF-αNF-O syndrome (S necrosis factor-alpha) are reserved for refractory forms and their efficacy is uncertain [1]. Bisphosphonates (BPs) seem to have potential interest [2].

Objectives: The main objective of this study was to investigate the response to treatment with BPs and/or immunosuppressive drugs (DMARDs - *Disease modifying anti-rheumatic drugs*), *c*onventional synthetic *c*s-DMARDs or biologic (*b*-DMARDs), according to the clinical form of rheumatological SAPHO (bony predominantly versus articular or mixed predominantly.

Methods: All patients aged 18 years or older with SAPHO syndrome meeting Benhamou's criteria whose clinical, biological and radiological data were available in the files and who received at least one DMARD or BP treatment for their disease were included in Rouen (thanks to the health data warehouse), Caen, Le Havre/Lillebonne and Dieppe Centres. Each imaging examination was reviewed blinded to the treatments by a radiologist with expertise in osteoarticular disease. Patients were classified into 2 groups (bony versus joint/mixed) according to imaging data and clinical history. The response to treatment was considered positive if symptoms were improved by at least 50% (cut-off used in the literature). An χ^2 patients aged 18 years or older with SAPHO syndrome meeting Benhamou's criteria whose clinical, biological and a Mann-Whitney test for quantitative variables using SPSS software.

Results: Thirty-four patients with SAPHO who had received DMARD or BP treatment were included and classified as follows: 13 in the bone group and 21 in the joint or mixed group. The 2 groups were comparable on demographics, duration of follow-up, previous chest involvement, existence of associated dermatological or inflammatory bowel disease, exposure to smoking, duration of exposure to a previous NSAID or antibiotic. Only the age of onset of symptoms differed between the two groups, with a younger onset of disease in the bone group (p=0.043). The prescribers' therapeutic attitude differed significantly between the 2 groups (p=0.043) with a greater prescription of BPs as first line in the bone group (5/13 patients) and a DMARD in the joint/mixed group (19/21). Regarding treatment efficacy, 10/13 patients had effective treatment without escape during their follow-up in the bone group, which was not significantly different from the joint/mixed group (17/21). BPs achieved escape-free efficacy in significantly more cases in the bone group than DMARDs in the joint or mixed group (p= 0.002). The bone group used significantly fewer specific treatment lines (DMARDs or BP) than the joint/mixed group (1 specific line vs. at least 2) (p =0.046).

Conclusion: BPs appear to be more effective in SAPHO with predominantly bone involvement. This appears to be easier to treat compared to SAPHO with articular or mixed forms.

Background: Ocular Cicatricial Pemphigoid (OCP) is an infrequent, systemic cicatricial immune-mediated disease, belonging to the group of membranous-mucosal pemphigoids (MMP). Due to the possibility of coexistence of multiple autoimmune diseases (ADs), OCP could be associated with other diseases. In the literature, association of OCP and ADs is reported in 9-35% of patients, but most reports correspond to MMP.
Objectives: To assess the prevalence of autoimmune diseases associated with OCP and to analyse clinical, laboratorial and treatment associations between these entities.
Methods: A multicentre cross-sectional study of patients with a diagnosis (clinical and/or by biopsy) of OCP derived from ophthalmology was performed.
The population was divided into two groups according to their association or not with other ADs. Clinical, laboratorial and treatment variables were described and compared between both groups. In addition, a multivariate descriptive logistic regression analysis was performed to identify variables that could suggest the association between OCP and ADs.
Results: A total of 88 patients were recruited, 66 (75%) females, with a mean age at diagnosis of 64.3 years (SD 11.9). The median follow-up time was 1 year. The diagnosis was done by biopsy in 86,8%. Ocular bilateral disease was present in 95,3% of patients. There was a median delay from symptoms onset to diagnosis of 2 years. A history of malignancy was reported in 13,6%. Extraocular involvement was evidenced in 11,5% (4% compromised skin and 9,1% other mucous membranes). Regarding the previous clinical findings, no statistically significance was found between the groups with and without ADs. Systemic treatment was depicted as follows: oral corticosteroids (60,2%) (p-value < 0.001), corticosteroids pulses (5,7%), dapsone (3,4%), methotrexate (79,5%), mycophenolate (15,9%), azathioprine (23,9%), rituximab (5,7%), immunoglobulin (1,1%); topical corticosteroids (96,6%) and ocular infiltration (2,3%). The group associated ADs included 24 patients (27.3%). Within them, the most prevalent diagnosis was Sjogren's syndrome (13.6%), followed by Hashimoto´s thyroiditis (9,1%) and rheumatoid arthritis (3,4%). Most of the patients presented Foster stages 1 (45.3%) and 2 (29.3%) at diagnosis. In the ADs group, statistically significant associations were observed with ANA, SS-A and SS-B antibodies, rheumatoid factor, and hypergammaglobulinemia. In the descriptive multivariate logistic regression model, it was detected that hypergammaglobulinemia was associated with ADs and OCP, adjusted for age, sex, smoking, skin and mucosal involvement, and erythrocyte sedimentation rate (OR 8.7; 95% CI 1.6 to 46.8; p= 0.012), Table 1.

Table 1. Multiple logistic regression analysis with OCP associated with ADs as dependent variable.

	OR	CI95	P value
Gender	0.2	0.04 - 1.1	0.07
Age at diagnosis	1.02	0.9 - 1.1	0.25
Smoking	0.5	0.1 - 1.7	0.26
Skin and mucosa compromise	1.2	0.2 - 8.2	0.83
ESR	0.98	0.95 - 1.02	0.58
Hypergammaglobulinemia	8.7	1.6 - 46.8	0.012

ESR: Erythrocyte Sedimentation Rate. OR: Odd Ratio. CI95: confidence interval

Conclusion: Due to the autoimmune nature of OCP, it could coexist with other ADs. In this research, it was observed that more than a quarter of the population presented with such association and hypergammaglobulinemia could suggest it. A systematic search for this coexistence should be carried out to avoid sequelae or incomplete treatment in pathologies that are currently potentially treatable.

POS1335 ADHERENCE TO COLCHICINE PROPHYLAXIS AMONG PATIENT WITH FAMILIAL MEDITERRANEAN FEVER TREATED WITH INTERLEUKIN-1 INHIBITORS

Y. Levinsky[1], G. Amarilyo[1]. *[1]Schneider Children's Medical Center of Israel, Pediatric Rheumatology, Petah Tikva, Israel*

Background: Colchicine is the only drug proven to prevent secondary amyloidosis among familial Mediterranean Fever (FMF) patients. Therefore, the common recommendation is to continue colchicine during the treatment with IL-1 inhibitors, despite clinical remission.
Objectives: Our aim was to estimate the adherence to colchicine among FMF patient treated with IL-1 inhibitors.
Methods: The databases of Maccabi Health Services (MHS), a 2.6 million member state-mandated health provider in Israel was searched for patients with FMF diagnosis. Medication possession ratio (MPR) was used as main outcome measure. Patients treated with IL-1 inhibitors ("combination group") were matched in a ratio of 1:4 to patients on colchicine only ("single treatment"). In the second phase, patients with IL-1 inhibitors were matched to themselves, before and after starting the treatment.
Results: The final cohort included 4526 patients. Among them, 108 patients were treated with IL-1 inhibitors. They were matched to 432 "single treatment" patients. The total MPR in each groups was similar (78.9 ±41.4 versus 82.5 ± 80.6, P=0.5). In sub-analyses females treated with IL-1 inhibitors had less MPR than in the matched group (81.4 ± 33.2 versus 85.1 ± 91, P=0.03). In the second phase, The MPR was higher after starting IL-inhibitors among the total population (19.7±13.1 before versus 32.2±14.5 after, p<0.01).
Conclusion: Contrary to initial concerns, the adherence to colchicine is excellent among patients treated with IL-1 inhibitors and is similar to the general FMF population. Moreover, the adherence increases among the same patients after starting IL-1 inhibitors, which may reflect the improvement in disease perception following the need to start the biological treatment.

POS1336 BEHCET'S DISEASE AND PREGNANCY OUTCOMES

Z. Alekberova[1], R. Goloeva[1], A. Lila[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Advisory Department, Moscow, Russian Federation*

Background: Behcet's disease (BD) is multisystemic disease of unknown cause. The relationship between BD and pregnancy is reported in limited number of studies.
Objectives: To evaluate outcomes of pregnancies in BD patients (pts).
Methods: We retrospectively collected data of 45 women with BD diagnosis (according to ISGBD 1990 and ICBD 2014) and their 118 pregnancies. Pts' mean age was 31,3 [27;35] years., disease duration 6,0 [3;8] years. 11,1% pts had severe BD according to Ch.Zouboulis classification (due to generalized uveitis, retinal vasculitis and parenchymatous CNS lesions), 31,1% pts had a moderate disease, 57,8% pts had a mild disease with mainly dermal-mucous manifestations.
Results: 118 pregnancies in 35 pts resulted in 75 live birth (6 cesarean section in 3 pts). Thirty-nine incomplete pregnancies were observed in 26 patients. Ten patients had 20 medical abortions on request before 12 weeks of gestation, one patient had an abortion due to medical reasons (rubella on the 7 th week of gestation), two patients had premature birth at 28 and 32 weeks with subsequent perinatal death of the baby. Fifteen out of 35 pts had 20 adverse pregnancy outcomes: 8 spontaneous abortion, 12 missed miscarriage. Nine patients had 12 Missed miscarriage at 6-11 weeks of gestation, one patient had 3 missed miscarriage, two had 2, and the others had 1 missed miscarriage. Six patients had 8 spontaneous abortions (early miscarriage). In the control group of 15 women, 7 had 15 pregnancies, 13 live birth of healthy children on time. Table 1 presents a comparison of pregnancy outcomes in patients with BD and healthy control.

Table 1. Pregnancy outcomes

Pregnancy, n	BD, n=118 (%)	Control, n=15 (%)	*p*
Birth	77 (65)	13 (87)	0,01
Abortion	21 (18)	0	0,00
Unfavorable pregnancy outcome	20 (17)	2 (13)	ns
Missed miscarriage	12 (10)	0	ns
Spontaneous abortion	8 (7)	2 (13)	ns

Patients with BD were more likely to terminate pregnancy of their own volition compared to control group. All women with unfavorable pregnancy outcomes are re-pregnant, have healthy children born on time, all had a second or subsequent pregnancy with an unfavorable outcome. Immunosuppressive therapy of BD was not received by any of the pregnant women, which makes it possible to exclude the connection of the outcome of pregnancy with BD therapy.
The manifestation of BD with skin-mucous lesion of the patient in the first and third trimester of pregnancy was noted by 3 patients. In one patient, the appearance of a recurrent ulcer on the vulva was an indication for cesarean section.
Only three women had one favorably completed pregnancy, all the others had from 2 to 7 pregnancies. Out of 45 patients, 10 patients did not have pregnancies, 9 of them are not married, 1 patient is planning a pregnancy.
Table 2 shows the frequency of pregnancy pathology with varying degrees of severity of BD.

Table 2. BD Severity and pathology of pregnancy

BD Severity	N = 45 (%)	Intrauterine deaths/Miscarriage
Mild	25 (57,8)	5/6
Moderate	6 (31,1)	1/1
Severe	14 (11,1)	2/5

Adverse pregnancy outcomes were observed with varying severity of BD. Out of 77 babies children born by BD patients only two had relapsing aphthous stomatitis and one – congenital glaucoma ("Neurobehcet" inherited from the mother).

Conclusion: Patients with BD were more to terminate pregnancy compared to control group. Unfavorable outcomes of pregnancy were documented in pts regardless (with all grades of) BD severity.

Background: Aging is a physiological, multidimensional, and irreversible process, occurring in humans over time. Interestingly, multiple lines of evidence have recently suggested that some diseases, generally affecting young adults, are nowadays described in the elderly, although possibly associated with different symptoms or complications. In this context, a possible occurrence of adult onset Still's disease (AOSD) in elderly has been suggested. This is a rare inflammatory disorder of unknown origin usually observed in young adults [1-3].
Objectives: In this study, we aimed at describing the clinical characteristics, life-threatening complications occurrence, and mortality of AOSD patients with an elderly onset. The manifestations of these patients were also compared with those with a younger onset. Furthermore, the predictive role of age was evaluated on clinical features and disease outcomes. Finally, in these patients, an assessment of associated comorbidities was also performed.
Methods: A retrospective assessment of prospectively followed patients, from January 2001 to April 2021, was provided to analyse clinical features, life-threatening complications occurrence, and mortality in AOSD patients with onset in elderly. AOSD patients, who were included in multicentre *Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale* (GIRRCS) cohort, were evaluated.
Results: Out of 221 assessed patients, 37 (16.7%) had an onset of the disease aged over than 60 years. When compared with younger patients, these were characterised by a higher prevalence of pericarditis (p=0.008), comorbidities (p<0.0001), and mortality (p=0.023).
Additionally, our analysis showed that pleuritis and pericarditis positively correlated with age (coefficient=0.227, p=0.001; coefficient=0.213, p=0.001, respectively). Furthermore, the occurrence of parenchymal lung disease was significantly related with age (coefficient=0.168, p=0.012). The presence of comorbidities positively correlated with age (coefficient=0.443, p<0.0001). Moreover, age was negatively related to the polycyclic pattern (coefficient=-0.209, p=0.002). A correlation between mortality and age was also retrieved (coefficient=0.158, p=0.019).

Age predicted the presence of serositis in both univariate (HR: 1.02, 95%CI: 1.01-1.03, p=0.007) and multivariate analyses (HR: 1.02, 95%CI: 1.01-1.04, p=0.007). Age was also a significant predictor of parenchymal lung disease in both univariate (HR: 1.03, 95%CI: 1.01-1.05, p=0.017) and multivariate analyses (HR: 1.03, 95%CI: 1.00-1.05, p=0.048). No significant results were observed assessing the predictive role of age on occurrence of macrophage activation syndrome. Furthermore, age resulted to be a negative predictor of polycyclic pattern only in univariate analysis (HR: 0.99, 95%CI: 0.97-1.00, p=0.048). Finally, age significantly predicted the mortality in both univariate (HR: 1.03, 95%CI: 1.00-1.06, p=0.034) and multivariate analyses (HR: 1.05, 95%CI: 1.01-1.08, p=0.012).

Conclusion: Clinical features of AOSD patients with elderly onset were described in our multicentre cohort. Although the main clinical characteristics were similar comparing older and younger patients, patients aged over 60 years at disease onset were characterised by an increased prevalence of serositis, comorbidities, mostly cardiometabolic, and a higher mortality rate. Age predicted the presence of parenchymal lung disease and mortality, and it could be considered a further negative prognostic factor in AOSD.

POS1338 CENTRAL SENSITIZATION AND RELATED FACTORS IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

F. N. Yücel[1], H. H. Gezer[2], J. Jandaulyet,[1], N. Öz[2], S. Acer Kasman[2], M. T. Duruöz[2]. *[1]Marmara University School of Medicine, PMR Department, Istanbul,Turkey; [2]Marmara University School of Medicine, PMR Department, Rheumatology Division, Istanbul,Turkey*

Background: Central sensitization (CS) is an increased responsiveness of nociceptive neurons in the central nervous system to their normal or subthreshold afferent input is an important manifestation involved in many different rheumatic diseases [1].

Objectives: This study aims to investigate the CS in patients with Familial Mediterranean Fever (FMF) and its associations with other parameters.

Methods: This ongoing study included 73 patients (57 female, 16 male) who were diagnosed with FMF according to the Tel-Hashomer criteria. Clinical characteristics including age, gender, disease duration, age at onset, genetic mutations, comorbid disease and medications were noted. Disease activity was assessed with a PRAS disease activity score. Evaluations included the Health Assessment Questionnaire (HAQ), FMF quality of life (FMF-QoL), Pittsburg Sleep Quality Index (PSQI), Fibromyalgia Rapid Screening Tool (FiRST), and the Hospital Anxiety and Depression Scale (HADS). The symptoms of CS were assessed with the Central Sensitization Inventory (CSI; range 0-100) which is a self-report outcome measure designed to identify patients who have symptoms that may be related to CS or central sensitivity syndromes (CSS) such as fibromyalgia, neck injury, temporomandibular joint disorder or migraine/tension headaches [2]. Descriptive analysis was performed for all parameters. The Mann-Whitney U-test and chi-squared test were used in statistical analysis. P<0.05 was considered statistically significant.

Results: The mean age of the patients was 37.6 (SD:13.6) years. Sacroiliitis occurred in 8 patients (11%), amyloidosis in 1 (1.4%), and erysipelas-like erythema in 8 (11%). The most prevalent genetic mutation was M694/any compound heterogeneous (16.4%) followed by M69V homogeneous (15.1%). Disease activity was mild in 42.5%, moderate in 32.9% and severe in 12.3% of the patients. The mean CSI was 38.4 (SD:18.7) and thirty-four (46.6 %) of 73 patients had CS according to the CSI. CSI scores were significantly higher in females than in males (p=0.009). Eleven (15%) patients had colchicine resistance, and those with colchicine resistance had significantly higher CS scores. In patients with central sensitization, PRAS, HAQ FMF-QoL, FiRST, PSQI, and HADS scores were significantly higher than in patients without central sensitization (Table 1).

Table 1. Disease characteristics in terms of central sensitization

	Central sensitization *Yes (n=34)*	Central sensitization *No (n=39)*	*p*
Gender, female	31 (91.2%)	26 (66.7%)	**0.02**
BMI, kg/m^2	28.8 (8.8)	26.2 (6.8)	0.282
Disease duration	9.3 (6.9)	12.9 (9.9)	0.156
Number of attacks in the last 3 months	2.05 (2.1)	0.8 (1.6)	**<0.001**
Number of attacks in the last 6 months	3.7 (3.3)	1.5 (3.2)	**<0.001**
PRAS	6.3 (2.1)	4.8 (2.3)	**0.004**
HAQ	0.4 (0.6)	0.08 (0.2)	
FMF-QoL	38.2 (13.7)	17.3 (15.2)	**<0.001**
FiRST	3.9 (1.9)	1.7 (1.7)	**<0.001**
PSQI	9.9 (3.9)	6.4 (2.8)	**<0.001**
HAD-Anxiety	9.6 (4.4)	4.9 (3.8)	**<0.001**
HAD-Depression	7.08 (4)	4.4 (3.2)	**0.003**

BMI: Body Mass Index, HAQ: Health Assessment Questionnaire, FiRST: Fibromyalgia Rapid Screening Tool, FMF-QoL: Familial Mediterranean Fever Quality of Life, PSQI: The Pittsburgh Sleep Quality Index, HADS: the Hospital Anxiety and Depression Scale

Conclusion: CS is present in approximately half of FMF patients. CS in patients with FMF was associated with high disease activity, fibromyalgia, anxiety, depression, impaired function, poor quality of life and sleep.

POS1339 FACTORS RELATED TO SERUM IGG4 ELEVATION AND DEVELOPMENT OF IGG4-RELATED DISEASE: DATA FROM RESIDENT EXAMINATION

S. Tsuge[1], H. Fujii[1], M. Tamai[2], I. Mizushima[1], M. Yoshida[1], N. Suzuki[1], Y. Takahashi[1], A. Takeji[1], S. Horita[1], Y. Fujisawa[1], T. Matsunaga[1], T. Zoshima[1], R. Nishioka[1], H. Nuka[1], S. Hara[1], Y. Tani[1], Y. Suzuki[1], K. Ito[1], K. Yamada[1], S. Nakazaki[3], A. Kawakami[2], M. Kawano[1]. *[1]Kanazawa University Hospital, Department of Rheumatology, Kanazawa, Japan; [2]Division of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Nagasaki, Japan; [3]Kanazawa Johoku Hospital, Department of Rheumatology, Kanazawa, Japan*

Background: Elevated serum IgG4 levels are one of the characteristic findings in immunoglobulin G4 (IgG4)-related disease (IgG4-RD). Serum IgG4 levels have an impact to a certain extent on the diagnosis of IgG4-RD although there are some issues in their sensitivity and specificity. In the reports from Japan, China, USA, and Europe, elevated serum IgG4 levels were reported to be observed in 83-97% of patients with IgG4-RD [1-5]. In the past investigations of hospital patients, some studies reported that 10-15% of hospital patients with elevated serum IgG4 levels had IgG4-RD [6,7]. However, in general adults with no symptom, investigations of prevalence of elevated serum IgG4 levels and/or IgG4-RD have rarely been conducted.

Objectives: This study aimed to investigate the frequency of serum IgG4 elevation in the general Japanese population and its associated factors using data from resident examinations.

Methods: We measured the serum IgG4 levels in 1,204 residents who underwent a general medical examination in Ishikawa prefecture, Japan. Logistic regression analysis was used to search for factors related to elevated serum IgG4 levels. Secondary examinations were conducted for participants in whom elevation was identified.

Results: The mean serum IgG4 level was 44 mg/dL, and elevated serum IgG4 levels were observed in 42 patients (3.5%). Univariate logistic regression analyses showed that male sex, older age, lower estimated glomerular filtration rates based on cystatin C (eGFR-CysC), serum high-density lipoprotein cholesterol levels, and higher hemoglobin A1c (HbA1c) levels were associated with elevated serum IgG4 levels. Subgroup analyses in men showed that older age, lower eGFR-CysC levels, and higher serum HbA1c levels were associated with elevated serum IgG4 levels. In contrast, the analyses in women found no significant factors. One of the 10 residents who underwent secondary examinations was diagnosed with possible IgG4-related retroperitoneal fibrosis.

Conclusion: In the general population, elevated serum IgG4 levels are more common in elderly men, which is similar to the epidemiological features of IgG4-RD.

POS1340 BASELINE CLINICAL DISEASE ACTIVITY IS NOT CRITICAL FOR PREDICTING REMISSION OF ADULTS ONSET STILL´S DISEASE

J. Groetsch[1], K. Tascilar[1], G. Schett[1], D. Foell[2], J. Rech[1]. *[1]Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [2]Universitätsklinikum Münster, Klinik für Pädiatrische Rheumatologie und Immunologie, Münster, Germany*

Background: The clinical course of adult-onset Still's disease (AoSD) is highly variable, ranging from subtle constitutional symptoms to life-threatening complications such as macrophage activation syndrome. Therefore, it is of interest whether baseline disease activity in AoSD predicts the clinical course, i.e. clinical and serological remission.
Objectives: The aim of this study was to compare whether two instruments to measure AoSD disease activity, Pouchot-Score and Still-Activity-Score (SAS), at baseline predict later remission of disease. We also assessed whether serum levels of calprotectin (S100A8/A9) are associated with clinical disease activity as measured by SAS at follow up.
Methods: AoSD was diagnosed according to the Yamaguchi criteria. In all patients Pouchot-Score and Still-Activity Score (SAS) were assessed at baseline and SAS score also at follow-up. Clinical remission was defined as absence of all AoSD symptoms (i.e. fever and arthralgia), while serological remission was defined as normalization of Ferritin, IL-18 and S100A8/A9 (calprotectin) levels. To investigate the prediction accuracy of the baseline Pouchot-Score and SAS for clinical and serological remission, a calculation of the areas under the receiver operating characteristic (ROC) curves was performed.
Results: 42 AoSD patients (19 males/23 females; mean+/-SD age:41+/-17 years) were assessed. Baseline Pouchot-Score was 5.3 +/- 1.6, baseline SAS was 5.7 +/- 1.0. With treatment of AoSD, clinical disease activity decreased reaching a mean SAS of 2.2 +/- 1.8 after a mean follow up time of 48 +/- 90 months. Glucocorticoids were used by 33%, methotrexate by 21%, IL-1 inhibitors by 33% and IL-6 inhibitors by 29% of the patients. 62% (N=26) of the 42 patients obtained clinical remission and 36% (N=15) serological remission. Neither Pouchot-Score (0.57) nor SAS (0.51) at baseline predicted clinical remission of AoSD. Furthermore, also serological remission was not predicted by baseline SAS (0.62) or Pouchot-Score (0.56) (Figure 1). With respect to activity of AoSD during treatment serum calprotectin levels were closely associated with SAS disease activity ($r = 0.54$, $p < 0.0003$) (Figure 2).
Conclusion: Baseline AoSD disease activity as measured by Pouchot-Score and SAS does not predict clinical or serological remission. Serum calprotectin level is closely related to AoSD disease activity during the treatment phase.

POS1341 EVALUATION OF DAMAGE CAUSED BY SEPTAL PANNICULITIS ASSOCIATED WITH ACUTE SARCOIDOSIS

O. Egorova[1], G. Tarasova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation*

Background: Joint involvement in combination with septal panniculitis, erythema nodosum (EN), febrile reaction, and intrathoracic lymphadenopathy is the criteria for acute sarcoidosis (Löfgren's syndrome, LS) – a granulomatous multisystem inflammatory disease of unknown etiology.
Objectives: to develop an index of damage caused by septal panniculitis for express-assessment of the X-ray stage of LS.
Methods: We examined 142 patients (31 men and 111 women) in case of EN associated with LS, average age 39.3±11.1 years. All patients underwent a comprehensive clinical, laboratory and instrumental examination, including ultrasound of the joints and computed tomography (CT) of the chest organs.
Results: In 96% of cases, widespread EN was detected, which correlated with the level of CRP ($p=0.006$; $r=0.38$). In 124 patients (87%) there were signs of joint damage with predominantly periarticular changes in the area of ankle joints. The relationship between the duration of the articular syndrome and the duration of inflammatory changes in the subcutaneous tissue and the number of nodes was registered ($p=0.02$; $r=0.45$). The level of CRP had a significant direct correlation with the number of nodes ($p=0.008$; $r=0.29$) and the severity of articular syndrome ($p=0.003$; $r=0.29$). An elevated level of angiotensin-converting enzyme was detected in 97 patients (78%). The assessment of the probable radiological stage (c) of LS was performed according to the formula obtained using step-by-step discriminant analysis:
$c= 1,06*X1+0,98*X2+5,21*A+ 1,68*CRP$
X1 – the number of sides of the lower/upper limbs with the detected diffuse lesions of the skin and subcutaneous fat; X2 – the number of erymatous nodes (or induration); A – the number of arthritis; CRP – concentration of C-reactive protein in absolute values. The value of $c\leq 28.72$ indicated x-ray Stage 0; $28.72<c<109.02$ – x-ray Stage I, $c \geq 109.02$ – x-ray Stage II of the LS of the chest organs. The developed technique made it possible to determine Stage I of LS in 69% of cases and Stage II in 15% of cases, which was confirmed by CT of the lungs. For the selected total value of the discriminant function of 3.984, the sensitivity is 79%, the specificity is 96%.
Conclusion: The developed assessment is a low-cost, affordable and fast way to assess the verification of the X-ray stage of LS at any stage of the disease, which contributes to the immediate prescription of adequate therapy.

POS1342 DEPLETION OF KLRG1+ T CELLS IN A FIRST-IN-HUMAN CLINICAL TRIAL OF ABC008 IN INCLUSION BODY MYOSITIS (IBM)

N. Goel[1,2], M. Needham[3,4,5,6], D. Soler-Ferran[1], M. M. Cotreau[1], J. Escobar[1], S. Greenberg[1,7,8]. *[1]Abcuro, Inc, Newton, MA, United States of America; [2]Duke University School of Medicine, Internal Medicine, Division of Rheumatology, Durham, NC, United States of America; [3]Fiona Stanley Hospital, Neurology, Murdoch, Australia; [4]The University of Notre Dame Australia, School of Medicine, Fremantle, Australia; [5]Murdoch University, Centre for Molecular Medicine and Innovative Therapeutics, Murdoch, Australia; [6]Perron Institute for Neurological and Translational Science, South Metropolitan Health Service, Nedlands, Australia; [7]Brigham and Women's Hospital, Neurology, Boston, MA, United States of America; [8]Harvard Medical School, Neurology, Boston, MA, United States of America*

Background: Inclusion body myositis (IBM), a relentlessly progressive autoimmune skeletal muscle disease, has no effective available pharmacological therapy. A prominent feature of IBM on microscopy is highly differentiated effector CD8+ cytotoxic T (Tc) cells invading non-necrotic myofibers [1]. These Tc cells, known to be relatively resistant to apoptosis, express markers including killer cell lectin-like receptor G1 (KLRG1) [2]. ABC008, a first-in-class humanized, afucosylated monoclonal antibody (mAb) specific for KLRG1, selectively depletes these highly differentiated Tc cells while sparing other blood cell populations, e.g., naïve, central memory, and regulatory T cells and B cells. ABC008 has been designed to treat diseases mediated by these Tc cells, including IBM and T-cell large granular lymphocytic leukemia (T-LGLL). IBM and rheumatoid arthritis overlap clinically with T-LGLL and share similar expansions of large granular lymphocytes (LGLs), which also express KLRG1. We report here our preliminary data from our ongoing trial of ABC008 in IBM (NCT04659031).
Objectives: Evaluate the safety, pharmacodynamics (PD), and pharmacokinetics (PK) of ABC008 administered subcutaneously (SC) in adults with IBM.
Methods: In this first-in-human, open-label, single ascending dose trial with 3 + 3 design evaluating ABC008 SC, eligible participants must have clinicopathologically defined, clinically defined, or probable IBM according to the European Neuromuscular Centre 2011 research diagnostic criteria [3] and an IBM Functional Rating Scale (IBMFRS) score ≤38. Four dose cohorts are planned: ABC008 0.1, 0.5, 2.0, and 5.0 mg/kg. PD, PK, safety, and disease severity assessments are performed pre-dose (Day 0) and during the 6-month follow-up period.
Results: Five of the 6 (83.3%) participants were male with baseline mean age = 65.7 years, mean IBM disease duration = 6.8 years, and mean IBMFRS score = 27.5 (Table 1). Each received a single dose of ABC008 SC: Cohorts 1 (C1) and 2 (C2) received 0.1 and 0.5 mg/kg and have completed 168 and 56 days of follow-up, respectively.

Table 1. Baseline Demographics

Baseline Characteristics	ABC008 SC Treatment Groups		
	Cohort 1 0.1 mg/kg SC (n=3)	Cohort 2 0.5 mg/kg SC (n=3)	ABC008 Overall (N=6)
Age (years), mean ± SD	64.0 ± 11.36	67.3 ± 6.66	65.7 ± 8.52
Male sex, n (%)	3 (100)	2 (66.7)	5 (83.3)
Caucasian	3 (100)	3 (100)	6 (100)
Body Mass Index (kg/m^2)	28.5 ± 3.58	28.3 ± 4.25	28.4 ± 3.52
Disease Duration (years), mean ± SD	9.7 ± 5.97	3.9 ± 4.48	6.8 ± 5.70
IBMFRS score, mean ± SD	30.0 ± 4.08	25.0 ± 6.16	27.5 ± 5.80

Abbreviations: IBMFRS, Inclusion Body Myositis Functional Rating Scale; n or N, number; SC, subcutaneous; SD, standard deviation.

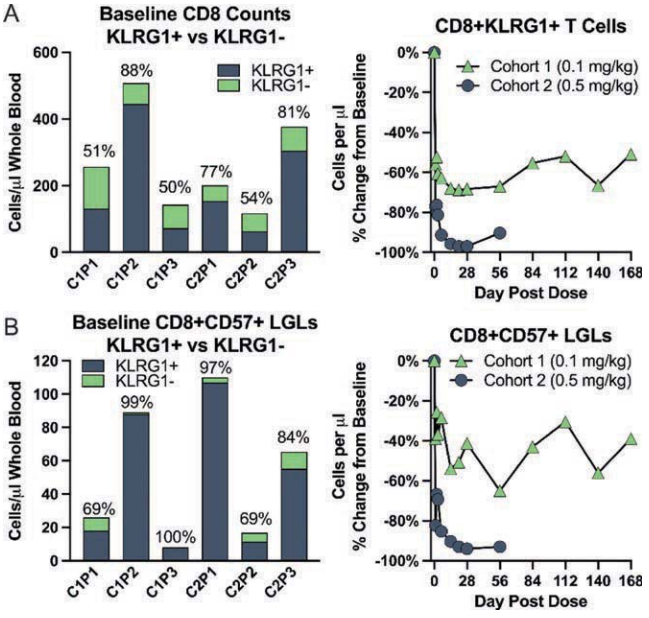

Figure 1. Key pharmacodynamic parameters in Study ABC008-IBM-101. Baseline and change (A) of KLRG1+CD8+ T cells and (B) CD8+CD57+ large granular lymphocytes (LGLs). C1 and C2 are Cohorts 1 and 2; P1, P2, and P3 are Participants 1, 2, and 3.

Maximum depletion of CD8+KLRG1+ cells for C1 and C2 ranged from 46-96% and 98-99%, respectively (Figure 1A), with depletion evident by the next assessment on Day 1. Recovery in C1 began at Day 84 with Day 168 depletion at 29-71%. Other hematologic parameters generally were stable (e.g., T regulatory and B cells). CD8+CD57+ LGLs, mostly KLRG1+, were also depleted (Figure 1B). Preliminary PK showed that ABC008 SC displays a long absorption phase and slow clearance properties typical of mAb therapies. No severe adverse events (AEs) or discontinuations due to AEs have been reported. One unrelated serious AE of fall with muscle tear in a C1 participant with a prior history of falls occurred.
Conclusion: In study participants with IBM, single SC doses of 0.1 and 0.5 mg/kg of ABC008 resulted in the depletion of CD8+KLRG1+ cells and CD8+CD57+ LGLs with clear evidence of a dose response for KLRG1+ T cell depletion and no apparent safety signals. Based on these results, a study evaluating ABC008 for the treatment of T-LGLL is planned.

POS1343

TREATMENT OF RESISTANT RAYNAUD'S PHENOMENON WITH SINGLE-PORT THORACOSCOPIC SYMPATHICOTOMY: ONE-YEAR FOLLOW-UP

S. Van de Zande[1], M. Kuijpers[2], A. Van Roon[1], A. J. Stel[3], A. Smit[1], W. Bouma[2], M. Dejongste[4], M. Mariani[2], T. Klinkenberg[2], D. J. Mulder[1]. *[1]University Medical Center Groningen, Vascular Medicine, Groningen, Netherlands; [2]University Medical Center Groningen, Cardiothoracic Surgery, Groningen, Netherlands; [3]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands; [4]University Medical Center Groningen, Cardiology, Groningen, Netherlands*

Background: Raynaud's phenomenon (RP) usually results in discoloration of the extremities when provoked by cold or emotional stress [1]. Some patients do not respond to conventional therapies, such as lifestyle interventions and vasodilatory medication. These patients are confronted with limited options for treatment. In a previous study we have shown that minimally invasive Single-Port Thoracoscopic Sympathicotomy (SPTS) objectively and subjectively improves treatment-resistant RP, after one month [2]. This procedure for treatment-resistant RP is minimally invasive and potentially highly effective, because it specifically targets the sympathetic nerve at the third rib (R3), while leaving the ganglia untouched [3]. The procedure was only performed on the left side in the pilot study, which objectively resulted in improvement of left-hand perfusion in all patients after one month, when compared to the right hand. Furthermore, patient satisfaction after surgery was high and RP attacks of the left hand were less frequent and of shorter duration. Previous studies have shown that long-term effects of conventional sympathectomy is stable in the long run in the majority of patients [4, 5]. We have previously published the one-month results of SPTS for treatment-resistant RP in a concise report [2]. In the current study we sought to report the one-year follow-up results of SPTS for treatment-resistant RP in the same cohort of patients.
Objectives: Follow-up of patients with treatment-resistant Raynaud's phenomenon (RP) one-year after single-port thoracoscopic sympathicotomy (SPTS).
Methods: Eight patients (six males, two females, median age of 45 years) with treatment-resistant RP underwent left-sided SPTS at the third rib (R3), unilaterally. Perfusion was assessed with a cooling and recovery procedure at baseline and one year after SPTS. Furthermore, laser speckle contrast analysis, pulse wave velocity, heart rate variability and nailfold capillaroscopy were performed. In addition, questionnaires were taken, and number and duration of RP attacks were reported over a 2-week period.
Results: One year after SPTS the duration of the attacks of was reduced with 1.9 hours in the left hand versus 0.9 hours in the right hand. Furthermore, three aspects of the questionnaire showed a significant improvement (role limitations due to physical health (p=0.017), pain (p=0.027) and physical functioning (p=0.025)). The total area under the curve of the total cooling and recovery procedure of the left hand was larger one year after surgery (101 (75–140) at baseline versus 118 (95–190) one year post-operatively, p=0.012), implying a better perfusion in the fingers. This was mainly due to the improvement during the recovery phase (21 (1–41) at baseline versus 38 (24–43) one year post-operatively, p=0.028).
Conclusion: One year after unilateral R3 SPTS there is clear benefit with regard to the majority of outcome variables, though some effects seem to attenuate. Long-term effects and five-year follow-up results will be investigated in an on-going study.

POS1344 USEFULNESS OF TRADITIONAL AND NOVEL BIOMARKERS FOR EVALUATION OF ADULT-ONSET STILL's DISEASE ACTIVITY

V. Myachikova[1], E. Kuvardin[2,3], K. Zotkina[1], O. Tkachenko[4], S. Lapin[4], A. Maslyanskiy[1,5]on behalf of FUNDING This work was financially supported by the Ministry of Science and Higher Education of the Russian Federation (Agreement No. 075-15-2020-901).. *[1]Almazov National Medical Research Centre, Laboratory of Rheumatology and Immunopathology, Saint-Petersburg, Russian Federation; [2]Almazov National Medical Research Centre, rheumatology, Saint-Petersburg, Russian Federation; [3]Almazov National Medical Research Centre, Rheumatology Department, Saint-Petersburg, Russian Federation; [4]First Pavlov State Medical University of Saint Petersburg, Center for Molecular Medicine, Saint-Petersburg, Russian Federation; [5]Saint Petersburg State University, Scientific, Clinical and Educational Center of Gastroenterology and Hepatology, Saint-Petersburg, Russian Federation*

Background: Adult-onset Still's disease (AOSD) is a rare systemic autoinflammatory disorder with unknown etiology. The main problem for rheumatologists is a lack of generally accepted methods for assessing AOSD activity.
Objectives: To compare the usefulness of traditional and novel biomarkers for assessing the AOSD activity
Methods: The cross-sectional study included 27 patients over the age of 18 with a relapse of AOSD who were examined at the Almazov National Medical Research Centre from 2018 to 2021. All patients fulfilled the AOSD classification criteria by Yamaguchi. Clinical manifestations were scored in a Pouchot AOSD activity score. The serum concentrations of IL-1, IL-6, IL-18, ferritin, calgranulin, procalcitonin and the level of glycosylated ferritin (GF) were examined. Standard commercial reagents were used for detection clinical analysis of blood, C-reactive protein (CRP) and aminotransferases. Statistical analysis was performed using the licensed statistical applications Statistica 10.0 for Windows (StatSoft Inc., USA), and Prisma GraphPad 8.0 (GraphPad Software, USA). Results were expressed as median (25th–75th percentile) and analysed for statistical significance using nonparametric tests. For quantitative features comparison, the Mann–Whitney U test was used. The correlation coefficient was obtained by nonparametric Spearman's rank correlation test. P values < 0.05 were considered statistically significant. Data from commercial test systems are taken as the basis for normal biomarker indicators.
Results: Clinical data were available from 27 patients with AOSD (6 male and 21 female). The median age was 41.3 [26;50]. The median Pouchot activity score was 6 [4.5;7]. The course of AOSD was monocyclic in 1 patient, polycyclic in 23, and chronic in 3. Elevated leukocyte count > 10,000/μl was detected in 17 patients (63%), 9 patients (33%) had an elevated leukocyte count > 15,000/μl.
An increase in biomarkers was detected in most patients: calgranulin was increased in 24 out of 26 patients (92.3%), ferritin was increased and GF was decreased in 21 out of 25 patients (84%). Among those 25 patients, the decrease in GF was less than 20% in 13 patients (52%). IL-18 increased in 17 patients (63%), IL-6 increased in 22 patients (81.5%), and procalcitonin increased in 16 out of 26 patients (61.6%). The median of procalcitonin concentration was 0.08 [0.01; 30.1]. No increase in IL-1 beta was detected.
A correlation analysis revealed a direct relationship between the concentration of IL-18, ferritin and the Pouchot system score. An inverse relationship existed between these indicators and the level of GF (rs=0.803, p=0.001) and between calgranulin and IL-6 (rs=0.46, p=0.02). It was noted that the younger the age of the patients, the higher the concentration of IL-18 (rs=-0.449, p=0.019).
Conclusion: The most promising additional laboratory biomarkers for assessing AOSD activity are calprotectin, IL-18, and ferritin. Despite a slight increase in procalcitonin as one of the indicators of the acute phase of inflammation, it remains an effective biomarker of sepsis; however, it is recommended to focus on threshold concentrations above 0.5.

POS1345 BEYOND PULMONARY ARTERY ANEURYSM; PULMONARY INVOLVEMENT IN BEHCET'S SYNDROME

R. Yildirim[1], M. Dinler[1], S. Oğuzman[1], N. S. Yasar Bilge[1], T. Kaşifoğlu[1].
[1]Osmangazi University School of Medicine, Rheumatology, Eskişehir,Turkey

Background: Pulmonary involvement (PI) other than pulmonary artery aneurysm (PAA) in Behcet's syndrome (BS) is still an area of investigation.
Objectives: Herein, we aimed to retrospectively evaluate all types of pulmonary involvement associated with Behcet's syndrome (BS).
Methods: Among 800 BS patients according to International Study Group for Behcet's Disease (ISG) criterias, 28 patients were selected based on their radiologic examination consistent with BS-related PI. Demographic features, other clinical manifestations of BS, treatment modalities and types of PI were analyzed.
Results: The overall prevalence of PI was estimated 3,5% among all BS patients. PI was more common in males (82.1% vs 17.9%). Mean age for BS diagnosis and onset of PI were as following; 32 ± 10,9 and 37 ± 11,4 years. Deep vein thrombosis (DVT) was the most common accompanying vascular involvement (53,6%). PAA, pulmonary vasculitis (PV), and pulmonary thromboembolism (PTE) were seen in 7 (25%), 13 (46,3%), and 18 (64,4%) of patients, respectively. In 5 patients, intracardiac thrombosis was present simultaneously in the right ventricle. Cyclophosphamide (CYC) was the most common preferred agent (78%) followed by azathioprine (AZA) as first line. Warfarin used in 18 patients (Table 1) Mortality was seen in 3 patients during follow up (1 due to PAA bleeding, others with unknown causes).

Table 1. Characteristics of pulmonary involvement in BS patients

Male/Female, (n), (%)	23/5 (82,1%/17,9%)
Age of diagnosis, years (Mean± SD)	32 ± 10,9
Age of pulmonary involvement, years (Mean ± SD)	37 ± 11,4
Oral ulcer, (n), (%)	28 (100%)
Genital ulcer, (n), (%)	20 (71,4%)
Osteofollicular lesion,(n), (%)	20 (71,4%)
Erythema nodosum, (n), (%)	13 (46,4%)
Uveitis, (n), (%)	8 (28,6%)
DVT, (n), (%)	15 (53,6%)
Cardiac involvement, (n), (%)	5 (17,8%)
Pulmonary involvement, (n)	28
-PAA, (n), (%)	7 (25%)
-PV, (n), (%)	13 (46,4%)
-PTE, (n), (%)	18 (64,3%)
Immunosuppression (first line agents)	26/28
-Steroid, (n), (%)	26/28
-CYC, (n), (%)	22/26 (84,6%)
-AZA, (n), (%)	4/26 (15%)
Anticoagulation (warfarin), (n), (%)	18

PAA; pulmonary artery aneurysm, PTE; pulmonary thromboembolism, PV; pulmonary vasculitis, CYC; cyclophosphamide, AZA; azathioprine, DVT; deep vein thrombosis

Conclusion: Despite the importance of PAA in BS patients, capillaritis and thromboembolism other than PAA may occur commonly in BS as well. Onset at young age, male gender and previous DVT seem to be significant risk factors for the development of PI.

PREVALENCE, PHENOTYPICAL CLINICAL CLUSTERS AND TREATMENT OF NEUROBEHÇET'S DISEASE. STUDY IN NORTHERN SPAIN

A. Herrero-Morant[1], C. Álvarez-Reguera[1], L. Sanchez-Bilbao[1], D. Martínez-López[1], J. L. Martín-Varillas[2], G. Suárez-Amorín[1], R. Fernández Ramón[1], M. C. Mata Arnaiz[2], M. Á. González-Gay[1], R. Blanco[1]. *[1]Marqués de Valdecilla University Hospital, Rheumatology and Ophthalmology, Santander, Spain; [2]Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain*

Background: Behçet's disease (BD) may present with different clinical phenotypes. Ocular and Neurobehçet's Disease (NBD) are severe complications [1-4]. Data on NBD epidemiology, clinical phenotype and therapy are scarce and controversial.

Objectives: In a wide unselected single-center series of BD our aims were to assess **a)** NBD prevalence, **b)** associations with other clinical clusters and **c)** treatment.

Methods: Cross-sectional study of all 120 patients diagnosed with BD in Northern Spain, between January 1, 1999 to December 31, 2019. Finally, 96 patients were included in this study according to 2014 International Criteria for Behçet Disease (ICBD) [5]. NBD was diagnosed according to the International Consensus Recommendation (ICR) criteria [4].

Results: NBD was diagnosed in 23 of 96 (24%) patients (15 women/8 men) (mean age: 44±13.9 years). NBD was classified as parenchymatous (n=10, 43.5%), non-parenchymatous (n=10, 43.5%) and mixed (n=3, 13%). HLAB51 was positive in 5 out of 13 (38.4%) patients tested. The main cluster of clinical associations were oral aphthae (n=20, 87%); ocular (n=14, 60.9%), cutaneous (n=10, 43.5%), articular (n=9, 39.1%), vascular (n=4, 17.4%) and intestinal (n=1, 8.7%) involvement (Figure 1).

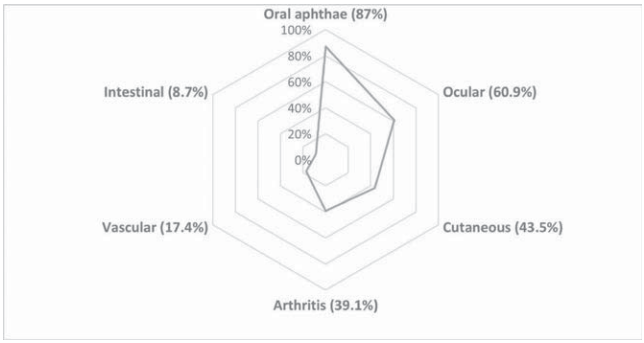

Figure 1. Clusters of clinical associations of NBD

Treatments were oral corticosteroids (n=16; 69.6%; mean maximum dose 42±12.5 mg/ day, conventional immunosuppressants (n=13, 56.5%) and Biological Therapy (BT) (n= 7; 30.4%). BT was used in patients who were refractory to conventional immunosuppressants. Monoclonal anti-TNFα were used as the first option in all patients who received BT. In 3 out of 7 (42.7%) patients BT was switched due to inefficacy. Table 1 shows the main NBD clinical subtypes and treatment.

Complete remission was achieved in 18 of 23 cases (78.2%), partial response in 2 out of 23 cases (8.7%). No severe adverse effects were observed.

Conclusion: NBD was observed in 24% of patients with BD. The most frequent clinical clusters of NBD were oral aphthae and ocular involvement. All patients treated with either conventional immunosuppressant or BT achieved clinical remission.

POS1347

BIOLOGICAL THERAPY IN NEUROSARCOIDOSIS. STUDY OF 30 PATIENTS FROM A SERIES OF 234 SYSTEMIC SARCOIDOSIS FROM A UNIVERSITY HOSPITAL

A. Herrero-Morant[1], D. Martínez-López[1], L. Sanchez-Bilbao[1], I. Gonzalez-Mazon[1], J. L. Martín-Varillas[2], R. Fernández Ramón[1], C. Álvarez-Reguera[1], M. Á. González-Gay[1], R. Blanco[1]. *[1]Marqués de Valdecilla University Hospital, Rheumatology and Ophthalmology, Santander, Spain; [2]Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain*

Background: Neurosarcoidosis (NS) is a severe complication of sarcoidosis [1,2]. NS may be classified according to several subtypes [1]. Data on therapy, including biological therapy (BT) is scarce.

Objectives: To assess efficacy and safety of BT in refractory NS subtypes.

Methods: Study of NS from a large cohort (n=234) of all consecutive patients diagnosed with sarcoidosis in a single university hospital from January 1, 1999 to December 31, 2019. Diagnosis of sarcoidosis was established according to ATS/ERS/WASOG criteria [3].

Efficacy was considered as complete or partial response and no-response according to the resolution of the neurological syndrome (signs and/or symptoms) after the BT onset.

Results: NS was observed in 30 (19 women/11 men) of 234 (12.8%) patients; mean age, 55.0±15.8 years. NS subtypes were chronic headache (n=13, 43.4%), peripheral neuropathy (n=6, 20%), cranial neuropathy (n=5, 16.7%), spinal cord abnormalities (n=3, 10%) and aseptic meningitis (n=3, 10%). A total of 26 (86.7%) patients received oral corticosteroids (CT) (mean maximum dose: 50±19.2 mg/dL) and 7 (23.3%) IV CT. In addition, conventional immunosuppressants were administered to 18 (60%) patients and BT to 12 (40%) patients. No treatment was administered to 4 (13.3%) patients. Table 1 shows treatment according to NS subtypes. A total of 12 patients received treatment with 22 BT. Most used BT were monoclonal anti-TNFα (n=18, 81.8%), infliximab (IFX) (n= 10, 45.5%) and adalimumab (ADA) (n=5, 22.7%). After 12 months since the initiation of BT, complete, partial or no response was observed in 14 of 17 (82.4%), 2 (11.8%) and 1 patient (5.9%), respectively (Figure 1). Severe allergic reaction was

POS1348

PATIENTS WITH VEXAS DIAGNOSED IN A DANISH TERTIARY RHEUMATOLOGY SETTING HAVE HIGHLY ELEVATED INFLAMMATORY MARKERS, MACROCYTIC ANEMIA, AND NEGATIVE AUTOIMMUNE BIOMARKERS.

M. Nyhuus Bendix Rasch[1], F. Szabados2, J. M. B. Jensen[3,4], K. O. Nielsen[3], E. M. Hauge[2,5], A. Troldborg[2,6]. *[1]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [1]Aarhus University Hospital, Rheumatology, Aarhus, Denmark; [3]Aarhus University Hospital, Clinical Immunology, Aarhus, Denmark; [4]Aarhus University Hospital, Molecular Medicine, Aarhus, Denmark; [5]Aarhus University, Clinical Medicine, Aarhus, Denmark; [6]Aarhus University, Biomedicine, Aarhus, Denmark*

Background: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome was described in 2020 with overlapping features of rheumatology and hematology. VEXAS is an autoinflammatory condition caused by somatic mutations in the *UBA1* gene at methionine-41.

As patients present with highly variable clinical symptoms [1], their path in the clinical system is often complicated, and characterized by many strenuous examinations and biopsies. It is pivotal, that we familiarize with the VEXAS phenotype and advance identification of patients with VEXAS.

Objectives: We aimed to characterize patients diagnosed with VEXAS in a tertiary rheumatology referral center since December 2020 when the syndrome was described [2].

Methods: All patients were identified and diagnosed at the department of Rheumatology, Aarhus University Hospital (AUH), Denmark. Patients underwent testing for the *UBA1* somatic mutations using sanger sequencing at the department of Clinical Immunology, AUH. Sequencing analyzed for somatic variants in/at exon 3 (NM_003334.4: c.118-1G>C, c.121A>C/G, c.122T>C og c.167C>T). Clinical and biochemical data were retrieved from the hospital electronic patient chart. Continuous variables are presented as median with interquartile range (IQR) and categorical variables as percentages.

Results: A total of 11 male patients with clinical suspicion of VEXAS underwent sequencing. Five men were identified in the period December 2020 to December 2021 with *UBA1* somatic mutations. Median age at diagnosis was 84 (75-87). Symptoms debuted on average 22 months (IQR 20-40) before diagnosis. All patients had significantly elevated markers of inflammation: median CRP 297 (196-386), IL-2-receptor, and ferritin and presented with macrocytic anemia. None of the patients were positive for autoimmune biomarkers like ANA, ACPA, MPO-, or PR3-ANCA.

Conclusion: This is, to the best of our knowledge, the first report of Danish patients with the VEXAS syndrome. Patients are males with persistent inflammation, constitutional symptoms, and heterogeneous clinical presentations.

Common features for all patients in this study were highly elevated inflammatory markers, macrocytic anemia, and negative autoimmune biomarkers.

POS1349 IMMUNOGLOBULIN G4-RELATED KIDNEY DISEASE'S PREDISPOSITION TO CHRONIC RENAL DYSFUNCTION, COMPLICATIONS OF MALIGNANCY, AND MORTALITY: A LONG-TERM NATIONWIDE MULTICENTER STUDY IN JAPAN

I. Mizushima[1], T. Saeki[2], D. Kobayashi[3], H. Hayashi[4], Y. Taniguchi[5], H. Nakata[6], S. Matsui[7], T. Nagasawa[8], M. Yanagita[6], M. Kawano[1]on behalf of the IgG4-related kidney disease working group in the Japanese Society of Nephrology. *[1]Kanazawa University Hospital, Rheumatology, Kanazawa, Japan; [2]Nagaoka Red Cross Hospital, Internal Medicine, Nagaoka, Japan; [3]Niigata University, Clinical Nephrology and Rheumatology, Niigata, Japan; [4]Fujita Health University School of Medicine, Nephrology, Toyoake, Japan; [5]Kochi University, Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi, Japan; [6]Kyoto University, Nephrology, Kyoto, Japan; [7]University of Toyama, Health Administration Center, Toyama, Japan; [8]Tohoku University Hospital, Nephrology, Endocrinology, and Vascular Medicine, Sendai, Japan*

Background: In immunoglobulin G4-related kidney disease (IgG4-RKD), persistent renal insufficiency may be observed despite the good initial response to glucocorticoids[1, 2]. However, its long-term prognosis in relation to renal function as well as malignancy and mortality has not been well clarified.

Objectives: To clarify the long-term renal prognosis, complications of malignancy, mortality, and factors related to those outcomes in IgG4-RKD.

Methods: We retrospectively reviewed the medical records of patients with IgG4-RKD diagnosed by the expert members of the IgG4-RKD working group in the Japanese Society of Nephrology. We investigated clinical, radiological, and histopathological features at baseline and course of renal function, complications of malignancy, and mortality during the long-term observation periods (median 71 months) in 75 patients. Using collected data, we calculated the crude incidence rates (IR) of chronic kidney disease (CKD) status, malignancy, and death. Cox regression analyses were performed to assess CKD-related factors. Additionally, we calculated the standardized incidence ratio (SIR) of malignancy and standardized mortality ratio (SMR) using national Japan statistics.

Results: Fifty-nine patients were male, and 16 were female (median age 70 years). At diagnosis, their median eGFR was 45.1 mL/min/1.73m^2 (interquartile range [IQR] 28.6-69.9). Seventy-two patients (96%) were treated with prednisolone at a median initial dose of 30 (IQR 30-39) mg/day, leading to a reasonable initial improvement of renal function. The IR of CKD was 30.2/100 person-years, and 66.7% (50/75) of the patients showed CKD at the last visit. Age- and sex-adjusted Cox regression analyses indicated that lower eGFR (per 10 mL/min/1.73m^2, hazard ratio [HR] 0.70, 95% confidence interval [CI] 0.61-0.80), pre-existing hypertension (HR 2.39, 95% CI 1.32-4.34), and wider areas with inflammation (>50% vs. <10%, HR 2.55, 95% CI 1.07-6.08) or fibrosis (>50% vs. <5%, HR 2.84, 95% CI 1.18-6.85) in the biopsied renal specimens at treatment initiation had a significant impact on the time to CKD. Eight patients (10.7%) died during follow-up due to malignancy, severe infection, cerebral hemorrhage, or myocardial infarction. The crude mortality rate was 1.76/100 person-years, and a SMR calculated according to national Japan statistics was 0.97 (95% CI 0.42-1.90). On the other hand, 15 patients were diagnosed as having malignancies during follow-up. The IR of malignancy was 3.71/100 person-years, and the SIR of malignancy was 1.80 (95% CI 1.03-2.93).

Conclusion: This study suggests that pre-treated renal insufficiency and extensive renal inflammatory and fibrotic lesions are related to CKD under glucocorticoid therapy in IgG4-RKD. Similarly with the whole IgG4-related disease, IgG4-RKD may have an increased incidence of malignancy but a mortality rate equivalent to the age- and sex-matched Japanese population.

*p<0.01

Background: Adalimumab remains the only biologic approved by the EMA and FDA for the treatment of non-infectious uveitis [1-6]. The reports on efficacy of other anti-TNF drugs such as Certolizumab Pegol (CZP) are scarce.
Objectives: to determine the efficacy and safety of CZP in refractory uveitis secondary to Immune-mediated Inflammatory Diseases (IMIDs).
Methods: national multicenter study of 80 patients with uveitis due to IMID refractory to glucocorticoids and conventional immunosuppressants treated with CZP. Efficacy was assessed with the following ocular parameters: best corrected visual acuity (BCVA), anterior chamber cells, vitritis, macular thickness and presence of retinal vasculitis. The efficacy of CZP was compared between the baseline visit, 1st week, 1st and 6th month, and 1st year. Statistical analysis was performed with IBM SPSS Statistics v.23.
Results: we studied 80 patients/111 affected eyes (33 men/47 women) with a mean age of 41.6±11.7 years. The IMIDs included were: spondyloarthritis (n=43), Behçet's disease (10), psoriatic arthritis (8), Crohn's disease (4), sarcoidosis (2), JIA (1), reactive arthritis (1), rheumatoid arthritis (1), relapsing polychondritis (1), TINU (1), pars planitis (1), Birdshot (1) and idiopathic uveitis (6). Anterior was the most frequent uveitis pattern (n=61).
In 20 patients, besides the presence of refractory uveitis, desire of pregnancy was the reason for CZP initiation.
Prior to CZP, patients had received: methotrexate (n=38), sulfasalazine (28), azathioprine (14), cyclosporine (10), leflunomide (3), mycophenolate mofetil (4), and cyclophosphamide (1). Previous biologic therapy was administered in 52 patients (63%), with a median [IQR] of 2 [1-3] drugs per patient. The most used biologic was adalimumab (n=48), followed by infliximab (32), golimumab (15), tocilizumab (5), etanercept (7), rituximab (1), anakinra (1) and secukinumab (1). CZP was administered as monotherapy in 39 patients.
After 24 [12-36] months of follow-up, all parameters analyzed showed a rapid and maintained improvement (Table 1). A decrease in the mean number of uveitis flares was observed before and after CZP, (2.6±2.3 vs. 0.6±0.4, p<0.001). CZP was discontinued in 16 patients due to: ocular remission (n=3), insufficient ocular response (4) and incomplete response of extraocular manifestations (9). No serious adverse effects were found.
Conclusion: CZP seems to be effective and safe in the control of uveitis associated to different IMIDs.

Blanco[2]. *[1]Hospital de Laredo, Rheumatology, Laredo, Spain; [2]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain; [3]Hospital Clinic, Ophthalmology, Barcelona, Spain; [4]Complejo Asistencial de León, Ophthalmology, León, Spain; [5]Hospital Clínico San Carlos, Ophthalmology, Madrid, Spain; [6]Complejo Hospitalario de Navarra, Internal Medicine, Pamplona, Spain; [7]Hospital Universitario de Alava, Rheumatology, Alava, Spain; [8]Complejo Hospitalario Universitario de Toledo, Rheumatology, Toledo, Spain; [9]Hospital Universitario Virgen de Valme, Rheumatology, Sevilla, Spain; [10]Hospital General Universitario de Alicante, Rheumatology, Alicante, Spain; [11]Hospital Sant Pau, Rheumatology, Barcelona, Spain; [12]Hospital 12 de Octubre, Pediatrics, Madrid, Spain; [13]Hospital de Sagunto, Rheumatology, Valencia, Spain; [14]Hospital Universitario Marqués de Valdecilla, Internal Medicine, Santander, Spain*

Background: Cystoid Macular Edema (CME) is the leading cause of blindness in non-infectious uveitis. Behçet's disease (BD) is one of the diseases most frequently associated with CME [1-4].
Objectives: to compare the efficacy and safety of Certolizumab (CZP) and Adalimumab (ADA) in CME due to BD refractory to conventional therapy.
Methods: multicenter study of patients with CME secondary to BD refractory to glucocorticoids (GC) and at least 1 conventional immunosuppressant. All patients had CME (OCT>300µ) at baseline. Efficacy was assessed with the following ocular parameters: macular thickness (µm), visual acuity (BCVA) and GC-sparing effect. The efficacy of CZP vs. ADA was compared between the baseline visit, 1st and 6th month, and 1st and 2nd year. Statistical analysis was performed with IBM SPSS Statistics v.23.
Results: We studied 21 patients/38 affected eyes were studied. 10 patients were treated with CZP (200 mg c/2 weeks) and 11 with ADA (loading dose of 80 mg and subsequently 40 mg c/2 weeks).
No statistically significant baseline differences were observed in both groups (CZP vs. ADA) in sex (♂/♀; 3/7 vs 5/6; p=0.65) and mean age (36.1±8.0 vs 42.2±8.6; p=0.10). However, CZP group was more severe with a longer time between EB diagnosis and biologic initiation (91.6±71.4 vs 34.4±21.3 months, p=0.02), and a greater median [IQR] number of previous biologic drugs (2 [0.75-3] vs 0 [0-0]). In CZP group, 8 patients were previously treated with ADA.
Combined therapy with conventional DMARDs was used with ADA in 81.8% vs. 18.2% of CZP patients.
Regarding the efficacy outcomes analyzed, a rapid and maintained improvement in macular thickness, measured by OCT, was observed after 2 years of follow-up in both groups with no statistically significant differences between them (Table 1). Improvement in visual acuity and a GC-sparing effect was also observed (Table 1). No serious adverse events were observed in either group.
Conclusion: Our study suggests that both CZP and ADA are effective in the treatment of CME due to BD refractory to conventional treatment. CZP was equally effective despite most patients were refractory to ADA.

POS1352 A PROSPECTIVE, ONE-YEAR FOLLOW-UP STUDY OF PATIENTS NEWLY DIAGNOSED WITH NEUROSARCOIDOSIS

K. E. Byg[1,2,3], Z. Illes[2,4], T. Sejbaek[4,5,6], N. Nguyen[7], S. Möller[3,8], K. Lambertsen[4], H. Nielsen[2,4], T. Ellingsen[3,9]. *[1]Odense University Hospital, Rheumatology Research Unit, Odense, Denmark; [2]Odense University Hospital, Neurology, Odense, Denmark; [3]University of Southern Denmark, Department of Clinical Research, Odense, Denmark; [4]University of Southern Denmark, Neurobiology Research, Institute of Molecular Medicine, Odense, Denmark; [5]South West Jutland Hospital, South Danish University Hospital, Neurology, Esbjerg, Denmark; [6]University of Southern Denmark, Regional Health Research, Odense, Denmark; [7]Odense University Hospital, Radiology, Odense, Denmark; [8]Odense University Hospital, Open Patient Data Explorative Network, Odense, Denmark; [1]Odense University Hospital, Rheumatology Research Unit, Odense, Denmark*

Background: Sarcoidosis is a granulomatous inflammation of unknown etiology. Neurosarcoidosis (NS) occurs in 5–10% of patients with sarcoidosis and is a severe manifestation of sarcoidosis. The clinical presentation is heterogeneous and depends on the inflammation within the nervous system.
Objectives: This study aimed to describe NS patients and their clinical course of treatment. Our outcomes were changes in 1) enhancing lesions on MRI of the central nervous system (CNS), 2) cerebrospinal fluid (CSF), 3) disability and dependency in daily activities assessed by the modified Rankin Scale (mRS), 4) cognitive function assessed by the Symbol Digit Modality Test (SDMT), 5) quality of life assessed by Short-Form 36 Health Survey (SF-36), 6) fatigue assessed by Fatigue Assessment Scale (FAS), and 7) depression measured by Beck Depression Inventory-II (BDI-II).
Methods: In this observational cohort study with a one-year follow-up, we consecutively recruited NS patients (N=20), not including patients with polyneuropathy, from the Departments of neurology and rheumatology at Odense University Hospital between January 2016 and August 2020. Patients were examined clinically, with questionnaires and MRI at baseline (V) and after three months (V3), six months (V6), and 12 months (V12). Cerebrospinal fluid (CSF) was examined at baseline, V6, and V12.
Results: The median age was 51.6 years, and the median duration of sarcoidosis symptoms was 8 months before inclusion.
At baseline, 60% of NS patients had headache, followed by vertigo (55%) and tinnitus (50%). Objective neurological findings were peripheral sensory signs (50%), peripheral motor signs (40%), and cranial nerve involvement (30%). At V12, there were significant improvements in vertigo (p=0.03), cranial nerve involvement (p=0.03), and joint symptoms (p=0.03).
At baseline, 60% of patients had abnormal findings on MRI of CNS. During the study, the number of contrast-enhancing lesions on MRI decreased significantly (p<0.0001).
The mRS declined significantly from mean (SD) 3.0 (0.8) at baseline to 1.8 (1.1) at V12 (p<0.0001), and 75% of patients experienced clinically important improvement (mRS≥1).
The SDMT score improved significantly from mean (SD) 38 (9) at baseline to 45 (12) at V12 (p<0.0001).
The SF-36 Physical (PCS) and Mental Component Summary scores (MCS) improved significantly from baseline: PCS mean (SD) 35 (11) to 41 (12) at V12 (p=0.003) and MCS mean (SD) 41(9) to 48 (10) at V12 (p=0.03).
The proportions of patients with substantial fatigue (75%) and high depression score (35%) were unchanged.
Conclusion: One year of immunosuppression in NS patients improved several outcomes, and 75% of patients experienced clinically important improvement.

POS1353 COMPOSITION AND ASSOCIATIONS OF THE GUT MICROBIOTA IN BECHET'S DISEASE WITH PERIPHERAL LYMPHOCYTE SUBSETS AND CYTOKINES

J. Luo[1,2,3], Q. Y. Su[1,2,3], J. Q. Zhang[1,2,3], J. Qiao[1,2,3], S. X. Zhang[1,2,3], C. Wang[1,2,3], X. F. LI[1,2,3]. *[1]Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Academy of Microbial Ecology, Shanxi Medical University, Taiyuan, China; [3]Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China*

Background: Bechet's disease (BD) is a chronic multisystemic vasculitis with genetic and abnormal immune response. Growing evidences suggests gut microbiota compositional alteration may have an association with immune dysfunction in patients with BD.
Objectives: This study aims to investigate the gut microbiota between BD and healthy controls (HCs) and analyse relevancy between bacterial and peripheral lymphocyte subsets and cytokines.
Methods: Fecal samples obtained from 22 BD patients and 22 normal-age and gender-matched HCs in this study. The gut microbiota were assessed with 16s rRNA sequencing and the flow cytometry was used to dectect peripheral lymphocyte subsets. C-reaction protein (CRP), Erythrocyte sedimentation rate (ESR), complement C3 and C4 were also assigned for disease activity measure. The edgeR package was used for differential abundance analysis. Difference of alpha diversity indices, bacterial abundances, and the F/B ratio were carried out using the Wilcoxon rank-sum test (R v.4.0.1). The differential abundance of flora and CRP, ESR, C3 and C4 between BD patients and HCs was assessed by pearson's correlation analysis.
Results: As for alpha diversity, the Shannon ($p < 0.05$) and Simpsonance analysis. Difference of alpha diversity indices, bacterial abundances, and the F/B ratio were carried out using the Wilcoxon rank-sum test (R v.4.0.1). The differential abundamicrobial community structures between BD and HCs ($R = 0.053$, $p = 0.051$; Figure 1B). The gut microbiota compositions of BD differed form those of HCs (Figure 1C). Four species of flora distinctly difference were found in BD ($p < 0.05$; Figure 1D). There was significant positive correlations between Tregs and Verrucomicrobiota ($p < 0.05$), and Proteobacteria ($p < 0.05$), Th1 and Proteobacteria ($p < 0.05$), ESR and Verrucomicrobiota ($p < 0.01$), but negatives correlation between TNF-α and Desulfobactbiota ($p < 0.05$; Figure 1E).
Conclusion: Pattients with CTD had disbiosis of gut microbiota charaterized by impared diversity and abnomal composition, which was closely correlated with peripheral lymphocyte subsets and disease activity measures.

ANALYSIS OF FACTORS ASSOCIATED WITH GOOD THERAPEUTIC RESPONSE TO IMMUNOSUPPRESSIVE DRUGS IN PATIENTS WITH NON-INFECTIOUS UVEITIS: A SURVIVAL ANALYSIS

A. Gomez-Gomez[1], A. Madrid García[2], L. Borrego-Sanz[3], M. P. Álvarez Hernandez[2], R. Méndez-Fernández[3], P. Arriola-Villalobos[3], E. Pato[2], D. Díaz Valle[3], L. Rodriguez Rodriguez[2]on behalf of Madrid Uveitis Study Group.
[1]Hospital Infanta Sofia, Rheumatology, San Sebastián de los Reyes, Spain; [2]Instituto de Investigación Sanitaria San Carlos, Rheumatology, Madrid, Spain; [3]Instituto de Investigación Sanitaria San Carlos, Ophthalmology, Madrid, Spain

Background: Non-infectious uveitides (NIUs) encompass a varied group of inflammatory diseases affecting the uvea and adjacent tissues, with evidence suggesting an immune-mediated cause. A correct management of these conditions is essential to prevent substantial and sometimes permanent visual loss and the development of ocular complications. Although immunosuppressive drugs (ISDs) have shown effectiveness in achieving a sustained control of the inflammatory process, not all patients achieve a satisfactory response.
Objectives: To identify factors affecting the response rate to ISDs in subjects with NIUs.
Methods: Longitudinal retrospective study, with patients collected from the Hospital Clinico San Carlos Uveitis Clinic, included from 1991 until December 2018, and followed-up until December 2019. Patients entered the study at ISD prescription and were followed-up until a) the achievement of a good therapeutic response (GTR), b) ISD treatment change (withdrawal of the prescribed ISD and/or addition of a new ISD), c) 12 months of follow-up, or d) loss of follow-up or end of the study (December 31th, 2019). GTR was defined as the complete resolution of the eye inflammatory manifestations and oral corticosteroid ≤10 mg of prednisone equivalent a day. Furthermore, this situation had to be maintained in at least two consecutive visits spanned at least 28 days. Kaplan-Meier (KM) curves were set to account for GTR. Associated demographic, clinical and treatment-related factors were analyzed using bivariate and multivariate Cox robust regression models. Different models were compared using the Akaike Information Criteria, to select the fittest model to the data. Proportional hazard assumption was tested using Schoenfeld residuals and the scaled Schoenfeld residuals. In case a variable or certain category of a categorical variable were non-proportional, they were included in the Cox models with a time-varying effect, in case the interaction with time was significant ($p<0.05$).
Results: 73 patients (100 episodes of ISD prescription) were analyzed. In 44 episodes, a GTR was achieved (incidence rate 102.0 [95% Confidence Interval (CI): 75.9 to 137.1] per 100 patient-years). Figure 1 shows the KM curve for GTR. In the bivariate analysis, several variables showed a significant association with GTR, including gender, diagnosis of Behçet Disease, prescription of Cyclosporine A (CYA), number of previously prescribed ISDs, previous use of the same ISD, previous discontinuation of a ISD due to inefficacy, higher systemic corticosteroid use in the previous year before ISD prescription, presence of macular edema (ME), and longer intermediate and posterior activity before ISD prescription. Table 1 shows the results of the multivariate analysis. Prescription of CYA was associated with a higher hazard of GTR, compared with the use of other ISDs (methotrexate, azathioprine or biologic drugs). In addition, the higher dosage of oral corticosteroids used in the previous year before ISD prescription, the lower the hazard of achieving a GTR. Finally, presence of ME at prescription was associated with lower hazard of GTR, although this risk diminished with time.

Table 1. Multivariate Cox robust regression to analyze variables independently associated with the achievement of good therapeutic response.

Variable	HR (95% CI)	p value	Schoenfel test p value
CYA prescription	2.04 (1.14-3.67)	0.017	0.56
Number of previous ISDs			
0	Reference	-	-
1	12.61 (2.07-76.73)	$5.9x10^{-3}$	0.001
≥2	3.54 (1.55-8.05)	$2.6x10^{-3}$	0.56
1 previous ISD X Time	0.01 (0.001-1.00)	0.005	
Higher oral corticosteroids dosage (mg) in the previous year	0.98 (0.97-0.99)	0.013	0.83
Macular edema	0.14 (0.04-0.45)	$9.3x10^{-3}$	0.001
Macular edema X Time	14.20 (1.55-103.10)	0.019	

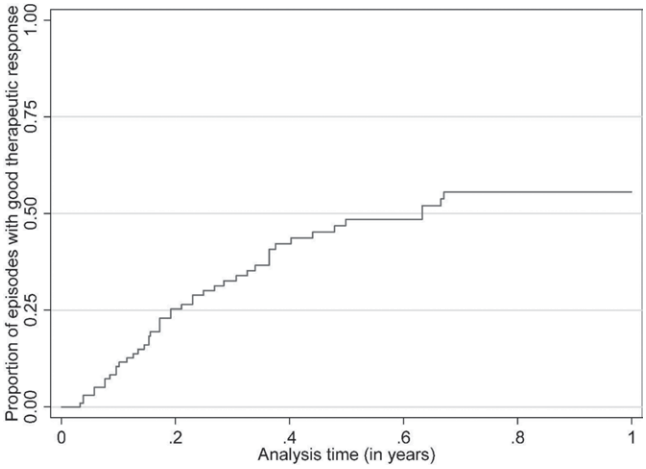

Figure 1. Kaplan-Meier failure curves representing good therapeutic response after immunosuppressive drug prescription for non-infectious uveitis.

Conclusion: We have identified several variables associated with therapeutic response to ISDs in NIUs patients.

POS1355

TO COMBINE OR NOT TO COMBINE: INFLUENCE OF IMMUNOSUPPRESSIVE DRUG COMBINATION IN THE INDUCTION OF THERAPEUTIC RESPONSE IN NON-INFECTIOUS UVEITIS

M. P. Álvarez Hernandez[1], A. Madrid García[2], A. Gomez-Gomez[3], L. Borrego-Sanz[2], R. Méndez-Fernández[2], P. Arriola-Villalobos[2], E. Pato[1], D. Díaz Valle[2], L. Rodriguez Rodriguez[1]on behalf of Madrid Uveitis Study Group. *[1]Instituto de Investigación Sanitaria San Carlos, Rheumatology, Madrid, Spain; [2]Instituto de Investigación Sanitaria San Carlos, Ophthalmology, Madrid, Spain; [3]Hospital Infanta Sofia, Rheumatology, San Sebastián de los Reyes, Spain*

Background: Non-infectious uveitides (NIUs) include a heterogeneous group of sight-threatening and incapacitating conditions. Their correct management sometimes requires the use of immunosuppressive drugs (ISDs), prescribed in monotherapy or in combination. Several observational studies showed that the use of ISDs in combination could be more effective than their use in monotherapy. However, a direct comparison between these two treatment strategies has not been carried out yet.
Objectives: To analyze the effect of ISDs combination therapy (CT) on the response rate in patients with NIUs.
Methods: Patients attending a Uveitis Outpatient Clinic from a tertiary care center in Madrid, Spain, and prescribed with ISDs from 1991 to 2018 were included. Patients were assigned as controls or cases based on whether they were prescribed with ISDs in monotherapy (MT) or CT. ISD treatment changes during the observation period were also considered. The primary outcome was good therapeutic response (GTR), defined as the complete resolution of the eye inflammatory manifestations and oral corticosteroid dosage ≤10 mg of prednisone equivalent a day. Furthermore, this situation had to be maintained in at least two consecutive visits spanned at least 28 days. Several propensity score based and non-based weighting techniques for data balancing, followed by Cox regressions, were performed to estimate the effect of CT on the response rate. Random forest (RF) models and clinical appraisal were used to select the variables to be balanced.
Results: 100 episodes of ISD prescription belonging to 73 patients were included in this analysis. In 32 episodes, patients were prescribed with CT (in 3 episodes CT was the initial therapeutic strategy; in 29, combination was the result to adding a second or third ISD). The most frequent drug used in MT was cyclosporine A (CYA; n=39), and the most frequent CT was synthetic + biological ISD (n=21). After RF, the number of previously used ISDs, the prescription of CYA, the dosage of oral corticosteroids at prescription, a previous ISD withdrawal due to inefficacy, and duration of disease were selected for balancing. In addition, after clinical appraisal, uveitis diagnosis, prescription with azathioprine, prescription

with methotrexate, and eye activity features at prescription (presence of cells in anterior chamber, vitreous haze, macular edema, active chorioretinal lesions) were also balanced. The Energy balancing method showed the best balance for GTR. After Cox-regression, CT prescription did not show a statistically significant effect in the hazard of response (p=0.43; Table 1).

Table 1. Cox models showing the effect of combination therapy in the hazard of good therapeutic response after balancing covariates using the Energy method.

Variable	HR (95% CI)	p value	Schoenfel test p value
Combination Therapy	0.66 (0.24-1.83)	0.43	0.82
Cyclosporine A prescription	3.36 (1.22-9.27)	0.019	0.96
Methotrexate Prescription	2.20 (0.72-6.71)	0.16	0.95
Presence of cell in anterior chamber	1.75 (0.83-3.72)	0.14	0.89

Conclusion: The use of CT in our study was not associated with a better therapeutic response in NIU patients compared with the prescription of MT. Considering that most CT episodes were the result of the addition of a new ISD in a patient already treated and still active, the effectiveness of CT as the initial therapeutic strategy remains unanswered.

POS1356 TREATMENT OF IMMUNE CHECKPOINT INHIBITOR-INDUCED INFLAMMATORY ARTHRITIS AND POLYMYALGIA RHEUMATICA

M. Liapi[1], K. Chatzidionysiou[1]. [1]*Karolinska Institute, Rheumatology Unit, Karolinska University Hospital, Department of Medicine Solna, Stockholm, Sweden*

Background: Therapy with immune check point inhibitors (ICIs) has revolutionized cancer treatment during the last years. Despite their high efficacy, ICIs are associated to a new spectrum of adverse events, the immune-related adverse events (irAEs). Inflammatory arthritis and polymyalgia rheumatica (PMR) are two of the most common rheumatic irAEs. The optimal management of irAEs remains unclear. Treatment guidelines largely support the use of glucocorticoids (GCs) as first line therapy [1]. Preclinical data raise concerns regarding the potential risk of impaired antitumoral effect with use of GCs. The high efficacy and potential synergistic effect (according to recent findings) [2] of targeted immunomodulation, such as interleukin 6 (IL-6) blockade, could support a paradigm shift, where targeted treatments are considered earlier in the treatment sequence.

Objectives: To assess how frequently a disease modifying anti-rheumatic drug (DMARD) treatment in patients with ICI induced arthritis and/or PMR, after inadequate response to GCs, is initiated and to assess its effectiveness.

Methods: We retrospectively identified patients who were diagnosed with inflammatory arthritis and/or PMR at the rheumatology department at Karolinska University Hospital, after referral from the oncology department due to suspicion of a rheumatic irAE, between Jan 2020 and Dec 2021. Treatment response was defined as sustained low disease activity or remission according to the rheumatologist evaluation at 6 months (+/- 1 month) after initiation of DMARD.

Results: A total of 20 patients were identified, who were diagnosed with arthritis (N=11), PMR (N=6) or both (N=3). The median (IQR) age was 70 (46-76) years; 50% of patients were females. The type of cancer was urogenital (N=8), melanoma (N=6), lung cancer (N=2), and other (N=4). 14 patients received a PD-1 inhibitor (9 nivolumab, 4 pembrolizumab, 1 cemiplimab), 3 received a PDL-1 inhibitor (2 atezolizumab, 1 avelumab), 2 received a combination of nivolumab and the CTLA-4 inhibitor ipilimumab and one patient combination of nivolumab and pembrolizumab. The median time from start of ICI treatment to symptom debut was 2 (1.25-3.75) months.

83% of patients with PMR and/or arthritis responded well to GCs without the need for treatment escalation. On the contrary,

11 out of 14 patients (79%) with inflammatory arthritis (with or without PMR) responded inadequately to GC treatment, despite receiving moderate-high doses (median 20mg/day Prednisolone or equivalent), or flared when the dose was reduced below 10mg/day. A conventional synthetic DMARD was initiated in 7 patients (methotrexate N=6, hydroxychloroquine N=1), with a response rate of 71%. 3 patients received a biologic DMARD as first-line DMARD, either because of contraindication for methotrexate and/or high disease activity, and 2 patients after methotrexate failure. All 5 patients tocilizumab, with a response rate of 100%. Subsequently 1 of these patients discontinued tocilizumab due to suspected side effects, and started with a TNF inhibitor. After initiation of tocilizumab all patients were able to reduce the dose of GCs to less than 5mg/day.

Conclusion: The majority of patients developing ICI-induced arthritis are refractory to GCs and need a DMARD treatment, although selection bias cannot be formally excluded, since the most severe forms of arthritis might be referred to the rheumatology department. csDMARDs are effective in a significant proportion of patients. Tocilizumab is highly effective and well tolerated in ICI-induced arthritis. ICI-induced PMR seems to respond adequately to GCs.

POS1357 THE 10-YEAR OUTCOME OF PATIENTS WITH BEHCET'S SYNDROME: A SINGLE-CENTER EXPERIENCE

A. Dogan[1], E. Tekgoz[1], S. Colak[1], M. Çınar[1], S. Yilmaz[1]. [1]*Gulhane Training and Research Hospital, Rheumatology, Ankara, Turkey*

Background: Behcet's syndrome (BS) is a vasculitis characterized by recurrent oral and genital ulcers, as well as ocular, cutaneous, vascular, gastrointestinal, musculoskeletal, and central nervous system manifestations.

Objectives: The study aimed to evaluate the 10-year outcome of patients with BS.

Methods: A cohort of 682 patients diagnosed with BS between January 2007 and December 2009 in the rheumatology outpatient clinic of Gulhane Training and Research Hospital were re-evaluated in November 2021. The data regarding the clinical course of 84 patients (84/682) were obtained from patients' files and detailed telephone interviews.

Results: The study included 84 patients (63 male, 21 female) with a mean age of 47.1±10.6 years. The mean disease duration was 17.6±5.7 years. At the time of the diagnosis, the mean age of the patients was 29.5±9.4 years. Oral ulcer (100%), papulopustular lesions (82.1%), genital ulcer (77.4%), and erythema nodosum (59.5%) were the most frequent manifestations at the time of diagnosis. Ocular (46.4%), musculoskeletal (35.7%), vascular (19%), gastrointestinal (3.6%), and neurological (1.2%) manifestations were seen in decreasing frequency. The most frequent ocular disease was posterior uveitis, whereas superficial thrombophlebitis and deep venous thrombosis were the most prevalent forms of vascular involvement. One patient had transverse myelitis as neurological involvement. Colchicine (88.1%) and corticosteroids (57.1%) were the most preferred drugs for the initial treatment. Fifty-one (60.7%) patients received at least one immunosuppressive agent. After 10-year, there was a statistically significant decrease in all manifestations of BS (Table 1). Nevertheless, 9 (10.7%) patients (8 male, 1 female) had new clinical findings. Five patients had (5.9%) mucocutaneous, 2 (2.4 %) arthritis and 2 (2.4%) vascular lesions as new clinical manifestations. The mean age of the patients with newly onset clinical findings was 48±8.9 years. There was no statistically significant difference between patients with and without new clinical findings with respect to age (p=0.79). The new onset mucocutaneous manifestations were genital ulcer and erythema nodosum. Besides, new onset vascular lesions were superficial and deep venous thrombosis of the lower extremities. The mean age of the patients who developed venous thrombosis at the time of the assessment was 37.0±7.07 years. Vascular involvement was detected more frequently in younger patients

Table 1. Clinical manifestations of Behcet's syndrome

		Initial	After 10 years		p
			No	Yes

*McNemar-Bowker Test, **McNemar Test

(p=0.03). However, ocular involvement is a frequent symptom after mucocutaneous involvement at the beginning, none of the patients had new eye involvement at the end of the follow-up. Colchicine, corticosteroid, and azathioprine were associated with the highest drug survival. Twenty-one (41.1%) patients of who were administered immunosuppressive agents as initial therapy were still using immunosuppressives 10 year later. The most frequently prescribed immunosuppressives were azathioprine and cyclosporine during the follow-up.

Conclusion: The frequency of newly onset clinical manifestations decreases with age in BS, especially after age 40. Besides, especially male Behcet's patients should be followed-up regularly for complications that may develop regardless of age.

POS1358 CLINICAL PRESENTATION AND MANAGEMENT OF IDIOPATHIC GRANULOMATOUS MASTITIS IN A MIDDLE EASTERN POPULATION

Z. Abdulelah[1], S. Qurashi[1], L. El-Asir[2], S. Alsayed[1]. *[1]Abdali Hospital, Department of Rheumatology, Amman, Jordan; [2]Abdali Hospital, Women's Health and Breast Center, Amman, Jordan*

Background: Idiopathic Granulomatous mastitis (IGM) is a rare inflammatory disease of the breast with poorly understood aetiology or risk factors. IGM has a predilection towards women of child-bearing age with a history of breastfeeding, particularly among Hispanic and Asian ethnicities. However, the true prevalence is unknown with IGM being poorly studied in Middle Eastern Arab and Levantine women who have different genetic, epidemiological, and environmental characteristics.

Objectives: To study the clinical features of Middle Eastern women diagnosed with biopsy-confirmed IGM.

Methods: A retrospective observational study of patients with a biopsy-confirmed diagnosis of IGM, referred to two different private outpatient rheumatology clinics in Amman- Jordan between 2016-2021. The Patients' characteristics, clinical presentation, treatment, and outcomes were recorded

Results: A total of 25 patients were identified in this study. The mean age was 34.9 ± 5.2 years. All females presented with a breast nodule and tenderness, while only 16% reported associated skin changes in the breast and 12% reported galactorrhoea. Bilateral breast involvement occurred in only 4 patients (16%) while 21 patients had unilateral breast involvement. Systematic manifestations including myalgia/arthralgia, skin changes, fever, and axillary lymphadenopathy were reported by 44%, 16%, 20%, and 16% of patients, respectively.

Notably, all enrolled females were married at the time of presentation and 3 of them were pregnant or postpartum during the onset of symptoms. The majority of patients (n= 21, 84%) had a prolonged period of breastfeeding (> 6 months). Moreover, 80% of patients had ≥3 pregnancies with 60% having their youngest child aged 3-5 years.

20 patients (80%) had a complete resolution of symptoms, and 20% (n=6) were lost to follow-up. Among patients who completed follow-up, treatment duration lasted for ≥ 1 year in 36% (n=9) of patients, whereas 11 patients had a complete resolution in less than a year. Azathioprine, methotrexate, antibiotics, and steroids were used in the treatment of 20%,36%, 60%, and 68%, respectively. Of note, only 1 patient underwent surgical intervention during treatment.

Conclusion: Many theories had suggested different aetiology for IGM but, in our cohort, it appears that being multiparous and prolonged breastfeeding carry higher risks of developing granulomatous mastitis. Although the aetiology is unclear, early diagnosis and the introduction of treatment using steroid therapy and immunosuppression can improve prognosis and prevent unnecessary surgery. Most of our patients that were treated with corticosteroid, Azathioprine, and Methotrexate had a complete resolution of symptoms after one year of therapy.

POS1359 TRANSIENT ELASTOGRAPHY (FIBROSCAN) AS A NON-INVASIVE METHOD FOR DETECTING AMYLOID DEPOSITION IN TRANSPLANTED KIDNEYS IN PATIENTS WITH AA AMYLOIDOSIS

M. Bektaş[1], B. Çavuş[2], A. B. Dirim[3], S. Sarı[1], V. Şenkal[2], N. Koca[1], B. Ince[1], B. F. Agargun[4], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], H. Yazıcı[3], S. F. Beşışık[2], A. Gül[1]. *[1]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Gastroenterology, Istanbul, Turkey; [3]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Nephrology, Istanbul, Turkey; [4]Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*

Background: Amyloidosis is characterized by accumulation of insoluble fibrils composed of different monomers in extracellular spaces of different organs, and demonstration of deposits by non-invasive methods is important especially for organs difficult to sample. Transient elastography (Fibroscan) is a diagnostic method of measuring liver stiffness (LS) being used in chronic liver diseases.

Objectives: We herein aimed to search potential of fibroscan detecting kidney stiffness (KS) associated with amyloid deposition in patients with AA who received kidney transplants.

Methods: Renal transplant recipients (RTR) because of AA amyloidosis-related kidney failure (amyloidosis group; AG) and RTR due to other underlying diseases (control group; CG) enrolled into this study. KS and LS were measured by the same physician blinded to diagnosis. The stiffness results were expressed in kilopascals (kPa). Local ethics committee approval and patient consents were obtained.

Results: Nineteen AG and 16 CG patients included into the study. Patient age (p=0.4), gender (p=1), body mass index (BMI) (p=0.4), donor type (p=0.2), donor age (p=0.3), frequency of rejection history (p=0.4) and graft loss (p=0.2) did not show significant difference between two groups. Frequency of diabetes mellitus (DM) (p=0.01), median creatinine (p=0.015) and proteinuria (p<0.001) were higher in AG group than CG. Although median KS was higher in CG group (19.8 [IQR:34] vs 15.8 [IQR:16]), the difference was not significant (p=0.5). Baseline clinical and laboratory features were similar in AG patients with recurrent-amyloidosis (n=6) and non-recurrent AG patients (n=13). Median KS score was higher in recurrent compared to non-recurrent AG patients (p< 0.001). However median LS did not differ between two groups (p=0.4). In multivariate analysis only KS was associated with renal recurrence of AA (p=0.031; OR=1.18, 95% CI 1.015-1.362). In ROC analysis, a cut-off value of 24.55 kPa provided 83.3% sensitivity and 92.3% specificity (LR=10.8, AUC=0.936, p=0.003). Median KS was higher in patients with a history of rejection both among the patients with AG and CG, but the difference was not significant. Additionally, LS scores were similar between two groups.

In FMF-associated AA, median KS was higher in patients with one MEFV variant compared to those with two variants and tended to be higher in other MEFV variants compared to M694V homozygotes (p=0.027 and p=0.08, respectively). There was no correlation between the patient age, disease duration, duration of renal transplantation, donor age, BMI, LS, creatinine, CRP, proteinuria, and KS both in patients with AG and CG.

Table 1. Comparison of clinical and laboratory features between patients had amyloidosis recurrence and not

Variables	Total	Recurrence -	Recurrence +	p value
Age (years)*	48 (22)	47 (17)	50 (27)	1
Gender, male ‡	13 (68.4)	9 (69.2)	4 (66.7)	1
Duration of amyloidosis (months)*	206 (89)	220 (99)	163 (203)	0.08
Diagnosis age of amyloidosis (years)*	28 (17)	27.5 (17)	28 (20)	1
Duration of renal transplantation (months)*	145 (137)	144 (110)	123 (50)	0.7
Kidney stiffness (kPa)*	15.8 (15.8)	10.9 (7.7)	29.3 (18.9)	***<0.001***
Liver stiffness (kPa)*	5.45 (2.8)	5.4 (2.7)	5.9 (8.9)	0.4
Rejection ‡ (n, %)	3 (15.8)	2 (15.4)	1 (16.7)	1
Creatinine (mg/dL)*	1.4 (0.6)	1.4 (0.7)	1.7 (0.5)	0.24
CRP (mg/L)*	2.7 (4.4)	1.3 (4.1)	3.5 (13.9)	0.3
Proteinuria ‡	3 (15.8)	1 (7.7)	2 (33.3)	0.2
Proteinuria (g/day)*	0.4 (1.2)			0.4

*median; IQR ‡ n, %

Conclusion: Median KS scores were similar between AG and CG groups; however it was higher in AG patients with recurrent kidney amyloidosis than those without recurrent disease, which may support using the fibroscan method as a useful screening method for establishing AA recurrence. Additionally, higher KS scores in patients with one MEFV variant compared to those with two variants need further studies to be able to identify other yet unidentified amyloidogenic factors.

TRANSIENT ELASTOGRAPHY (FIBROSCAN); AS A NEW NON-INVASIVE DIAGNOSTIC METHOD FOR DETECTING HEPATIC INVOLVEMENT OF AMYLOIDOSIS

M. Bektaş[1], B. Çavuş[2], B. F. Agargun[3], V. Şenkal[2], N. Koca[1], B. Ince[1], P. Özer Karaca[4], M. Mestanzade[5], M. Büyük[6], M. Z. Buğra[4], M. Güllüoğlu[6], S. Kalayoğlu Beşışık[5], Y. Yalçınkaya[1], B. Artim-Esen[1], M. Inanc[1], S. F. Beşışık[2], A. Gül[1]. *[1]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Gastroenterology, Istanbul, Turkey; [3]Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey; [4]Istanbul Faculty of Medicine, Cardiology, Istanbul, Turkey; [5]Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Hematology, Istanbul, Turkey; [6]Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey*

Background: Demonstration of deposits by non-invasive methods is important especially for organs difficult to sample in amyloidosis. Transient elastography (fibroscan) is a diagnostic method being used to measure liver stiffness (LS) in different chronic liver diseases.

Objectives: We herein aimed to test the place of fibroscan method for detecting increased LS associated with amyloid deposition in patients (pts) with amyloidosis.

Methods: Six categories of pts enrolled into this cross-sectional study; AA amyloidosis (AA-a), AL amyloidosis (AL-a), Familial Mediterranean Fever (FMF) pts without amyloidosis, cirrhotic chronic liver disease, non-cirrhotic chronic hepatitis B infection (CHB) and healthy controls (HC). LS assessment by fibroscan were categorized as normal for kPa<7, significant stiffness for kPa≥7, advanced stiffness for kPa≥9.5 and kPa≥F4 stiffness. FIB-4 and APRI scores were calculated for each patient when they indicated chronic liver disease. Pts with known chronic liver disease and viral hepatitis excluded from amyloidosis and FMF groups.

Results: A total of 165 pts (AA-a, n=65; AL-a, n=15; FMF, n=20; cirrhotic pts, n=16; CHB, n=22; HC, n=27) constituted the study group. Average age was higher in the AL-a group compared to others. Median LS was highest in cirrhotic pts, and it was also higher in AA-a and AL-a pts compared to FMF and HC. Median LS was numerically higher in AL-a compared to AA-a, but it did not reach statistical significance. Median LS was also higher in FMF pts compared to HC. FIB-4 and APRI scores were lower compared to cirrhotic patients in AA-a and AL-a. ALP levels were higher in AA-a and AL-a groups compared to FMF, CHB and HC. FIB-4 and APRI scores, ALP and GGT levels were correlated with LS both in AA-a (r=0.534***,r=0.485***,r=0.437***, r=0.506***) and, AL-a (r=0.536*, 0.579*, r=0.645*, r=0.752**) and FMF-AA (r=0.584***, r=0.566***,r=0.322*, r=0.306*; *p<0.001, **p<0.01, *p<0.5) groups. Higher patient age, age at diagnosis of amylodosis, FIB-4 and LS scores, ALP levels, non-FMF causes of AA were associated with hepatic AA amyloid involvement in biopsy-proven pts. A cut-off value 12.05 kPa of LS provided 100% sensitivity and 85.5% specificity (LR=6.9, AUC=0.901, 95% CI 0.81-0.99) for pts with AA-a.

Conclusion: In our single center cohort, we showed a higher median LS by fibroscan in both AL-a and AA-a pts compared to CHB, FMF and HC. It was thought to be that fibroscan may be useful in detecting hepatic amyloid involvement.

THE CANADIAN RESEARCH GROUP OF RHEUMATOLOGY IN IMMUNO-ONCOLOGY (CANRIO): A NATIONWIDE MULTI-CENTER PROSPECTIVE COHORT

S. Jamal[1], L. Gonzalez Arreola[2], J. Tan[1], C. Ye[3], J. Roberts[4], A. Fifi-Mah[5], M. Hudson[6], S. Hoa[6], J. Pope[7], I. Colmegna[6], C. T. Appleton[7]on behalf of CanRIO Investigators. *[1]University of British Columbia, Medicine, Rheumatology, Vancouver, Canada; [2]University of British Columbia, Epidemiology, Vancouver, Canada; [3]University of Alberta, Medicine, Rheumatology, Edmonton, Canada; [4]Dalhousie University, Medicine, Rheumatology, Halifax, Canada; [5]University of Calgary, Medicine, Rheumatology, Calgary, Canada; [6]McGill University, Medicine, Rheumatology, Montreal, Canada; [7]University of Western Ontario, Medicine, Rheumatology, London, Canada*

Background: Immune Checkpoint Inhibitors (ICI) have altered the landscape of cancer therapy. However, toxicities are common and up to 80% of patients will develop immune-related adverse events (irAE), including rheumatic irAEs (Rh-irAE), which can often limit their cancer treatment. Our knowledge of clinical manifestations and optimal management of patients with Rh-irAE continues to evolve as these agents are being used to treat a wider variety of cancers. Currently available data is limited to retrospective case series and case reports. There is also scarce data on the use of ICI in patients with pre-existing autoimmune disease (PAD) as these patients are often excluded from clinical trials.

Objectives: To describe the clinical presentation, management and early outcomes of patients exposed to ICI with Rh-irAE or PAD recruited and followed prospectively from multiple sites across Canada.

Methods: Adult patients with Rh-irAE from cancer immunotherapy (CTLA-4, PD-1 or PDL-1 inhibitors) or those with PAD exposed to cancer immunotherapy are prospectively recruited across 9 academic sites in Canada. Standardized clinical and biologic data are also collected. We describe clinical characteristics and management of patients recruited between January 2020 and October 2021, stratified based on the presence or absence of PAD.

Results: 103 patients were recruited from 9 sites. From those, 85 had Rh-irAE, 47 had pre-existing musculoskeletal and rheumatic diseases, and 20 had other PAD. The most frequent Rh-irAE were joint manifestations (n = 73). Other Rh-irAE included muscle symptoms (n = 7), connective tissue disease (n = 6), vasculitis (n=2) and sarcoid (n = 3). Prednisone was the most common treatment (n = 53). Intraarticular corticosteroids were used in 7 patients. Eleven patients required conventional synthetic disease-modifying anti-rheumatic drugs (DMARD) and only one required biologic DMARD to control the Rh-irAE. Anti-PD-1 therapies were the most used ICI (56.3%), followed by combination therapy (35.9%). Response to index immunotherapy at 6 months was available for 21 patients. Most patients had partial response (57.1%) and only 4 patients had tumor progression (19.1%). The ICI was permanently discontinued due to an irAE in 21 patients (38.1% with PAD and 61.9% without PAD). There were no deaths related to Rh-irAE.

Conclusion: The initial sample of the CanRIO prospective national cohort suggests that demographic characteristics and tumor representation in people with PAD and without PAD is similar. Patients with PAD are less likely to receive

combination therapy (n= 12 vs. n=25) and are less likely to have tumor progression on ICI (n=1) compared to those without PAD (n=3). Selection bias is noted in this initial sample since half of recruited patients have PAD. The CanRIO cohort provides valuable insight into real-world spectrum and management of Rh-irAE secondary to immunotherapy for cancer.

POS1362 THE EFFICACY AND CYTOKINE PROFILES DURING TREATMENT WITH APREMILAST IN PATIENTS WITH BEHÇET 'S DISEASE

R. Wakiya[1], Y. Ushio[1], K. Ueeda[1], H. Shimada[1], S. Nakashima[1], M. Kato[1], T. Miyagi[1], K. Sugihara[1], M. Mizusaki[1], R. Mino[1], T. Kameda[1], H. Dobashi[1]. *[1]Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Facility of Medicine, Kagawa, Japan*

Background: Apremilast has been shown to be effective in patients with Behçet's disease (BD) in domains other than oral ulcers; however, its long-term efficacy is yet to be determined. Although serum cytokine modulation by increasing intracellular cAMP levels has been suggested as a mechanism for the efficacy of apremilast on skin areas of psoriasis [1], the relationship between efficacy and cytokine on various domains in BD has not been fully investigated.

Objectives: This study aims to evaluate the long-term clinical efficacy of apremilast in BD and its effect on serum cytokines.

Methods: In this study, patients with BD who received apremilast for active oral ulcers were included. For 12 months, the improvement rates of oral and genital ulcers, skin lesions, and arthritis were assessed every three months. Serum levels of cytokines, including interferon-gamma (IFN-γ), interleukin 10 (IL-10), and IL-17A were determined using Simple Plex (Protein Simple, CA, USA) at baseline and three months after apremilast treatment. Other cytokines, including tumor necrosis factor-alpha (TNF-a), IL-6, IL-8, and IL-23, were also measured in serum using a multiplex immunoassay (Luminex Assay, R&D Systems).

Results: Fifteen patients were included in this study. Table 1 shows the characteristics of the patients who participated in this study. Oral ulcers disappeared in 66.7% and 92.3% of the patients after 3 and 6 months of apremilast treatment, respectively. Genital ulcers disappeared in all patients after 6 months of apremilast treatment and were maintained for 12 months. The efficacy of apremilast in oral ulcers could be divided between two groups: 8 patients in the oral ulcer remission group (OU-R group) whose oral ulcers completely disappeared after 3 months of apremilast administration and persisted for 1 year, and 7 patients in the oral ulcer non-remission group (OU-NR group) whose oral ulcers persisted after 3 months of apremilast treatment. Genital ulcers improved more rapidly in the OU-R group than in the OU-NR group, and completely disappeared within 3 months. Skin and joint lesions generally improved after 6 months, but recurred after 9 months.

Table 1. Baseline characteristics of the studied patients with Behçet's disease

Characteristics	N = 15
Age (years), mean ± SD	46.7 ± 13.0
Sex (female), n (%)	11 (73.3)
Disease duration (years), mean ± SD	10.4 ± 8.8
Active Behçet's disease manifestation at the time of enrollment, n (%)	
Oral ulcer	15 (100)
Genital ulcer	5 (33.3)
Skin lesion (erythema nodosum or pustules)	10 (66.7)
Arthralgia	9 (60.0)
Arthritis	5 (33.3)
Ocular involvement	0 (0)
Gastrointestinal involvement	1 (6.7)
Neurological involvement	0 (0)
Vascular involvement	0 (0)

SD, standard deviation; n, number.

Serum cytokines could be analyzed in seven of the 15 cases. There was no significant association between serum baseline cytokine levels and the presence of lesions or severity of disease. Compared to baseline, TNF-α and IL-23 levels were significantly lower after apremilast treatment and IFN-γ levels were trending upwards; however, IL-6, IL-8, and IL-10 levels showed no constant trend (TNF-α and IL-23: p <0.05, IFN-γ: p = 0.078). In addition, the rate of decrease in serum IL-6, IL-10, and IL-23 levels was significantly greater in the OU-R group than in the OU-NR group (Figure 1). However, the rate of change in serum cytokines was not associated with efficacy of apremilast for skin lesions, arthralgia, or arthritis.

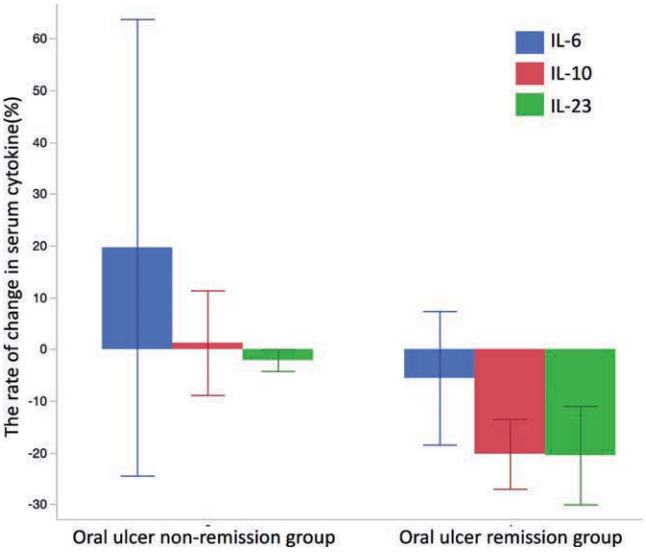

Figure 1. The rate of change in serum interleukin (IL)-6, IL-10, and IL-23 levels up to 3 months after apremilast treatment in the oral ulcer remission group and the oral ulcer non-remission group.

Conclusion: Apremilast has shown long-term efficacy in the treatment of oral and genital ulcers in patients with BD. The efficacy of apremilast against oral ulcers in BD may be attributed to its modulatory effect on serum cytokines as previously reported. Future exploratory studies for biomarkers associated with the presence of efficacy against genital ulcer and arthritis are needed.

POS1363 THE VALIDITY AND RELIABILITY OF THE TURKISH VERSION OF BEHÇET'S SYNDROME OVERALL DAMAGE INDEX IN A RETROSPECTIVE COHORT

Y. Yagiz Ozogul[1], Y. Ozguler[1,2], D. Ucar[2,3], U. Uygunoglu[2,4], Z. Kutlubay[2,5], V. Hamuryudan[1,2], G. Hatemi[1,2]. *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Behçet's Disease Research Center, Istanbul, Turkey; [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Ophtalmology, Istanbul, Turkey; [4]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurology, Istanbul, Turkey; [5]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, Istanbul, Turkey*

Background: Behçet's syndrome Overall Damage Index (BODI) is a newly developed damage index specific to Behçet syndrome (BS).

Objectives: We aimed to evaluate validity, reliability and feasibility of the Turkish version of BODI and evaluate its performance for use in retrospective cohort studies for different phenotypes of BS.

Methods: The study included 295 patients with at least 3 visits at 6 months intervals out of 590 consecutive BS patients who were admitted between January 2015 and August 2017. Turkish version of the BODI form was developed by translating into Turkish and backwards by 2 people. BODI scores were calculated for each year during the follow-up period. The test-retest reliability of BODI was assessed by scoring the same 50 patients at 6-month intervals by the same observer (YYO). Two different observers (YYO- YO) assessed the same 50 patients for inter-observer agreement. The intra-class correlation coefficient (ICC) was used to assess the inter and intra-observer agreement. We also evaluated the median time to fill out the form in patients with different types of involvements.

Results: Among the 295 (158 F/137 M) patients, mean age was 39 (9.9) and the mean disease duration was 8.8 (5.9) years. Clinical features of BS patients were summarized in the Table 1. BODI median score was 1 (IQR=0-1). We observed

an increase in BODI score in 111 (38%) patients during follow-up. The main reasons for increasing BODI scores were eye, vascular and neurological involvement (Table 1). The mean ICC for inter-observer agreement was 0.94 (95% CI, 0.89-0.96) and for intra-observer agreement was 1. The median (range) time to complete the form was 2 (1-8) minutes.

Table 1. Clinical features and BODI scores of Behçet syndrome patients.

Oral ulceration	99.7
Genital ulceration	81.3
Erythema nodosum	57.1
Papulopustular lesions	89.5
Joint involvement	25.2
Ocular involvement	47.3
Vascular involvement	21.4
Neurologic involvement	3.1
Gastrointestinal involvement	2.7
N of patients with more than 3 BODI scores*(%)	194 (66)
Causes for increase in BODI score**(n=111) (%)	
Ocular involvement	77 (69)
Vascular involvement	17 (15)
Neurological involvement	8 (7)
Gastrointestinal involvement	3 (3)
Mucocutaneous inv.	6 (5)
Cardiovascular inv.	1 (0.9)
Diabetes mellitus	4 (4)
Avascular necrosis	2 (2)
Osteoporosis related fracture	1 (0.9)

*All patients had at least 3 BODI scores, **Some patients had more than 1 type of involvement

Conclusion: This study showed that the Turkish version of BODI was a reliable and feasible instrument that could capture the change over time in damage, and could be used in retrospective cohort studies. Ocular involvement was the most common cause of progressive damage in this cohort.

POS1364 ATTACKS OF MYALGIA IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: OTHER THAN CALF PAIN

D. Yildirim[1], E. Tahta[2], R. C. Kardaş[1], B. Özkızıltaş[1], I. Vasi[1], H. Küçük[1], M. A. Ozturk[1], A. Tufan[1]. *[1]Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey; [2]Abdurrahman Yurtaslan Education and Research Hospital, Internal Medicine, Ankara, Turkey*

Background: Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever, serositis, and musculoskeletal symptoms [1, 2]. Arthritis is the most common musculoskeletal symptom of attacks and also included in diagnostic criteria of FMF [3]. If it is specifically queried, myalgia may be detected in up to 20-25% of the patients with FMF. [4, 5].

Objectives: In our study, we aim to assess the localization of attack-related myalgia and associated parameters in patients with FMF.

Methods: A total of 349 consecutive patients followed by FMF in our clinic were enrolled in the study and asked for attack-induced myalgia and if present, localization of muscle groups on the mannequin body parts diagram.

Attack frequency, duration, and disease activity were evaluated with the Auto-Inflammatory Diseases Activity Index (AIDAI) scoring system [6]. Patients were also asked for work/study day loss during attacks and patient acceptable symptom state (PASS) status [7].

Results: 126 patients showed attack myalgia (36%); attack duration, frequency, severity were significantly higher in patients with attack-myalgia (p<0,005). Most common muscle groups were calves, lower back, and latissimus dorsi muscles in order. Myalgia was most commonly accompanied by arthritis (p<0,002). Patients with myalgia have a higher frequency of colchicine resistance and work/study day loss due to attacks.

Conclusion: Our results conclude that myalgia is an important domain of attacks and causes absenteeism and uncontrolled disease activity.

POS1365 THE FMF&AID SURVEY - A PATIENT ORGANIZATION DRIVEN SURVEY FOR AUTOINFLAMMATORY DISEASES

J. Rech[1], K. Tascilar[1], A. Tufan[2], M. Gattorno[3], J. B. Kuemmerle-Deschner[4], S. Ozen[5], T. Krickau[6], E. Cohen[7], L. Oliveira Mendonca[8], A. Kontzias[9], M. Vetterli[7]. *[1]Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology; Deutsches Zentrum für Immuntherapie, Erlangen, Germany; [2]Gazi University Ankara, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey; [3]UOSD Centro Malattie Autoinfiammatorie e Immunodeficienze, IRCCS Istituto Giannina Gaslini, Genoa, Italy; [4]University Hospital Tübingen, Department of Pediatrics; Division of Pediatric Rheumatology and Autoinflammation Reference Center Tübingen, Tuebingen, Germany; [5]Hacettepe University Ihsan Dogramaci Children's Hospital, Department of Pediatric Rheumatology, Ankara, Turkey; [6]Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Pedeatrics, Erlangen, Germany; [7]FMF & AID Global Association, www.fmfandaid.org, Zuerich, Switzerland; [8]Universidade de São Paulo, School of Medicine, Discipline of Clinical Immunology and Allergy, São Paulo, Brazil; [9]Stony Brook University School of Medicine, Division of Rheumatology, Allergy and Immunology, Stony Brook, NY, United States of America*

Background: Autoinflammatory diseases (also referred to as hereditary periodic fever syndromes) are caused by defects in the innate immune system. Many autoinflammatory syndromes arise from inherited genetic mutations which begin in childhood and persist throughout adult life. These diseases are often present in several members and generations within a family. Newer research also reflects that, cases can often present at any age through-out childhood, teenage years, and even into older adulthood. These cases appear to be acquired, perhaps due to the interplay of genetic, immune, and environmental factors (somaticism). It

is not uncommon that a patient is diagnosed with rheumatoid arthritis, multiple sclerosis or another autoimmune issue, as many physicians are not aware of monogenic inborn errors, nor how to conduct a thorough work up due to a lack of medical knowledge.

Objectives: Unfortunately, the knowledge base that many doctors have with regards to autoinflammatory genetic diseases is minimal to non-existent, when compared to the well-established expertise of autoimmune disease management. Concerns about the increasing patient accounts detailing lack of medical diagnosis, treatment, and pain management, lead to the important decision to collect further data from the autoinflammatory patient community. The aim of the survey responses collected, and post data aggregation will help identity patient trends and use this information to educate and increase awareness amongst the medical community as to the unmet diagnostic and treatment requirements for the autoinflammatory population.

Methods: A questionnaire comprised of thirty questions was developed by members of the patient organization FMF & AID Global Association (Executive Director, Malena Vetterli with Research Director, H. Ellen Cohen) under the guidance of Dr. med. Juergen Rech focused on collecting basic information (e.g. age, country, onset and duration of symptoms, pain and fatigue). The survey was published at the end of 2020 on social media (Facebook) and on the FMF&AID website (www.fmfandaid.org). Participation was voluntary and the patients agreed that the anonymised response information of the survey may be evaluated and published. This international survey was approved by the ETHICS Committee FAU in Erlangen-Nuremberg, Germany.

Results: Worldwide, over a thousand patients or parents/caregivers of patients (younger than 18 years) in fifty-two countries took part in this survey and answered the questionnaire. Eighty percent (80%) of the participants had already been diagnosed with an autoinflammatory disease. However, despite classic periodic symptom presentation, twenty percent (20%) of the participants were still without a concise diagnosis. FMF - forty-three percent (43%) was cited as the most common diagnosis and M. Behçet thirty percent (30%) as the second, with a variety of others (e.g. PFAPA, CAPS, HIDS, TRAPS, DADA, Yao syndrome, and uSAID). The minimum age at diagnosis ranged from 1 to 70+ years old with an average age of 33 years when properly diagnosed. Three-hundred and nine (309) patients reported that their pain had not been taken seriously and adequately treated in the past. Pain and fatigue, as measured by the standard visual analogue scale (VAS 0-10), was high in the past 30 and 7 days, respectively. VAS pain 30 days was 4.8 (SD +/-2.7) or 7 days with 4.2 (SD +/- 3), as well as fatigue VAS 30 days 5.7 (SD +/- 2.8) or fatigue VAS 7 days with 5.5 (SD +/- 3).

Conclusion: One-fifth of patients with classic symptoms of autoinflammatory diseases remain undiagnosed and therefore not specifically treated. Although, the rest of the participants eighty percent (80%) have a diagnosis of an autoinflammatory disease, therapy does not appear to be sufficient to manage their wide-ranging and debilitating symptoms, in particular pain and fatigue. Patients continue to carry the burden of receiving mental diagnosis vs actual medical diagnosis and are still forced to seek additional medical support, often incurring travel or relocation costs to obtain proper care.

POS1366 RITUXIMAB IN IGG4-RD: AN OPEN-LABEL NON-RANDOMIZED OBSERVATIONAL STUDY

J. Vikse[1,2], Ø. Midtvedt[3], Ø. Molberg[3,4], B. T. Svanes Fevang[2,5], Ø. Palm[3], T. Garen[3], K. B. Norheim[1,2], G. Bakland[6], M. Wallenius[7,8], A. M. Hoffmann-Vold[3]. *[1]Stavanger University Hospital, Rheumatology, Stavanger, Norway; [2]University of Bergen, Clinical Science, Bergen, Norway; [3]Oslo University Hospital, Rheumatology, Oslo, Norway; [4]University of Oslo, Clinical Medicine, Oslo, Norway; [5]Haukeland University Hospital, Rheumatology, Bergen, Norway; [6]University Hospital of North Norway, Rheumatology, Tromsø, Norway; [7]St. Olav University Hospital, Rheumatology, Trondheim, Norway; [8]Norwegian University of Science and Technology, Neuromedicine and Movement Science, Trondheim, Norway*

Background: IgG4-related disease (IgG4-RD) is a rare, heterogenous and potentially severe disease. An open-label trial demonstrated efficacy of rituximab (RTX) in IgG4-RD [1]. Recently, four distinct phenotypes of IgG4-RD were identified [2]. There is a paucity of studies investigating RTX efficacy across these phenotypes.

Objectives: Investigate efficacy and safety of RTX in IgG4-RD and segregated by phenotypes.

Methods: This is an open-label non-randomized single center observational study. All patients with IgG4-RD (diagnosed by expert opinion) at the Oslo University Hospital treated with ≥ 1 dose of RTX with 12 months follow-up were included. Two experts (JV, ØMi) assigned patients to phenotypes. Glucocorticoid (GC) treatment was allowed. We measured disease activity by the IgG4-RD Responder Index (IgG4-RD RI) at baseline, 6 months, and 12 months. We defined a composite primary outcome consisting of two measures; (i) reduced disease activity (i.e., ≥2 points improvement in IgG4-RD RI from baseline and/or IgG4-RD RI score 0 at follow-up), and (ii) no disease flares (i.e., no ≥2 points worsening of IgG4-RD RI and no need to increase GC dose) at 6 months. Secondary outcomes were (a) reduced disease activity at months 6 or 12, (b) remission (IgG4-RD RI score 0 and GC dose ≤ 7.5 mg) at 6 or 12 months and (c) safety. Descriptive statistics were applied.

Results: We included 40 patients, of which 30 (75%) were male and 35 (88%) Caucasian. Mean age and disease duration at time of first RTX infusion was 58 and 3 years, respectively. Seventeen of the 40 patients (43%) received RTX as add-on therapy (following GC for > 3 months), while 13 (33%) received RTX as upfront combination therapy with GC, and 10 (25%) received RTX as upfront monotherapy. All 40 patients received an infusion of 1000 mg RTX at study baseline (dose 1A at week 0) and 39 of these 40 patients (98%) received a second RTX infusion (dose 1B) at week 2. Additional infusions of 500-1000 mg RTX were administered at weeks 26 (dose 2A) and 28 (dose 2B) in 24 (60%) and 7 (18%) patients, respectively. The composite primary endpoint was met by 31/40 patients (78%). Reduced disease activity at 6 and 12 months were seen in 34 (87%) and 35 (90%) patients, respectively. Fifteen patients (38%) were in remission at 6 months, and 22 (56%) were in remission at 12 months. "Retroperitoneum and Aorta" showed lowest response rates, while "Head and Neck-Limited" had the highest rate of flares (Table 1). Mild infusion reaction occurred in 8 (20%) patients. Hypogammaglobulinemia was observed in 4 (10%). Infection requiring hospitalization occurred in 6 (15%), including one fatal infection which was the only death in the study period.

Table 1.

	All 40 (100)	Pancreato-Hepato-Biliary 9 (23)	Retroperitoneum and Aorta 6* (15)	Head and Neck-Limited 14 (35)	Mikulicz and Systemic 11 (28)
Baseline (n=40)					
Male, n (%)	30 (75)	8 (89)	5 (83)	8 (57)	9 (82)
Caucasian (%)	35 (88)	9 (100)	6 (100)	12 (86)	8 (73)
Age, years (SD)	58 (14)	63 (9)	66 (3)	49 (18)	60 (11)
Disease duration, years (SD)	3 (4)	4 (3)	3 (4)	2 (2)	5 (6)
2019 ACR/EULAR classification criteria (%)	28 (70)	8 (89)	3 (50)	6 (43)	11 (100)
IgG4-RD RI at diagnosis (SD)	10 (6)	10 (5)	7 (4)	7 (3)	17 (4)
IgG4-RD RI at RTX 1A, (SD)	8 (6)	9 (4)	5 (4)	6 (4)	12 (7)
6 months (n=39)*					
IgG4-RD RI (SD)	2 (2)	3 (3)	2 (2)	1 (1)	1 (2)
Primary outcome, n (%) (n=40)	31 (78)	9 (100)	3 (50)	9 (64)	10 (91)
Reduced disease activity, n (%)	34 (87)	9 (100)	3 (60)	12 (86)	10 (91)
Remission, n (%)	15 (38)	4 (44)	0	6 (43)	5 (46)
Flare, n (%)	3 (8)	0	0	3 (21)	0
12 months (n=39)*					
IgG4-RD RI (SD)	1 (1)	1 (1)	0 (1)	1 (1)	1 (2)
Reduced disease activity, n (%)	35 (90)	9 (100)	4 (80)	12 (86)	10 (91)
Remission, n (%)	22 (56)	7 (78)	3 (60)	7 (50)	5 (45)
Flare, n (%)	4 (10)	1 (11)	1 (20)	2 (14)	0

*One patient died shortly after 1A, and is not included in secondary efficacy outcomes

Conclusion: In our observational study, RTX appears safe and effective in IgG4-RD, with the highest response in patients with Pancreato-Hepato-Biliary phenotype. Relatively low remission rates across all phenotypes indicate an unmet need for improved treatment.

POS1367 THE PREVALENCE AND RISK FACTORS FOR CARDIAC DISEASE IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

Y. Butbul[1,2], L. Gabay[3], Y. Braun-Moscovici[2,4]. [1]*Pediatric Rheumatology Service, Ruth Rappaport Children's Hospital, Rambam Medical Center, Haifa, Israel, Pediatric B, Haifa, Israel;* [2]*The Ruth and Bruce Rappaport Faculty of Medicine, Technion - Israel Institute of Technology, Haifa, Israel, The Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel;* [3]*Maccabitech Institute for Research and Innovation, Maccabi Healthcare Services, Tel Aviv, Israel, Maccabitech Institute for Research and Innovation, Tel Aviv, Israel;* [4]*Rambam Health Care Campus, Haifa, Israel, B. Shine Department of Rheumatology, Haifa, Israel*

Background: Familial Mediterranean fever (FMF) is a genetic disorder manifested by recurrent attacks of peritonitis, pleuritis and arthritis, and characterized by clinical and laboratory evidence for localized and systemic inflammation. Colchicine treatment usually prevents the attacks and the associated inflammation. Inflammation may play an important role in the initiation and progression of atherosclerosis. Recently colchicine was suggested as a therapy that help to prevent coronary heart disease.

Objectives: To study the effect of FMF and colchicine treatment on the cardiovascular morbidity and the overall mortality.

Methods: We studied using the data base from health insurance in Israel (Maccabi Healthcare Services-MHS) the presence of IHD and its risk factors in 492 FMF patients aged 40 years or more, and in a control groups matched by age gender and socioeconomic status.

Results: The incidence of cardiac disease in FMF patients was similar to the control group (6.5% vs 5.7% p- 0.594), smoking kidney disease and gout were higher in FMF compared to the control group (16.1 % vs 12.8% p- 0.022, 9.3% vs 5.1 p- 0.01 and 4.5% vs 0.2% p<0.001 respectively), but hypertension and diabetes were similar. The overall mortality in average follow up of 3174.37 ±1738.84 days was similar in both groups.

Conclusion: The incidence of cardiac disease among FMF patients was not increased compared to the control group, despite the exposure to recurrent inflammation. We suggest that colchicine may have a protective role in these patients. Further studies are required.

POS1368 DIVERSITY OF HEMODYNAMIC TYPES IN CONNECTIVE TISSUE DISEASE ASSOCIATED PULMONARY HYPERTENSION: MORE THAN A SUBGROUP OF PULMONARY ARTERIAL HYPERTENSION

X. Dong[1], Y. Shi[1], Y. Xia[2], X. Zhang[1], J. Qian[3], J. L. Zhao[3], J. Peng[2], Q. Wang[3], L. Weng[2], M. LI[3], B. Du[2], X. Zeng[3]. [1]*Peking Union Medical College Hosp., Department of International Medicine, Beijing, China;* [2]*Peking Union Medical College Hosp., Medical Intensive Care Unit, Beijing, China;* [3]*Peking Union Medical College Hosp., Department of Rheumatology, Beijing, China*

Background: Connective tissue disease (CTD) associated pulmonary hypertension (PH) is classified as a subgroup of WHO group 1 PH, also called pulmonary arterial hypertension (PAH). However, not all CTD-PH fit the hemodynamic definition of PAH. This study investigates the diversity of hemodynamical types of CTD-PH, their different clinical characteristics and outcomes.

Objectives: This study investigates the diversity of hemodynamical types of CTD-PH, their different clinical characteristics and outcomes.

Methods: We performed a retrospective cohort study. CTD-PH patients underwent right heart catheterization (RHC) were enrolled and divided into WHO group1 PH, WHO group 2 PH and high output PH (PVR<3WU and PAWP<15mmHg) according to hemodynamic features. Patients with obvious lung diseases, left heart disease and pulmonary embolism were excluded. Baseline characteristics, inflammatory markers, autoantibodies, cardiac function status, echocardiogram parameters, hemodynamics and survival rates were compared.

Results: 207 CTD-PH patients were included, including 139 in WHO group 1 PH, 36 in WHO group 2 PH and 32 in high output PH. Incidence of anti-ribonucleoprotein antibody was lower in WHO Group 2 PH. High output PH is less severe, presenting lower NT-proBNP level, better WHO functional class, lower mPAP and PVR, higher cardiac output, and less cardiac remodeling. Among patients with elevated PAWP, combine pre& post-capillary PH had higher mPAP and larger right ventricle diameter. Association of mild to moderate interstitial lung disease didn't show significant difference in disease characteristics. Short-term survival was significantly worse in WHO group 2 PH, yet 5-year survival rates didn't differ between groups.

Conclusion: Pre-capillary PH is not the only hemodynamic type of CTD-PH. Different types of CTD-PH present different clinical phenotypes and outcome. Carefully phenotyping PH in CTD-PH patients is important.

POS1369 PULMONARY ARTERY WALL THICKNESS IS INCREASED IN BEHÇET'S DISEASE

S. Kutluğ Ağaçkıran[1], M. Sunbul[2], D. Kocakaya[3], S. Kayacı[3], H. Direskeneli[1], F. Alibaz-Oner[1]. [1]*Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey;* [2]*Marmara University Faculty of Medicine, Department of Cardiology, Istanbul, Turkey;* [3]*Marmara University Faculty of Medicine, Department of Pulmonology, Istanbul, Turkey*

Background: Behçet's Disease (BD) is a unique systemic vasculitis that mainly involves veins, in contrast to other vasculitides [1, 2]. Prior studies showed that pulmonary arteries have a similar structure with systemic veins in terms of wideness, thin-walled, increased compliance, and low resistance [3]. We have recently shown increased venous wall thickness in lower extremity veins of BD patients.

Objectives: In this study, we aimed to assess pulmonary artery (PA) wall thickness by transthoracic echocardiography (TTE) in BD compared to healthy controls and patients with non-inflammatory pulmonary embolism (NIPE).

Methods: Patients with BD (n=77), NIPE (n=33) and healthy controls (n=57) were included in the study. PA wall thickness was measured with TTE by a cardiologist blinded to cases. PA wall thickness was measured from the mid-portion of the main PA (approximately 1 to 2 cm distal to the pulmonary valve) as demonstrated in Figure 1.

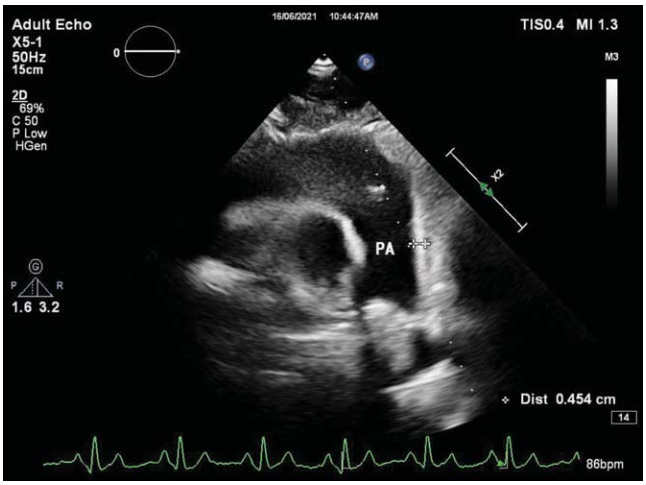

Figure 1. Measurement of pulmonary artery wall thickness by Transthoracic Echocardiography

Results: PA wall thickness was significantly lower in controls (0.36 mm (SD:0.03) compared to NIPE (0.44 mm (SD:0.05) and BD (0.44 mm (SD:0.06) (p<0.001 for both). PA wall thickness was also found to be significantly higher in BD patients with major organ involvement (0.47 mm (SD:0.04) compared to healthy controls and NIPE (p <0.001 and p=0.006, respectively). PA wall thickness was similar between BD and NIPE (p= 0.6). Among patients with BD, PA wall thickness was significantly lower in patients with only mucocutaneous involvement compared to patients with major organ involvement (0.37 mm vs 0.47 mm, p< 001), it was also similar between patients with only mucocutaneous involvement and healthy controls (0.37 mm vs 0.36 mm, p= 0.3). PA wall thickness was comparable between patients with vascular and non-vascular major organ involvement (0.46 mm vs 0.47 mm, p= 0.3). Patients with vascular and non-vascular major organ involvement had significantly higher PA wall measurements compared with NIPE patients (p= 0.04, p= 0.02, respectively).

Conclusion: We found that PA wall thickness was significantly higher in BD with major organ involvement compared to BD patients with only mucocutaneous

involvement regardless of major organ involvement type. These results suggest that increased PA wall thickness in BD may be the predictor of the major organ involvement during follow-up.

POS1370 INCREASED INFERIOR VENA CAVA WALL THICKNESS AS A SIGN OF VENOUS INFLAMMATION IN BEHÇET'S DISEASE

S. Kutluğ Ağaçkıran[1], M. Sunbul[2], H. Direskeneli[1], F. Alibaz-Oner[1]. *[1]Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Marmara University Faculty of Medicine, Department of Cardiology, Istanbul, Turkey*

Background: Vascular involvement of Behçet's disease (BD) involves both arterial and venous vessels of all sizes [1]. Femoral (superficial, deep, and common) and popliteal veins are the most frequently affected veins. We have previously shown that femoral wall thickness is increased in BD patients and can be used as a diagnostic test [2].

However, many other sites including vena cava inferior/superior and pulmonary arteries may also be involved [3]. Despite the dominance of venous vessel involvement, there is limited data assessing the large veins in BD.

Objectives: In this study, we aimed to assess inferior vena cava wall thickness (IVC) by transthoracic echocardiography (TTE) in BD compared with healthy controls.

Methods: Patients with BD (n=70) and age and sex-matched healthy controls (n=51) were included in this study. Assessment of inferior vena cava (IVC) wall thickness was performed by an experienced cardiologist blinded to cases. Measurement of IVC wall thickness was made at end-expiration and approximately 0.5 to 2.0 cm proximal to the ostium of the right atrium as demonstrated in Figure 1.

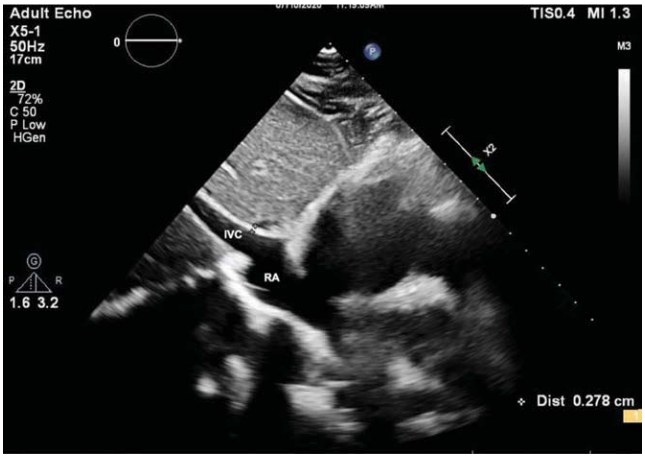

Figure 1. Measurement of inferior vena cava wall thickness by transthoracic echocardiography

Results: IVC wall thickness of patients with BD (0.29 mm (SD: 0.03) was significantly higher than healthy controls (0.26 mm (SD: 0.03) (p<001). Although IVC wall thickness was higher in patients with BD with vascular involvement (0.30 mm (SD:0.04) and history of pulmonary embolism (0.30 mm (SD:0.04)), the difference did not reach statistical significance. There was no difference between IVC wall thicknesses in patients who used immunosuppressive and anti-TNF treatments due to major organ involvement, compared to those who did not. Similarly, no difference is observed between IVC thicknesses among Behçet's patients according to age, gender, and activity status at the last visit. Although no correlation was found between IVC wall thicknesses, disease duration, and BDCAF scores at the last visit in the BD group, there was a low-grade correlation between age and IVC wall thickness (r=0.31, p=0.09)

Conclusion: Increased IVC wall thickness shows vasculitic involvement of large venous structures in BD and can be easily measured by TTE which is an easily accessible, noninvasive modality without radiation. The role of IVC wall thickness assessment for the diagnosis or management of BD requires further studies.

POS1371 HYPOMETHYLATION OF CIRCULATING IMMUNE CELLS IN PATIENTS WITH GRAVES' ORBITOPATHY – A PRELIMINARY STUDY

V. Kaskova[1], A. Petráčková[1], J. Schovánek[2], M. Karhanova[3], J. Savara[1], E. Kriegova[1]on behalf of OLGEN. *[1]Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Immunology, Olomouc, Czech Republic; [2]Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Internal Medicine III – Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Olomouc, Czech Republic; [3]Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Ophthalmology, Olomouc, Czech Republic*

Background: Graves' orbitopathy (GO) is an eye disease occurring in patients with autoimmune thyroid disorders (AITD), most commonly Graves´ disease. It is characterized by inflammation affecting soft tissues of the orbit. A recent study demonstrated an association between fibroblast hypomethylation and disease activity in GO (Virakul *et al*., Front Endocrinol, 2021). Because procurement of fibroblast from GO patients require an invasive sampling, we wondered whether analysis of global DNA methylation in circulating immune cells obtained from peripheral blood could contribute to early detection of GO from patients with AITD.

Objectives: To compare global DNA methylation pattern in circulating immune cells obtained from AITD patients with GO and without GO history and healthy controls.

Methods: Global DNA methylation was quantified in circulating immune cell populations by flow cytometry using 5-methylcytosine antibody in patients with GO (n=10), AITD without GO history (n=9) and healthy controls (n=8). Immune populations ($CD4^+$ and $CD8^+$ T cells, B cells, monocytes and $CD56^{dim/bright}$ NK cells) and their activation status were identified using CD3/4/8/14/16/19/25/45/56/69 antibodies.

Results: In patients with GO, global DNA methylation was reduced by ~50% in the activated ($CD25^+$) $CD8^+$ T cells and by ~35% in the whole $CD8^+$ T cell population compared to patients with AITD (p=0.006). Moreover, percentage of $CD8^+$ T cells, but not activated subpopulation, was higher in GO when compared to AITD (p=0.04). Hypomethylation by ~20% was detected in monocytes as well as in $CD56^{dim}$ NK cells and their activated ($CD69^+$) subpopulation when GO was compared with AITD (p≤0.02). Of these cell populations, percentage of monocytes was also higher in GO when compared to AITD (p=0.04). Global methylation in B cells, $CD4^+$ T cells and $CD56^{bright}$ NK cells did not differ between patients with GO and patients with AITD (p>0.05). Of these populations, higher percentage of B cells was detected in GO when compared to AITD group (p=0.02). Analysis of larger patient cohorts is in progress with particular emphasis on the relationship of methylation patterns to GO disease activity.

Conclusion: This is the first study identifying the different global methylation profile of circulating immune cells in patients with GO characterized by DNA hypomethylation in $CD8^+$ T cells, $CD56^{dim}$ NK cells and monocytes compared to patients with AITD. Our study nominates hypomethylation as a non-invasive biomarker of GO and should be validated in a larger cohort of patients.

Background: The Interleukin-1 (IL-1) mediated systemic autoinflammatory diseases (SAIDs), including the cryopyrin-associated periodic syndromes (CAPS), tumor necrosis factor receptor-associated periodic syndrome (TRAPS), mevalonate kinase deficiency (MKD), and deficiency of the IL-1 receptor antagonist (DIRA) belong to a group of rare immunodysregulatory diseases that primarily present in early childhood with variable multiorgan involvement. When untreated, patients with severe clinical phenotypes have a poor prognosis, and diagnosis and management of these patients can be challenging. However, recently-approved treatments targeting the pro-inflammatory cytokine IL-1 have been life-changing and have significantly improved patient outcomes.

Objectives: We aimed to establish evidence-based recommendations on diagnosis, treatment, and monitoring to standardize the management of these patients.

Methods: A multinational, multidisciplinary task force consisting of physician experts including rheumatologists, patients or caregivers, and allied health care professionals was established. Evidence synthesis including systematic literature review and expert consensus (Delphi) via surveys were conducted. Consensus methodology was utilized to formulate and vote on statements to guide optimal patient care.

Results: The task force devised five overarching principles, 14 statements related to diagnosis, 10 on therapy, and 9 focused on long-term monitoring that were evidence and/or consensus-based for patients with IL-1 mediated diseases. An outline was developed for disease-specific monitoring of inflammation-induced organ damage progression and reported therapies of CAPS, TRAPS, MKD, and DIRA.

Conclusion: The 2021 EULAR/ACR points to consider provide state-of-the-art knowledge based on published data and expert opinion to guide diagnostic evaluation, treatment, and monitoring of patients with CAPS, TRAPS, MKD and DIRA, and inform the various stakeholders about optimized patient care to improve disease outcomes.

POS1373

THE DIAGNOSTIC ROLE OF PATHERGY TEST IN PATIENTS WITH BEHÇET'S DISEASE FROM WESTERN EUROPE

A. Vitale[1], V. Berlengiero[1], J. Sota[1], S. Barneschi[1], M. Mourabi[1], C. Fabiani[1], S. Gentileschi[1], V. Caggiano[1], G. M. Tosi[1], B. Frediani[1], L. Cantarini[1]on behalf of Research Center of Systemic Autoinflammatory Diseases and Behçet's Disease Clinics. *[1]Viale Mario Bracci, Department of Medical Sciences, Surgery and Neurosciences, Siena, Italy*

Background: pathergy is the term used to describe the hyper-reactivity of the skin in response to a minimal trauma, as the consequence of an exacerbated response of the innate immune system [1]. Pathergy test has a central role for the diagnosis of Behçet's disease (BD), especially in doubtful and atypical cases. However, while its incidence has been decreasing over the past few decades, there are significant variations in the frequency of pathergy among different geographic contexts [2]. These aspects affect the diagnostic role of pathergy test for patients with suspected BD.

Objectives: to evaluate the frequency and features of positive pathergy test (PPT) in Italy, its role in the diagnosis of BD, and any association with other BD-related manifestations.

Methods: 29 BD patients, 15 patients with spondyloarthritis (SpA) and 19 healthy controls (HCs) underwent two types of pathergy test, which were performed on the hairless part of the volar forearm ipsilaterally: intradermal injection of 0.5 ml normal saline and intradermally needle soaked with fresh self-saliva. Both pricks were done with a monouse 25 gauge hypodermic needle inserted with a vertical approach at a depth of 5 mm into the skin. The needle was withdrawn with a twisting movement. Skin reactions were observed 48 hours after prick. The results of pathergy tests were statistically analysed in the light of demographic, clinical, and therapeutic features of subjects enrolled. The BD activity at the time of the pathergy test was assessed with the Behçet's Disease Current Activity Form (BDCAF) [3].

Results: pathergy test performed with saline solution resulted always negative in all groups. Skin prick test using self-saliva resulted in the occurrence of a papule in 2 (6.9%) BD patients and in 1 (6.7%) patient with SpA. A ≥15 mm erythematous area surrounding the needle prick site was observed in 12 (41.4%) BD patients, in 4 (26.7%) patients with SpA (including the patient with the papule), and in 1 (5.6%) HCs (p=0.022). The frequency of skin erythema was significantly higher among BD patients compared to HCs (p=0.015); no statistically significant differences were observed between BD and SpA patients (p=0.53) as well as between SpA patients and HC (p=0.21). The occurrence of skin erythema was not associated with any of the BD-related clinical manifestations. No statistically significant differences were observed between BD patients with positive and negative pathergy test according to sex (p=0.873); HLA-B51 positivity (p-value=0.461); age at the pathergy test (p=0.929); and disease duration at the pathergy test (p=0.487). The mean BDCAF was 1.33±0.65 among patients with PPT and 0.82±0.72 among patients with negative pathergy test (p=0.092). Erythema at self-saliva prick test showed a sensitivity of 41.4% (C.I. 23.52%-61.06%) and a specificity of 85.3% (C.I. 68.94%-95.05%); the positive likelihood ratio was 2.81 (C.I. 1.12-7.05) and the negative likelihood ratio was 0.69 (C.I. 0.49-0.96).

Conclusion: this study confirms the lower frequency of PPT in Western European BD patients if considering the development of a papule or a pustule in the site of pathergy test. Conversely, the onset of a ≥15 mm erythematous area surrounding the prick site could be sufficient to unveil the hyper-reactivity of the innate immune system in BD patients from Western Europe. Pathergy test is not pathognomonic of BD, as its positivity can be also observed in other innate immune system disorders, as observed for SpA patients.

Background: Autoinflammatory diseases (AID) are characterized by severe systemic and organ inflammation as well as high burden of disease for patients and their families. Treatment with the monoclonal antibody canakinumab (CAN), an interleukin-1β inhibitor, has been proven to be safe and effective in clinical trials and real-life.

Objectives: The present study explores the long-term efficacy and safety of CAN in routine clinical practice conditions in pediatric (age ≥2 years) and adult patients with CAPS (cryopyrin-associated periodic syndromes), FMF (familial Mediterranean fever), TRAPS (tumor necrosis factor receptor-associated periodic syndrome) and HIDS/MKD (hyperimmunoglobulinemia D syndrome/mevalonate kinase deficiency).

Methods: RELIANCE is a prospective, non-interventional, observational study based in Germany. Patients with clinically confirmed diagnoses of AID routinely receiving CAN are enrolled. Besides efficacy parameters regarding disease activity and remission, safety parameters were recorded at baseline and assessed at 6-monthly intervals.

Results: Here, we present the interim analysis of patients with AID (N=199) enrolled in the RELIANCE Registry between October 2017 and December 2021. Mean age in this cohort was 24.4 years (2–79 years) and the proportion of female patients was 53% (N=104). At baseline, median duration of prior CAN treatment was 2 years (0–12 years).

A total of 123 patients (62%) experienced any AE (N=653) among which nasopharyngitis, increase of inflammatory markers and pyrexia were the most frequent AE with incidence rates per 100 patient years (IR) of 8.3, 6.2, and 6.2, respectively. 29 patients (15%) were affected by severe AE (SAE, total number N=90) including 11 patients (6%) with SAE suspected to be drug-related (SADR; total number N=30) with IR from 0.2 to 0.7 (Table 1). Overall, 16 AE comprised upper respiratory tract infections (URI). One death (COVID-19, not related) and one malignancy (skin papilloma, not related) were reported. No vertigo and no hypersensitivity reactions were observed. N=10 (IR 2.36) vaccination reactions were reported (no SAE).

Table 1. Overview of the CAN safety data of the RELIANCE study across all study indications (N=199 patients).

Type of event	Number of events	IR‡
AE total	653	154.43
AE non-serious	563	133.15
AE, non-serious, not related	317	74.97
AE, URI	16	3.78
AE, non-serious adverse drug reaction	246	58.18
SAE, total	90	21.28
SAE, not related	60	14.19
SADR#, total	30	7.09

#Abdominal pain; Alport's syndrome, appendicitis, arthralgia, blister, cardiovascular disorder, chest pain, circulatory collapse, dehydration, diplopia, dyspnoea, erythema, febrile convulsion, gastroenteritis, glomerulonephritis, Haemophilus test positive, myalgia, oedema, pneumonia, premature delivery, skin discoloration, tachycardia, tonsillitis bacterial, tonsillitis streptococcal, vision blurred (each n=1 event, IR 0.24‡), tonsillectomy (2 events, IR 0.47‡), pyrexia (3 events, IR 0.71‡), not yet coded (hospital admission due to exsiccosis upon gastroenteritis, 1 event, IR 0.35‡)‡IR, incidence rate per 100 patient years; AE, adverse event; URI, upper respiratory tract infection; SAE, severe adverse event, SADR, severe adverse drug reactionIncidence rate = number of events * 36,525 / sum of observation days (=154,442)

Conclusion: The interim data from the RELIANCE study, the longest running real-life canakinumab registry, confirm safety of long-term canakinumab treatment across the entire study population. A trend for dose-related increase of SAE/SADR requires continuous close monitoring and awareness in patient groups (children, severe phenotypes, certain genotypes) requiring greater than standard dose treatment regimens.

POS1375 THE EVALUATION OF OBESITY IN ADULT-ONSET STILL'S DISEASE, DATA FROM A LARGE MULTICENTRE COHORT.

I. DI Cola[1], C. DI Muzio[1], F. Sensini[1], R. Giacomelli[2], P. Cipriani[1], P. Ruscitti[1]on behalf of AOSD GIRRCS Study Group. *[1]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy; [2]University of Rome Campus Biomedico, Department of Medicine, Rome, Italy*

Background: Over the last few decades, obesity has become an increasing public health problem worldwide [1]. This is a complex disease characterised by as an abnormal or excessive fat accumulation which is usually assessed by body mass index (BMI). A value of BMI over 30 identifies the threshold to define the obesity. High BMI is common feature among patients with rheumatic disease and it is associated with higher disease activity and disability [2]. Thus, the presence of obesity may be considered as a negative prognostic factor in these patients. Against this background in rheumatic disorders, the prevalence of obesity in adult onset Still's disease (AOSD) has not been entirely clarified so far. Similarly, the impact of being obese on disease features and outcomes has not been fully elucidated in these patients. AOSD is a rare inflammatory disease usually characterised by fever, arthritis, and evanescent skin rash associated with a typical hyperferritinemia [3].

Objectives: In this study, we aimed at evaluating the prevalence of obesity in patients with AOSD. Furthermore, we descriptively assessed the clinical characteristics of these patients. We also described the occurrence of life-threatening complications, the disease courses, and the rate of mortality of obese patients with AOSD than non-obese ones.

Methods: A retrospective assessment of prospectively followed patients, from January 2001 to April 2021, was provided to analyse clinical features of patients with AOSD characterised by a BMI≥30. AOSD patients were evaluated among those included in the multicentre *Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale* (GIRRCS) cohort. This is a large cohort of patients with AOSD comprising almost 200 patients [4]. The presence of obesity was evaluated at the time of diagnosis of the disease. In this evaluation, only patients with available data about BMI were included.

Results: In this assessment, 139 patients, who had BMI registered in our database, were evaluated. Out of those, 26 (18.7%) had a BMI≥30 and were defined as having obesity. These patients had a mean age of 39.3±13.6 years and were 46.2% male. Concerning main clinical features, obese patients with AOSD were characterised by fever (96.2%), skin rash (84.6%), arthralgia (76.9%), myalgia (65.4%), and arthritis (61.5%). An explorative comparison between obese and non-obese patients was performed. A lower rate of obese patients showed sore throat (38.5% vs 63.7%, p=0.026) than others. The prevalence of serositis was observed at lower frequency in obese patients with AOSD. Pericarditis (7.7% vs 29.2%, p= 0.024), and pleuritis (7.7% vs 25.7%, p=0.035) were less frequently recorded in obese patients when compared with non-obese ones. In addition, obese patients with AOSD showed higher values of C-reactive protein (CRP) [99.2 (117.0) mg/L vs 52.0 (84.3) mg/L, p=0.046] than others. Conversely, no significant differences were retrieved assessing systemic score, ferritin, erythrocyte sedimentation rate, life-threatening complications, disease patterns, and mortality in obese than non-obese patients.

Conclusion: Clinical features of obese patients with AOSD were described in our multicentre cohort. Almost 20% of patients with AOSD were obese at the time of diagnosis of the disease. These patients were characterised by a lower prevalence of sore throat, pericarditis and pleuritis, and by higher values of CRP. However, obesity did not appear to influence the main disease features and outcomes in AOSD, although further studies are needed to fully elucidate this issue.

POS1376 LONG-TERM EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH HIDS (HYPER-IGD SYNDROME) - INTERIM ANALYSIS OF THE RELIANCE REGISTRY

P. Oommen[1], T. Kallinich[2], J. Rech[3], N. Blank[4], J. Weber-Arden[5], J. B. Kuemmerle-Deschner[6]. *[1]Heinrich-Heine-University Düsseldorf, Clinic of Pediatric Hematology, Oncology and Clinical Immunology, Division of Pediatric Rheumatology, Duesseldorf, Germany; [2]Charité University Medicine Berlin, Department of Pediatrics, Division of Pulmonology, Immunology and Critical Care Medicine, Berlin, Germany; [3]Friedrich-Alexander University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany; [4]University Hospital Heidelberg, Rheumatology, Heidelberg, Germany; [5]Novartis Pharma GmbH, IHD, Nuernberg, Germany; [6]University Hospital Tuebingen, Department of Pediatrics, Division of Pediatric Rheumatology, Tuebingen, Germany*

Background: Hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) is a rare autoinflammatory condition caused by a defect in the gene coding for mevalonate kinase. This periodic fever syndrome is characterized by severe systemic and organ inflammation. Treatment with interleukin-1β inhibitor canakinumab (CAN), approved and applied for treatment of HIDS/MKD patients since 2017 [1], resulted in rapid remission of symptoms and normalization of laboratory parameters in most patients in clinical trials [2] as well as in real-life.

Objectives: To explore the long-term efficacy and safety of CAN under routine clinical practice conditions in pediatric (age ≥2 years) and adult HIDS/MKD patients.

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a 3-year follow-up period. Patients with clinically confirmed diagnoses of TRAPS, CAPS, FMF or HIDS/MKD who routinely receive CAN are enrolled in order to evaluate efficacy and safety of CAN under standard clinical practice conditions at baseline and at 6-monthly intervals.

Results: The present interim analysis shows baseline data of 8 HIDS/MKD patients enrolled by December 2021 as well as preliminary 18-month data. Of these patients, 5 (63%) were females and median age at baseline was 8 years (2–39 years). The median duration of prior CAN treatment at baseline was 1.5 years (0–5 years). Standard, low, and high dose CAN treatment was evenly distributed at every interval.

Table 1. Baseline characteristics and interim analysis data of patients with HIDS.

	Baseline (N=8)	6 months (N=7)	12 months (N=6)	18 months (N=4)
Number (%) of patients in disease remission (physician assessment)	4 (50)	6 (86)	4 (67)	3 (75.0)
Physician assessment of disease activity, percentage of absent/mild-moderate/severe rating	37 / 50 / 13	71 / 29 / 0	50 / 33 / 17	50 / 50 / 0
Patient´s assessment of current disease activity; 0–10, median (min; max)	0 (0; 7)	2.0 (0; 7)	0.0 (0; 8)	0.0 (0; 0)
Patient´s assessment of current fatigue; 0–10, median (min; max)	2.5 (0; 7)	3.0 (0; 7)	1.0 (0; 4)	1.0 (0; 2)
Number (%) of patients without impairment of social life by the disease	3 (50)	4 (67)	4 (80)	1 (33)
Number (%) of patients with days absent from work/school during last 6 months	2 (25)	3 (43)	0 (0)	1 (25)
CRP, median (mg/dl)	0.2	0.5	0.3	2.1
SAA, median (mg/dl)	0.6	0.7	0.8	0.5
ESR, median (mm/h)	10.0	6.0	8.0	13.0

CRP, c-reactive protein; SAA, serum amyloid A; ESR, erythrocyte sedimentation rate

Preliminary results indicate stable remission and disease control by physicians´ and patients´ assessment as well as laboratory parameters (Table 1). In total, 4 patients were affected by adverse drug reactions, however, none of these events was classified as serious.

Conclusion: Baseline characteristics and preliminary data of HIDS/MKD patients from the RELIANCE study indicate good clinical and laboratory disease control and no unexpected safety concerns at the 18 months interim analysis.

POS1377 LUNG INVOLVEMENT IN VEXAS SYNDROME

M. Casal Moura[1], M. Baqir[1], Y. Tandon[2], M. Samec[3], K. Reichard[4], A. Mangaonkar[5], R. Go[5], K. J. Warrington[3], M. Patnaik[5], M. Koster[3], J. H. Ryu[1].
[1]Mayo Clinic, Divsion of Pulmonary and Critical Care Medicine, Department of Medicine, Rochester, United States of America; [2]Mayo Clinic, Radiology, Rochester, United States of America; [3]Mayo Clinic, Division of Rheumatology, Department of Medicine, Rochester, United States of America; [4]Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, United States of America; [5]Mayo Clinic, Division of Hematology, Department of Medicine, Rochester, United States of America

Background: Vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic (VEXAS) syndrome is a recently identified disorder caused by somatic mutations in the *UBA1* gene of myeloid cells. Various manifestations of pulmonary involvement have been reported, but a detailed description of lung involvement and radiologic findings is lacking.

Objectives: To describe lung involvement in VEXAS syndrome.

Methods: A retrospective cohort study was conducted of all patients identified at the Mayo Clinic with VEXAS syndrome since October 2020. Clinical records and chest high resolution computed tomography (HRCT) scans were reviewed.

Results: Our cohort comprised 22 white men with a median age of 69 years (IQR 62-74, range 57-84). Hematologic disorders including multiple myeloma, myelodysplastic syndrome and pancytopenia were present in 10 patients (45%), rheumatologic diseases including granulomatosis with polyangiitis, IgG4-related disease, polyarteritis nodosa, relapsing polychondritis, and rheumatoid arthritis were found in 10 patients (45%), and 4 patients had dermatologic presentations including Sweet syndrome, Schnitzer-like syndrome or drug rash with eosinophilia skin syndrome (DRESS). VEXAS syndrome-related features included fever (18, 82%), skin lesions (20, 91%), lung infiltrates (12, 55%), chondritis (10, 45%), venous thromboembolism (12, 55%), macrocytic anemia (21, 96%), and bone marrow vacuoles (21, 96%). Other manifestations observed were arthritis, scleritis, hoarseness and hearing loss. Median erythrocyte sedimentation rate (ESR) was 69 mm/1st hour (IQR 34.3-118.8) and median C-reactive protein (CRP) of 55.5 mg/dL (IQR 11.4-98.8). The somatic mutations affecting methionine-41 (p.Met41) in UBA1 gene were: 11 (50%) p.Met41Thr, 7 (32%) p.Met41Val, 2 (9%) p.Met41Leu, and 2 (9%) in the splice site. All patients received glucocorticoids (GC) (median duration of treatment was 2.6 years); 21 (96%) received conventional immunosuppressive agents (methotrexate, azathioprine, mycophenolate, leflunomide, cyclosporin, hydroxychloroquine, tofacitinib, ruxolitinib) and 9 (41%) received biologic agents (rituximab, tocilizumab, infliximab, etanercept, adalimumab, golimumab, abatacept). Respiratory symptoms included dyspnea and cough present in 21 (95%) and 12 (55%), respectively, and were documented prior to VEXAS diagnosis. Most of the patients were non-smokers (14, 64%) and obstructive sleep apnea (OSA) was present in 11 patients (50%). Seven patients (32%) used non-invasive ventilation, 6 used C-PAP, and 1 used Bi-PAP. Bronchoalveolar lavage (BAL) was available in 4 patients, and the findings were compatible with neutrophilic alveolitis in 3. Two patients had lung biopsies (2 transbronchial and 1 surgical) that showed ATTR amyloidosis and organizing pneumonia with lymphoid interstitial pneumonia, respectively. Pulmonary function tests were available in 9 (41%) patients and showed normal results in 5; 3 patients had isolated reduction in DLCO and 1 with mild restriction. On chest HRCT, 16 patients (73%) had parenchymal changes including ground-glass opacities in 9, septal thickening in 4, and nodules in 3; pleural effusions were present in 3 patients, air-trapping in 3 patients and tracheomalacia in 1 patient. Follow-up chest HRCT was available for 8 patients (36%), the ground-glass opacities resolved in 5 patients, 3 patients manifested new or increased ground-glass opacities, and 1 patient had increased interlobular septal thickening. After 1 year of follow-up, 4 patients (17%) had died; 3 due to pneumonia (2 COVID-19,1 bacterial) and 1 due to heart failure. VEXAS flares occurred in 18 patients (82%), the maximum number of relapses was 7, and they were mainly managed with GC and with changes in the immunosuppressive regimen.

Conclusion: Pulmonary involvement was documented by chest HRCT in most patients with VEXAS syndrome. Respiratory symptoms occurred in over one half of patients and about 20% had PFT abnormalities. The pulmonary manifestations of VEXAS are nonspecific and characterized predominantly by inflammatory parenchymal involvement.

POS1378 ARTHRITIS IN PATIENTS WITH FAMILY MEDITERRANEAN FEVER

S. Yenigun[1], A. Y. Ayla[1], S. N. Baspinar[1], M. B. Yuzbasioglu[1], A. Alkan[1], I. Durucan[1], M. Kirman[1], B. C. Polat[1], S. Ergun[1], H. Ozdogan[2], S. Ugurlu[2].
[1]Cerrahpasa Medical Faculty, Internal Medicine, Istanbul, Turkey; [2]Cerrahpasa Medical Faculty, Internal Medicine, Division of Rheumatology, Istanbul, Turkey

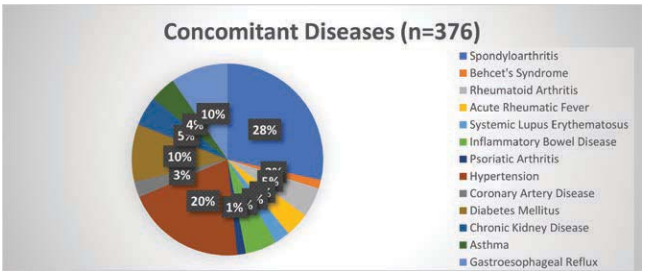
Background: Familial Mediterranean fever (FMF) is an inherited autoinflammatory disease characterized by recurrent episodes of fever and serositis. Arthritis is one of the most common attack manifestations. Arthritis in FMF is usually in the form of acute mono- or oligoarthritis of the large joints of the lower extremities. While acute attacks of arthritis usually heal without causing permanent deformity, the severe, long-lasting form of chronic arthritis can last for months or even years and result in permanent deformity.

Objectives: In this study, we described the characteristics of joint involvement in FMF in a single cohort.

Methods: The medical records of patients with joint involvement from our cohort of 2350 patients who were diagnosed with familial Mediterranean fever were retrospectively scanned through the files and hospital database. The prevalence, demographic information, genetic test results, clinical features, features of joint involvement, treatments and responses, acute phase values in the attack and remission periods, and family history of patients with joint involvement were recorded.

Results: 953 patients (n=953) from a total of 2350 patients had arthralgia or arthritis (40%). In our study, the male/female ratio was found to be

Table 1. Concomitant diseases of our FMF cohort



0.49 (male n=316, female n=637). The number of patients who underwent genetic testing was 787 (82%), and 702 (89%) of these patients had mutations in the MEFV gene. The most common pathogenic mutation is the M694V mutation with a rate of 43%. Concomitant diseases and their frequencies are shown in Table 1, the most common accompanying disease was spondylarthritis at a rate of 27%. Arthritis was present in the first attack in 55% (n=531), while arthritis was found in the ongoing attacks in 45%. The duration of the attack was between 24-96 hours in 77% (n=837) of the patients, and the duration was longer than 96 hours in 23% (n=116). The most common finding accompanying the attacks was exercise-related leg pain. Family history was present in 61% (n=580). 73% of the patients (n=696) were involved in the ankle and 51% were involved in the knee (n=492). The incidence of sacroiliitis was 14% (n=142). As for the number of joints, 91% of the patients had mono- and oligoarthritis. Asymmetric involvement was detected in 77% of the patients. Red arthritis was present in %73 of our study group. HLA-B27 was examined in 185 patients, 24 of them were positive (12%). It was found that 43% of the patients had treatment changes due to arthritis. Colchicine dose increases and changes were performed in 32% of these patients. NSAIDs were started in 21%, corticosteroids in 15%, DMARDs in 12%, anti-TNF in 10%, and anti-IL-1 in 8%. The mean dose of colchicine was as 1.56 ± 0.5 mg. Unresponsiveness to colchicine was found in 21% (n=122).

Conclusion: FMF diagnosis should definitely be considered in people with red mono-oligoarthritis in the large joints of the lower extremities. One of the most important features of joint involvement in FMF patients is the short duration of arthritis. The accompanying effort-related leg pain is an important symptom that should suggest FMF. In patients with a diagnosis of FMF and arthritis, the required colchicine dose in the treatment and the rate of colchicine unresponsiveness are higher than in other attack types. The incidence of sacroiliitis and spondyloarthropathy increases in patients with FMF, and joint involvement features are similar. FMF should be considered in the differential diagnosis of patients with inflammatory low back pain.

POS1379 HYPERMETABOLIC BONE SARCOIDOSIS ON 18F-FDG PET-CT: IMPACT ON TREATMENT AND DISEASE RELAPSE IN A COHORT OF 165 PATIENTS FROM A SINGLE UNIVERSITY HOSPITAL

A. Bouchut[1], R. Lhote[1], P. Maksud[2], T. Ben Salem[1], A. Fustier[3], Q. Moyon[1], J. Haroche[1], M. Soussan[4], A. Mathian[1], M. Hié[1], Z. Amoura[1], F. Cohen[1].
[1]Groupe Hospitalier Pitié Salpêtrière, Service de Médecine Interne 2, Maladies Auto-Immunes et Systémiques, Paris, France; [2]Hôpitaux Universitaires Pitié-Salpêtrière Charles-Foix, Médecine Nucléaire, Paris, France; [3]Groupe Hospitalier Pitié-Salpêtrière, Service de Radiologie, Paris, France; [4]CHU Avicenne, Médecine Nucléaire, Bobigny, France

Background: Sarcoidosis is a multisystemic granulomatosis of unknown cause. Prevalence of bone sarcoidosis is estimated between 3 and 30%. Bone sarcoidosis is symptomatic in about half of the cases. 18F-fluorodeoxyglucose (FDG) positron emission tomography-computed tomography (PET-CT) is a useful imaging modality in sarcoidosis, to search for a biopsiable site, evaluate organ involvement or assess disease activity. It is a sensitive imaging modality to detect bone involvement. However, clinical and prognostic significance of hypermetabolic bone involvement of sarcoidosis is not well known.

Objectives: The aim of this study was to compare the characteristics of patients with and without hypermetabolic bone involvement of sarcoidosis and to evaluate the impact of metabolic bone involvement on treatments and outcomes.

Methods: This was an observational, comparative, retrospective monocentric study of prospectively collected data. Inclusion criteria were a diagnosis of sarcoidosis according to the World Association of Sarcoidosis and Other Granulomatous diseases (WASOG) criteria and at least one 18F-FDG PET-CT during follow-up. Metabolic bone involvement of sarcoidosis was defined as bone hypermetabolism for which alternative causes had been reasonably excluded, following the WASOG criteria of « at least probable » bone sarcoidosis. Characteristics of patients with and without bone involvement were compared using bilateral Fisher or Mann-Whitney tests. Relapse-free survival curves were constructed following the Kaplan-Meier method and compared using a log-rank test. A p-value < 0.05 was considered significant.

Results: Among 503 patients with sarcoidosis, 165 with definite sarcoidosis who had undergone at least one 18F-FDG PET-CT were included. Fourteen patients had positive bone PET-CT findings which were attributed to other cause than sarcoidosis. Metabolic bone involvement of sarcoidosis was found in 29 patients (18%), among which 9 (31%) had structural bone lesions on CT. Metabolic bone involvement of sarcoidosis was associated with more frequent intrathoracic lymph node involvement (28 [96%] and 107 [79%], $p < 0.001$), extrathoracic lymph node involvement (15 [52%] and 40 [30%], $p = 0.03$) and a higher number of organ involvements (median [interquartile range], 6 [4-7] and 4 [2-5], $p < 0.001$). Patients with metabolic bone involvement received more frequently corticosteroids (29 [100%] and 99 [73%], $p < 0.001$), methotrexate (26 [90%] and 66 [48%], $p < 0.001$), tumor necrosis factor (TNF) alpha inhibitors (22 [76%] and 41 [30%], $p < 0.001$), and a higher number of treatments (3 [3-4] and 2 [1-3], $p < 0.001$). Despite more intensive treatments, disease relapse occurred significantly sooner in patients with metabolic bone involvement of sarcoidosis (median time to the first relapse, 63 [44-84] months and 96 [72-156] months respectively, $p = 0.01$).

Conclusion: Metabolic bone involvement on PET-CT was present in 18% of patients with sarcoidosis. It was predominantly axial and without structural lesions. In this comparative study, patients with metabolic bone involvement received significantly more treatments and had a shorter time to relapse. It could therefore reflect a more severe multisystemic involvement and chronic evolution of the disease. This could help adjust individual therapeutic strategy for patients with sarcoidosis.

Diagnostics and imaging procedures

POS1380 AUTOANTIBODIES ARE ASSOCIATED WITH EROSIVE DAMAGE IN THE SECOND AND THIRD METACARPOPHALANGEAL JOINTS ASSESSED BY HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY IN PATIENTS WITH RHEUMATOID ARTHRITIS.

R. Klose-Jensen[1,2], J. Therkildsen[1,2], A. B. Blavnsfeldt[1,2], B. Langdahl[2,3], J. Thygesen[4], K. Keller[1,2], E. M. Hauge[1,2,5]. *[1]Palle Juul-Jensens Blvd. 59, Department of Rheumatology, Aarhus, Denmark; [2]Aarhus University, Department of Clinical Medicine, Aarhus C, Denmark; [3]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus C, Denmark; [4]Aarhus University Hospital, Department of Clinical Engineering, Aarhus N, Denmark; [5]Rigshospitalet, DANBIO Registry and Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Glostrup, Denmark*

Background: The presence of anti-citrullinated protein antibodies (ACPAs) and rheumatoid factor (RF) are prognostic for erosive severity by radiography in patients with rheumatoid arthritis (RA) [1]. However, others have shown that RF mainly acts as an enhancer for ACPAs mediated bone loss [2]. High-resolution peripheral quantitative computed tomography (HR-pQCT) has a very high resolution with a voxel size of 82 μm^3, and has been proposed to monitor disease activity in patients with RA. In the current study, erosive damage was assessed by HR-pQCT according to the presence of autoantibodies. The hypothesis is that the presence of RF and especially ACPA is associated with erosive damage in two metacarpophalangeal (MCP) joints assessed by HR-pQCT; this has previously been shown using 44 joints assessment of both hands and feet by conventional radiography.

Objectives: The objective was to investigate if the presence of the autoantibodies, RF and ACPAs, was associated with a higher erosive burden in two MCP joints assessed by HR-pQCT.

Methods: Patients with RA and disease duration ≥ 5 years had their second and third MCP joints imaged by HR-pQCT. Age, sex, disease duration, ACPAs and RF status were acquired. From the Danish Clinical Quality Program – The Danish Rheumatologic Database (DANBIO) [3], the average 28-joint Disease Activity Score (DAS28-CRP) and Health Assessment Questionnaire (HAQ) from five years before inclusion were extracted. Statistical significance was investigated for the following groups, who were ordered according to the expected erosive burden: RF+/ACPA+ patients, RF-/ACPA+ patients, RF+/ACPA- patients, and autoantibodies negative patients. Analysis of variance was used to investigate the difference between the groups for age and sex. Cuzick's Rank-sum test for trend of ordered groups was used to test for trend for disease duration, 5-year average HAQ, 5-year average DAS28, number of erosions, total erosive volume, and average erosion volume.

Results: A total number of 353 patients with RA were included in this study. 203 was RF+/ACPA+ positive, 52 was RF-/ACPA+ positive, 24 were RF+/ACPA- positives, and 74 were autoantibodies negative. The groups were comparable with respect to age, sex distribution, disease duration and mean disease activity during the last five years, according to mean DAS28-CRP and mean HAQ during the previous five years.

There was a statistically significant test for trend for total erosive volume (p = 0.016) and average erosion volume (p = 0.043), but not for the number of erosions (p = 0.053) (Figure 1). A significant difference between the groups was only observed between double-positive patients and patients negative for autoantibodies.

Conclusion: In the current study, HR-pQCT scanning of only two MCP joints supports previous findings by radiography of both hands and feet, showing the accumulated erosive burden is higher in patients double-positive for RF and ACPA.

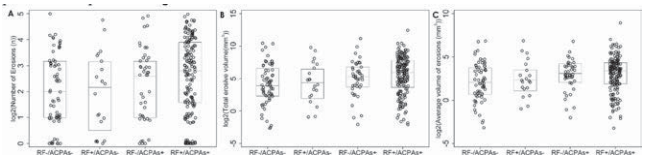

Figure 1. Scatterplot showing the number of erosions (A), total erosive volume (B) and the average volume of erosions (C) in the second and third MCP joint per patient according to the presence of the autoantibodies, ACPAs, as well as RF. Boxes denote the median and 25th and 75th percentile of the groups.

Background: In Diffuse idiopathic Skeletal Hyperostosis (DISH) o Forestier-Rotés disease the enthesis is also the hallmark of extraspinal manifestations. Despite being a characteristic hallmark of the disease, it has been poorly investigated.

Objectives: To assess the usefulness of the Madrid Sonographic Enthesitis Index (MASEI) to classify patients with DISH and to analyse the ultrasound findings in hyperostotic entheses.

Methods: We recruited 35 patients with DISH, according to Resnick classification criteria, who were compared with 33 healthy patients age, sex and body mass index-matched. An ultrasound was performed strictly following the MASEI protocol. The ultrasound examiners, with extensive experience in musculoskeletal ultrasound (ECOCAT group), were blinded to the diagnosis of the patients. The interobserver reliability of MASEI index measured by an ICC was 0.97 (95%, CI 89-99) [1]. Demographic, cardiovascular risk factors, clinical, radiological and MASEI-related variables were collected. We categorized into MASEI- inflammatory (MASEI-I) and MASEI-damage (MASEI-D) as previously published [2] but also into MASEI-DISH, which included the variables of thickness, structure and calcification. In the statistical analysis, patients' data were depicted by using descriptive statistics and the comparison between groups with the Chi-square test for categorical variables and the T-Student test for numerical variables. The validity of the index was examined using the area under the ROC curve and its corresponding 95% confidence interval (CI). The optimal cut-off point was defined as the one that maximizes sensitivity (S) and specificity. (Spe). The statistical program used was R software.

Results: In the analysis of the elemental lesions, the alterations in structure, thickness and calcification of the distal quadriceps (DQT) and Achilles tendons (AQT) stood out (p <0.05). In the total MASEI, the ultrasound score of ≥ 16.50 (S80%, Spe 85%), obtained with an AUC of 0.877 (95% CI, 0.79 to 0.96), was the best cut-off to differentiate patients from healthy subjects. In the categorized indices, MASEI-I: cut-off 5.50 (S 89%, Spe 76%) and AUC 0.835 (95% CI 0.73 to 0.94); MASEI-D: 7.50 (S 86%, Spe 76%) and AUC 0.850 (95% CI, 0.75 to 0.94) and MASEI-DISH: 16.50 (S 74%, Spe 91%) and AUC (95% CI 0.76 to 0.95).

The total MASEI in the DISH group was 27.46 (SD 14.4) compared to 10.30 (SD 6.4) in healthy controls (p<0.001) as well as in those categorized as MASEI-I, MASEI-D or MASEI-DISH (p <0.001).

Conclusion: Entheses lesions of the AQT and the DQT mark the differences between DISH and healthy patients. The optimal cut-off point was 16.50, and we did not observe any advantages in establishing MASEI categorizations that could be useful in clinical practice. Although the MASEI is an index designed to classify patients with spondyloarthritis, our study shows that it also allows differentiating DISH patients from healthy subjects. It would also be interesting to analyse the capacity of the MASEI to distinguish DISH from spondyloarthritis.

POS1382 AN OVERVIEW OF NAILFOLD CAPILLAROSCOPY IN ITALY: RESULTS FROM A NATIONAL SURVEY

F. Ingegnoli[1,2], M. Cornalba[1], R. De Angelis[3], S. Guiducci[4], D. Giuggioli[5], C. Pizzorni[6], V. Riccieri[7], M. Sebastiani[5], A. Sulli[6], M. Cutolo[6]on behalf of CAPSIR study group. *[1]ASST Gaetano Pini-CTO, Dept. of Rheumatology, Milano, Italy; [2]Università degli Studi di Milano, Dept. of Clinical Sciences & Community Health, Milano, Italy; [3]Polytechnic University of Marche, Department of Clinical and Molecular Sciences, Jesi, Italy; [4]University of Florence, Department of Experimental and Clinical Medicine, Division of Rheumatology, Florence, Italy; [5]Azienda Policlinico di Modena, University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences for Children and Adults, Modena, Italy; [6]University of Genova—IRCCS San Martino Polyclinic Hospital, Department of Internal Medicine, Research Laboratories and Academic Division of Rheumatology, Genova, Italy; [7]Università Sapienza, Dipartimento di Scienze Cliniche, Internistiche, Anestesiogiche e Cardiovascolari, Roma, Italy*

Background: In May 2020, the executive committee of the Italian Society of Rheumatology (SIR) endorsed the Italian study group (SG) on capillaroscopy and microcirculation in rheumatic diseases (CAPSIR) that first convened at the virtual annual meeting the same year. Nowadays capillaroscopy is a well-established, non-invasive technique with useful clinical applications in the assessment of connective tissue diseases (CTDs) [1] and mandatory for the differential diagnosis of Raynaud's phenomenon (Rp) [2]. Despite growing interest in the use of this imaging technique in clinical and research settings, data on its current usage to assess microcirculation in rheumatic diseases in Italy are not available.

Objectives: To obtain an insight into the current utilization of capillaroscopy in the assessment of rheumatic patients in the Italian clinical setting.

This survey aimed: 1) to obtain an overview on the usage of capillaroscopy in rheumatological clinical practice in Italy, and 2) to gauge expert's attitudes on factors influencing its use and the potential critical issues.

Methods: This online survey was devised to evaluate the opinions of the members of the SIR about nailfold capillaroscopy. It was designed with the contributions of the steering committee of CAPSIR SG, and emails with a link to the survey were sent to physicians affiliated with the SIR between July and August 2021 on behalf of the CAPSIR SG. At the beginning of the survey, the physician most experienced in capillaroscopy was asked to complete the questionnaire on behalf of his/her center. Questions were about the use of this technique in clinical practice and its critical issues. Data were reported with a descriptive analysis.

Results: One hundred and one centers, with at least one representative for each of the twenty Italian Region, completed the survey. 51.5% of respondents were in non-university hospitals, and 70 (69.3%) centers perform more than 100 capillaroscopy per year. The respondents were mainly practicing capillaroscopy for more than 5 years (85%) and gained certification of national or international dedicated training courses (84%). 43% of respondents had at least one scientific publication on this topic. Videocapillaroscope with 200X magnification was the most used instrument (91%). In public health services, the waiting time to schedule capillaroscopy is less than 3 months in 62.4% of centers. The survey has identified attitudes toward the use of capillaroscopy in the assessment and management of CTDs. In the screening phase of Rp, it is performed every 12 (mean value) months in patients with antinuclear antibodies (ANA) negative and every 6 months for those with positive ANA. Capillaroscopy is performed every 12 months (mean value) as part of the staging of CTDs (including systemic sclerosis). In more than 60% of centers, there is no specific diagnostic program for the screening of Rp and there is no connection with the general practitioners. 70% of the centers use capillaroscopy to follow the effect of therapies at least in systemic sclerosis.

Conclusion: At least one center for each Italian Region participated in this national survey, thus ensuring good geographical coverage. Moreover, the personnel who perform the exam had certified training and experience thus supporting the reliability of results. This survey indicates that the Italian public health system allows an acceptable waiting time to schedule the exam (less than 3 months). Italian Rheumatologists prescribe capillaroscopy as part of the clinical routine in the screening of Rp and as part of the annual checkup of CTDs. Critical issues remain the lack of a specific program and network with the general practitioners. To have a wider vision on this topic, our survey could be further extended to other European countries.

POS1383 DIFFERENTIAL DIAGNOSTICS OF POLYMYALGIA RHEUMATICA IN A UNIVERSITY HOSPITAL IN FINLAND

J. Paltta[1,2], S. Suuronen[2], L. Pirilä3,4, A. Palomäki3,4. *[1]Turku University Hospital, Rheumatology, Turku, Finland; [2]University of Turku, Faculty of Medicine, Turku, Finland; [1]Turku University Hospital, Rheumatology, Turku, Finland; [2]University of Turku, Faculty of Medicine, Turku, Finland*

Background: Polymyalgia rheumatica (PMR) is an inflammatory disease that causes muscle pain and morning stiffness, especially in the shoulders and hips. Diagnosing PMR can be difficult, as the diagnosis is mainly clinical without a definitive diagnostic test, and many symptoms and findings of PMR may also be present in other conditions. There is little recent data on differential diagnostics of PMR.

Objectives: The aim of our study was to analyse patients diagnosed with polymyalgia rheumatica (PMR) in Turku University Hospital in Finland and determine how often a competing diagnosis better explaining the patients' symptoms was found during further evaluation and clinical follow-up. We also aimed to find out what are the most common conditions initially misdiagnosed as PMR.

Methods: All patients with a new primary diagnosis of PMR (International Classification of Diseases – 10th revision [ICD-10] code M35.3) on at least one (in- or outpatient) visit during years 2016–2019 were identified from the hospital discharge register of Turku University hospital in Finland. We did a chart review of the patient charts including the full clinical follow-up period (median 34 months). We studied how often the primary diagnosis of PMR changed after further diagnostic evaluation or during follow-up.

Table 1. Demographic and clinical characteristics of the study sample.

Number of patients	382
Female (%)	218 (57.1%)
Age at diagnosis in years [IQR]	70.0 [64.0–77.8]
Follow-up in months [IQR]	34.0 [21.0–49.0]
Diagnosed in rheumatology (%)	299 (79%)
Treated in rheumatology (%)	310 (81%)
Nr. of visits [IQR]	6.5 [3.0–12.0]
Diagnosis changed during follow-up (%)	125 (32.7%)
Final diagnosis in 125 patients whose initial diagnosis of PMR changed	
Inflammatory arthritides (%)	45 (36.0%)
Degenerative or stress-related musculoskeletal disorder (%)	16 (12.8%)
Infection (%)	12 (9.6%)
Malignancy (%)	12 (9.6%)
Giant cell vasculitis (%)	8 (6.4%)
Other vasculitis (%)	8 (6.4%)
Other rheumatological disease (%)	7 (5.6%)
Fibromyalgia or other chronic pain syndrome (%)	4 (3.2%)
Gout or other crystal arthropathy (%)	2 (1.6%)
Endocrinological disease (%)	2 (1.6%)
Other or unknown (%)	14 (11.2%)

Continuous variables are expressed as medians with interquartile ranges, and categorical variables are described as counts with percentages.

Results: In 125 (32.7%) of the 382 patients, the initial diagnosis of PMR changed during further diagnostic evaluation or follow-up. Most common diagnoses initially misdiagnosed as PMR were inflammatory arthritides 36.0% (45/125), degenerative or stress-related musculoskeletal disorder 12.8% (16/125), infection 9.6% (12/125), malignancy 9.6% (12/125), giant cell vasculitis 6.4% (8/125) and other vasculitis 6.4% (8/125) (Table 1). Diagnosis changed in 19% (39/207) of patients fulfilling the 2012 ACR/EULAR PMR classification criteria and in 49% (86/175) of patients who did not.
Conclusion: In a university hospital setting, a third of initial diagnoses of PMR were changed during further evaluation and follow-up. Our findings highlight that thorough consideration of differential diagnosis is always essential when diagnosing PMR. Especially in patients with atypical presentation, there is a substantial risk for misdiagnosis.

POS1384 NON-INVASIVE IN VIVO METABOLIC PROFILING OF INFLAMMATION IN JOINTS AND ENTHESES BY OPTOACOUSTIC IMAGING

K. Tascilar[1,2], F. Fagni[1,2], A. Kleyer[1,2], S. Bayat[1,2], R. Heidemann[1,2], F. Steiger[1,2], G. Krönke[1,2], D. Bohr[1,2], A. Ramming[1,2], F. Hartmann[1,2], D. Klett[2,3], A. Federle[2,3], A. Regensburger[2,4], A. L. Wagner[2,4], F. Knieling[2,4], M. F. Neurath[2,3], G. Schett[1,2], M. Waldner[2,3], D. Simon[1,2]. *[1]Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany; [2]FAU Erlangen-Nuremberg and Universitätsklinikum Erlangen, Deutsches Zentrum fuer Immuntherapie (DZI), Erlangen, Germany; [3]FAU Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Internal Medicine 1, Erlangen, Germany; [4]FAU Erlangen-Nuremberg and Universitätsklinikum Erlangen, Department of Pediatrics and Adolescent Medicine, Erlangen, Germany*

Background: An in-depth metabolic characterization of joints and entheses at the tissue level can help in the early diagnosis and treatment selection for patients with inflammatory arthritis [1]. However, current knowledge about the metabolic profiles of synovitis and enthesitis is limited. Multispectral optoacoustic tomography (MSOT), a novel metabolic imaging technology, could be used to undertake metabolic profiling of joints and entheses non-invasively using near-infrared multispectral laser to stimulate tissues and detect the emitted acoustic energy, enabling quantification of tissue components in vivo based on differential absorbance at multiple wavelengths [2, 3].
Objectives: To explore the metabolic characteristics of arthritis and enthesitis using MSOT.
Methods: We performed a cross sectional study on healthy controls (HC) and patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) (Table 1). Participants underwent clinical, ultrasound (US), and MSOT examination of metacarpophalangeal joints, wrists, entheses of lateral epicondyles, patellar, quadriceps and Achilles tendons. MSOT-derived hemoglobin, oxygen saturation, collagen and lipid levels were measured. We calculated scaled mean differences (SMD) between affected and unaffected joints and entheses as defined by clinical examination or US using linear mixed effects models.
Results: We obtained 1535 MSOT and 982 US scans from 87 participants (36 HC, 34 PsA, 17 RA). Entheseal tenderness was not associated with metabolic changes, whereas US enthesitis was associated with increased total hemoglobin, oxygen saturation and collagen content. In contrast, clinical and US arthritis showed increased hemoglobin levels but reduced oxygen saturation and reduced collagen content. Synovial hypertrophy was associated with increased lipid content in the joints (Figure 1).
Conclusion: MSOT allows a non-invasive characterization of metabolic changes in arthritis and enthesitis. These findings can be interpreted as a reflection of increased synovial cellularity, collagen degradation, and metabolic demand in synovitis, and of an increased tissue apposition and vascularization in enthesitis. Our results suggest that synovitis and enthesitis do not only differ at the clinical and anatomical-functional level, but also exhibit divergent metabolic changes.

Background: Musculoskeletal Ultrasonography (US) is a suitable tool for the clinical assessment in juvenile idiopathic arthritis (JIA). Recently US definitions for normal components of pediatric joints and synovitis have been developed by the OMERACT US working group. Currently this group is working on development and validation of US definition for tenosynovitis as it is also an essential prerequisite for the reliable use of this technology in the pediatric age group.
Objectives: To produce consensus-based definitions for US tenosynovitis in JIA through a Delphi process.
Methods: We undertook a Delphi process on US-defined tenosynovitis in children that consisted of two steps. As a prior systematic literature review showed that US anatomy of the tendons is similar to adults, a Delphi questionnaire was written based on the consensual definitions developed for and used in adults with rheumatoid arthritis [1, 2]. The Delphi questionnaire was sent to rheumatologists and pediatricians who perform pediatric US examination, asking them to rate their level of agreement with each statement of US-defined tenosynovitis. Group agreement was considered if ≥80% of responders scored an item as either 4 or 5.In the second step, the definitions were validated on 88 standardized US images displaying various degrees of tenosynovitis obtained from JIA patients at various ages. Tendons often involved in JIA were selected (foot and ankle tendons, hand and wrist tendons, bicep tendon.). US images of both normal and tenosynovitis elementary lesions were collected by the 18 experts participating in the OMERACT US task force on pediatric tenosynovitis. An agreement ≥70% was considered mandatory for accepting the definition as applicable in the rated image.
Results: The response rate was 75% (28 out of 37) from the first Delphi questionnaire. Strong group agreement (≥86%) was obtained for the US definitions tested. The response rate was 88.9% (16 out of 18) from the Web-exercise after four rounds. The final definitions were validated on still images for all tendons, except for the biceps tenosynovitis in the age group 2-4 years (the definitions of elementary lesions and the global definition of tenosynovitis) as no image was available for this location and age group. Despite not reaching group agreement after the second and the third round for the US-defined normal finger pulley in children aged 8 years and younger (roughly 68% and 69% respectively), it reached a score of 99.8% after the fourth round.
Conclusion: US definitions of tenosynovitis and its elementary components covering a wide pediatric age range were successfully developed through a Delphi questionnaire and validated in a web-based still images exercise. These results provide the basis for the standardized US assessment of tenosynovitis in clinical practice.

POS1386 THE OCCURRENCE OF INFUSION-RELATED REACTIONS TO RITUXIMAB IS ASSOCIATED WITH LOW PLASMA LEVELS OF MYELOPEROXIDASE-DNA COMPLEXES.

C. H. Lu[1,2], T. J. Lee[1], C. L. Yu[1], S. C. Hsieh[1]. *[1]National Taiwan University, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China; [2]National Taiwan University, Graduate Institute of Clinical Medicine, College of Medicine, Taipei, Taiwan, Republic of China*

Background: Rituximab (RTX), a chimeric anti-CD20 antibody, is used in the treatment of rheumatic diseases. Infusion-related reactions (IRRs) are the most common adverse event, and premedication may reduce the incidence [1]. To date, there is still no effective predictor for the occurrence of IRRs.
Objectives: To identify factors predicting the occurrence of IRRs during the first course of RTX therapy in patients with rheumatic diseases.
Methods: We prospectively enrolled 29 patients with rheumatic diseases underwent the first course of RTX infusion, which consisted of two 500-mg intravenous infusions separated by about 2 weeks. Each patient received 100 mg intravenous methylprednisolone 60 minutes prior to each RTX infusion. Complete blood counts and C-reactive protein tests were performed before each infusion. The plasma levels of IL-1β, IL-6, IL-8, TNF-α, B-cell activating factor (BAFF) and plasma levels of myeloperoxidase (MPO)-DNA complexes were measured. All-grade IRRs occurring within 24 hours after infusions were recorded. Mann-Whitney U test was conducted to analyze factors associated with IRRs.
Results: The demographics and characteristics of the patients were shown in Table 1. Two patients reported IRRs in the first infusion, and three patients had IRRs in the second infusion of the first course. Among the five IRRs, four were skin rashes and one was headache. No serious events were found. A significant association between the low levels of MPO-DNA complexes and IRRs in the second infusion was noted (p = 0.011). The low plasma levels of MPO-DNA complexes also tended to be associated with the occurrence of IRR in the first infusion. The IRRs were not significantly correlate with absolute neutrophil counts, absolute lymphocyte counts, and the plasma levels of IL-1β, IL-6, IL-8, TNF-α, and BAFF.

Table 1. The characteristics of the patients received the first course of RTX treatment (n = 29).

Age (years)‡	44.9 (38.4 to 50.9)	
Gender, female (%)	26 (89.7)	
Diagnosis		
Antiphospholipid syndrome, n (%)	11 (37.9)	
Autoimmune thyroid disease, n (%)	6 (20.7)	
Sjögren's syndrome, n (%)	4 (13.8)	
Systemic lupus erythematosus, n (%)	2 (6.9)	
Rheumatoid arthritis, n (%)	1 (3.4)	
Others, n (%)#	5 (17.2)	
Blood test during each infusion	Before first infusion	Before second infusion
MPO-DNA complexes levels‡¶	11% (3% to 53%)	15% (3% to 32%)
IL-6 (pg/mL)‡	8.3 (6.9 to 11.2)	12.1 (8.5 to 13.8)
IL-8 (pg/mL)‡	14.4 (12.6 to 15.9)	13.0 (12.1 to 14.9)
TNF-α (pg/mL)‡	8.9 (6.9 to 12.7)	8.1 (6.1 to 11.2)
BAFF (pg/mL)‡	155.1 (121.3 to 231.9)	276.8 (201.3 to 331.2)
IL-6 (pg/mL)‡	8.3 (6.9 to 11.2)	12.1 (8.5 to 13.8)
Absolute neutrophil count (/μL) ‡	4380 (3441 to 5890)	4360 (3286 to 8195)
Absolute lymphocyte count (/μL) ‡	1511 (1198 to 1799)	1214 (854 to 1465)
C-reactive protein (mg/dL) ‡	0.03 (0.01 to 0.10)	0.04 (0.02 to 0.21)

‡ Data are presented in median and interquartile range.# Other diagnoses include systemic sclerosis, dermatomyositis, vasculitis, pemphigus, myasthenia gravis.¶ Data are presented in ratio to positive control.

Conclusion: Plasma MPO-DNA complexes represent neutrophil extracellular traps released by activated neutrophils. Neutrophils could be involved in the response to RTX therapy [2]. In this study, the risk of IRRs to RTX tended to increase when the plasma level of MPO-DNA complexes is low. Further research is needed to clarify the impact of activated neutrophils on RTX therapy.

POS1387 ULTRASOUND FINDINGS OF JOINTS AND ENTHESES FOLLOWING ONE HOUR OF AGE AND GENDER ADJUSTED WEIGHT TRAINING

J. K. Schreiner[1], F. Recker[2], D. Scheicht[3], P. Karakostas[1], J. Ziob[4], C. Behning[5], P. Preuss[6], P. Brossart[1], V. Schäfer[1]. *[1]University Hospital Bonn, Clinic of Internal Medicine III, Department of Oncology, Haematology, Rheumatology and Clinical Immunology, Bonn, Germany; [2]University Hospital Bonn, Department of Obstetrics and Prenatal Medicine, Bonn, Germany; [3]Porz am Rhein Hospital,*

Department of Rheumatology, Cologne, Germany; [4]University Hospital Bonn, Department of Dermatology and Allergy, Bonn, Germany; [5]University Hospital Bonn, Institute for Medical Biometry, Informatics and Epidemiology, Bonn, Germany; [6]University Bonn, University Sports Division, Bonn, Germany

Background: Joint effusion and enthesitis are common ultrasound findings in rheumatologic diseases like rheumatoid arthritis or spondyloarthritis. Physically active individuals and athletes were also found to exhibit structural and vascular changes in their entheses, as well as joint effusion through different imaging approaches [1, 2].
Objectives: The aim of this study was to evaluate the development of joint and entheseal ultrasound findings in large and medium joints of young healthy individuals after one hour of standardised weight training.
Methods: A total of three musculoskeletal ultrasound examinations were performed in healthy individuals under the age of 30 years. The first examination was carried out before the individuals conducted one hour of standardized weight training, the second examination 24 hours later and the third examination 48 hours later. The examination comprised shoulder, elbow, wrist, hip, knee, and ankle joints, as well as associated entheseal sites. Poisson mixed effects models were applied to analyse the development of the ultrasound findings within 48 hours after the weight training.
Results: Fifty-one healthy individuals with a mean age of 23.7 years (± 2.5, range: 19-30) (52.9% female) were enrolled in this study. Fourteen participants (27.5%) presented with at least one abnormal enthesis at baseline, increasing to 24 (47.1%) after 24 hours and to 29 (56.9%) 48 hours after the weight training. Hyperperfusion was the only entheseal pathology detected by ultrasound after the training.
The number of individuals with at least one joint effusion increased from 37 (72.6%) at baseline to 45 (88.2%) after 24 hours and to 48 (94.1%) 48 hours after the weight training. The Poisson mixed effects models showed a significant increase of the number of joints with effusion and entheses with pathologies with time after the weight training ($p < 0.001$, Exp(b) = 1.63 and $p < 0.001$, Exp(b) = 1.58).
Conclusion: Prevalence of joint effusion in large and medium joints as well as the prevalence of entheseal pathology increase significantly within 48 hours after one hour of weight training. As a result, the individual's physical activity should be considered when performing a musculoskeletal ultrasound examination.

POS1388 CLINICAL RELEVANCE OF ANTI-SSA ANTIBODIES: A SINGLE-CENTRE EXPERIENCE

C. Mazeda[1], S. P. Silva[1], R. Monteiro[2], R. Aguiar[1], A. Barcelos[1]. *[1]Centro Hospitalar Baixo Vouga, Rheumatology, Centro Académico Clínico Egas Moniz, Aveiro, Portugal; [2]Centro Hospitalar Baixo Vouga, Clinical Pathology, Aveiro, Portugal*

Background: Anti-Ro/SSA antibodies are directed against different proteins of intracellular small ribonucleic acid (RNA)-protein complexes, Ro60 (60 kDa) and Ro52 (52 kDa) and are the most frequently detected autoantibodies in patients´ sera. The clinical associations with antibodies to the Ro60 protein is well documented and includes systemic lupus erythematosus (SLE) and Sjögren syndrome (SS). [1]The presence of anti-Ro52 antibodies has been reported in a large variety of diseases, such as neoplastic diseases or viral infections [1, 2].
Objectives: The aim of this study was to analyze the clinical relevance and the disease phenotype of patients with anti-Ro52 and/or anti-Ro60 autoantibodies in a single portuguese tertehospital.
Methods: Retrospective and descriptive study included all patients screened for anti-nuclear antibodies (ANA) in the database of the immunology laboratory of our Hospital between 2017 and 2021. Only adult patients (≥ 18-years-old) with positive anti-Ro52 and/or Ro60 were included in the study and divided into three groups: group 1 – Ro52+/Ro60-, group 2 – Ro52+/Ro60+ and group 3 – Ro52-/Ro60+. The presence of ANA was tested by indirect immunofluorescence (threshold of positivity established at titer 1/160) and further screened for anti-extractable nuclear antigen (ENA) antibodies. Socio-demographic and clinical data were collected. Descriptive analysis was performed, p-value≤0.05 was statistically significant.
Results: Among 1210 patients, 277 were positive for the antibody anti-Ro52 and/or Ro60. Most of the patients included were women (79.8%) with a mean age of 58.87±16.12. Immune-mediated rheumatologic diseases were diagnosed in 173 (62.5%) patients, while 104 (37.5%) had non-rheumatologic disease. About 38.6% were exclusively anti-Ro52 positive, 30.3% of patients were anti-Ro60 positive alone and 31% tested positive for both. The clinical data of the patients in these three groups is represented in Table 1. In each of the three groups, the most frequent pattern was nuclear fine speckled (AC-4). In group 2, SS was the most frequent diagnosis (46.5%), followed by SLE (19.6%). Regarding ANA titers, a higher amount was observed in this group ($p<0.05$). The most frequently associated autoantibodies were anti-La (15.1%). In group 3, the diagnosis of SS was the most frequent (23.8%) followed by undifferentiated connective tissue disease (16.7%). Lupus anticoagulant (7.1%) and anti-RNP (6.0%) were more represented in this group. Finally, in group 1, non-rheumatologic disease was the most represented group of disease. In the case of SLE and systemic sclerosis, there were no statistically significant differences between the three groups and the different types of organ involvement. In SS, sicca symptoms were more prevalent in group 2, with statistically significant differences between the groups (p=0.027).

Table 1.

	Group 1 Ro52+/ Ro60- (n=107)	Group 2 Ro52+/ Ro60+ (n=86)	Group 3 Ro52-/ Ro60+ (n=84)	*p*
Immune-mediated rheumatologic diseases (n)	**51**	**69**	**53**	**0.004**
Systemic lupus erythematosus	10	16	7	0.396
Sjögren syndrome	21	40	20	**0.050**
Systemic sclerosis	2	1	2	0.618
Inflammatory myositis	4	0	1	**0.024**
Rheumatoid arthritis	9	2	7	**0.020**
Undifferentiated connective tissue disease	4	9	14	**0.025**
Other diseases	1	1	2	0.824
Non-rheumatologic disease (n)	**56**	**17**	**31**	0.369
Infections	3	1	2	0.978
Neoplasms	7	2	1	0.319
Liver cirrhosis	6	2	8	0.178
Interstitial lung disease	2	0	2	0.637
Chronic kidney disease	2	0	1	0.736
Unclassified	36	12	17	0.444

Conclusion: In line with published studies, our work demonstrated that, among the sera tested, autoreactivity to anti-Ro52 alone was the most often observed and in most patients the presence of this antibody alone was not associated with immune-mediated rheumatologic disease, but mainly with malignancies. We also identified the clinical phenotype of patients with positive anti-Ro52 and/or anti-Ro60. Thus, we reinforce the importance of specific detection such as Ro-52 or Ro60 as they present individual diagnostic utility.

POS1389 SUGGESTION OF OPTICAL SPECTRAL TRANSMISSION IMAGING (HANDSCAN) CUT-OFF VALUES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND CORRELATIONS WITH CLINICAL AND LABORATORY DISEASE ACTIVITY MARKERS.

K. Triantafyllias[1], K. Altamimi[2], M. De Blasi[1], A. Schwarting[1,2]. *[1]Rheumatology Center Rhineland-Palatinate, Rheumatology, Bad Kreuznach, Germany; [2]Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany*

Background: Optical spectral transmission (OST) is a modern diagnostic modality able to assess the blood-specific absorption of light transmitted through a tissue, promising quantification of inflammation in the finger and wrist joints of

patients with rheumatoid arthritis (RA) (HandScan -Demcon/Hemics, The Netherlands). Early data on OST revealed both correlations with clinical and arthrosonographic activity markers of RA, as well as a high diagnostic value during disease follow-up [1-3]. However, in a previous work we could detect and describe several OST confounding factors that complicate the establishment of universal cut-off values [2].

Objectives: Aim of this study was to examine and suggest OST-cut-off values after adjusting for the effect of statistically identified confounding factors. Moreover, we sought to describe a clinical model that would represent the probability of a positive RA diagnosis on the basis of OST values and presence of confounders in every individual patient.

Methods: Newly diagnosed RA patients (ACR-EULAR Classification Criteria 2010) were examined by OST and compared with healthy controls. Moreover, RA patients underwent clinical (tender & swollen joint counts, DAS28) and laboratory (inflammation markers) examinations. To identify factors that could have a confounding effect on OST, we performed logistic multivariate regression analyses, taking into account patient-associated characteristics such as age, gender, BMI, hand size, nicotine use. After identifying confounders, we determined OST cut-offs for different patient categories. In addition, we calculated the probability of the presence of an RA-diagnosis, based on the measured OST value and the presence of the identified influencing factors. Finally, we examined correlations of OST with clinical and laboratory RA activity parameters.

Results: 74 early RA patients [64%♀; median age 59 years (53-70, IQR); median DAS28 4.58 (3.5-5.3, IQR)] and 101 controls [80%♀; median age 45 years (35-56, IQR)] were recruited. Male gender and advanced age were statistically identified as OST influencing factors. Receiver operating characteristics (patients vs. controls) revealed an OST cut-off value of 11.2 (sensitivity 85%, specificity 72%) for female and an OST cut-off of 16.07 (sensitivity 75.7%, specificity 72.7%) for male patients. Two models were shown to be statistically appropriate for calculating the probability of the presence of RA based on the measured OST values and confounders: one model with included age for females and one model with included age and smoking status for males (Table 1). OST showed statistically significant moderate correlations with DAS28 (r=0.42, p<0.001), swollen joint count (r=0.437, p<0.001), VAS (r=0.355, p=0.002) and a weak significant correlation with CRP (r=0.23, p=0.045).

Table 1. Statistical models for calculating the probability of the presence of rheumatoid arthritis based on measured OST values and OST confounding factors.

Statistical model
Women $P(RA)=\frac{e^{(-7.85+(0.057xX_1)+(0.347xX_2)}}{1+e^{(-7.85+(0.057xX_1)+(0.347xX_2)}}$
Men $P(RA)=\frac{e^{(-7.561+(0.109xX_1)+(0.113xX_2)+(2.53xX_3)}}{1+e^{(-7.561+(0.109xX_1)+(0.113xX_2)+(2.53xX_3)}}$

OST: optical spectral transmission; P(RA): probability of RA diagnosis X1 for age, X2 for OST; X3 for nicotine use

Conclusion: The establishment of OST cut-off values adjusted for confounding factors and the suggested statistical models could contribute to an increase of the diagnostic value of HandScan and assist clinicians during patient screening. To our knowledge, this is the first report in the literature on the specific topic. Further patient recruitment and research regarding additional confounders are currently taking place with the aim of improving the diagnostic capabilities of this new and promising diagnostic technology.

POS1390 **ULTRASOUND BASED WITHDRAWAL OF BIOLOGICS IN RHEUMATOID ARTHRITIS (RA-BIOSTOP)**

C. Dejaco[1,2], I. Gessl[3], R. Husic[1], T. Deimel[3], A. Lackner[1], G. Supp[3], J. Hermann[1], J. S. Smolen[3], M. Stradner[1], D. Aletaha[3], G. Schwantzer[4], P. Mandl[3]. *[1]Medical University of Graz, Rheumatology, Graz, Austria; [2]Ospedale di Brunico, Rheumatology, Brunico, Italy; [3]Medical University of Vienna, Rheumatology, Wien, Austria; [4]Medical University of Graz, Institute for Medical Informatics, Statistics and Documentation, Graz, Austria*

Background: Discontinuation of biological (b)DMARDs may be considered in rheumatoid arthritis (RA) patients in persistent clinical remission [1]. Some earlier studies reported that baseline ultrasound may predict successful tapering or withdrawal of bDMARDs, while others found that ultrasound had little additional value over clinical parameters alone [2-4]. The majority of these studies, however, were limited by small sample size, inadequate remission criteria and variable tapering regimens.

Objectives: To test the hypothesis whether ultrasound-verified subclinical inflammation might predict a relapse in RA patients in stringent clinical remission who discontinue bDMARDs.

Methods: Prospective, phase IV clinical trial including RA patients in persistent clinical remission according to the ACR/EULAR criteria treated with a combination of conventional synthetic (cs)DMARD plus bDMARDs. Upon stopping the bDMARD, 9 study visits were conducted within 52 weeks. At each visit, patients underwent clinical examination and ultrasound of 14 joints. The primary hypothesis was that a Power Doppler (PD) score >0 predicted a relapse until week 16 after bDMARD cessation. Relapse was defined as change from remission to moderate/high disease activity according to the simplified disease activity index.

Results: Although 110 patients were required by the protocol, inclusion had to be stopped after reaching 38 (34.5%) due to insufficient recruitment. There were 9, 10 and 13 relapses between baseline and weeks 16, 24 and 52, respectively. Relapses till week 16 tended to be more common in patients with PD score >0 at baseline than in those without [9/30 (30.0%) vs. 0/7 (0%), p=0.160)]. Similar observations were made for weeks 24 [9/30 (30.0%) vs. 1/7 (14.3%), p=0.647)] and 52 [12/30 (40.0%) vs. 1/7 (14.3%), p=0.383)]. Kaplan-Meier plot indicates the relapse-free survival in patients with and without PD+ synovitis at baseline (Figure 1).

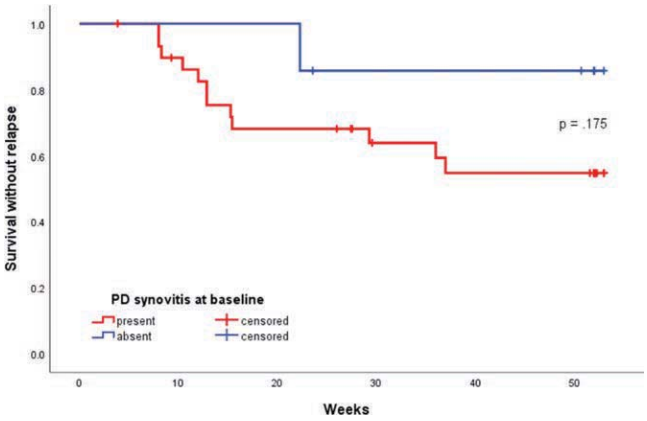

Figure 1. Kaplan-Meier analysis of relapses according to presence or absence of Power Doppler (PD) synovitis at baseline.

PD scores were higher at the time of relapse as compared to the preceding visits [mean difference in the PD score 3.2 (±4.5) points, p=0.034]. PD scores were also higher at visits preceding a relapse [mean 5.6 (±3.9), n=13] as compared to the mean PD score across all visits of patients without a relapse [mean 2.0 (±1.5), n=24, p=0.003, respectively]. There were trends towards a higher mean baseline PD score in patients who had a relapse between baseline and week 16 as compared to those who remained in remission (5.2 ± 5.8 vs. 2.3 ± 3.0, p=0.079). Similar observations were made for relapses until weeks 24 and 52. No difference was observed comparing mean residual swollen or tender joint counts at baseline between patients with and without a relapse. There were 9 adverse events. All of them were mild to moderate.

Conclusion: In RA patients in strict clinical remission, PD assessment at baseline but not clinical joint count could help identify patients who will relapse after the cessation of a bDMARD. Due to insufficient recruitment and limited power of the present trial, however, no definitive conclusion can be made.

POS1391 DEEP LEARNING-BASED PANNUS LOCALIZATION SOFTWARE IN THE HANDS OF INFLAMMATORY ARTHRITIS USING TIME-INTENSITY CURVE (TIC) SHAPE CLASSIFICATION ON DYNAMIC MRI DATASET

W. Fang[1], Y. An[2], H. Sugimori[1], S. Kiuch[3], T. Kamishima[1]. [1]*Faculty of Health Sciences, Hokkaido University, Sapporo, Japan;* [2]*Graduate School of Health Sciences, Hokkaido University, Sapporo, Japan;* [3]*AIC, Yaesu Clinic, Tokyo, Japan*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with significant functional impairment and disability, linked to inflammatory and structural articular and peri-articular damage [1]. Synovitis is a characteristic feature of RA, and is considered an important factor in disease activity and the best predictive marker of joint damage [2]. Therefore, accurate quantification of synovitis can play an important role in clinical evaluation and treatment serving as a biomarker. Pixel-by-pixel time–intensity curve (TIC) shape analysis is a dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) technique to help visualize differently shaped TICs [3]. Pixels having TIC shape type 4, which is characterized as early enhancement followed by washout phase, were regarded as synovitis pixel [4]. A deep residual network called ResNet-50 model, a convolutional neural network (CNN) that is 50 layers deep, might effectively classify TIC shapes.

Objectives: This study aimed to develop software that can automatically demonstrate the distribution of enhancing synovial pannus of patients with inflammatory arthritis on DCE-MRI.

Methods: Modified ResNet-50 was used on MATLAB. Two investigators drew regions of interest (ROIs) of muscle, bone, and synovitis under expert guidance and obtained TICs for each tissue on DCE-MRI of ten rheumatoid patients. Through cross-validation and batch evaluation, we verified the confusion matrices for the performance of the classifier. Then we identified the pixels of enhancing synovial pannus by image classification from the obtained pixel-by-pixel TIC shape and displayed them in color. The software performance was evaluated using a visual assessment on seven hand joints of one patient.

Results: 150 ROIs for muscles, 150 ROIs for bones, and 59 ROIs for synovitis on DCE-MRI of the hand joints were drawn in ten patients and obtained 4049, 3825, and 1041 TIC shape images, respectively. The classifier's accuracy, precision, sensitivity, and specificity were 99.6%, 99.3%, 98.4%, and 99.7%, respectively. Out of seven joints, four were assessed as good, two as fair, and one as fail.

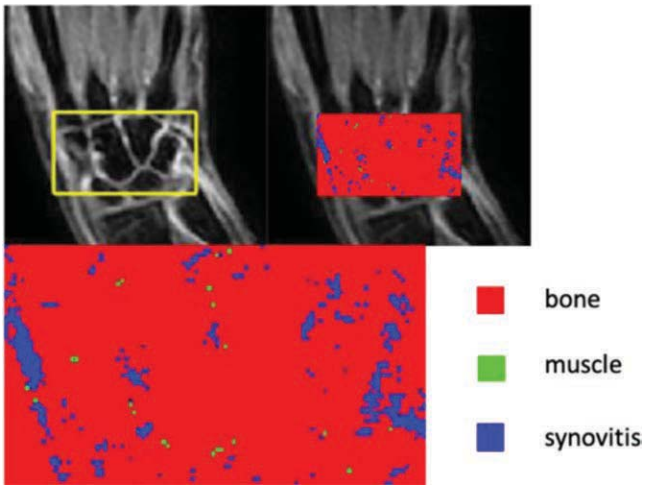

Figure 1. Software performance on contrast enhanced dynamic MRI of the wrist

Conclusion: Our classifier showed high accuracy, precision, sensitivity, and specificity. And through the comparison between manual outlining and the result of software, our software had relatively good performance. This automatic software developed using deep learning with CNN might accurately display the enhancing synovial pannus in RA.

POS1392 TISSUE DOPPLEROGRAPHY AS A DIAGNOSTIC TOOL FOR MYOCARDIAL DYSFUNCTION IN PATIENTS WITH RHEUMATIC DISEASES

L. Feiskhanova[1]. [1]*Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*

Background: Pathology of the cardiovascular system has a significant impact on the mortality rate in the population of patients with rheumatic diseases, including rheumatoid arthritis (RA) and ankylosing spondylitis (AS). Involvement of the cardiovascular system determines the course and prognosis of many rheumatic diseases. In the general population, left ventricular diastolic dysfunction is an independent predictor of mortality and symptomatic chronic heart failure. However, routine screening for diastolic dysfunction is rarely performed in patients with RA and AS, especially in those who do not have clinical symptoms.

Objectives: to identify early preclinical signs of myocardial dysfunction in patients with RA and AS.

Methods: 142 people with verified rheumatic diseases were examined. All patients were divided into 2 groups. The first group consisted of patients with RA - 95 pts (average age 46.5±11.1 years). The second group consisted of patients with AS, 47 pts (average age 42.3±10.3 years). The control group included 70 healthy individuals (average age 43.7±12.1 years). All patients underwent standard laboratory and instrumental diagnostic tests, which included joint radiography

(group 1), magnetic resonance imaging of the spine and ileosacral joints (group 2). In addition, we performed echocardiography and tissue dopplerography of the heart on the GE Vivid E9 ultrasound machine.

Results: The parameters e'L, e'S, e'R were the lowest in patients with RA (9.95 [8; 12], 8.2 [6; 10], 12 [10; 14], respectively) compared to both the group with AS (11.1 [9; 13.7], 9.8 [7.2; 12], 13.1 [12; 14], respectively), and with the control group (12.1 [10; 14], 9.8 [8; 11], 13.4 [11; 15], respectively) (p<0.005). This indicates a significant deterioration in the diastolic function of both ventricles in patients with RA. We found a similar picture when comparing the systolic velocities of the fibrous ring of the left and right atrioventricular openings S'L, S'S, S'R. In the group of patients with RA, these parameters were the smallest (9.1 [8; 10], 7.4 [7; 8], 12.9 [12; 14], respectively) compared to the other two groups (p<0.0005). These results indicate a significant deterioration in the diastolic and systolic function of both ventricles in patients with RA. Diastolic dysfunction of both the left ventricle (25.3%) and both ventricles (16.8%) was more common among patients with RA compared to the control group (5.7%, 0%, respectively) (p<0.01). The same pattern was found in the group with AS: 17 and 10.6%, respectively (p<0.01). At the same time, there were no statistically significant differences between the 1st and 2nd groups. In addition, the calculation of the relative risk showed that the presence of RA 4.42 times increases the risk of developing diastolic dysfunction of the left ventricle compared with control group (CI 1.6-12.2). It should be noted that in the control group, diastolic dysfunction of the left ventricle was diagnosed only type 1, whereas among people with RA out of 24 pts, 10 had a pseudonormal type, and among patients with AS out of 8 pts, it was detected in four pts.

Conclusion: Patients with RA and AS are characterized by deterioration of the diastolic function of the left ventricle or both ventricles simultaneously. Quantitative characteristics obtained during tissue dopplerography confirm these changes. In addition, in people with RA, there is also a decrease in the systolic function of both ventricles. Thus, in order to detect early myocardial dysfunction in patients with RA and AS, it is advisable to conduct not only two-dimensional echocardiography, but also tissue dopplerography.

POS1393 ULTRASOUND AS A POTENTIAL TOOL TO DETECT INTERSTITIAL LUNG DISEASE IN DAILY CLINICAL SETTING OF PATIENTS WITH RHEUMATOID ARTHRITIS

M. Gutierrez[1,2], S. Ruta[3], D. Clavijo-Cornejo[1], G. Fuentes-Moreno[1], S. Reyes-Long[4], C. Bertolazzi[1]. *[1]Instituto Nacional de Rehabilitacion, Division of Musculoskeletal and Rheumatic Diseases, Mexico City, Mexico; [2]Excellence Center of Rheumatology, Rheumatology, Mexico City, Mexico; [3]Hospital Italiana de La Plata, Rheumatology, La Plata, Argentina; [4]Instituto Nacional de Rehabilitacion, Division of Neurociencias, Mexico City, Mexico*

Background: Interstitial lung disease (ILD) is the most common and relevant pulmonary complication, that contributes significantly to increased morbidity and mortality in rheumatoid arthritis (RA). Thus, increased awareness of this complication is a real challenge in the clinical setting; in particular, an accurate strategy to detect RA-ILD is crucial to assure the survival and quality of life of RA patients. In the last years, the pulmonary ultrasound (US) has been proposed to assess ILD in rheumatic diseases [1, 2]. Preliminary results have demonstrated a positive correlation between their findings and those of HRCT and diffusion capacity of carbon monoxide (DLCO).

Although these results are exciting, the value and potential application of US in detect ILD in daily clinical setting of patients with RA remain to be clearly delineated.

Objectives: To investigate the potential role of US in the detection of ILD in a real-life cohort of patients with RA.

Methods: Patients with diagnosis of RA were consecutively enrolled. All patients underwent pulmonary examination, laboratory data, DLCO measure, chest HRCT and radiographs, and US examination. A healthy group was included as control group.

US was performed according the 14-intercostal space scanning protocol using the following semiquantitative scale [0 = normal (≤5 B-lines); 1 = slight (≥6 and ≤15 B-lines); 2 = moderate, (≤16 and ≥30 B-lines); 3 = severe (≥30 B-lines)].

Results: A total of 74 RA patients and 74 healthy controls were included. Thirty of 74 patients (40.5%) showed US signs of ILD with respect to the healthy controls (3 subjects, 4.1%) (p=0.0001); whereas HRCT showed ILD in 27 (36.4%) of 74 patients.

Among the 30 patients that showed US findings of ILD, 17 (56.6%) were asymptomatic from respiratory view-point. The sensitivity and specificity of US were 92% and 89% respectively.

A positive correlation between US and HRCT findings were found (p= < 0.0001) whereas no correlation was found with chest radiographs and DLCO findings (p = 0.2971 and 0.7856 respectively). Positive association between US findings and DAS28-ESR, RF and anti-CCP (p=0.0076, 0.0044, 0.0074 respectively) was found.

Feasibility, represented by the mean time spent to perform the pulmonary US assessment was 7.8 minutes (± SD 1.2, range 6 to 10 minutes).

Conclusion: Our results support the potential of US in detect accurately ILD in a real-life cohort of patients with RA and provide a rationale to consider it as a friendly screening tool to be implemented in early phases of the disease.

POS1394 ULTRASOUND MAY DETECT SUBCLINICAL INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS.

M. Gutierrez[1,2], C. Bertolazzi[3], D. Clavijo-Cornejo[1], E. Cruz-Arenas[4], L. E. Gomez-Quiroz[5], F. Salaffi[6]. *[1]Instituto Nacional de Rehabilitacion, Division of Musculoskeletal and Rheumatic Diseases, Mexico City, Mexico; [2]Excellence Center of Rheumatology, Rheumatology, Mexico City, Mexico; [3]Instituto Nacional de Rehabilitacion, Division of Musculoskeletal and Rheumatic Diseases, Mexico City, Mexico; [4]Instituto Nacional de Rehabilitacion, Unit of Epidemiology, Mexico City, Mexico; [5]Universidad Autonoma Metropolitana, Division de Ciencias Biologicas y de la Salud, Mexico City, Mexico; [6]Rheumatology Clinic, Rheumatology, Jesi, Ancona, Italy*

Background: Interstitial lung disease (ILD) is common in systemic sclerosis (SSc) patients and despite recent advances in the treatment represents still the major cause of death. It may be established within the first 4 years of SSc and frequently is subclinical [1].

To evaluate the presence of ILD, there are different available tools in addition to the clinical evaluation including respiratory functional tests (RFT) and imaging methods, especially HRCT which remain the mainstay for the diagnosis of SSc-ILD.

It has been recently proposed that pulmonary ultrasound (US) may have a potential role for the assessment of ILD in patients with SSc [2, 3]. Despite the growing body of evidence, there are no established data regarding its potential role in both detecting ILD in subclinical stages and on the follow-up of SSc patients.

Objectives: To investigate the validity of US in detecting subclinical ILD in SSc and to determine its potential in the follow-up of these patients.

Methods: 133 patients without respiratory symptoms and 133 healthy controls were included. Borg scale dyspnea index, Rodnan skin score (RSS) and pulmonary auscultation were performed. X-ray and respiratory function tests (RFT) were performed the same day. An expert rheumatologist blinded to clinical assessment performed the US. To determine the concurrent validity high-resolution CT (HRCT) scans was performed. HRCT findings were scored according to Warrick score whereas US findings were classified according the previously proposed scale. An inter-observer reliability was performed. A follow-up including US, RFT and Borg scale was done every 3 months for 12 months.

Results: A total of 54 of 133 SSc patients (40.6%) showed US signs of ILD in contrast to healthy controls (4.8%) (p=0.0001). The clinical and laboratory variables associated with ILD were anti-centromere antibodies (p=0.005) and RSS (p=0.004). A positive correlation was demonstrated between the US and HRCT findings (p=0.001). Sensitivity and specificity of US in detecting ILD was 91.2% and 88.6% respectively. A good inter-observer reliability was also observed (k = 0.72).

In the follow-up, a total of 30 patients (22.6%) that demonstrated US signs of ILD at baseline showed US worsening. Nine patients (30%) developed symptoms of ILD.

Conclusion: US is valid to detect subclinical ILD-SSc. Our results showed a high prevalence of this complication. Despite encouraging data, it seems still controversial its role in monitoring the ILD progression in SSc.

POS1395 NEUROFILAMENT LIGHT CHAIN, AN EARLY BIOMARKER FOR POLYNEUROPATHY IN HEREDITARY ATTR AMYLOIDOSIS.

A. F. Brunger[1], M. Berends[2], J. Bijzet[1], P. Van der Zwaag[3], B. J. Kroesen[4], C. Teunissen[5], S. In 't Veld[5], G. Drost[6], F. Lange[6], R. Gans[2], B. Hazenberg[1], H. L. A. Nienhuis[2]on behalf of Amyloidosis Center of Expertise, University Medical Center Groningen. *[1]University Medical Center Groningen, Rheumatology & Clinical Immunology, Groningen, Netherlands; [2]University Medical Center Groningen, Internal Medicine, Groningen, Netherlands; [3]University Medical Center Groningen, Medical Genetics, Groningen, Netherlands; [4]University Medical Center Groningen, Laboratory Medicine, Groningen, Netherlands; [5]Amsterdam UMC, Locatie VUmc, Clinical Chemistry, Amsterdam, Netherlands; [6]University Medical Center Groningen, Neurology, Groningen, Netherlands*

Background: Serum neurofilament light chain (sNfL) is a sensitive marker for polyneuropathy (PNP) in hereditary transthyretin-related (ATTRv) amyloidosis patients and correlates with the severity of polyneuropathy [1-4]. We hypothesized that sNfL may diagnose neuronal damage in patients with hATTR amyloidosis before the onset of symptoms and before PNP can be detected by electromyography (EMG) examination.
Objectives: To establish the course of sNfL in three different groups: 1. persistently asymptomatic variant carriers (with and without detected amyloid), 2. ATTRv amyloidosis patients with PNP on treatment, 3. variant carriers who develop PNP.

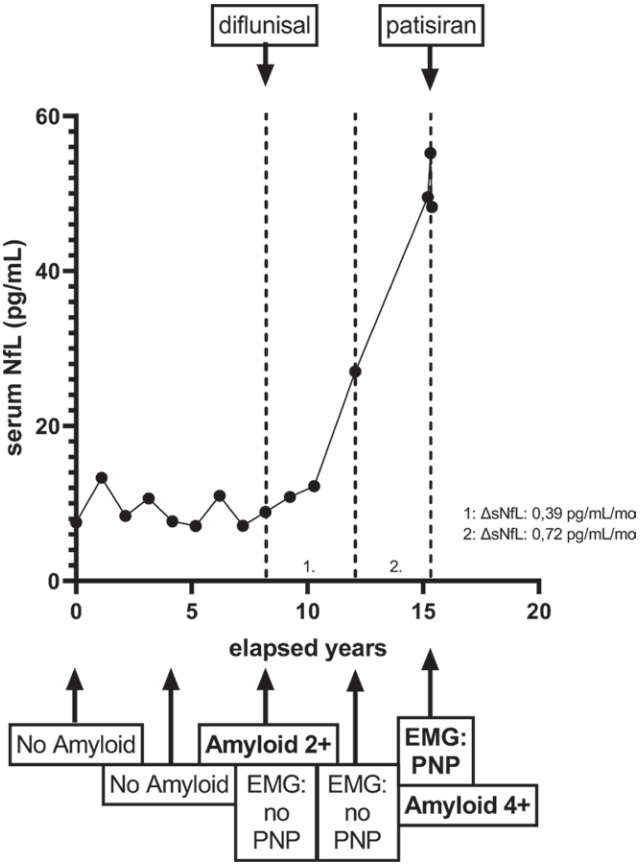

Figure 1.

Methods: sNfL levels were assessed longitudinally in asymptomatic variant carriers (with and without detectable amyloid), ATTRv amyloidosis patients with PNP on treatment (either a transthyretin (TTR) stabilizer or patisiran, an RNA interference therapeutic), and variant carriers who developed PNP. PNP was established by EMG examination. The single-molecule array (Simoa) assay was used to assess sNfL levels.
Results: sNfL levels significantly increased over 1 year in 20 persistently asymptomatic carriers (p<0.001), with the strongest increase in variant carriers (n=8) with detectable amyloid in the subcutaneous abdominal fat tissue. In 21 symptomatic ATTRv amyloidosis patient with PNP on treatment with a TTR stabilizer, sNfL levels remained stable over 1 year. In 24 patients treated with patisiran, sNfL levels significantly decreased after 1 year of treatment (p=0.01). In 8 out of 9 variant carriers who developed PNP a rise in the sNfL level could be observed before the onset of symptoms and establishment of PNP by EMG examination (Figure 1).
Conclusion: sNfL is a marker for early neuronal damage since a rise in sNfL level occurs before abnormalities can be detected by EMG examination. Our data support the use of sNfL in monitoring disease progression, screening asymptomatic variant carriers and monitoring of treatment effect.

POS1396 PSORIASIS, WITHOUT RHEUMATOLOGICAL MANIFESTATIONS, IS ASSOCIATED WITH STRUCTURAL CHANGES OF THE SACROILIAC JOINT, A CONTROLLED STUDY USING CT SCAN

T. Leriche[1], O. Fakih[1], F. Aubin[2], M. Chouk[1], C. Prati[1,3], D. Wendling[1,4], F. Verhoeven[1,3]. *[1]CHU Besancon, Rheumatology, Besançon, France; [2]CHU Besancon, Dermatology, Besançon, France; [3]Université de Franche Comté, EA 4267 PEPITE, Besançon, France; [4]Université de Franche Comté, EA 4266 EPILAB, Besançon, France*

Background: Plaque Psoriasis (PsO) is an inflammatory disorder that could be associated with rheumatological manifestations defining Psoriatic arthritis. Moreover, recent studies showed that the presence of plaque psoriasis is associated with more structural damage In axial Spondyloarthritis [1]. To our knowledge, no study has specifically evaluated the extent of structural lesions of the sacroiliac joints (SIJs) on computed tomography (CT) in patients with PsO, without rheumatological manifestations, compared with healthy controls.
Objectives: To describe SIJ CT characteristics in patients with PsO and compare them with those of age- and sex- matched controls.
Methods: An observational, retrospective study was performed using medical records from Besançon University Hospital's rheumatology and dermatology departments, which were screened to identify patients with PsO, diagnosed by a dermatologist. A search was then carried out for patients in the hospitals' imaging archiving system to identify those who had undergone a CT which included the SIJs in their entirety. Non-inclusion criteria were the existence of pelvic bone lesions and a history of pelvic radiotherapy. Each patient was then matched with a control of the same age and sex, recruited through the hospital's imaging archiving system.
For each individual, CT was interpreted by two independent readers using a score previously used by Diekhoff et al. [2], dividing each SIJ into 12 regions, for each of which joint space narrowing (JSN), erosions, and sclerosis are assessed. For this study, we also observed the existence of intra-articular gas and diffuse idiopathic skeletal hyperostosis (DISH) lesions for each region. Quantitative variables were compared using Student's t-test. Qualitative variables were compared using the Chi-2 test.
Results: 60 patients and 457controls were included. Mean (SD) age was 52,2 ± 17,7 in the PsO group and 53,6 ± 16.7 in the control group. 31 (52%) were male in PsO group and 30 (54%) in the control group. In the PsO group, BMI was 27,7± 6 versus 26,9 ± 6,44 in control group (p= 0.55). There is a trend for more frequent active smoking in PsO (69% in PsO group versus 54% in control group; p=0.075). In PsO patients, mean disease duration was 20.2 ± 17,6 years, the skin area affected was 41,8% ± 22,6 and the mean number of bDMARDs used was 2.25 (± 1.16). The global SIJ score was higher in the PsO group (6,63 ± 10,7) in comparison with the control group (2,84 ± 4,87). Erosion and sclerosis scores were similar in both group but joint space narrowing score was significantly higher in the PsO group (0.873

(±4.62) versus 4.15 (±10.8); p =0.035). There were no correlations between the global score and the disease duration (Pearson score 0.166 (-0.131; 0.435)) and the severity of the psoriasis (Pearson 0.00937 (-0.259; 0.276)).The number of gestation, active smoking, alcohol intake and physical work have no impact on the global Score.
Conclusion: The CT characteristics of SIJs from patients with Pso were different to those of age- and sex-matched controls essentially secondary to joint space narrowing.

POS1397 USEFULNESS OF ^{18}F-FDG PET/CT FOR POLYMYALGIA RHEUMATICA DIAGNOSIS

C. Casadepax-Soulet[1], B. Crestani[2], K. Benali[3], M. Forien[1], E. Ebstein[1], P. A. Juge[1], P. Dieudé[1], S. Ottaviani[1]. *[1]Hopital Bichat-Claude Bernard, Rheumatology, Paris, France; [2]Hopital Bichat-Claude Bernard, Pulmonary department, Paris, France; [3]Hopital Bichat-Claude Bernard, Nuclear medicine, Paris, France*

Background: Polymyalgia rheumatica (PMR) is an inflammatory disorder affecting elderly people. The diagnosis is based on clinical and imaging findings such as ultrasonography. The interest of ^{18}F-fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (^{18}F-FDG PET/CT) in PMR is increasing. However, its exact place in the diagnosis or management of PMR patients remains unclear.
Objectives: We aimed to describe the utility ^{18}F-FDG PET/CT for PMR diagnosis.
Methods: We performed an observational retrospective study of patients with new onset of PMR having a ^{18}F-FDG PET/CT. Diagnosis of PMR was done according to ACR/EULAR 2012 classification criteria. A control group, including patients with sarcoidosis, neoplasia or infection, was also analyzed. The following sites were assessed for the presence of hypermetabolism (SUVmax ≥ 2): shoulders, acromioclavicular and sternoclaviculaire joints, hips, symphysis pubis, ischial tuberosities, great trochanters, cervical and lumbar interspinous process and large vessels. The number of hypermetabolic sites (0-18), the median SUVmax and the highest SUVmax were analyzed.
Results: A total of 85 PMR patients (60% of female, mean age 70.7 years) and 75 controls (51% of female, mean age 65 years) were analyzed. Among PMR patients, hypermetabolism was mostly observed in shoulders (93%), hips (91%), great trochanters (87%), ischial tuberosities (89%) and lumber interspinous process (71%). Large vessel vasculitis was only observed in 7% of PMR patients. In comparison to control patients, PMR had higher number of hypermetabolic sites (11.3 ±3.3 vs. 0.85 ±1.1, p<0.001), and mean SUVmax score (3.9 ±0.8 vs. 2.7 ±0.4, p<0.001). After adjustment to age, the number of hypermetabolic sites (OR 2.57 [1.84; 4.51], p<0.001) and the mean SUVmax were associated with the diagnosis of PMR (OR 1.49 [1.30; 1.78], p<0.001). Among PMR patients, the C-reactive protein (CRP) levels were correlated with the mean SUVmax (r=0.38, p<0.001), the number of hypermetabolic sites (r=0.34, p<0.01) and the highest SUVmax (r=0.38, p<0.001).
Conclusion: ^{18}F-FDG PET/CT appears to be a sensitive imaging for PMR. The number of hypermetabolic sites and the man SUVmax are correlated with CRP levels and PMR diagnosis.

POS1398 ASSOCIATION OF FUNCTIONAL SALIVARY TESTS WITH SALIVARY GLAND ULTRASOUND AND BIOPSY IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME.

S. Garcia-Cirera[1], C. Galisteo[1], S. Retamozo[1], M. Moreno[1], E. Casado[1], E. Costa Moya[1], J. Gratacos-Masmitja[1], J. Calvet[1]. *[1]Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí (I3PT), Rheumatology, Sabadell, Spain*

Background: Salivary gland ultrasonography is useful to assess salivary gland involvement in primary Sjögren Syndrome. Different publications have describes the association between decreases salivary flow and the degree of involvement with ultrasound.
Objectives: This study aims to assess the association of functional salivary tests evaluated by stimulated and unstimulated salivary flow (SSF and USF) with salivary major gland ultrasound scores (SGUS) and a positive focus score in a minor salivary gland biopsy.
Methods: A cross-sectional study including 98 subjects fulfilling the ACR-EULAR 2017 classification criteria for pSS. All patients underwent salivary functional tests, an ultrasound of salivary glands and a minor salivary gland biopsy requested as per clinical practice. The ultrasound images were graded using three different scoring systems: De Vita (0-3), Salaffi (0-4) and Omeract (0-3), obtained as the highest score achieved in the four evaluated glands, left and right parotid and submandibular. Positive biopsy was considered if focus score ≥1
Results: This study included 98 patients with pSS. We evaluated the different ultrasound scoring systems and each score individually assessed in parotid and submandibular gland with the salivary functional tests. USF is associated with all SGUS independently of the measurement, with a 2.5 ml/15min higher in negative compared to positive SGUS. Similar results were shown for SSF, with a 3 ml/5 min higher in negative compared to positive SGUS (Table 1). We observed no association between USF or SSF and a positive focus score in the minor salivary gland biopsy.

Table 1. Association between salivary flows and ultrasound scoring systems.

		Unstimulated Salivary Flow			Stimulated Salivary Flow		
Ultrasound score	Group	N(%)	Means[95%CI]	p-val	N(%)	Means[95%CI]	p-val
Vita	N	54 (55.1%)	4.076 [3.056, 5.096]	0.004	54 (55.1%)	6.745 [5.042, 8.447]	0.011
	P	44 (44.9%)	1.839 [0.709, 2.969]		44 (44.9%)	3.436 [1.550, 5.322]	
Vita Parotid	N	60 (61.2%)	3.886 [2.912, 4.861]	0.008	60 (61.2%)	6.575 [4.961, 8.190]	0.011

Vita Submandibular	N	55 (56.1%)	4.002 [2.986, 5.017]	0.007	55 (56.1%)	6.668 [4.977, 8.358]	0.014
	P	43 (43.9%)	1.881 [0.733, 3.030]		43 (43.9%)	3.458 [1.546, 5.370]	
Salaffi	N	52 (53.1%)	4.050 [3.005, 5.095]	0.007	52 (53.1%)	6.754 [5.015, 8.493]	0.014
	P	46 (46.9%)	1.965 [0.854, 3.076]		46 (46.9%)	3.570 [1.721, 5.419]	
Salaffi Parotid	N	58 (59.2%)	3.857 [2.861, 4.853]	0.016	58 (59.2%)	6.578 [4.931, 8.225]	0.014
	P	40 (40.8%)	1.932 [0.733, 3.132]		40 (40.8%)	3.347 [1.365, 5.330]	
Salaffi Submandibular	N	54 (55.1%)	4.011 [2.985, 5.037]	0.007	54 (55.1%)	6.689 [4.982, 8.396]	0.014
	P	44 (44.9%)	1.918 [0.782, 3.054]		44 (44.9%)	3.505 [1.614, 5.395]	
Omeract	N	56 (58.9%)	3.727 [2.727, 4.726]	0.01	56 (58.9%)	6.313 [4.612, 8.014]	0.043
	P	39 (41.1%)	1.854 [0.656, 3.051]		39 (41.1%)	3.574 [1.536, 5.613]	
Omeract Parotid	N	61(64.2%)	3.562 [2.598, 4.526]	0.040	61 (64.2%)	6.227 [4.599, 7.854]	0.036
	P	34 (35.8%)	1.874 [0.582, 3.165]		34 (35.8%)	3.326 [1.147, 5.506]	
Omeract Submandibular	N	57 (60.0%)	3.661 [2.667, 4.656]	0.028	57 (60.0%)	6.246 [4.557, 7.935]	0.052
	P	38 (40.0%)	1.903 [0.685, 3.120]		38 (40.0%)	3.603 [1.534, 5.671]	

N: Negative, P: Positive

Conclusion: USF and SSF are associated with SGUS system independently of the salivary gland evaluated but not with positivity in the biopsy, pointing to salivary ultrasound as a good technique to evaluate functionality. Neither USF nor SSF are associated with positivity in the biopsy indicating no link between histology and functionality.

POS1399 THE INTEREST OF DOPPLER ULTRASOUND IN THE EVALUATION OF THE CARPAL TUNNEL SYNDROME SEVERITY

N. El Amri[1], S. Jriri[1], S. Guizani[2], K. Baccouche[1], N. Mahdhi[3], E. Bouajina[1]. *[1]Farhat Hached, Rhuematology, Sousse, Tunisia; [2]Farhat Hached, Family Medecine, Sousse, Tunisia; [3]University Hospital Sahloul, Plastic Surgery Department, Sousse, Tunisia*

Background: Several studies have proven the value of Doppler ultrasound (DpUS) in the diagnosis of carpal tunnel syndrome (CTS) with satisfactory sensitivity and specificity. Yet, unlike the Nerve Conduction Studies (NCS), the interest of this technique in the severity diagnosis in CTS remains uncertain to this day. Several studies have focused on this subject. However, the morphological signs of gravity are not yet consensual.

Objectives: Compare US data with clinical and electromyographic data in order to determine the place of DpUS in the severity diagnosis in CTS.

Methods: A bicentric cross-sectional study including patients with uni or bilateral CTS, confirmed by NCS, referred from the plastic surgery department. All the patients underwent a clinical examination, a NCS of both hands as well as a DpUS of the wrists by the same rheumatologist.

Results: After screening and application of all exclusion criteria, a total of 72 wrists of 47 patients were included. The median age was 54,23 ± 11 years [21-77 years] and 89,4% of wrists were from female patients. Hand numbness was the most frequent functional sign (94.4%) and the Phalen sign was the most noted examination sign (73.6%). Clinically, the patients presented respectively 32 mild, 14 moderate and 26 severe lesions. According to the NCS, there were 18 mild, 21 moderate and 33 severe CTS with 73.6% of the wrists with sensorimotor impairment. On US, the hypoechoic image was the dominant qualitative sign (84.7%). Regarding the quantitative measures, the mean Median Nerve (MN) cross sectional area (CSA) was 14.5 mm2 [9-30 mm2] and the mean flattening index was 3 [1.8-8.92]. Intraneural hypervascularisation was present in 57 writs (79,2 %). Statistically significant associations were detected between the MN CSA and both history of diabetes mellitus (p=0.045), diabetes duration (p=0.040) and disease duration (P=0.021). But there was no association between MN CSA and age (p=0,406), gender (p=0,690) and BMI (p=0,414). the mean MN CSA during mild clinical stage was 13.5 mm2. For moderate stage it was 17 mm2 while for severe stage it was 15 mm2.No relationship was found between US quantitative and morphological parameters and clinical severity grades. We detected significant correlation between MN hypervascularization and the CTS severity grades on NCS (p=0,044). For the other qualitative US signs, there was no statistically significant difference between the different grades of electromyographic severity (Notch sign (p=0.364), Hypoechoic image (p=1.000), Disappearance of the fascicular aspect (p=0.248), Decreased mobility of the tunnel contents of the canal during wrist movements (p=0.140)). the mean MN CSA during mild electromyographic stage was 13 mm2. For moderate stage it was 14 mm2 while for severe stage it was 15 mm2 and We did not find a statistically significant difference in MN CSA (P=0.494) between the different grades of severity of CTS on NCS. There is no statistically significant association between qualitative US signs and the type of NCS impairment; pure sensory or sensorimotor. However, we found a significant association between the MN CSA and pure sensory or sensorimotor damage on NCS (P=0,009).

Conclusion: MN DpUS could be a complementary procedure to the clinical examination which allows, in addition to the positive diagnosis, to evaluate the severity of the CTS based on the MN CSA and the intraneural vascularization in power Doppler.

POS1400 CLINICAL EVIDENCE OF THE DIFFERENCE IN CIRCULATING CALPROTECTIN LEVELS BETWEEN RHEUMATOID ARTHRITIS AND HEALTHY INDIVIDUALS, NON-INFLAMMATORY ARTHRITIS OR OTHER INFLAMMATORY ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

C. Andalucia[1], R. Albesa[2], M. Mahler3. *[1]Werfen, Research and Development, Barcelona, Spain; [2]Werfen, Headquarters & Technology Center Autoimmunity, Research and Development, San Diego, United States of America; [2]Werfen, Headquarters & Technology Center Autoimmunity, Research and Development, San Diego, United States of America*

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease mainly characterized by a chronic inflammation of the joints. Early diagnosis and treatment with disease-modifying antirheumatic drugs (DMARDs) is essential to prevent or slow down the structural damage. Diagnosis might be difficult in patients with mild and unspecific clinical signs and symptoms though. A differential diagnosis in patients presenting arthritis is needed for an appropriate patient management. Acute-phase reactants (ESR or CRP) are non-specific inflammatory biomarkers used to aid in the diagnosis of RA and to assess disease activity. In the recent years, studies published have shown that calprotectin may be an alternative biomarker of active inflammatory disorders as well as a prognostic or monitoring biomarker.

Objectives: To collect all available evidence on the difference between circulating calprotectin (cCalpro) levels in rheumatoid arthritis (RA) patients and other control populations such as healthy individuals (HI), osteoarthritis (OA), psoriatic arthritis (PsA) or spondyloarthritis (SpA).

Methods: Electronic databases searches (Scopus, Pubmed and Cochrane Library), complemented by registry and hand searching, were conducted (February 4th, 2021) to identify fully paired studies comparing cCalpro levels in RA and HI, non-inflammatory arthritis (NIA), or other inflammatory arthritis. As recommended by Cochrane, the Hedge´s standardized mean difference (SMD) and its 95% confidence intervals were used to synthetize the difference in cCalpro levels from studies using different matrices (serum or plasma) or laboratory methods. Sample size, mean and standard deviation of each group were extracted from the individual studies to conduct a random-effects model meta-analysis in STATA MP v17.0. When cCalpro levels were reported in median and range or inter-quartile, a formula was used to estimate the mean and standard deviation. Sensitivity analysis, subgroup analyses and meta-regression analyses on matrix type (serum or plasma) and cCalpro commercial test were performed, when feasible, to investigate heterogeneity.

Results: The systematic review retrieved 27 studies comparing cCalpro levels between RA and controls. One study reported cCalpro levels in three different RA and HI cohorts. Most of RA and controls were age and gender matched. Calprotectin was measured in serum in 72,4% of the comparisons. Thirteen different commercial calprotectin tests and four homemade tests were used. In 21 studies cCalpro levels were measured in 2678 RA and 1096 HI. cCalpro levels were significantly higher in RA than in HI (SMD=2,13;95%CI=1,27-2,98;p<0,0001), and significant heterogeneity was observed. A meta-regression on matrix and assay manufacturer indicated that 22% of the between-study variance might be explained by the type of calprotectin test used. Five studies compared cCalpro levels in 207 RA and 187 NIA (78,57% OA). cCalpro levels were significantly higher in RA than in NIA (SMD=2,914;95% CI=0,957-4,872;p=0,0035), significant heterogeneity was observed. cCalpro levels in 1217 RA and 411 PsA patients were reported in 5 studies. cCalpro levels were slightly higher in RA than in PsA (SMD=0,54; 95%CI=0,424-0,656; p<0,0001), while no significant heterogeneity was observed. A comparison between cCalpro levels in RA and SpA was included in 4 studies. cCalpro levels were slightly higher in RA than in SpA (SMD=0,35; 95%CI=0,129-0,576; p=0,0020), and no significant heterogeneity was observed.

Conclusion: In this systematic review and meta-analysis, rheumatoid arthritis patients showed significantly higher circulating calprotectin levels than healthy individuals, non-inflammatory arthritis, psoriatic arthritis and spondyloarthritis. Pooled standardized mean difference between groups should be interpretated with cautious due to substantial heterogeneity or small number of studies.

POS1401 **PROGNOSTIC VALUE OF COMMON FEMORAL VEIN WALL THICKNESS IN BEHÇET DISEASE: A PROSPECTIVE FOLLOW-UP STUDY**

K. Abacar[1], R. Ergelen[2], F. Temiz[3], Y. Yıldız[3], T. Ergun[4], H. Direskeneli[1], F. Alibaz-Oner[1]. *[1]Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Marmara University, School of Medicine, Department of Radiology, Istanbul, Turkey; [3]Marmara University, School of Medicine, Department of Internal Medicine, Istanbul, Turkey; [4]Marmara University, School of Medicine, Department of Dermatology, Istanbul, Turkey*

Background: We reported the first controlled doppler ultrasound study showing increased common femoral vein (CFV) thickness in Behçet Disease (BD). Following that, we recently showed that increased CFV thickness is a distinctive feature of BD, rarely present in other inflammatory or vascular diseases such as ankylosing spondylitis, systemic vasculitides, venous insufficiency, and non-inflammatory DVT (deep venous thrombosis) with a specificity higher than 80% for the cut-off value of ≥ 0.5 mm. However, the association between CFV thickness and any organ involvement, disease course or treatment during the prospective follow-up has not been demonstrated so far.
Objectives: This study aimed to assess the longitudinal course and prognostic value of CFV thickness measurement during prospective follow-up BD patients.
Methods: In this prospective study, we included 195 patients with diagnosed BD. The clinical, demographic, treatment data and laboratory were recorded during the routine visit. Bilateral CFV thickness was measured with ultrasonography by an experienced radiologist at the same day. Patients were started to follow up prospectively with 3-6 months intervals and in any urgent visit. In 47 patients, the second CFV thickness measurement was done mean 19.79 (10.10) months after the first visit.
Results: At baseline, 98.6% of patients had increased CFV thickness above the cut-off value of ≥0.5 mm. The baseline and last follow-up clinical characteristics were shown in Table 1.

Table 1. The baseline and follow-up clinical characteristics of patients with Behçet's Disease.

	Baseline (n=139)	Last Follow-up (n=139)	Relapses or New Involvement during follow-up
Age mean (SD)	34.85 (8.27)		
Gender F/M ratio	43/96		
Pathergy (positive/negative)	59/44		
Right CFV Wall Thickness mean (SD) mm	0.791 (0.253)		
Left CFV Wall Thickness mean (SD) mm	0.797 (0.207)		
Oral aftous n (%)	134 (95)	134 (95)	13 (9.4)
Genital Ulcer n (%)	84 (60.4)	89 (64.5)	6 (4.3)
Eritema Nodosum n (%)	62 (44.6)	69 (49.6)	9 (6.5)
Arthritis (%)	48 (34.5)	48 (34.5)	10 (7.2)
Major Organ Involvement n (%)	103 (74.1)	110 (78.6)	39 (28.1)
Vascular Involvement n (%)	84 (60.4)	96 (69.1)	35 (25.2)
Deep Venous Thrombosis (%)	61 (43.9)	65 (46.8)	6 (4.3)
Pulmonary trombosis n (%)	35 (25.2)	52 (37.4)	23 (16.5)
Neuro-Behcet n (%)	14 (9.9)	16 (11.5)	2 (1.4)
Uveitis n (%)	33 (23.7)	40 (28.8)	7 (5)

In 47 patients, the second CFV thickness measurement was done mean 19.79 months after the first visit. There was no statistically significant difference between the first and second CFV venous wall thickness measurements for both right and left of our patients (First vs. second for right CFV: 0.791 mm vs. 0.755, p=0.264; first vs. second for left CFV: 0.787 mm vs. 0.753, p=0.264). We did not find any change in CFV wall thickness with the treatment, new organ involvement and relapses. 139 of 195 patients had prospective clinical follow-up data with the mean of 26.52 (16.94) months. New major organ involvement or relapse leading to treatment change was seen in 39 (28%) patients. While 22 (15.8%) patients had new major organ involvement, 12 (8.6%) of them were diagnosed with new vascular involvement, seven (5%) with new uveitis. Among 36 patients with only mucocutaneous disease at baseline, new major organ involvement developed in 9 patients during follow-up. These nine patients had had higher baseline CFV thicknesses compared to patients not developing major organ involvement despite not achieving clinical significance (0.83 mm vs 0.73 mm for right CFV; 0.80 mm vs 0.73 mm for left CFV: p >0.05 for both)
Conclusion: CFV wall thickness measurement with ultrasonography which is a new non-invasive diagnostic tool for BD, does not show a major change over time with treatment, new organ involvement or disease relapses. However, our preliminary results suggest that mucocutaneous BD patients with higher CFV thickness may have a higher risk of developing major organ involvement during follow-up. The results of our prospective cohort with longer follow-up and increased patients' number would clarify the prognostic value of CFV thickness in BD.

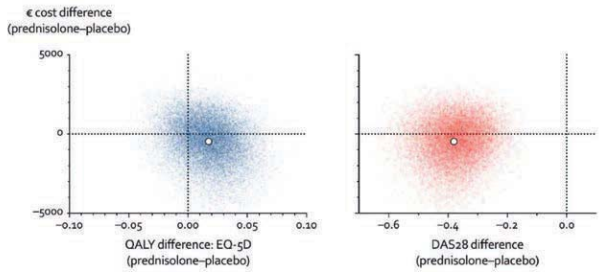
Background: Rheumatoid arthritis (RA) is a disease with substantial impact on quality of life, healthcare and societal costs [1]. Current treatment strategies, especially biologic drugs, result in high costs [2]. Previous studies have already found that a combination treatment strategy of disease-modifying antirheumatic drug(s) with initially medium-to-high doses of prednisolone resulted in better effects and lower costs compared to the treatment strategies without prednisolone [3, 4]. However, to our knowledge the cost-effectiveness of low-dose glucocorticoids (GCs), and that of GC overall in established RA has not been examined separately.

Objectives: To evaluate the cost-effectiveness and cost-utility of low-dose prednisolone in RA patients aged 65+.

Methods: The economic evaluation was performed as part of the placebo-controlled GLORIA trial of RA patients aged 65+ with a disease activity score in 28 joints (DAS28) ≥2.60. Eligible patients were randomized to 2 years 5 mg/day prednisolone or placebo. Patients were recruited from 28 clinical centers in seven European countries. All co-treatment, except for chronic oral GC, was allowed. The economic evaluation had a societal perspective with a time horizon of two years. Cost data were collected with questionnaires and from recorded events, and valued with unit prices of 2017. The primary effectiveness outcome was the DAS28. For cost-utility, quality-adjusted life years (QALYs) were estimated from the EuroQol-5 Dimension (EQ-5D) questionnaire. Standard regression models were used to estimate incremental costs and effects between the treatment groups. Bootstrapping assessed the uncertainty around the average differences in costs and health outcomes.

Results: In total, 444 of 451 randomized patients were included in the modified-intention-to-treat analysis (see main GLORIA study abstract). Patients were on average 72 years and had median 4 active comorbidities at baseline. Mean total costs over 2 years were k€10.8 in the prednisolone group, k€0.4 (95% CI –3.7; 1.9) lower than in the placebo group. Total direct medical costs were k€0.5 (95% CI –4.0; 1.5) lower in the prednisolone group. The mean number of QALYs was similar in both groups (difference 0.02 [–0.03; 0.06] in favor of prednisolone). The DAS28 was 0.38 lower in the prednisolone group than in the placebo group (0.19;0.56). The cost-effectiveness plane shows that the majority of the bootstrapped cost-effect pairs was situated in the southwest quadrant of the plane confirming the larger effects (i.e. decrease in DAS28) and non-significant lower costs in the prednisolone group (Figure 1). The cost-utility plane shows that the number of QALYs was similar for both groups and that the bootstrapped cost-utility pairs were slightly more located in the southeast quadrant confirming a very small increase in QALYs and slightly lower costs in the prednisolone group (Figure 1).

Figure 1. Cost-effectiveness and cost-utility planes representing the differences in cost (€) and health (EQ-5D and DAS28) between prednisolone and placebo treatment.



Conclusion: With greater effectiveness at non-significantly lower costs, low-dose, add-on prednisolone is cost-effective for RA compared to placebo over two years. QALYs were equal in both groups, most likely due to the impact of multiple comorbidities.

POS1403 CLINICAL CHARACTERISTICS, HEALTH CARE RESOURCE UTILIZATION, AND COSTS ASSOCIATED WITH FLARES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN GERMANY

B. Ding[1], M. Pignot[2], E. Garal-Pantaler[3], B. Villinger[4], B. Desta[5], K. Schmidt[6], S. Golam[1], H. Stirnadel-Farrant[7], A. Schwarting[8].
[1]AstraZeneca, BioPharmaceuticals Medical, Gothenburg, Sweden; [2]ZEG Berlin GmbH, Center of Epidemiology and Health Research Berlin, Berlin, Germany; [3]Team Gesundheit GmbH, Health Economics Department, Essen, Germany; [4]AstraZeneca, BioPharmaceuticals Medical, Nürnberg, Germany; [5]AstraZeneca, BioPharmaceuticals Business Unit, Gaithersburg, MD, United States of America; [6]AstraZeneca, BioPharmaceuticals Medical, Wedel, Germany; [7]AstraZeneca, BioPharmaceuticals Medical, Cambridge, United Kingdom; [8]University Medicine of Johannes Gutenberg University Mainz, Rheumatology and Clinical Immunology, Mainz, Germany

Background: Longitudinal data describing real-world systemic lupus erythematosus (SLE) disease characteristics, health care resource utilization (HCRU), and costs associated with flares in Germany are limited.

Objectives: To evaluate the clinical characteristics of patients with SLE and estimate the impact of flares on HCRU and costs in a cohort of adults with SLE in Germany.

Methods: CHaracteristics and impact of flares on clinicAl and econoMic OutcoMes In patients with systemic Lupus Erythematosus: a German Claims Database Study (CHAMOMILE) was an observational, retrospective cohort study. Adult patients with SLE were identified from the German Betriebskrankenkassen health insurance fund database between 1 July 2010 and 31 December 2013, and followed for up to 9 years. Baseline period was defined as the first year since the first quarter with the earliest SLE diagnosis during the identification period, including this quarter. Resource utilization measures included number of hospitalizations, duration of stay, and associated costs per person-year (PY) by follow-up year for patient subgroups defined by flare exposure (no, mild, or moderate/severe flares) during baseline. Cost measures included total PY costs in flare-exposure subgroups.

Results: Of 2088 patients included in the study, the mean (SD) age was 51.4 (16.1) years and 1767 (84.6%) were female. The most common SLE manifestations were cutaneous (66.8%), osteoarticular (28.7%), and vascular (23.0%). Patients were receiving treatment with glucocorticoids (54.8%), antimalarials (40.2%), nonsteroidal anti-inflammatory drugs (39.1%), and/or immunosuppressants (32.7%). During the baseline period, 750 patients (35.9%) experienced moderate/severe flares, 622 (29.8%) experienced mild flares, and 716 (34.3%) experienced no flares. Patients with no flares or mild flares during the baseline period had similar costs, and a similar number and duration of hospital stays per PY, which remained consistent from baseline up to 9 years of follow-up. Patients with moderate/severe flares during the baseline period had 2- to 3-fold higher hospital costs, 1- to 2-fold more hospital stays, and hospital stays that were 2-fold longer in duration, compared with the no-flares or mild-flares groups during baseline and each year of follow-up (Table 1). During the baseline period, annual total costs were more than 2-fold greater for patients with moderate/severe flares (€11,048/PY) than patients with mild (€5148/PY) or no flares (€4734/PY). In all subsequent years, costs for patients with moderate/severe flares exceeded costs for patients with mild or no flares. Annual total costs gradually increased over time to €7761/PY for patients with mild and to €7564/PY for patients with no flares at Year 9, whereas costs reduced sharply at follow-up Year 1 to €8801/PY and remained similar to Year 9 for patients with moderate/severe flares (Figure 1).

Table 1. Mean Costs, Number, and Duration of Hospital Stays per Person-Year by Baseline Flares

	Flare-Exposure Subgroup	Year									
		Baseline	1	2	3	4	5	6	7	8	9
Patients, n	**No**	716	716	701	676	658	634	603	526	444	315

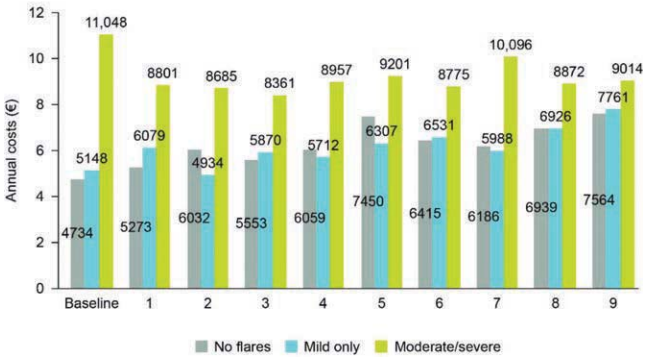
Figure. Annual Total Person-Year Costs by Baseline Flare Exposure Subgroups



Conclusion: Patients with moderate or severe flares following diagnosis place a large burden on the health care system in Germany. Earlier diagnosis and treatment may reduce flare severity and the associated high health care costs.

POS1404 SHARED DECISION MAKING AND INTERNET USE FOR GATHERING HEALTH INFORMATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A MULTICENTER CROSS-SECTIONAL STUDY

T. Ichikawa[1], Y. Shimojima[1], D. Kishida[1], N. Yajima[2], R. Yoshimi[3], K. E. Sada[4,5], Y. Miyawaki[5], N. Oguro[2], N. Sakurai[3], C. Hidekawa[3], K. Hayashi[5], K. Shidahara[5], Y. Ishikawa[6], Y. Sekijima[1], N. Kurita[7,8]. *[1]Shinshu University School of Medicine, Department of Medicine (Neurology and Rheumatology), Matsumoto, Japan; [2]Showa University School of Medicine, Division of Rheumatology, Department of Medicine, Tokyo, Japan; [3]Yokohama City University Graduate School of Medicine, Department of Stem Cell and Immune Regulation, Yokohama, Japan; [4]Kochi Medical School, Kochi University, Department of Clinical Epidemiology, Nankoku, Japan; [5]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama, Japan; [6]University of Occupational and Environmental Health School of Medicine, The First Department of Internal Medicine, Kitakyusyu, Japan; [7]Fukushima Medical University Hospital, Department of Innovative Research and Education for Clinicians and Trainees (DiRECT), Fukushima, Japan; [8]Fukushima Medical University, Department of Clinical Epidemiology, Graduate School of Medicine, Fukushima, Japan*

Background: It is well known that providing appropriate health information to patients with systemic lupus erythematosus (SLE) has an advantage in the treatment decision making process. In modern information society the growing popularity of smartphones and social networking services, patients have more access to online health information. However, there are concerns that Internet use may inversely affect the shared decision making (SDM) process with their attending physicians if they receive inaccurate information.

Objectives: This study aimed to investigate how online information gathering behavior affects SDM with their attending physicians.

Methods: In this cross-sectional study, information of 386 patients with SLE, which were enrolled from five Japanese institutions between June 2020 and August 2021, were analyzed. The main exposure was time spent on the Internet per day (excluding time used for working). It was divided into four categories (none, <1 hour, 1-2 hours, > 2 hours). Patients were asked to select the source of health care information they would like to access first and were categorized into physicians, the Internet, and other media sources (family and friends, healthcare professionals other than physicians, or TV and radio, etc.). Outcome was shared decision making measured via the 9-item Shared Decision Making Questionnaire (SDM-Q-9 [scores 0-100]). To assess the relationship between the time of Internet use and SDM, we fitted general linear models adjusted for age, gender, education level, household income, marital status, history of cancer, disease duration, and disease activity. Chained equations were used to impute missing values of covariates.

Results: This study ultimately employed 334 patients whose mean age and female ratio were 45.3 years (standard deviation 13.8) and 87.7%, respectively. 68.9% of the patients indicated that they would like to access their physicians first, and 19.5% indicated that they would like to access the Internet first. Compared to patients who chose their physician as their first access to health information, there was no difference in SDM-Q-9 among patients who chose the Internet, but patients who chose other media had significantly lower SDM-Q-9 (-7.7 point, 95% confident interval [CI] -14.4 to -0.92, P=0.026). Besides, SDM-Q-9 scores were significantly lower in patients who did not use the Internet compared to those who used it for more than two hours except for their work activities (-9.6, 95%CI -18.9 to -0.26, P=0.044).

Conclusion: The present study suggests that SDM between physicians and patients is positively rather than adversely associated with online information-gathering behavior. Rheumatologists also need to be aware that how patients prefer to access health information to establish a good physician-patient relationship for SDM. In addition, rheumatologists may need to introduce their patients to websites offering appropriate health information.

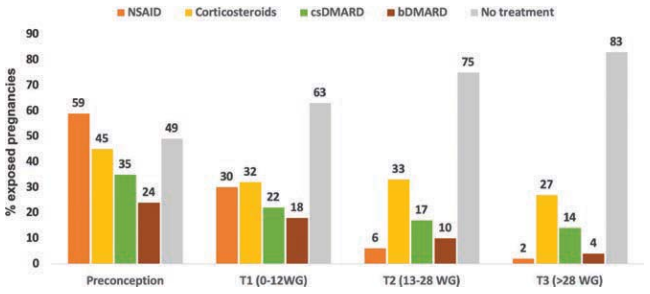
POS1405 LESS THAN 50% FEMALES WITH CHRONIC RHEUMATIC INFLAMMATORY DISEASES CONTINUE A DMARD DURING PREGNANCY: A DESCRIPTIVE ANALYSIS OF THE NATIONAL FRENCH SOCIAL SECURITY DATABASE

A. Moltó[1], A. Ajrouche[2], D. Tran[2], B. Roux[2], N. Costedoat-Chalumeau[3], E. Elefant[4], V. Tsatsaris[5], J. Fresson[6], B. Bader-Meunier[7], B. Fautrel[8], F. Tubach[2]. *[1]Cochin Hospital, Assistance Publique Hôpitaux de Paris, Rheumatology, Paris, France; [2]APHP, CEPHEPI, Paris, France; [3]Cochin Hospital, Assistance Publique Hôpitaux de Paris, Internal Medicine, Paris, France; [4]Hopital Trousseau, Assistance Publique Hôpitaux de Paris, CRAT, Paris, France; [5]Port-Royal Maternity, Assistance Publique Hôpitaux de Paris, Obstetrics, Paris, France; [6]CHU Nancy, Public Health, Nancy, France; [7]Hôpital Necker, Assistance Publique Hôpitaux de Paris, Pediatric Immuno-hematology,*

Paris, France; [8]Hôpital Pitié Salpêtrière, Assistance Publique Hôpitaux de Paris, Rheumatology, Paris, France

Background: Treatment of patients with chronic rheumatic inflammatory diseases (CRID) during pregnancy has changed in the last decade, namely due to the availability of new DMARDs labelled to be used during pregnancy.
Objectives: To describe the anti-rheumatic drug use during pregnancy in women with CRID (i.e. rheumatoid arthritis (RA) or spondyloarthritis (SpA)) in France over the past decade.
Methods: This is a retrospective cohort study within the French Healthcare database (SNDS), which covers 98% of the French population. Adult women were included if they had RA or SpA according to CIM-10 codes, had started a singleton pregnancy between 2008 and 2017 (index date), and were continuously covered by this health insurance from 1-year before pregnancy onset to 1-year after end of the pregnancy or death (whichever comes first). The treatment exposures of interest were: NSAIDs, oral corticosteroids, csDMARD (methotrexate, leflunomide, sulfasalazine, azathioprine, hydroxychloroquine), biologics (anti-TNF, rituximab, abatacept, tocilizumab, ustekinumab, anakinra). Exposure during pregnancy was defined as at least one drug reimbursement from the 6 months before the last menstrual period (LMP) to the end of pregnancy period.
Results: Among the 35,737 adult women with a CIRD (40.7% with RA and 59.3% with SpA) who had a past history of DMARD reimbursement, 11,274 (41.7%) started a singleton pregnancy during the study period. In total, during preconception and pregnancy, 4,773 (42.3%) women were not delivered any DMARD nor corticosteroids, 769 (6.8%) were delivered corticosteroids alone, 3,639 (32.2%) a csDMARD alone and 2,862 (25.4%) a biologic (among whom 33.1% associated a csDMARD). Biologics delivered during pregnancy were mainly anti-TNFs (92.1%). Exposure to NSAIDs was more frequent during the first trimester (30% patients) of pregnancy but occurred all along the pregnancy (6% and 2% in the second and third trimesters, respectively). Conversely, exposure to oral corticosteroids was stable during the pregnancy (33% to 27%); however, more than half of the prescriptions corresponded to doses higher than 10mg. Exposure to DMARDs including bDMARDs during pregnancy was more frequent during the first trimester, compared to the rest of the pregnancy (see graph).



Conclusion: Overall, less than 50% of women with a CRID who received a DMARD prior to the pregnancy continued to retrieve such treatment during pregnancy, and overall less than 20% were delivered biologics during pregnancy. Whether the withdrawal of DMARDs led to unfavorable maternal and pregnancy outcomes needs to be evaluated.

POS1406 EVALUATING THE QUALITY OF CARE FOR HEART FAILURE HOSPITALIZATIONS IN INFLAMMATORY ARTHRITIS- A POPULATION-BASED COHORT STUDY

B. Kuriya[1], L. Eder[2], J. Widdifield[3], L. Ferreira-Legere[3], I. J. Jeong[3], J. Fang[3], A. Chu[3], J. Udell[3,4]. *[1]Sinai Health System, University of Toronto, Rheumatology, Toronto, Canada; [2]Women's College Hospital, University of Toronto, Rheumatology, Toronto, Canada; [3]ICES, Sunnybrook Health Sciences Centre, ICES, Toronto, Canada; [4]Women's College Hospital, Cardiology, Toronto, Canada*

Background: Individuals with inflammatory arthritis (IA) have an increased risk of heart failure (HF). Little is known if the quality of HF care differs among patients with IA compared to other chronic diseases such as diabetes mellitus (DM).
Objectives: We examined adherence to quality-of-care indicators for HF hospitalizations among patients with IA compared to those with DM but no IA and the general population (without IA or DM).
Methods: We linked multiple population-based health datasets to construct a cohort of adults living in Ontario, Canada on January 1, 2011 and followed to December 2020. The IA cohort was identified using validated case definitions and included patients with rheumatoid arthritis, ankylosing spondylitis and psoriatic arthritis. Comparison cohorts included adults with DM but no IA and general comparators without DM or IA. We included all subjects with a first HF hospitalization and who were alive at the time of discharge. We summarized the percentage of subjects in each of the 3 exposure groups who achieved recommended quality process measures [1]: (1) % receiving echocardiogram, (2) % receiving electrocardiogram, (3) % receiving a chest x-ray; and (4) % seen by a physician within 7 days of discharge. For those over the age of 65 years in whom medication information was universally available, we examined how many were dispensed evidence-based therapies: (5) % prescribed β-blocker, (6) % prescribed angiotensin-converting enzyme inhibitor or angiotensin receptor blocker, (7) % prescribed mineralocorticoid receptor antagonist. We categorized adherence as perfect, moderate, or poor based on the number of measures achieved and compared proportions using pair-wise chi-squared tests.
Results: A first HF hospitalization occurred in 5,836 IA patients, 33,553 DM patients and 62,256 general comparators. The crude incidence rate for HF in IA was 2.70 per 1000/PY and was significantly higher compared to the general population (0.84 per 1000/PY), but lower compared to the DM cohort (5.01 per 1000/PY, p< 0.001). Mean age at time of HF hospitalization was significantly higher in the IA group (78 years) with more females affected (58%) compared to either the DM or general population group (p<0.001). All groups had high achievement of testing process measures and there were no differences in perfect adherence between the IA vs. DM and IA vs. general population comparators (Table 1). For those >65 years of age, patients with IA were less likely to achieve perfect adherence for medication quality indicators compared to either the DM or general population.

Table 1. Percentage in each of three exposure groups achieving the recommended HF quality measures.

Process Measure	IA Group	DM Group	General Population
1.Echocardiogram	90.6%	91.1%	89.5%
2.Electrocardiogram	97.4%	97.4%	97.3%
3.Chest x-ray	99.7%	99.6%	99.6%
4.Health care provider visit within 7 days of discharge	39.0%	38.9%	38.7%
Perfect Adherence (achieving 1, 2,3 and 4 above)	33.0%	33.0% (p=0.43, IA vs. DM)	32.2% (p=0.15, IA vs general population)
5.Beta-blocker prescribed	64.8%	70.5%	66.6%
6.Angiotensin-converting enzyme inhibitor or angiotensin receptor blocker prescribed	54.8%	61.3%	56.2%
7.Mineralocorticoid receptor antagonist prescribed	20.3%	19.9%	21.2%
Perfect Adherence (achieving 5, 6 and 7 above)	10.6%	12.0% (p=<0.001, IA vs. DM)	12.0% (p=0.02, IA vs general population)

Conclusion: HF quality indicators are adhered to in a high proportion of patients with IA following HF hospitalization. However, reasons for lower HF medication prescribing in IA compared to other high-risk conditions, such as DM, requires further evaluation. It will also be important to determine if adherence to HF quality of care translates to reduced long-term outcomes such as repeat HF hospitalizations and cardiovascular mortality, which we are currently exploring.

Epidemiology, risk factors for disease or disease progression

POS1407

THE MANAGEMENT OF CONTEMPORARY EARLY UNDIFFERENTIATED ARTHRITIS: DATA ON EULAR'S RECOMMENDATION ON THE RISK OF PERSISTENT DISEASE

N. Den Hollander[1], M. Verstappen[1], T. Huizinga[1], A. Van der Helm-van Mil[2,3].
[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands;
[1]Leiden University Medical Center, Rheumatology, Leiden, Netherlands;
[3]Erasmus Medical Center, Rheumatology, Rotterdam, Netherlands

Background: EULAR recommendations for early arthritis recommend assessing the following risk factors for persistent disease in Undifferentiated Arthritis (UA): polyarthritis, acute phase reactants (i.e. c-reactive protein(CRP), erythrocyte sedimentation rate(ESR)), rheumatoid factor (RF), ACPA and imaging findings/erosions. However, these recommendations are based on an outdated definition of UA: not fulfilling 1987 RA criteria and having no alternative diagnosis ('conventional UA'). Since the introduction of the 2010 RA criteria the characterization of UA has changed. The contemporary definition of UA is: not fulfilling 1987- nor 2010 criteria, and having no alternative diagnosis. Therefore, predictors for persistent disease in conventional UA may not be applicable in contemporary UA.
Objectives: Our objective was to assess which risk factors for persistent disease, as mentioned in the EULAR recommendations, are applicable in contemporary UA.
Methods: Patients consecutively included in the Leiden Early Arthritis Clinic cohort with contemporary UA between 2006-2019, when DMARD start in UA was recommended, were studied. The outcome was sustained remission, defined as absence of clinical synovitis without DMARD use (including corticosteroids) for the entire follow-up (at least one year). Cox regression was used to test the association between the risk factors as mentioned in EULAR-guidelines and sustained remission. For comparison, patients with conventional UA (not fulfilling the 1987 criteria and no other diagnosis) were studied using similar analyses.
Results: Contemporary UA patients (n=710) were mostly ACPA negative (95%) and had a median of 2 swollen joints. Radiographic erosions were rare (1.8%). 60% of contemporary UA patients achieved sustained remission after median 1.5 years (IQR 1-3). After achieving remission patients were followed for 5.5 years without clinical arthritis, demonstrating sustainability. Univariably, CRP, ESR, ACPA and RF were associated with time to sustained remission, while polyarthritis was not. In multivariable analysis, only ACPA and CRP were independently associated with sustained remission (HR 0.10 (95%CI:0.03-0.32) and HR 0.67(0.50-0.91), respectively). 67% of contemporary UA patients had none of these risk factors. In contrast, only 2% had both CRP and ACPA. For comparison, multivariable analysis in conventional UA patients showed that ACPA, RF, CRP and polyarthritis were all independently associated with sustained remission.
Conclusion: The contemporary UA population is different from conventional UA and risk factors for disease persistence are partly dissimilar. ACPA and CRP remain to be predictive in contemporary UA. Other factors included in the current EULAR recommendation were uninformative (RF, ESR, polyarthritis) or rare (erosions). Therefore, risk factors recommended in future EULAR recommendations may require alterations.

POS1408

AN ULTRASOUND NEGATIVE FOR SUBCLINICAL SYNOVITIS IN PATIENTS WITH ARTHRALGIA: IS IT HELPFUL IN IDENTIFYING THOSE WHO WILL NOT DEVELOP INFLAMMATORY ARTHRITIS? A LONGITUDINAL STUDY IN FOUR ARTHRALGIA COHORTS

C. Rogier[1], G. Frazzei[2], M. Kortekaas[3], M. Verstappen[3], S. Ohrndorf[4], E. Van Mulligen[1,3], R. Van Vollenhoven[5], D. Van Schaardenburg[2], P. De Jong[1], A. Van der Helm-van Mil[1,3]. *[1]Erasmus MC, Rheumatology, Rotterdam, Netherlands; [2]Reade Amsterdam, Amsterdam Rheumatology and immunology Center, Amsterdam, Netherlands; [3]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [4]Charité-Universitätsmedizin Berlin, Rheumatology and Clinical Immunology, Berlin, Germany; [5]Amsterdam UMC, Rheumatology, Amsterdam, Netherlands*

Background: Ultrasound (US) has become an established method in the evaluation of joints and is often used in clinical practice to guide management decisions in arthralgia-patients. To date, studies on the prognostic value of MSUS in arthralgia focused on the positive predictive value of subclinical inflammation. However, also the absence of imaging-detected subclinical synovitis is now increasingly used in daily practice to exclude arthralgia-patients from further follow-up. Though, evidence on the value of a negative US in ruling out future IA development in arthralgia-patients (the negative predictive value) is mostly absent. According to the rules of Bayes, predictive values are highly dependent on the prior-risk of developing the disease. The NPV therefore, is strongly related to the prior-risk of not getting IA, which is quite considerable in arthralgia-patients.
Objectives: To investigate the negative predictive value (NPV) of musculoskeletal ultrasound (MSUS) in arthralgia patients at risk for developing inflammatory arthritis (IA).
Methods: An MSUS examination of hands and feet was performed in arthralgia-patients at risk for IA in four independent cohorts. Patients were followed for one-year on the development of IA. Subclinical synovitis was defined as greyscale≥2 and/or power Doppler≥1. NPVs were determined and compared with the prior risks of not developing IA. Outcomes were pooled using meta-analyses and meta-regression analyses. In sensitivity analyses, MSUS-imaging of tender joints only (rather than the full US-protocol) was analyzed and ACPA-stratification applied, the latter being in line with the use of US in daily care.
Results: After one-year 78%, 82%, 77% and 72% of patients in the four cohorts did not develop IA. The NPV of a negative US was 86%, 85%, 82% and 90%, respectively. The meta-analysis showed a pooled non-IA prevalence of 79%(95%CI: 75%-83%) and a pooled NPV of 86%(95%CI:81-89%) (Figure 1). Imaging tender joints only (as generally done in clinical practice) and ACPA-stratification showed similar results.

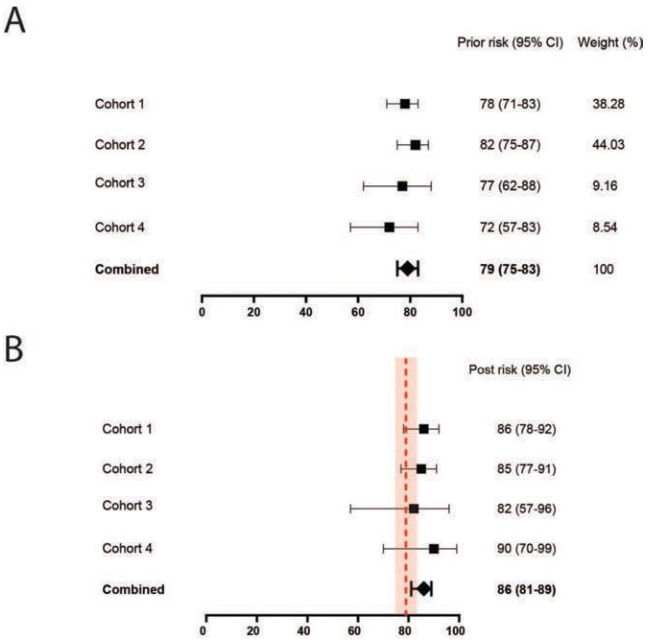

Figure 1. Full US protocol; Prior risks of not developing IA (A) and negative predictive values of MSUS (B) in the four cohorts. For comparison, the pooled prior risk and confidence interval from A are depicted in the red column in B.

Conclusion: A negative US result in arthralgia has a high NPV for not developing IA, which is mainly due to the high a-priori risk of not developing IA. The added value of a negative US (<10% increase) was limited.

POS1409

ASSOCIATION BETWEEN SHORT-TERM EXPOSURE TO ENVIRONMENTAL AIR POLLUTION AND PSORIASIS FLARE

G. Adami[1], F. Bellinato[2], A. Fassio[1], C. Benini[1], G. Girolomoni[2], P. Gisondi[2], M. Rossini[1]. *[1]University of Verona, Rheumatology Unit, Verona, Italy; [2]University of Verona, Dermatology Unit, Verona, Italy*

Background: Psoriasis is a chronic inflammatory disease with a relapsing-remitting course. Selected environmental factors such as infections, stressful life events or drugs may trigger disease flares. Whether the air pollution could trigger psoriasis flares is still unknown.

Objectives: To investigate whether the short-term exposure to environmental air pollution is associated to psoriasis flares.

Methods: Observational study with both case-crossover and cross-sectional design was conducted. We retrospectively analyzed longitudinal data from 2013 to 2020 of patients with psoriasis attending the outpatient dermatologic clinic of the University Hospital of Verona. For the case-cross over analysis patients with at least one disease flare, defined as PASI increase ≥5 between 2 consecutive assessments in a time frame of 3-4 months, were considered. In the case-crossover analysis each patient serves as its own control; the exposure of interest is compared in two different periods in the same group of patients followed longitudinally (Figure 1). For the cross-sectional analysis, patients receiving any systemic treatment for ≥6 months, with ≥2 consecutive PASI assessment were included. We compared the mean and cumulative (area under the curve) concentrations of several air pollutants (CO, NO2, NOx, C6H6, PM10 and PM2.5) in the 60 days preceding the psoriasis flare and the control visits.

Results: A total of 957 patients with plaque psoriasis with 4,398 follow-up visits were included in the study. More than 15,000 measurements of air pollutants concentration from the official, open-source, bulletin of the Italian Institute for Environmental Protection and Research (ISPRA) were retrieved. Among the overall cohort, 369 (38.6%) patients with psoriasis flare were included in the case-crossover study. We found that concentrations of all pollutants were significantly higher in the 60 days before psoriasis flare (median PASI at the flare 12, IQR 9-18), compared to the control visit (median PASI 1, IQR 1-3, p <0.0001). In the cross-sectional analysis, exposure to mean PM10 over 20 µg/m3 and mean PM2.5 over 15 µg/m3 in the 60 days before assessment were associated with a higher risk of PASI ≥5 point worsening, aOR 1.55, 95% CI 1.21-1.99 and aOR 1.25, 95% CI 1.0-1.57, respectively (Figure 1). Sensitivity analyses that stratified for trimester of evaluation, with various lag of exposure and adjusting for type of treatment yielded similar results.

Conclusion: Air pollution may be a trigger factor for psoriasis flare.

DEVELOPMENT OF PREDICTION MODELS FOR SENIOR PATIENTS WITH RHEUMATOID ARTHRITIS AND COMORBIDITIES TREATED WITH CHRONIC LOW-DOSE GLUCOCORTICOIDS IN THE GLORIA TRIAL

L. Hartman[1,2], J. A. P. Da Silva[3], F. Buttgereit[4], M. Cutolo[5], D. Opris-Belinski[6], Z. Szekanecz[7], P. Masaryk[8], M. Voshaar[9], M. W. Heijmans[2], W. Lems[1], D. Van der Heijde[10], M. Boers[1,2]. *[1]Amsterdam University Medical Centers, Vrije Universiteit, Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [2]Amsterdam University Medical Centers, Vrije Universiteit, Department of Epidemiology & Data Science, Amsterdam, Netherlands; [3]Faculdade de Medicina e Hospitais da Universidade de Coimbra, Reumatologia, Coimbra, Portugal; [4]Charité – University Medicine Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany; [5]University of Genova, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Genova, Italy; [6]Carol Davila University, Rheumatology, Bucharest, Romania; [7]University of Debrecen Faculty of Medicine, Department of Rheumatology, Institute of Medicine, Debrecen, Hungary; [8]National Institute for the Rheumatic Diseases, Rheumatology, Piešťany, Slovakia (Slovak Republic); [9]Tools Patient Empowerment, Amsterdam, Netherlands; [10]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) is a systemic, inflammatory disease primarily located in the joints resulting in pain, joint damage, functional disability and reduced quality of life. Treatment of RA is essential to prevent these outcomes, but the treatment itself may also result in adverse events and comorbidity [1]. Although many investigators are working on personalized medicine [2], better models to predict harm and benefit from a certain drug need to be developed before they can be used in daily clinical practice [3].

Objectives: To develop prediction models for individual patient harm and benefit outcomes in senior patients with RA and comorbidities treated with chronic low-dose glucocorticoid therapy or placebo.

Methods: In the GLORIA trial 451 RA patients aged 65+ were randomized to 2 years 5 mg/day prednisolone or placebo. Eight prediction models were developed from the dataset in a stepwise procedure. In preparation, to limit excessive statistical testing and false positive results, possible predictors were grouped into five predictor sets based on prior knowledge (Table 1). The first set of four models disregarded study treatment and examined general predictive factors. The second set of four models was similar but examined the additional role of study treatment, as main factor and as interaction factor with other predictive variables. In each set two models focused on harm (1: occurrence of ≥1 adverse event of special interest (AESI); 2: number of AESIs per year) and two on benefit (3: early clinical response–disease activity; 4: lack of joint damage progression). AESI comprised all serious adverse events, events leading to discontinuation of study treatment, and events related to glucocorticoid exposure (see main GLORIA study abstract). Linear and logistic multivariable regression methods with backward selection were used to develop the models. The final models were assessed and internally validated with bootstrapping techniques, and their performance was evaluated with model fit and discrimination measures.

Table 1. Predictor sets.

Personal factors	Disease factors	Comorbidities
Age	DAS28	Active comorbidity: cont, dich,
Sex	RA duration	GC-related
Education	RF	Prior comorbidity: cont, dich,
Smoking	Anti-CCP	GC-related
Alcohol	Damage (cont, dich)	# comorbidity medications
BMI	Coping RA	Joint surgery
Blood pressure	Impact RA	# patient symptoms
Medication	Health and daily functioning	
# concomitant medications	HAQ	
Previous use DMARD, bDMARD, GC	QoL	
Current use bDMARD	VAS health	
Adherence	SF36 physical, mental	
Switch antirheumatic drugs		

cont=continuous; dich=dichotomous; GC=glucocorticoid.

Results: Study treatment (i.e. prednisolone) was highly predictive as a main factor in models 5-8, increasing the risk of both benefit and harm. In addition, a few additional variables were slightly (but not relevantly) predictive for the outcome in one of the models (Figure 1). Their association was much weaker than that of study treatment. In three instances, prednisolone interacted with another predictive factor (see Figure 1). The quality of the prediction models was sufficient, the performance low to moderate: explained variance: 12-15%, AUC 0.67-0.69.

Figure 1. Baseline predictive factors for benefit and harm (other than prednisolone), and their interaction with prednisolone.
For benefit red means less benefit, for harm red means increase of harm.

To predict: / Baseline predictive factor:	Benefit*		Harm			
	Early response	No damage progression	≥1 AESI	Prednisolone effect	# AESIs	Prednisolone effect
More prior comorbidities						
More medication						
More joint damage				neutralized		
More adherence						decreased
No change of antirheumatic treatment at baseline						
No prior treatment with biologicals						
Prior occurrence of GC-related comorbidity						
More disability (HAQ)						

*For benefit prednisolone showed no interaction with other predictive variables.
AESI=adverse event of special interest; GC=glucocorticoid; HAQ=health assessment questionnaire.

Conclusion: Baseline factors are not helpful to select senior RA patients for treatment with low-dose prednisolone given their low power to predict the chance of benefit or harm.

POS1411

ARTIFICIAL INTELLIGENCE FOR IDENTIFYING NEW DISEASE CLUSTERS IN PATIENTS WITH PSORIATIC ARTHRITIS/PSORIASIS: A PROOF-OF-CONCEPT STUDY

P. Nishtala[1], N. Mchugh[1], W. Tillett[1], S. Skeoch[2], J. Humphreys[3], J. Pauling[2], O. Isupova[4], A. Mcgrogan[1], J. Snowball[1], S. Roy[5]. *[1]University of Bath, Pharmacy and Pharmacology, Bath, United Kingdom; [2]Royal United Hospital, Rheumatology, Bath, United Kingdom; [3]The University of Manchester, Division of Musculoskeletal & Dermatological Sciences, Manchester, United Kingdom; [4]University of Bath, Computer Science, Bath, United Kingdom; [5]University of Bath, Mathematical Sciences, Bath, United Kingdom*

Background: Psoriatic arthritis (PsA)/Psoriasis (PsO) patients present with multiple long-term conditions (MLTCs), and more than half of PsA patients have ≥1 LTC, which have an impact on the quality of life. We used the Clinical Practice Research Datalink (CPRD) in the UK to determine multimorbidity in patients with PsA/PsO. CPRD is a database of routinely collected UK patient data that can be used to examine multimorbidity over the life course of the disease. A understanding of clusters and timing may allow the development of tailored programmes for surveillance and early interventions to reduce MLTcs in PSA/PO.

Objectives: The overall objective of our study was to use CPRD to identify and interpret new and frequently-occurring disease clusters in the PsA/PsO population.

Methods: We identified PsA/PsO patients from the CPRD GOLD for the UK from 2009 to 2018 with at least one year of follow up but excluded patients in practices that had migrated to Aurum, a different electronic health record system held by CPRD. All patients were matched to controls at a 1: 4 ratio by age, sex, practice. We analysed 40 common MLTCs outlined by Barnett et al. to identify and interpret multimorbidity clusters. Multimorbidity clusters were identified using the network bi-clustering. Our methodology can be divided into three steps- (a) Separate the "case" and the "control" population, (b) Create a patient-condition matrix for each of "case" and "control" population and (c) From the patient-condition matrix in each case use a the Euclidean distance criterion to compute a similarity matrix of all the possible conditions among those patients.

Results: We identified 67,827 incident or prevalent PsA/PsO patients aged 20 years and above who were matched to 271,308 controls by age, sex and practice (Table 1). The median number of long-term conditions (LTCs) was higher in the cases than in the controls.

Table 1.

Characteristic	CASE, N = 67,827	CONTROL, N = 271,308
Age Group, n (%)		
<20	6,491 (9.6%)	27,897 (10%)
20-54	42,357 (62.4%)	169,008(62.3%)
55 and above	19,148 (28.2%)	74,403 (27.4%)
Ethnicity, n (%)		
White	28,200 (41.6%)	93,485 (34.5%)
Black, S.Asian and other	956 (1.4%)	3,735 (1.4%)
Unknown	38,671 (57%)	174,088(64.2%)
Sex, n (%)		
F	35,431 (52%)	141,724 (52%)
BMI category, n (%)		
20 to <25	11,183 (16.5%)	43,240 (15.9%)
25 to <30	13,565 (20%)	45,783 (16.9%)
30 to <35	7,584 (11.2%)	22,690 (8.4%)
35 to 40	3,048 (4.5%)	8,172 (3.0%)
Alcohol status, n (%)		
Non-drinker/ Ex-drinker	8,649/2,159 (15.9%)	33,983/7,579 (15.3%)
Drinker/Heavy drinker	47,316/3,030 (74.2%)	180,888/8,831 (69.9%)
Smoking status, n (%)		
Ex-smoker/Non-smoker	14,137/29,289 (64%)	48,110/142,295 (70.2%)
Smoker	24,018 (35%)	71,779 (26%)
Long term condition, Median (IQR)	1.00 (0.00, 3.00)	1.00 (0.00, 2.00)

We present the results obtained via spectral clustering on the similarity matrix obtained in each “case” and “control” population via Euclidean distance. There are 40 LTCs which are represented via two clusters in the “case” and the “control” population network (Figure 1). The LTCs in the same cluster are strongly connected within themselves compared to those in the other cluster. The noticeable part was clustering of diabetes, hypertension and chronic heart diseases in one group, especially in the “case” population over the “control” population. Interestingly depression, dementia and chronic heart diseases were in the same group in the clustering results for both the “case” and the “control” population. There are a central group of diseases (HYP, DEM, DIV, CHD etc.) in Figure 1, which seems to be connected with both sets of clusters. As mentioned earlier, diabetes has connections with these central groups of diseases, and it tends to be more pronounced in the “case” population.

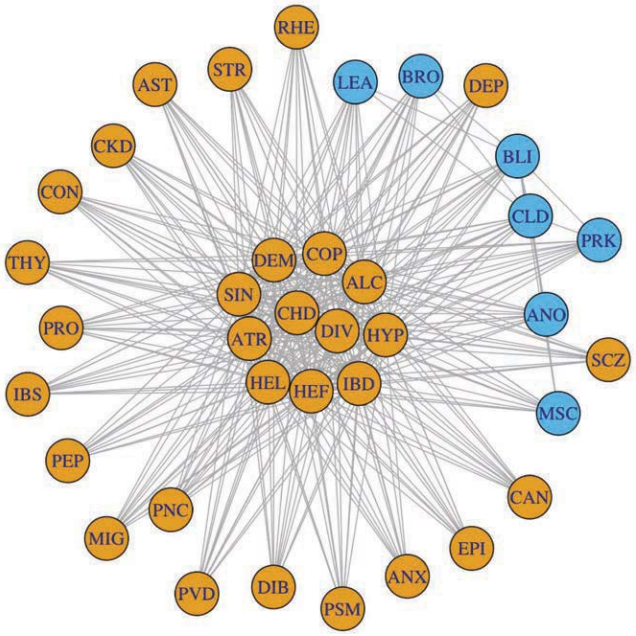

Figure 1.

Conclusion: MLTCs including diabetes, hypertension, chronic kidney disease and heart disease occurred together more commonly in patients with PsA/PsO than those without PsA/PsO.

The future goal is to identify frequently occurring clusters of MLTCs in the immune-mediated inflammatory disease population.

Background: In cancer immunotherapy, T-lymphocyte activation can lead to secondary autoimmune diseases named OASI for Opportunistic Autoimmunity Secondary to cancer Immunotherapy [1]. The epidemiology of OASI deserves to be further studied due to the unadapted reporting of clinical trials and the lack of prospective studies. Moreover, literature focuses on the most severe OASI and/or on specific OASI (myocarditis, colitis, arthritis).

Objectives: Our goal was to determine incidence, severity of all grade OASI using a multicentric prospective patient cohort starting treatment with cancer immunotherapy.

Methods: We present a multicentric, prospective, observational, longitudinal, real life, French e-cohort. 900 patients treated with ipilimumumab and/or nivolumab will be included. Data is collected from the patient and the oncologist at inclusion, then patients report directly any symptom that could be suggestive of OASI with the help of monthly digital questionaries. In case an OASI is suspected, further confirmation is made with the practician in charge and by a paired analysis with the Système National De Santé (SNDS), the French health insurance registry.

Results: On the 19/01/2022, 439 patients were included, 310 males (70.6%) and 129 females (29.4%). Mean age is 66 years old with a median follow up of 192 days. 354 patients (80.6%) are treated with Nivolumab alone, 7 (1.6%) with Ipilimumab alone and 76 (17.8 %) with combined Nivolumab + Ipilimumab. 136 patients (31.6%) are treated for a non-small cell lung carcinoma, 107 patients (24.9%) for a clear cell renal carcinoma, 91 patients (21.2%) for a skin melanoma, 49 patients (11.4%) for a head or neck epidermoid carcinoma, 24 patients (5.6%) for another lung cancer sub-type, and 32 patients (5.3%) for another histological cancer type. The mean follow-up is 294 days (+/- 192). 83 patients (18.9%) died since the beginning of the follow up.

47 patients (10.7%) developed 63 OASI. The mean delay between the beginning of cancer immunotherapy and the OASI is 134.7 days (+/- 103.4).

Approximately, one third of the OASI were musculoskeletal diseases. The OASI included polymyalgia rheumatica (3 patients), psoriatic arthritis (1 patient), polyarthritis (1 patient) systemic lupus (1 patient), arthralgias and myalgias (8 patients), colitis (11 patients), dysthyroïditis (6 patients), hepatitis (4 patients), nephritis (3 patients), pneumonitis (2 patients), hypophysitis (2 patients), adrenal insufficiency (4 patients), myocarditis (1 patient), hemophagocytic lympho-histiocytosis (1 patient), and other types of OASI (15 patients).

26 patients (55% of patients with OASI, 5,9% of all patients) had to stop cancer immunotherapy due to an OASI, one because of a rheumatic disease (systemic lupus). 52 patients were treated with corticosteroids, 1 patient with methotrexate (psoriatic arthritis), 3 patients with infliximab (colitis) and 1 patient with abatacept (myocarditis). 1 patient died after an OASI (colitis).

Conclusion: The first results of this prospective study, using an original patient-centered methodology, confirm the expected incidence of autoimmune events secondary to cancer immunotherapy and the role of rheumatologists in their therapeutic management.

POS1413 INTERSTITIAL LUNG DISEASE(ILD) PREVALENCE AND TRENDS IN SYSTEMIC LUPUS ERYTHEMATOSUS(SLE), RHEUMATOID ARTHRITIS(RA), SCLERODERMA(SCL), MYOSITIS AND MIXED CONNECTIVE TISSUE DISEASES(MCTD) ALONG WITH COMPARISON OF LENGTH OF HOSPITALIZATION STAY(LOS), COST AND RACIAL PREDISPOSITION AMONG THESE PATIENTS

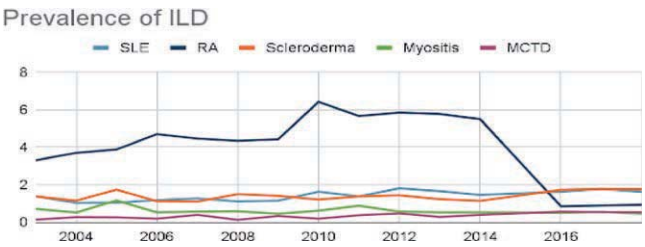
A. Hussain[1], P. Khandwala[1], D. Desai[1]. *[1]Crozer-Chester Medical Center, Internal Medicine, Upland, United States of America*

Background: ILD includes a category of lung disorders seen in a variety of autoimmune conditions. Prevalence of ILD in autoimmune diseases is variable and poorly studied. ILD is more commonly seen in systemic sclerosis, with 90% of patients showing some interstitial changes on High resolution CT scan. ILD is less common in SLE compared to SCL, with ILD not only a complication but also a poor prognostic factor in these patients. Prior studies have shown increased prevalence of ILD in RA patients over the years. For myositis, ILD can develop during the course of disease or can precede the diagnosis in a small subset of patients.

Objectives: Our study aims to determine the prevalence of ILD in diseases like SLE, Scleroderma, RA, MCTD, and Myositis over the years as well as identify racial predisposition, LOS, Cost of hospitalization in these patients

Methods: We used the Nationwide Inpatient Sample database (years 2003-2018) and extracted patients with ILD using validated International Classification of Disease (ICD) codes. Data from 2015 was excluded from the study in light of the transition of the coding system from version 9 to 10. We identified cases having the diagnosis of SLE, RA, Scleroderma, MCTD or Myositis. Prevalence as well as demographics, cost of hospitalization, and length of stay (LOS) was analyzed and charted. Data was analyzed using statistical analysis system 9.4 software.

Results:



We identified a total of 149,691 cases of ILD over 15 years. Patients with RA had the highest prevalence of ILD amongst the 5 studied autoimmune diseases. The prevalence rate of RA in ILD patients in 2003 was 3.3% which significantly reduced to 0.93% in 2018, with a peak of 6.42% seen in 2010 (p <0.0001). Prevalence rate of ILD with myositis decreased from 0.72% in 2003 to 0.46% in 2018 (p 0.0001). The prevalence rates of SLE, Scleroderma, and MCTD in cases with ILD significantly increased from 1.38% to 1.63%, 1.38% to 1.76%, and 0.14% to 0.54% from 2003 to 2018 respectively.

The average age of ILD cases with SLE was significantly younger compared to ILD without autoimmune disease (59.28 vs 72.32 years, p <0.0001), RA (69.72 vs 72.17 years, p <0.0001), Scleroderma (62.01 vs 72.28 years, p < 0.0001), Myositis (59.56 vs 72.19 years, p <0.0001) and MCTD (59.6 vs 72.18 years, p <0.0001). On examining the racial distribution, the African American population with ILD when compared to other races were more likely to have underlying SLE, MCTD, Myositis or Scleroderma. In ILD with RA, Native Americans were the most affected racial demographic followed by African Americans.

Average cost of hospitalization was higher in ILD with MCTD ($104,631 vs $71,264.6, p<0.0001), Myositis ($105,623 vs $71,232.9, p<0.0001) and Scleroderma ($88,736.2 vs $71,135.5, p<0.0001). Average LOS was significantly longer in RA (7.17 vs 6.66 days, p value 0.0006), MCTD (7.71 vs 6.67 days, p value 0.0008), Myositis (8.33 vs 6.66 days, p value <0.0001) and Scleroderma (7.07 vs 6.67 days, p value 0.0176). Though not significant, average LOS was longer in SLE (6.79 vs 6.67 days, p value 0.4999).

Conclusion: Our study shows that the prevalence of RA in ILD cases has significantly reduced through the years. This can be attributed to the better understanding of the disease and its risk factors as well as the availability and use of newer biologic agents to obtain better control. However, the prevalence of SLE, Scleroderma, and MCTD in ILD cases has increased over the years. This points to the need for better therapies as well as highlights the fact that the overall recognition and diagnosis of these diseases have increased over the years. Racial predilection also comes to light, suggesting the need for special attention to certain races to diagnose the autoimmune disease earlier. Average LOS and cost of hospitalization were also higher in ILD cases with autoimmune disease, reflecting the higher socioeconomic burden.

POS1414 RISK OF CANCER IN CONNECTIVE TISSUE DISORDERS IN THE NORTH EAST OF ITALY OVER 15 YEARS OF FOLLOW-UP

E. Treppo[1], F. Toffolutti[2], V. Manfrè[1], M. Taborelli[2], S. De Vita[1], D. Serraino[2], L. Quartuccio3. *[1]Division of Rheumatology, Department of Medicine, Udine, Italy; [2]Centro di Riferimento Oncologico (CRO), Unit of Cancer Epidemiology, Aviano, Italy; [1]Division of Rheumatology, Department of Medicine, Udine, Italy*

Background: Connective tissue diseases (CTD) include systemic lupus erythematosus (SLE), Sjögren's syndrome (SS), systemic sclerosis (SSc), polymyositis (PM), and dermatomyositis (DM). CTD are characterized by dysfunction of the immune system that leads to the loss of tolerance to self-antigens [1]. Shared genetics, environmental factors, medical treatment of autoimmune diseases and dysregulated immune function have led to speculation of an elevated cancer incidence in patients with autoimmune diseases [2].

Objectives: The present study aimed to evaluate the cancer risk associated with the most relevant CTD in the northern Italian region of Friuli Venezia Giulia over the years 2002-2017. The primary objective was to determine whether the risk of malignancy was higher among these rheumatic conditions than the age- and sex-corresponding general population.

Methods: A retrospective population-based cohort study was conducted using data from healthcare databases of the Friuli Venezia Giulia region, north-east of Italy (1,206,000 inhabitants). Information on demographic characteristics, hospital discharges, exemption from medical charges, drug prescriptions, were individually matched with data from the population-based cancer registry. The cancer risk was assessed in people diagnosed with the following diseases: SLE, SS, SSc, PM, and DM. To compare the cancer incidence in the cohort with the general population, Standardized Incidence Ratios (SIRs) were calculated as the ratio between the observed and the expected number of cancer cases. The cohort included subjects resident in the Friuli Venezia Giulia region, diagnosed with at least one of the following diseases: SLE, SSc, SS, DM, and PM. To guarantee the highest homogeneity and comparability of the exemptions codes, the analysis was restricted to the years 2002-2017.

Excluding criteria were: (1) follow-up shorter than 90 days; (2) concurrent diagnoses of rheumatoid arthritis (RA), psoriatic arthritis or ankylosing spondylitis; (3) ever use of biologic drug specific to treat RA (with the exception of rituximab), psoriatic arthritis or ankylosing spondylitis.

The patients were observed starting from 90 days after the first date when the diagnosis was mentioned in hospital discharges or exemptions, and they were followed until cancer diagnosis, death, change of regional residence, or December 31, 2017, whichever came first.

For the aim of this study, we excluded from the analysis NMSC (ICD-10: C44) and diagnoses based on autopsy only or Death Certificate Only.
Results: 2504 patients were followed-up for a total of 18,006 person-years (median follow-up: 6.8 years). After 5 and 10 years of follow-up, the cumulative cancer incidence was 2.6% and 8.5%, respectively. The most common cancers were breast (n=34), lung (n=24), colon-rectum-anus (n=20), and non-Hodgkin lymphomas (NHL) (n=20). Overall, no excess cancer risk was noted (SIR=0.87, 95% CI: 0.75-1.00), whereas the number of observed NHL cases was more than two-fold significantly higher than expected (SIR=2.52, 95% CI: 1.54-3.89). The subgroup analysis showed a higher risk of NHL among SS patients (SIR=3.84, 95% CI: 1.92-6.87) and SLE patients (SIR=2.69, 95% CI: 0.99-5.84). Conversely, the study population showed a decreased risk for cancers of breast (SIR=0.61, 95% CI: 0.42-0.85) and corpus uteri (SIR=0.21, 95% CI: 0.03-0.77).
Conclusion: The incidence of NHL was higher among patients with SS and SLE. A careful surveillance for haematological malignancies in these patients is recommended. The lower risk of cancer for breast and corpus uteri in CTD indirectly supports cancer screening programs and highlights the role of the continuous clinical follow-up for these chronic conditions.

POS1415 A MACHINE LEARNING ANALYSIS OF FACTORS PREDICTING ORGAN DAMAGE PROGRESSION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS USING THE SPANISH SOCIETY OF RHEUMATOLOGY LUPUS REGISTRY (RELESSER)

J. M. Pego-Reigosa[1], W. Fakhouri[2], S. Díaz-Cerezo[3], A. Cooper[4], A. M. Saunders[5], G. Segall[5], C. Sapin[6], S. Moyano[3], I. Rua-Figueroa[7]. *[1]University Hospital Complex of Vigo. IRIDIS (Investigation in Rheumatology and Immune-Mediated Diseases)-VIGO Group, Galicia Sur Health Research Institute (IISGS), Rheumatology Department, Vigo, Spain; [2]Eli Lilly and Company Ltd, Value, Evidence, and Outcomes (VEO), Bracknell, United Kingdom; [3]Eli Lilly and Company Ltd, Medical Affairs, Madrid, Spain; [4]IQVIA, Real World Solutions (RWS), London, United Kingdom; [5]IQVIA, Integrated Real World Evidence & Solutions (IRES), London, United Kingdom; [6]Eli Lilly and Company Ltd, Statistics-Europe, Neuilly Sur Seine, France; [7]Doctor Negrin University Hospital of Gran Canaria, Rheumatology Department, Las Palmas de Gran Canaria, Spain*

Background: Evidence shows that around half of the patients with systemic lupus erythematosus (SLE) develop irreversible organ damage due to the disease itself or to other factors (e.g., steroid treatment). It is essential to have a comprehensive understanding of factors that predict organ damage progression to identify at-risk patients and inform clinical decision making.
Objectives: To develop an algorithm, using machine learning (ML) methodology, that predicts organ damage progression in SLE patients.
Methods: The Spanish Society of Rheumatology Lupus Registry (RELESSER) with patient records from 45 Rheumatology Units across Spain was used. RELESSER data were collected from 2011 to 2021 and captured demographic and comprehensive clinical information. In this analysis, a sample of 2,676 patients was used. The Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) was used to measure organ damage progression between 2015 (start of the prospective data collection in RELESSER) and 2020.To predict the risk of an increase in the SDI, 102 variables were identified as potential predictors. A ML model (gradient boosting trees) was developed and validated by a simple logistic regression (LG) model. The area under the receiver operating characteristic curve (AUCROC) was used to quantify the improvement over random chance (an AUCROC of 0.5). Shapley Additive Explanation (SHAP) values were used in the ML model to identify predictors and their contribution to damage progression.
Results: Of all patients, 13% experienced organ damage progression, with 2-year patient follow-up. The ML algorithm was better at identifying these patients (AUCROC 0.68) than the LG model (AUCROC 0.63) (Figure 1). ML model performance can be contextualized using a random sample of 100 SLE patients of whom 13 suffered organ damage progression, the model would successfully identify 12. However, 66 additional patients would be incorrectly identified (True Positive 90%; False Positive 79%). The top 5 predictors of damage progression, across all patients, were patient age >49 years,

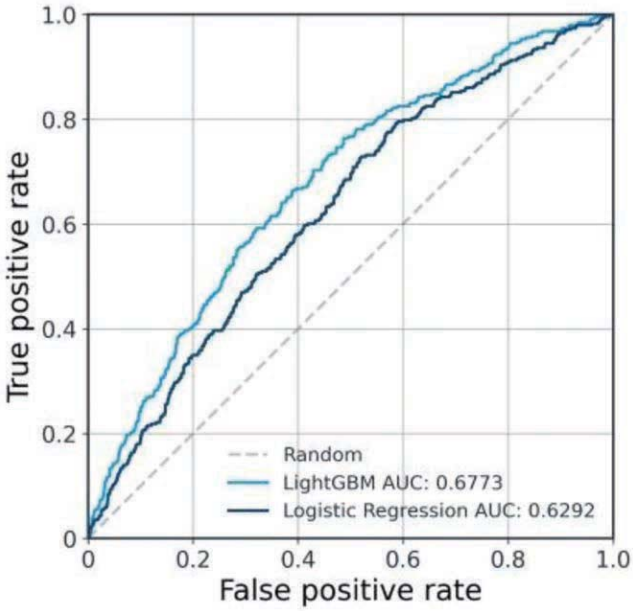

Figure 1. ROC AUC plot

Creatinine > 0.9 mg/dl, cardiovascular-related disease complications (> 3 complications), low hematocrit level recorded recently (<41.9 months ago), and triglycerides > 81.5 mg/dl. At the patient level, the 5 patients with the highest predicted risk had strong predictors of progression, with key predictors being patient age at study entry >49 years, age at diagnosis >40 years, cardiovascular-related disease complications, and increased creatinine >0.9 mg/dl. The 5 patients with the lowest predicted risk had strong predictors of no change with key predictors being not having a low hematocrit level recorded recently, triglycerides <81.5 mg/dl and patient age at study entry <49 years.
Conclusion: We developed a machine learning model, using an exhaustive set of variables in RELESSER which successfully predicted short-term organ damage progression in SLE patients, and outperformed a standard regression model. If the model were to be used as a clinical tool, only light-touch interventions should be carried out due to high false positive rate. Further model optimizations, including exposing the model to longer follow-up data and testing it in non-Spanish patients is needed.

POS1416 LONG-TERM OUTCOME OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE); DATA FROM THE LARGE POPULATION-BASED SOUTHEAST SLE COHORT (NOR-SLE)

S. R. Moe[1], H. Haukeland[1,2], T. Garen[1], A. Orre[3], G. Wivestad[4], T. Bøe[5], H. Øvreås[6], A. Botea[7], N. Damjanic[2], Ø. Molberg[1,8], K. Lerang[1]. *[1]Oslo University Hospital, Rikshospitalet, Department of Rheumatology, Oslo,*

Norway; [2]Martina Hansens Hospital, Department of Rheumatology, Gjettum, Norway; [3]Vestre Viken HF, Department of Rheumatology, Drammen, Norway; [4]Sørlandet Hospital Kristiansand, Department of Rheumatology, Kristiansand, Norway; [5]Hospital Vestfold, Department of Internal Medicine, Tønsberg, Norway; [6]Revmatismesykehuset, Department of Rheumatology, Lillehammer, Norway; [7]Betanien Hospital, Department of Rheumatology, Skien, Norway; [8]University of Oslo, Institute of Clinical Medicine, Oslo, Norway

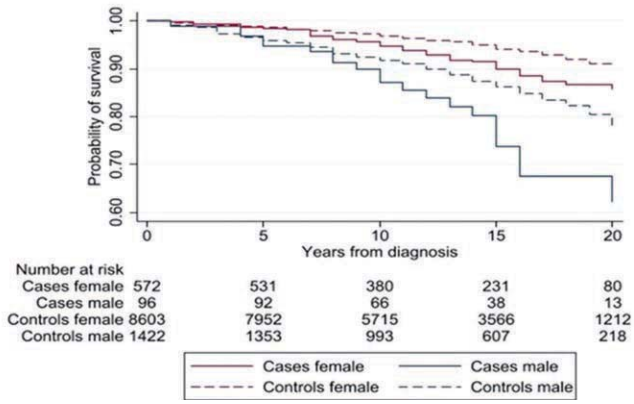
Background: Population-based studies on Systemic Lupus Erythematosus (SLE) patients with a verified diagnosis is considered the gold standard to find true outcomes in SLE, but few population-based SLE cohorts have follow-up over 15 years [1]. Norway is among the few countries worldwide where social and structural factors facilitate the gathering of complete population-based cohorts in rare disease like SLE due to its healthcare organization.
Objectives: To examine long-term outcome of SLE in a population-based setting and determine if immediate cause of death differs between SLE patients and the general population.
Methods: The study included all SLE patients who were resident in the South-east region of Norway during 1999 - 2017 and met the 1997 American College of Rheumatology classification criteria for SLE. All SLE diagnosis was confirmed by chart review. SLE patients and 15 controls for each case (matched by age, gender and ethnicity) were linked to the Norwegian Cause of Death Registry. We examined survival by means of Kaplan-Meyer estimates and used log rank test to test for differences. To estimate risk of death, we performed calculations of standard mortality rate (SMR) by dividing the number of deaths on the number of years observed. The excepted number of deaths referred to the number of deaths for the matched control group. All SLE cases were included in SMR. The 95 % confidence interval (CI) of SMR was calculated with Mid-P exact test. We defined immediate cause of death as the final event directly leading to death. An International Classification of Diseases 10th revision code of I00-99 or R96 classified as death from cardiovascular disease (CVD) (except pulmonary embolism and cerebral bleeding) and of infections A00-B99, J10-18, N39, M86 or U07.
Results: We identified 1298 SLE patients in the region, of whom 673 was incident cases; all captures within one year from diagnosis. Of the incident cases, 76 (11%) died during 8434 years of follow-up (Table 1). The five-, ten-, 15- and 20-year survival for incident SLE patients (controls) was respectively 98 (98), 94 (96), 87 (94) and 82 (88) % and differed significantly first after ten years of disease duration compared to controls. Figure 1 shows 20-year survival for incident SLE patients and matched controls; stratified by gender. SMR for all SLE cases was 2.3 (95 % CI 1.5. - 4.0); female SLE 2.5 (95 % CI 1.6 – 3.9) and male SLE 1.9 (95 % CI 1.3 – 2.2). The most common immediate cause of death in SLE patients was CVD; whereof myocardial infarction (21 %) was most frequent. SLE patients died more often of CVD than controls (29 % vs. 21 %, p = 0.01) and had a tendency to more infections (23 % vs. 18 %, p = 0.07), whereof pneumonia (58 %) was most frequent.

Table 1. Patient demographics, follow-up time and number of deaths in the total Systemic Lupus Erythematosus (SLE) cohort and in incident SLE patients.

	Total SLE cohort	Incident SLE	
		Female	Male
	n = 1298	n = 577	n = 96
Of European descent, n (%)	1140 (88)	472 (82)	86 (90)
Juvenile onset[a], n (%)	93 (7)	31 (5)	6 (6)
LN[b], n (%)	470 (36)	177 (30)	49 (51)
Cumulative ACR criteria[c], μ (SD)	5.4 (1.2)	5.3 (1.2)	5.1(1.1)
Follow-up years, total	19252	6160	1217
Deaths, n (%)	282 (23)	54 (9)	22 (23)
Age at diagnosis, years μ (SD)	35.5 (15.7)	37.4 (15.6)	44 (17.9)
Disease duration at death, years μ (SD)	20.4 (12.5)	9.6 (5.8)	10.6 (10.5)

μ: mean, n: number, SD: standard deviation[a] Diagnosed before age of 16 [b] Lupus Nephritis defined by 1999 American College of Rheumatology classification criteria for Systemic Lupus Erythematosus [c]1997 American Collee of Rheumatology classification criteria for Systemic Lupus Erythematosus

Figure 1. **Estimated 20-year survival in Systemic Lupus Erythematosus patients compared to controls; stratified by gender.**



Conclusion: Mortality in SLE is substantially increased. Differences in survival compared to the general population only appear after ten years of disease duration. CVD was the most common immediate cause of death and more frequent in SLE patients.

POS1417

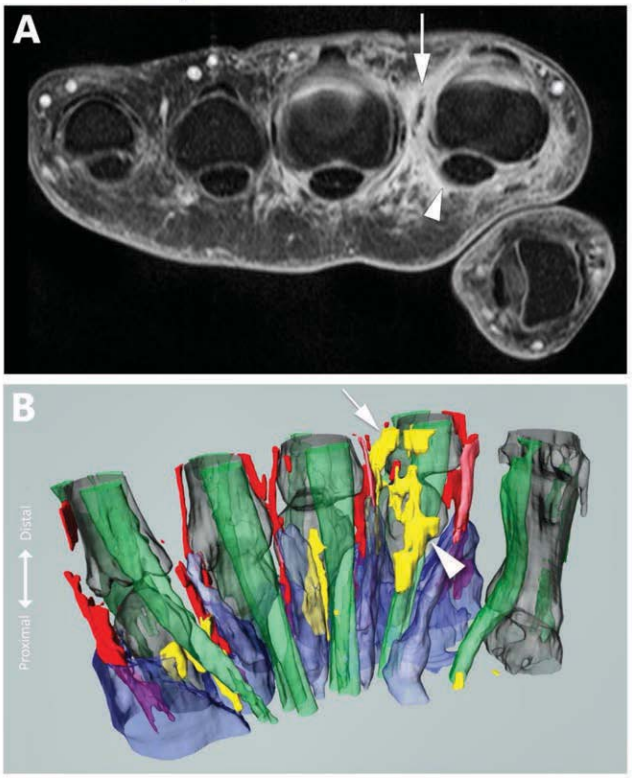
INTEROSSEOUS TENDON INFLAMMATION IN THE HANDS: A NOVEL FEATURE OF DEVELOPING RHEUMATOID ARTHRITIS? RESULTS FROM A LARGE MRI STUDY IN CLINICALLY SUSPECT ARTHRALGIA

B. Van Dijk[1], H. W. Van Steenbergen[1], M. Reijnierse[2], S. Khidir[1], L. J. Wisse[3], M. C. Deruiter[3], A. Van der Helm-van Mil[1]. *[1]Leiden University Medical Centre (LUMC), Rheumatology, Leiden, Netherlands; [2]Leiden University Medical Centre (LUMC), Radiology, Leiden, Netherlands; [3]Leiden University Medical Centre (LUMC), Anatomy & Embryology, Leiden, Netherlands*

Background: Inflammation around the tendons of the hand interosseous muscles (interosseous tendon inflammation; ITI) on MRI was recently reported in rheumatoid arthritis (RA) patients and in ACPA-positive individuals with musculoskeletal symptoms. We therefore hypothesized that ITI is an early RA-feature that precedes clinical arthritis.
Objectives: To examine this we assessed the frequency of ITI in clinically suspect arthralgia (CSA) patients and compared this to the frequency in the general population. Additionally we investigated the relation between ITI and other locally inflamed tissues (synovitis/tenosynovitis/osteitis) in MCP-joins of CSA patients as well as the association with future arthritis development.
Methods: 667 consecutive patients presenting with CSA and 193 symptom-free controls from the general population underwent contrast-enhanced hand-MRI. MRIs were evaluated for ITI and for synovitis/tenosynovitis/osteitis, using the rheumatoid arthritis MRI scoring system (RAMRIS). CSA patients were followed for clinical arthritis development (median follow-up 25 months). Logistic and Cox-regression were used. ACPA-stratification was performed. To gain a better understanding of the anatomical relationships, 3D MRI-reconstruction of the interosseous and lumbrical muscles and tendons was performed in a patient with ITI.
Results: At presentation, 10% of CSA patients had ITI, compared to 1% of symptom-free controls (p<0.001). ITI was more frequent in ACPA-positive than ACPA-negative CSA (27% versus 7%; p<0.001). 72% of patients with ITI also had synovitis and/or tenosynovitis at the MCPs (37% synovitis; 7% tenosynovitis; 27% both synovitis and tenosynovitis). Also in multivariable analyses, adjusted for simultaneous presence of synovitis/tenosynovitis/osteitis, ITI was more likely if synovitis (OR 2.2 (95%CI 1.2-4.2)) or tenosynovitis (9.7 (5.5-17.0)) was present at MCPs. The 3D MRI-reconstruction indicated that ITI is continuous with MCP flexor tenosynovitis (Figure 1). CSA patients with ITI developed arthritis

more frequent than those without (HR 4.5 (2.8-7.2)); this relation was stronger in ACPA-negative (3.9 (1.9-7.9)) than ACPA-positive CSA (1.8 (0.9-3.4)).

Figure Example MR-image (A) and 3D MRI-reconstruction (B) at the level of the MCP-joints in a CSA-patient with ITI continuous with flexor tenosynovitis at the 2nd MCP-joint



Legend

(A&B)	Arrows:	ITI
	Arrowheads:	flexor tenosynovitis
(B)	Yellow:	inflammation around interosseous and flexor tendons
	Grey:	metacarpal bones and phalanges
	Red:	interosseous tendons
	Green:	flexor/extensor tendons of the fingers
	Blue:	interosseous and lumbrical muscles

Conclusion: ITI is present in CSA and precedes clinical arthritis, suggesting that this peritendinous inflammation is an early RA-feature.

POS1418 SEPARATING THE EFFECTS OF CHILDHOOD AND ADULT BODY SIZE ON INFLAMMATORY ARTHRITIS: A MENDELIAN RANDOMISATION STUDY

S. S. Zhao[1], J. Bowes[2], A. Barton[2], G. Davey Smith[3], T. G. Richardson[3]. *[1]The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [2]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom; [3]University of Bristol, Population Health Sciences, Bristol, United Kingdom*

Background: Obesity is strongly associated with inflammation and inflammatory arthritis, but most studies to date have only examined adulthood body mass index (BMI). Whether childhood obesity has a direct and long-term influence on risk of inflammatory arthritis is unclear. This question is important as childhood obesity becomes a growing and global public health crisis [1], but traditional epidemiologic approaches may be limited by reverse causation (obesity can be cause and consequence of disease) and confounding. Mendelian randomisation (MR) uses genetic variants as instrumental variables to estimate the effect of an exposure on an outcome. Since variants are randomly allocated at conception, MR is less susceptible to reverse causation and confounding.

Objectives: To examine whether childhood body size affects risk of inflammatory arthritides – rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), gout and systemic lupus erythematosus (SLE) – after accounting for the effect of adult body size using two-sample univariable and multivariable MR.

Methods: Genetic instruments for childhood (age 10 years) and adult body size were derived using data from 453,169 individuals from the UK biobank study (313 and 580 variants respectively; r^2<0.001, p<5x10^{-8}), which have been previously validated using BMI data from three independent populations [2]. Participants recalled their body size at age 10 as "thinner", "about average" or "plumper". Adult body size was determined using BMI at a mean age of 57 years and, to facilitate comparison, split into three groups to match the proportions for childhood body size. Genome-wide association data comprised of 22,350 RA, 9,069 AS, 3,609 PsA, 13,179 gout and 5,201 SLE cases. We conducted univariable MR to estimate the total effects of childhood and adult body size on outcomes and multivariable MR to examine the independent effect of childhood body size after accounting for adult body size. F statistics were calculated for each exposure with a value >10 considered suggestive of adequate instrument strength.

Results: The F statistic for childhood and adult body size instruments were 30 and 23 respectively. Genetically predicted childhood body size had a total effect on risk of PsA (OR 2.18 per change in body size category; 95%CI 1.43, 3.31), gout (OR 2.18; 1.43, 3.31) and SLE (OR 2.44; 1.14, 5.22), but not RA (OR 0.95; 0.70, 1.29) or AS (OR 0.96; 0.61, 1.52). After accounting for adult body size, the direct effect of childhood body size was little changed for PsA (OR 1.92; 1.14, 3.25) and SLE (OR 2.69; 1.24, 5.87), but was attenuated for gout (OR 1.40; 0.94, 2.09).

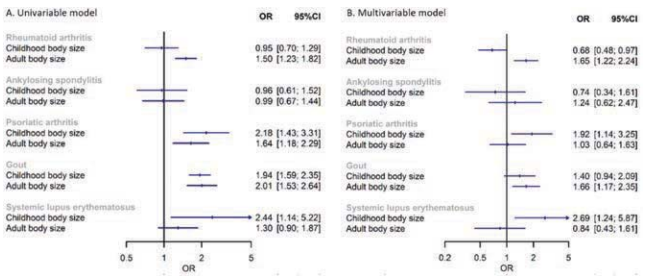

Figure 1. Mendelian randomisation estimates of the effect of childhood and adult body size on inflammatory arthritis.

Conclusion: Results of this study suggest that the risk conferred from having a larger body size during childhood may not be fully reversable even when a healthy size is achieved in adulthood. How the immune system is altered by early life adiposity to increase risk of PsA and SLE is unclear. Differential effect estimates of body size on each inflammatory arthritis (PsA vs AS, RA vs SLE) may help shed light on their unique pathophysiology in future studies.

POS1419 CANCER INCIDENCE IN PATIENTS WITH AUTOIMMUNE DISEASES TREATED WITH CYCLOPHOSFAMIDE

Á. Andreu-Suárez[1], M. Serrano Warleta[1], C. De la Puente Bujidos[1]. *[1]University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Cyclophosphamide (CYC) is one of the first-line drugs for some serious manifestations of autoimmune diseases [1]. It has been associated with the appearance of a secondary cancer [2]. Several studies showing a higher incidence of cancer in small-vessel vasculitis in relation to CYC treatment have been carried out [3], but there is not much evidence about this complication in other autoimmune diseases.

Objectives: -Estimating the incidence of cancer in patients treated with CYC for serious manifestations of autoimmune diseases.
-Comparing the incidence of cancer in autoimmune diseases treated with immunosuppressants (IS) against the incidence of cancer in the general population.

Methods: This is a single-center retrospective cohort study. We included patients over 18 years old assessed in outpatient clinics of the Rheumatology service at the Ramón y Cajal Hospital from 1990 to 2018. They had been diagnosed with: diffuse or limited cutaneous systemic sclerosis (dcSSc/LSSc), systemic lupus erythematosus (SLE), vasculitis or others. We divided the patients into two groups; those exposed to CYC throughout the follow-up and those not exposed to it (being treated with other IS). Patients who had an active cancer at the time of starting the immunosuppressive therapy were excluded.
A descriptive analysis was carried out. The incidence of cancer was compared to the incidence of cancer in the general population according to the 2020 Spanish

Network of Cancer Registries data. A multivariate analysis was subsequently performed.

Results: Regarding the baseline characteristics of the patients included, there were no significant statistical differences in the sex, median age, and personal history of cancer. There was a bigger percentage of smokers in the non-exposed group. The incidence of cancer was similar y both groups (7.5% vs. 4.1%; p0.211). The cumulative incidence of cancer in our sample was 55.55/1.000 patients (95% CI 32.1-94.6). The standardized incidence ratio was 2.19 (95% CI 3.30-11.92) and it was stratified by sex and age. The bivariate analysis is shown in Table 1.

Table 1. Comparison between patients with or without appearance of cancer during the follow-up.

	Cancer (n 12)	No cancer (n 204)	P value
Male sex	7 (58,33%)	31 (15,19%)	0,001
Age at the time of the study	69,92 (±7,54)	53,88 (±16,75)	0,001
Smoking habit	6 (50%)	45 (22,06%)	0,027
Personal history of cancer	5 (41,66%)	5 (2,45%)	<0,001
Treatment with classical IS	1 (8,33%)	49 (24,02%)	0,303
Treatment with cDMARDs	1 (8,33%)	21 (10,29%)	1
Treatment with bDMARDs	1 (8,33%)	8 (3,92%)	0,408
Treatment with corticosteroids	2 (16,66%)	38 (18,63%)	1
Method of administration of CYC			
Intravenous	7 (58,33%)	78 (38,24%)	1
Oral	0 (0%)	6 (2,94%)	1
Both	0 (0%)	2 (0,98%)	1
Total administered dose of CYC (grams)	7,28 (±2,36)	6,59 (±3,68)	0,626

Regarding the multivariate analysis, the variables that demonstrated a statistically significant association with the appearance of cancer were age at the time of the study (OR 1.18 [1.02-1.36], p 0.024) and personal history of neoplasia (OR 7.86 [1.30-47.47], p 0.010).

Conclusion: The incidence of cancer in patients with autoimmune diseases treated with CYC is not higher with respect to patients with similar diseases treated with other IS. The increased incidence of cancer is associated with the personal history of cancer and older age. Studies with a larger sample size and prospective studies are necessary to verify these results and determine more clearly the associated risk factors.

DOUBLY ROBUST ESTIMATOR FOR AVERAGE TREATMENT EFFECT AS SENSITIVITY ANALYSIS FOR COMPARATIVE EFFECTIVENESS RESEARCH. AN EXAMPLE COMPARING DRUG MAINTENANCE BETWEEN BARICITINIB AND ALTERNATIVE BIOLOGIC DMARDS.

R. Aymon[1], B. Gilbert[1], D. Mongin[1], E. Nham[1], C. Laedermann[2], R. Müller[3], K. Lauper[1,4], D. Courvoisier[1], A. Finckh[1]. *[1]Geneva University Hospitals, Division of Rheumatology, Genève, Switzerland; [2]Eli Lilly (Suisse) SA, Medical Department, Vernier, Switzerland; [3]Rheumazentrum Ostschweiz, Rheumazentrum Ostschweiz, St. Gallen, Switzerland; [4]University of Manchester, Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, Manchester, United Kingdom*

Background: Drug maintenance is a common outcome measure of real world effectiveness studies, because it combines a measure of drug effectiveness and its tolerance / safety. Major hurdles of observational studies are potential selection biases and confounding. Cox proportional hazard ratio models address this issue by adjusting for potential confounders, but misspecification of the model may lead to biased estimates. 'Augmented Inverse Probability Treatment Weighting' (AIPTW) has the attractive property of being doubly robust, meaning that only one of the two underlying models has to be correctly specified to obtain consistent estimates. It can be used as a sensitivity analysis for Cox models, when analyzing time-to-event data.

Objectives: To evaluate AIPTW estimator and test the robustness of the results obtained by a Cox model.

Methods: Previous analyses in the Swiss rheumatoid arthritis (RA) registry (SCQM) had demonstrated that time to all-cause-discontinuation was significantly longer in RA patients on bariticinib (BARI, N = 273) compared to TNF-inhibitors (TNFi, N = 473); but not compared to other mode of actions biologics (OMA, N = 378) [1], in an adjusted Cox regression including age, gender, BMI, concomitant csDMARD, prednisone, CDAI score, disease duration, smoking status, line of therapy and seropositivity. Here we repeat the same analysis using AIPTW, including the same potential confounders. We combine a propensity score using a logistic regression model and an inverse probability weighted Cox regression. Two implementations of the AIPTW estimator are considered. First we use the *RiskRegression* package in R, to obtain risk ratios. Then we implement the AIPTW manually to obtain the average treatment effect as the difference in median survival time.

Results: Time to treatment discontinuation measured with Cox model was significantly longer for RA patients on BARI compared to patients on TNFi according to the adjusted Cox model (HR = 1.79), and a similar non-significant trend existed when compared to OMA (HR = 1.29). When considering 90-day treatment discontinuation measured with the AIPTW, the results were qualitatively very similar: the risk ratio between BARI and TNFi groups is statistically significant (RR = 2.51), while that of BARI against OMA is larger than one (RR = 1.47), but not statistically significant. Confidence intervals are larger with the AIPTW estimation.

Table 1. Cox Regression HR and AIPTW risk ratios

	Cox Regression Hazard Ratio (95% CI)	AIPTW Estimate of 90-day risk ratio of treatment discontinuation (95% CI)
BARI vs. TNFi	1.79* (1.34-2.38)	2.51* (1.19 – 3.83)
BARI vs. OMA	1.29 (0.96-1.73)	1.47 (0.76 – 2.18)

Legend: BARI: baricitinib; TNFi: TNF-inhibitors; OMA: Other Mode of Actions biologics; AIPTW: Augmented Inverse Probability Treatment Weighting. 95% CI: 95% Confidence Interval. *: statistically significant result at the p<0.05 level.

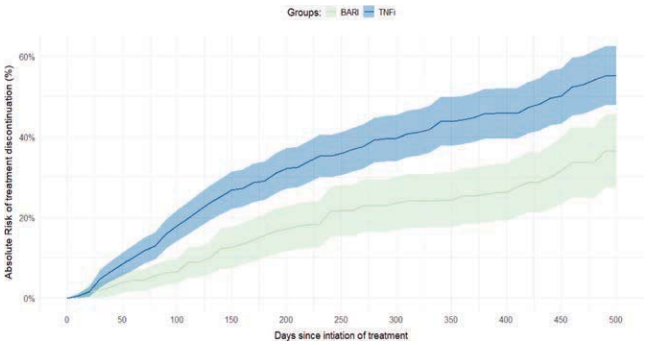

Figure 1. Absolute risk of treatment discontinuation over time between patients on baricitinib and patients on TNF inhibitors, estimated with AIPTW.

Conclusion: Time to treatment discontinuation measured with Cox model was significantly longer for RA patients on BARI compared to patients on TNFi according to the adjusted Cox model (HR = 1.79), and a similar non-significant trend existed when compared to OMA (HR = 1.29). When considering 90-day treatment discontinuation measured with the AIPTW, the results were qualitatively very similar: the risk ratio between BARI and TNFi groups is statistically significant (RR = 2.51), while that of BARI against OMA is larger than one (RR = 1.47), but not statistically significant. Confidence intervals are larger with the AIPTW estimation.

POS1421

AROMATASE INHIBITORS AND SKELETAL HEALTH – NATURAL HISTORY AND INTERVENTIONAL EPIDEMIOLOGY

A. Mirza[1], Z. Win Naing[1], P. Khonsari[1], H. Khan[1], P. Rezai[1], A. K. Abbas[1], M. Nisar[1]. [1]*Luton & Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: Breast cancer remains the most common cancer diagnosed in women worldwide. Aromatase inhibitors (AI) are employed for hormone sensitive disease in mainly postmenopausal women. AI related bone loss (AIBL) is a known complication; although data regarding the natural history in the real-world, long-term outcomes and the role of bone active therapy in fracture prevention is sparse.
Objectives: Our aim was to determine the real-world impact of AIBL and whether bone sparing therapy utilising standard risk stratification model is sufficient for fracture prevention.
Methods: We undertook a longitudinal study of patients prescribed AI for breast cancer over a seven-year period at our university teaching hospital. All the data was recorded electronically with full access to demographics, disease parameters, investigations and drug management. DEXA scans performed prior to initiation of AI were compared with subsequent imaging over a mean follow up of 3 years. Outcome data for cancer and all fractures was collected. Statistical analysis was done to investigate significant relationships amongst the variables of interest.
Results: 1001 women were identified during the study period. The mean age of the cohort was 64 years (range 29-93). 929 (93%) were Caucasian, 57 (6%) were Asian and 15 (1%) were Afro-Caribbean. 723 women (72%) were diagnosed with invasive ductal carcinoma and 863 women (86%) were postmenopausal. At diagnosis, 428 women (43%) had node positive disease and 35 women (4%) had metastases. 91 women (9%) had sustained fractures prior to their breast cancer diagnosis.
All women had a baseline DEXA: 496 (49.6%) had osteopenia, 151 (15%) had osteoporosis and 354 (35.4%) had a normal result. 478 (48%) of women had a repeat scan available. Overall, there was a decline (from a mean of 0.888 g/cm2 to 0.858 g/cm2, p<0.0001) in left neck of femur (LNOF) bone mineral density (BMD) over time (mean of 3 years, with a range of 1-6).
334 (33%) were prescribed bone active therapy with 276 women (83%) given oral bisphosphonates. This group had an improvement in BMD by 0.4% (LNOF mean BMD of 0.785 g/cm2 at baseline compared to LNOF mean BMD of 0.788 at repeat DEXA, p=0.82).
Women who were not offered any treatment (n=667, 66%), showed a significant decline in bone density with the decline being -5%. (LNOF mean BMD of 0.939 g/cm2 at baseline compared to LNOF mean BMD of 0.888 g/cm2 at repeat DEXA, p< 0.0001).
The rate of fractures remained the same between the treatment (19 fractures, 5.67%) and non-treatment group (38 fractures, 5.70%)
Conclusion: Our study provides long term data for AIBL and confirms a significant decline in BMD over seven years. It confirms that bone sparing therapy is effective in reducing the pace of decline in BMD. However standard risk stratification model such as FRAX based intervention thresholds in mainly those with WHO defined osteoporosis (T ≤-2.5) is ineffective in fracture prevention in keeping with prior literature. Since our study period overlaps with publication of newer guidelines recommending different T score-based risk model, further studies are required to confirm their utility.

POS1422

USE OF DISEASE MODIFYING ANTI-RHEUMATIC DRUGS AND RISK OF MULTIPLE MYELOMA IN PERSONS WITH RHEUMATOID ARTHRITIS

N. Singh[1], A. Peterson[2], A. Baraff[2], S. Chung[1], P. Bhatti[3], D. Coffey[4], J. Barton[5], C. Li[6], N. Smith[2], N. Weiss[6]. [1]*University of Washington, Medicine, Seattle, United States of America;* [2]*VA Puget Sound, Epidemiology, SEATTLE, United States of America;* [3]*University of British Columbia, Epidemiology, Vancouver, Canada;* [4]*University of Miami, Medicine, Miami, United States of America;* [5]*VA Portland, Medicine, Portland, United States of America;* [6]*University of Washington, Epidemiology, SEATTLE, United States of America*

Background: Biologic therapies used in the management of rheumatoid arthritis (RA) target several cytokines that have been implicated in the pathogenesis of multiple myeloma (MM). Yet little is known about the association between use of biologic or targeted synthetic disease modifying anti-rheumatic drugs (b or tsDMARDs) in RA and the incidence of MM.
Objectives: Our objective was to estimate the association between b/tsDMARD use and the risk of MM among persons with RA using Veterans Health Administration (VHA) data. We hypothesized that b-/tsDMARD use is associated with a lower incidence of MM compared with conventional synthetic DMARDs (csDMARDs).
Methods: In this retrospective cohort study, we identified patients >18 years of age diagnosed with RA in any United States VHA facility from 1/1/2002 and 12/31/2018. All patients met the following inclusion criteria: 1) two or more International Classification of Diseases Version 9 or 10 (ICD9 or ICD10) codes for RA at least 7 days apart but no more than 365 days apart 2) a prescription for a csDMARD within 90 days of the first RA diagnosis 3) one inpatient or outpatient visit 30 days to 2 years preceding first RA diagnosis (indicating a regular user of VHA). Medication data was derived from the outpatient prescription fills, bar coded medication administration (BCMA), and intravenous (IV) data domains. The csDMARDs included in these analyses were: methotrexate, sulfasalazine, leflunomide, and hydroxychloroquine. The bDMARDs included were tumor necrosis factor inhibitors (TNFi) and non-TNFi biologics such as tocilizumab, rituximab, abatacept, and biosimilars; tsDMARD was tofacitinib. Patients with MM before the diagnosis of RA were excluded. Incident MM was determined by 1 or more ICD9/10 code or ICD-oncology codes. Multivariable Cox proportional hazards model were performed to estimate the hazard ratio for developing MM among those during and following the use of a b-/tsDMARD relative to b-/tsDMARD-naïve persons adjusting for age, gender, race, and ethnicity.
Results: 27,540 veterans with RA met study eligibility criteria, of whom 8,322 (30%) had taken a b-/tsDMARD. Over the study period there were 77 incident MM over a total of 192,000 person years. There were 55 events in users of csDMARDs, an incidence rate (IR) of 0.40 (95% CI 0.30-0.52) per 1000 person-years and 22 in persons currently or formerly using b-/tsDMARDs (IR 0.41, 0.25-0.61 per 1000 person years). The unadjusted hazard ratio for MM following bDMARD use relative to csDMARD only use was 1.04 (0.63, 1.73), which increased to 1.28 (0.76, 2.16) after adjusting for demographic characteristics (Table 1).

Table 1. Multivariable Cox proportional hazards model for association between use of disease modifying anti-rheumatic drugs and incident multiple myeloma.

Clinical characteristic	Hazards ratio (95% CI)
csDMARD	Reference
b-/tsDMARD use	1.28 (0.76-2.16)
Age*	**1.04 (1.02-1.07)**
Female	0.58 (0.20-1.62)
Race	Reference
White	**2.11 (1.15-3.86)**
Black	0.70 (0.10-5.08)
Other	
Hispanic Ethnicity	0.71 (0.17-2.92)

Abbreviations: b-/tsDMARD- biologic or targeted synthetic disease modifying anti-rheumatic drug; CI: confidence interval*Hazards ratio reflects risk per every 1-year increase in ageModel adjusted for age, gender, race, and ethnicity

Conclusion: In this nationwide VA study, we did not observe an association between bDMARD use and the incidence of MM. Of note, the median interval from initiation of a bDMARD to the end of follow-up was approximately 5.8 years, which does not allow for an examination of a possible longer term influence.

POS1423

CHARACTERISTICS OF CYTOMEGALOVIRUS-POSITIVE VERSUS NEGATIVE, AND CYTOMEGALOVIRUS-TREATED VERSUS UNTREATED PATIENTS DURING IMMUNOSUPPRESSIVE THERAPY FOR RHEUMATIC DISEASES.

T. Shimada[1,2], M. Higashida-Konishi[1], K. Izumi[1,2], S. Hama[1], T. Oshige[1,2], H. Oshima[1], Y. Okano[1]. [1]*National Hospital Organization Tokyo Medical Center, Division of Rheumatology, Department of Medicine, Tokyo, Japan;* [2]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Immunosuppressive treatment is a common cause of cytomegalovirus (CMV) reactivation.
Objectives: To elucidate the characteristics of CMV-positive and negative patients during the treatment for rheumatic diseases.

Methods: We retrospectively evaluated consecutive patients admitted to our department from January 2006 to October 2021 whose C7-HRP antigen were measured. We collected their age, sex, primary problem and its lesion, and test results within 3 months before C7-HRP measurement. We also investigated the use of immunosuppressants, and maximum and cumulative dose of administered prednisolone within 6 months before C7-HRP measurement. Maximum and cumulative dose of prednisolone contained methylprednisolone pulse, which was converted into prednisolone equivalent. We investigated the characteristics of CMV-positive and negative patients, and those of CMV-positive patients with or without anti-CMV drug use.
Results: Of a total of 472 patients, 85 were positive and 387 were negative for C7-HRP. The average age was 71.2 vs. 64.4 (p=0.0021). Their male-to-female ratio was 20/65 vs. 120/267 (p=0.0290). The following diseases were significantly common among CMV-positive patients: microscopic polyangiitis (21.2% vs. 3.9%, p<0.0001), adult-onset Still's disease (7.1% vs. 1.3%, p=0.0002), and systemic sclerosis (4.7% vs. 2.1%, p=0.0273). Significantly common comorbidities of CMV-positive patients were interstitial lung disease (35.3% vs. 16.0%, p<0.0001), nephritis (23.5% vs. 11.6%, p=0.0005), peripheral nervous system disorders (11.8% vs. 5.7%, p=0.0070), alveolar hemorrhage (5.9% vs. 0.8%, p=0.0001), and peripheral circulatory disorders (4.7% vs. 1.6%, p=0.0111). Average neutrophil counts (7720 /μL vs. 6440 /μL, p=0.0001), serum creatinine (1.0 mg/dL vs. 0.9 mg/dL, p=0.0104), and hemoglobin A1c (6.3% vs. 5.7%, p=0.0030) were significantly higher among CMV-positive patients, whereas hemoglobin (10.1 g/dL vs. 11.1 g/dL, p<0.0001), lymphocyte counts (820 /μL vs. 1190 /μL, p<0.0001), platelet counts (233000 /μL vs. 259000 /μL, p<0.0001), and serum albumin (2.9 g/dL vs. 3.4 g/dL, p<0.0001) were lower. Higher maximum dose of prednisolone (534.9 mg/day vs. 135.5 mg/day, p<0.0001), intravenous cyclophosphamide (27.1% vs. 11.4%, p<0.0001), rituximab (9.4% vs. 2.1%, p<0.0001), azathioprine (23.5% vs. 14.2%, p=0.0053), cyclosporin (8.2% vs. 3.6%, p=0.0101) were significantly more often used among CMV-positive patients. Average cumulative dose of prednisolone was 3022.6 mg vs. 1408.7 mg (p<0.0001). We also performed multivariate analysis, including the patients' age, sex, maximum and cumulative dose of prednisolone, and the use of intravenous cyclophosphamide, rituximab, azathioprine, and cyclosporin. Elderly (p=0.0006), female (p=0.0293), high cumulative dose of prednisolone (p=0.0155), and the use of cyclosporin (p=0.0479) were significantly associated with CMV-positivity. Anti-CMV drug was administered to 63.5% of CMV-positive patients. The average age was significantly higher in anti-CMV-drug-treated patients than untreated patients (73.7 vs. 67.1, p=0.0492). The CMV-treated patients had significantly higher neutrophil counts (8540 /μL vs. 6280 /μL, p<0.0001), erythrocyte sedimentation rate (57.6 mm/h vs. 40.5 mm/h, p<0.0001), and C-reactive protein (5.3 mg/dL vs. 2.6 mg/dL, p<0.0001) than the untreated patients while the other data such as complete blood counts and serum chemistry revealed no significant difference. Average maximum dose of prednisolone was significantly higher in CMV-treated patients (617.1 mg/day vs. 391.1 mg/day, p=0.0261) while average cumulative dose of prednisolone and the use of any other immunosuppressants revealed no significant difference.
Conclusion: Intense immunosuppression, especially with higher dose of glucocorticoids, seemed to be the major risk factor of CMV reactivation. These medications may often require anti-CMV therapy.

POS1424 RISK FACTORS FOR ADVERSE EVENTS OF SULFAMETHOXAZOLE-TRIMETHOPRIM PROPHYLAXIS IN PATIENTS WITH SYSTEMIC RHEUMATIC DISEASES

K. Hiramoto[1], M. Akiyama[1], Y. Kaneko[1]. *[1]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: The prophylactic use of sulfamethoxazole-trimethoprim (SMX/TMP) can reduce the risk for developing pneumocystis pneumonia in immunosuppressed patients with systemic rheumatic diseases, whereas discontinuation of SMX/TMP prophylaxis is frequent due to adverse events (AEs) with this drug.
Objectives: The purpose of this study was to identify risk factors for AEs of SMX/TMP in patients with systemic rheumatic diseases.
Methods: All consecutive patients who were admitted in our hospital for induction treatment between 2012 and 2019 and newly received prophylactic SMX/TMP were included in the study. We divided them into two groups according to the presence or absence of AEs of SMX/TMP leading to discontinuation of the drug and compared clinical characteristics between the AE and non-AE groups. Multivariable analysis was performed to identify risk factors for AEs of SMX/TMP prophylaxis.
Results: A total of 438 patients were included in the study. Rheumatic diseases of the patients were systemic lupus erythematosus (25.3%), anti-neutrophil cytoplasmic antibody associated vasculitis (15.5%), rheumatoid arthritis (11.6%), polymyositis/dermatomyositis (10.7%), IgG4-related disease (8.5%), large vessel vasculitis (7.1%), adult-onset Still's disease (AOSD; 4.1%), and others (17.2%). Among them, 82 patients (18.7%) stopped SMX/TMP due to AEs. Most frequent AEs were skin rash (36.6%), followed by liver dysfunction (29.3%), thrombocytopenia (19.5%), elevation in serum creatinine levels (15.9%), hyperkalemia (14.6%), hyponatremia (11%), leukopenia (6.1%), and fever (6.1%). Baseline age (61.4±16.4 vs 56.3±16.9 years, p=0.014) and prednisolone dose for remission induction treatment (0.97 vs 0.91 mg/kg/day, p=0.03) were significantly higher in the AE group than in the non-AE group, respectively. In terms of disease type, significantly higher rates of AEs were observed in patients with AOSD than in those with the other diseases (66.7% vs 16.7%, p<0.001; Figure 1). Blood tests at SMX/TMP initiation demonstrated lower lymphocyte counts (10.1 vs 10.8 x10^2/μl, p=0.049), lower platelet counts (20.9 vs 25.8 x10^4/μl, p=0.045), lower albumin levels (3.2 vs 3.4 g/dl, p=0.007), higher AST levels (26 vs 23 U/L, p=0.04), higher creatinine levels (0.71 vs 0.67 mg/dl, p=0.047), and higher ferritin levels (167 vs 154 ng/ml, p=0.047) in the AEs group compared with the non-AEs group, respectively. Multivariable analysis identified an older age (OR 1.03, p=0.002) and AOSD (OR 9.72, p<0.001) as independent risk factors for AEs leading to SMX/TMP withdrawal (Table 1).

Figure

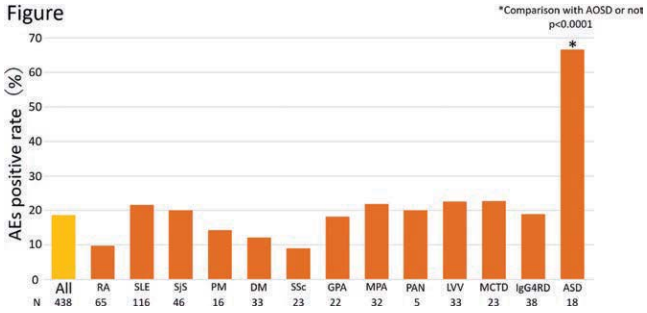

Table Risk factors for AEs due to SMX/TMP in systemic rheumatic disease patients

	Unadjusted odds			Adjusted odds		
	Odds ratio	95 % CI	P values	Odds ratio	95 % CI	P values
Gender (female)	0.913	0.544-1.532	0.73	0.837	0.472-1.483	0.543
Age	1.019	1.004-1.034	0.015	1.027	1.010-1.045	0.002
ASD	9.999	3.631-27.54	<0.001	9.718	3.224-29.29	<0.001
Induction PSL dose	3.588	1.143-11.26	0.029	2.569	0.778-8.484	0.122
Lymphocyte	0.9996	0.9991-0.9999	0.034	0.9996	0.9991-1.0002	0.066
Plt	0.999	0.9965-1.0006	0.165	0.998	0.9959-1.0005	0.120
Cr	1.198	0.739-1.940	0.46	0.906	0.519-1.585	0.731

Conclusion: Old age and AOSD were associated with AEs of SMX/TMP prophylaxis in patients with systemic rheumatic diseases.

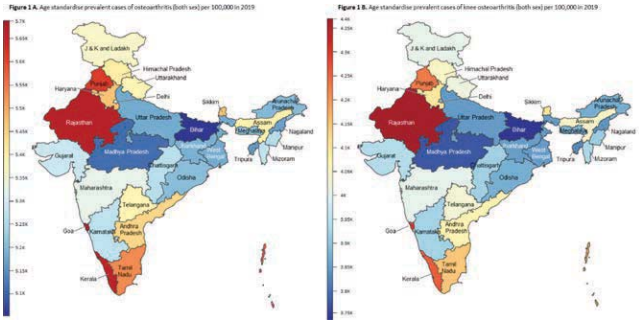
POS1425 THE BURDEN OF OSTEOARTHRITIS ACROSS THE STATES OF INDIA, 1990–2019: FINDINGS FROM THE GLOBAL BURDEN OF DISEASE STUDY 2019

A. Singh[1], S. K. Das[2], A. Chopra[3], D. Danda[4], B. J. Paul[5], L. March[6,7], A. J. Mathew[4,8], P. Shenoy[9], C. Gotay[10], A. J. Palmer[1], B. Antony[1]. *[1]University of Tasmania, Hobart, Tasmania, Australia, Menzies Institute for Medical Research, Hobart, Australia; [2]Era's University, Lucknow, India, Department if Rheumatology, Lucknow, India; [3]Apollo Jehangir Hospital, Pune University, Pune, India, Centre for Rheumatic Diseases, Pune, India; [4]Christian Medical College, Vellore, India, Department of Clinical Immunology and Rheumatology, Vellore, India; [5]KMCT Medical College, Calicut, Kerala, India, Department of General Medicine, Calicut, India; [6]University of Sydney, Sydney, Australia, Institute of Bone and Joint Research, Kolling Institute of Medical Research, Sydney, Australia; [7]University of Sydney Royal North Shore Hospital, St Leonards, Sydney, Australia, Florance and Cope Professorial Rheumatology Department, Sydney, Australia; [8]Center for Rheumatology and Spine Diseases, Copenhagen University Hospital - Rigshospitalet Glostrup, Denmark, The Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark; [9]Centre for Arthritis & Rheumatism Excellence, Kochi, Kerala, India, Department of Rheumatology, Kochi, India; [10]The University of British Columbia, Vancouver, BC Canada, School of Population and Public Health (SPPH), Vancouver, Canada*

Background: Few studies have reported the burden of osteoarthritis (OA) in different parts of India. However, no study has reported the detailed estimates of incidence, prevalence, and years lived with disability (YLDs) and its trends for OA (and its various sites) across the states of India over a long period of time.

Objectives: We aim to describe the state-wise prevalence, incidence, and YLDs for osteoarthritis (OA) in India from 1990 to 2019 according to age and sex.
Methods: Data from the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) 2019 were used. The burden of OA –including knee OA, hip OA, hand OA, and other OA– was estimated for India and its states from 1990 to 2019 through a systematic analysis of prevalence, incidence, and YLDs modelled data using the methods reported in the GBD 2019 Study. All estimates are presented as counts and age-standardised rates per 100,000 population, with uncertainty intervals (UIs).
Results: Around 23.46 million individuals in India had OA in 1990; this increased to 62.35 million in 2019. The age-standardised prevalence of OA increased from 4,895 (95% uncertainty interval (UI): 4,420–5,447) in 1990 to 5313 (95%UI: 4,799–5,898) in 2019, per 100,000. OA was the 20th most common cause of YLDs in India in 2019, accounting for 1·48% (95%UI: 0·88–2·78) of all YLDs; increasing from 23rd most common cause in 1990 (1·25% (95%UI: 0·74–2·34)). Knee OA was the most common form of OA, followed by hand OA. The prevalence, incidence, and YLDs for OA and knee OA were consistently higher in females than males. Uttar Pradesh (8.53 million (95%UI: 7.63–9.53), Maharashtra (6.37 million (95%UI: 5.75–7.06), and West Bengal (4.90 million (95%UI: 4.39–5.46) had the three highest levels of OA prevalence. Goa (5689 (95%UI: 5,125–6,282)), Rajasthan (5667 (95%UI: 5,097–6,305)), and Kerala (5658 (95%UI: 5,107–6,263)) had the highest age-standardised prevalence of OA in 2019, per 100,000 (Figure 1 A and B).



Conclusion: The burden and impact of OA in India are substantial and is increasing; however, it varied among states. Females were affected more commonly than males. Knee OA was the most prevalent site. With improvement in life expectancy and population ageing, greater increases are expected. Adopting suitable control and preventive community measures to reduce modifiable risk factors (such as obesity, injuries, occupational stress) are needed now to reduce the current and future burden of OA in India.

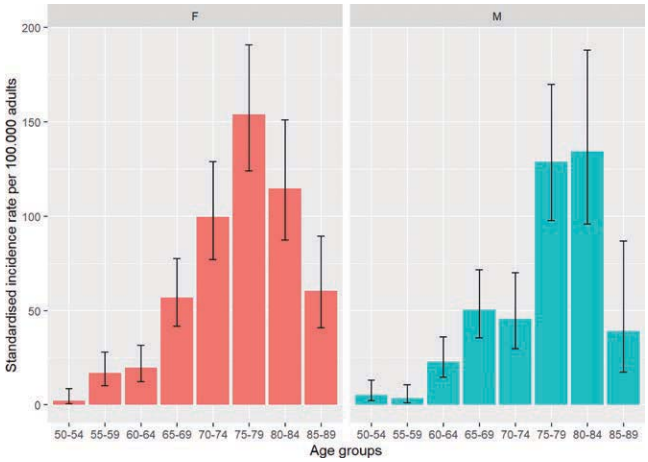
POS1426 INCIDENCE, CLINICAL FEATURES AND OUTCOMES OF PATIENTS WITH POLYMYALGIA RHEUMATICA IN SLOVENIA

S. Markez[1], A. Hočevar[1,2], M. Tomsic[1,2], J. Kramarič[1], Z. Rotar[1,2]. *[1]University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia; [2]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia*

Background: Polymyalgia rheumatica (PMR) is common in patients over the age of 50 years. Clinical symptoms promptly respond to glucocorticoid therapy, but there are wide variations of dosage tapering, treatment duration and rate of relapses. In Slovenia epidemiology of PMR is unknown.
Objectives: We aimed to determine the incidence rate of PMR, the clinical characteristics, the relapse frequency and length of glucocorticoid therapy.
Methods: A detailed single centre retrospective review of medical records of all patients diagnosed with PMR between 1 January 2014 and 31 December 2016 was performed at the Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia–the only secondary level rheumatology institution in serving the Central Slovenian and Gorenjska regions, which represent ~40% (7×105) of the Slovenian adult population. The outcomes were assessed up to1 October 2021.
Results: During the 3-year period 494 patients (460 from Ljubljana and Gorenjska regions) were diagnosed with PMR (64% females, median (IQR) age 75 (69, 80) years), resulting in an annual sex- and age-standardised incidence rate (IR) per 105 adults ≥ 50 years of 46.0 (95% CI 42.0, 50.4), with a female/male ratio of 1.5 (95% CI 1.3, 1.7). The IR peaked between 70–85 years (Figure 1). There was no seasonal variation in IR. The median (IQR) times from symptom onset, and from referral to rheumatology consultation were 6 (4, 11) weeks, and 1 (1, 1) day, respectively. 86% were referred by their GPs, 7% by other internists, and 6% by infectious disease specialists, and the rest by other specialists. At presentation, 96% had morning stiffness (71% lasting >45 minutes), 99% shoulder pain, 94% pelvic girdle pain, 49% weight loss, 13% peripheral arthritis, and 12% body temperature >37°C. Data on US of shoulders and hips was complete, partial, or missing for 38%, 24%, 39%, respectively. Elevated erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) was present in 98% of patients, the median (IQR) ESR was 55 (42, 71) and CRP 49 (26, 79) mg/l, and 58% had anaemia. RF and ACPA were positive in 4% and 3%, respectively. 8/12 had ACPA values less than 2× the reference value. During follow-up ACPA was repeated in 8/12 patients and negativized in 6/8 patients. Among other pre-existing conditions, 51 (10%) had history of malignancy diagnosed a median 7 (3–11) years prior to diagnosis of PMR. EULAR/ACR classification criteria for PMR were fulfilled in 68% and 71% based on clinical and extended ultrasound criteria (missing items were imputed with 0), respectively. 14 (3%) patients had clinically overt concurrent giant cell arteritis (GCA). All patients were treated with methylprednisolone, administered orally in 99.4%, 93% started at 16mg qd. By the end of follow-up, 295 (60%) patients successfully discontinued methylprednisolone after a median of 117 (104, 143) weeks. Steroid sparing leflunomide and methotrexate were used by 66 (13%) and 27 (6%) patients, respectively. During a median follow-up of 150 (98, 244) weeks, 146 (30%) had at least one relapse. Median time to first relapse was 111 (50, 141) weeks. 54% relapsed after glucocorticoid discontinuation after a median time of 4 (2, 18) weeks, 9% presented with GCA, 12% relapsed due to treatment non-adherence. During the follow-up 6% were diagnosed with malignancies.



Conclusion: (1) With the IR of 46 per 105 adults ≥50 years, PMR is more common as rheumatoid arthritis in Slovenia. (2) A considerable proportion of patients required long-term glucocorticoid treatment, leaving a huge unmet need for safer therapeutic options.

POS1427 CLINICAL COURSE IN PATIENTS WITH INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES (IPAF): REAL-LIFE DATA FROM A MULTICENTER ILD REGISTRY

C. Vadillo[1], M. A. Nieto[2], O. Sanchez Pernaute[3], F. Romero[3], M. J. Rodriguez[4], D. Freites Nuñez[1], G. Bonilla[5], T. I. Cobo[6], L. Cebrián Méndez[7], H. Godoy[8], M. T. Rio[9], L. Abasolo[10]. *[1]Hospital Clinico San Carlos, Rheumatology, Madrid, Spain; [2]Hospital Clinico San Carlos, Pneumology, Madrid, Spain; [3]Hospital Fundación Jimenez Diaz, Rheumatology, Madrid, Spain; [4]Hospital Fundación Jimenez Diaz, Pneumology, Madrid, Spain; [5]Hospital La Paz, Rheumatology, Madrid, Spain; [6]Hospital Infanta Sofia, Rheumatology, Madrid, Spain; [7]Hospital Infanta Leonor, Rheumatology, Madrid, Spain; [8]Hospital Puerta De Hierro, Rheumatolgy, Madrid, Spain; [9]Hospital de Getafe, Pneumology, Madrid, Spain; [10]Instituto de Investigacion Sanitaria San Carlos (IdISSC) Hospital Clínico San Carlos. Madrid. Spain., Rheumatology, Madrid, Spain*

Background: Several patients with Interstitial Lung Disease show autoimmune characteristics but do not meet the classification criteria for a connective tissue disease. In order to define this condition, the classification of patients with interstitial pneumonia with autoimmune features (IPAF) has been adopted (Fischer's criteria).
Objectives: To describe the sociodemographic, clinical, functional characteristics and therapeutic management of IPAF in clinical practice and to evaluate the incidence rate of functional respiratory impairment.

Methods: A longitudinal observational study was performed (NEREA registry). Patients diagnosed with IPAF according to Fischer's criteria were included from ILD diagnosis (Feb 2007 to Dec 2019) and followed until loss of follow-up or Jan 2021. The study was carried out by a multidisciplinary team (pneumologists and rheumatologists) in seven Hospitals of Madrid. The relative functional respiratory impairment, defined as a ≥ 5% decline in percent predicted forced vital capacity (FVC%) compared to the previous visit was set as main outcome. Respiratory function was measured at baseline and every 6-12 months. Covariates included: a) sociodemographic, b) clinical, c) radiological pattern (non-specific interstitial pneumonia [NSIP]; usual interstitial pneumonia [UIP], others); d) FVC% DLCO%; e) laboratory tests; f) therapy used. Survival techniques were used to estimate the incidence rate (IR) of relative functional respiratory impairment, expressed per 100 patient-semester with their respective confidence interval [95 % CI].

Results: 79 IPAF were included, with a follow up of 462.8 patients-semester and a maximum follow-up of 12.3 years. 79% were women with a mean age of 66±11 years. Along with obesity (40%), the most frequent comorbidities at baseline were hypertension, hypercholesterolemia, followed by ischemic heart disease. Baseline FVC% and DLCO% were 88.5±22.7 and 64.2±19.3, respectively. Distribution of IPAF classification criteria was: a) clinical domain: arthritis (46.2%), Raynaud`s phenomenon (35.8%) and mechanic hands (9.3%); b) serological domain: 80.8% positive ANA at >1/320 titer; 29% RF (> 40 IU/ml); 25% positive anti-Ro; c) morphological domain: 46.8% of NSIP and 36.7% of UIP. During the study period, 77.2% of patients (n=61) received treatment: glucocorticosteroids (n=52), mycophenolate (n=25), azathioprine (n=21), rituximab (n=15) and antifibrotics (n=11). During the follow-up, 50 patients presented 111 relative functional respiratory impairment events over time. The estimated IR was 23.9 [19.9-28.8] per 100 patient-semester, and 50% of the patients developed functional respiratory impairment at 16 months from diagnosis. IR was similar between patient gender, baseline overall comorbidity, baseline pulmonary functional tests, and age strata, with slight difference in patients >80 years of age. Patients with baseline associated emphysema (IR: 17.6 [10-31]) or without baseline associated fibrosis (IR: 21.1 [15-28]) had lower IR compared to the opposite (IR without emphysema: 24.5[19.3-31]; IR with fibrosis emphysema: 27.5 [19.9-37.9]). As expected, IR was higher in UIP (32.2 [24-42]) compared to NSIP or any other pattern. With respect to serologic markers, patients with ANA titers >=1/320 had a higher IR (26.7 [21-33]) in comparison with those with lower or non-titers of ANA (IR: 15.7 [9.9-25.1]).

Conclusion: In a multicenter registry of Madrid, we have performed a descriptive longitudinal study. IPAF were mostly women in their sixties. The most frequent clinical criteria were arthritis and Raynaud`s phenomenon. An NSIP radiological pattern predominated. At onset, patients have a slightly diminished lung function. The incidence rate of functional deterioration was estimated in 23.9% patient-semester and 50% of the patients developed pulmonary functional deterioration at 16 months from ILD diagnosis. This Incidence rate was higher in patients with an UIP pattern, baseline fibrosis or ANA at medium-high titers.

POS1428 IDENTIFICATION OF A WARM AUTOIMMUNE HEMOLYTIC ANEMIA (WAIHA) POPULATION USING PREDICTIVE ANALYTICS OF A KNOWN CLINICALLY PROFILED COHORT

K. R. Mccrae[1], T. Gooljarsingh[2,3], G. K. Jones[4], M. L. Tjoa[3]. *[1]Taussig Cancer Institute, Cleveland Clinic, Hematology and Medical Oncology, Cleveland, OH, United States of America; [2]Clinical Communications and Patient Advocacy, Editas Medicine, Medical Affairs, Cambridge, MA, United States of America; [3]Janssen Global Services, LLC, Medical Affairs and Communications, Cambridge, MA, United States of America; [4]IPM AI, Client Engagement, Cambridge, MA, United States of America*

Background: The disease burden of warm autoimmune hemolytic anemia (wAIHA), a rare disorder characterized by the destruction of red blood cells (RBCs) by pathogenic IgG autoantibodies, has not been well studied. At the time this claims database analysis was carried out a diagnostic code specific for wAIHA did not exist, which presented challenges in identifying patients with wAIHA.

Objectives: Despite the absence of a diagnostic code specific for wAIHA we aimed to 1) identify a wAIHA cohort using a collection of diagnostic codes, 2) bisect severe versus non-severe wAIHA patients, 3) compare the frequency of comorbidities, anemia symptoms, treatments, diagnostic tests, and healthcare provider visits in these two groups, and 4) use a predictive model to validate clinical variables and prevalence estimates.

Methods: A de-identified, longitudinal, patient-level claims database of >300 million US patients was used for this study. Patients with wAIHA were identified based on a diagnosis code of "autoimmune hemolytic anemia" (AIHA), chronic use of steroids (≥30 days) in the last 36 months, and chronic use of non-steroidal immunosuppressants. Patients were classified as severe if claims related to transfusion, high frequency of blood testing, high frequency interactions with a hematologist, and/or ≥2 ER visits per year were observed in the 36-month period. Codes for anemia symptoms, comorbidities, treatments, and diagnostic tests were grouped and analyzed within the most recent 12 months for each patient. Prevalence was estimated using Artificial Intelligence/Machine Learning (AI/ML) lookalike modeling, using known patients with wAIHA as the positive training class.

Results: A cohort of 1,548 patients with wAIHA was identified (n= 631 were classified as severe while n= 917 as non-severe). Median patient age was >65 years, and patients were evenly distributed by gender. The rate of disease-relevant claims was disproportionately higher in the severe cohort versus the non-severe cohort. Over the 12-month study period, there was a 61% higher rate for anemia symptomatology codes and a 570% higher rate for wAIHA specific testing and monitoring codes in the severe cohort. Primary hypertension, hyperlipidemia, gastro-esophageal reflux, and evidence of chemotherapy use were also present in wAIHA patients. All these conditions were observed more frequently in severe patients with the exception of lupus. Almost 44% of wAIHA claims for the full cohort were associated with Hospital/Emergency care - 48% for the severe group. AI/ML modeling predicted patients using claims variables for hemolytic anemia, other blood count abnormalities, and medical procedure claims commonly used for the diagnosis and management of wAIHA. The predicted population supports reported US prevalence estimates of 30,000-49,000 patients.

Conclusion: We developed and validated a method for defining wAIHA patients using de-identified claims data based on AIHA ICD-10 codes and relevant treatments. We observed that while disease manifestations are generally the same in the severe and non-severe wAIHA cohorts, there is an increased rate of occurrence in the severe cohort during the same 12-month period. This increase was also associated with higher utilization of healthcare resources. The comorbidity of lupus was more commonly associated with non-severe wAIHA patients. This may indicate that patients with a known diagnosis (in this case lupus) who are more closely monitored are less likely to reach the level of severity that would categorize them as patients with severe wAIHA.

POS1429 IMPROVING ACCURACY OF SELF-REPORTED DIAGNOSES OF POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS IN THE FRENCH PROSPECTIVE E3N COHORT: A VALIDATION STUDY

F. Barde[1], S. Ascione[1,2], C. Macdonald[1], C. Salliot[3], F. Artaud[1], X. Mariette[4,5], M. C. Boutron-Ruault[1], Y. Nguyen[1,6], R. Seror[4,5]. *[1]Université Paris-Saclay, UVSQ, Inserm, Institut Gustave Roussy,"Exposome and Heredity"Team, CESP, Villejuif, France; [2]Hôpital Lariboisière AP-HP, Rheumatology, Paris, France; [3]Centre Hospitalier Régional d'Orléans, Rheumatology, Orléans, France; [4]Université Paris-Saclay, AP-HP, Hôpital Bicêtre, Rheumatology, Le Kremlin Bicêtre, France; [5]Université Paris-Saclay, France, AP-HP, Hôpital Bicêtre, National Reference Center for Rare Systemic Autoimmune Diseases, INSERM UMR1184, Le Kremlin Bicêtre, France; [6]AP-HP.Nord, Hôpital Beaujon, Université de Paris, Internal Medicine, Clichy, France*

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are two associated inflammatory diseases that probably share common pathophysiological mechanisms. Data on environmental risk factors are lacking. Population based cohort studies are the most adequate and less biased sources for identifying such factors. But case validation of disease diagnoses is the first necessary step for running such studies, even though it is not easy to perform.

Objectives: To assess the accuracy of self-reported GCA/PMR diagnoses and to develop algorithms to ascertain GCA/PMR in a large French population-based cohort, using combined data of a dedicated questionnaire and medication reimbursement database.

Methods: The E3N cohort study (*Etude Epidémiologique auprès des femmes de la Mutuelle générale de l'Education Nationale*) includes 98,995 healthy French women born between 1925 and 1950, recruited in 1990 and was designed to investigate lifestyle and environmental factors associated with chronic conditions. Participants completed biennially mailed questionnaires to update their health-related information, lifestyle characteristics, and newly diagnosed diseases. Women who self-reported a diagnosis of GCA and/or PMR were sent a specific validation questionnaire designed to ascertain the diagnosis including clinical, biological, and therapeutic data, along with ACR 1990 classification criteria for GCA and ACR/EULAR 2012 classification criteria for PMR. We then devised algorithms based on self-reported answers and a medication reimbursement database, and evaluated their accuracy, comparing them with diagnoses obtained from medical chart review.

Results: Among the 98,995 participants, 1,392 women self-reported GCA/PMR. The specific questionnaire was sent to 1,143 (82.1%) of the eligible women (249 women could not be contacted because of death or withdrawn consent) and response was obtained for 830 women (59.6%). Among them, 202 women provided sufficient medical data to ascertain a diagnosis and study accuracy of developed algorithms. 56 women were classified as ACG and 121 as PMR. Self-reported diagnoses alone had an accuracy of 87.6% with medical chart review. If women additionally self-reported a diagnosis confirmation by a physician and the use of glucocorticoids for ≥ 3 months, the accuracy was improved to 89.9%. For patients who did not respond to validation questionnaire, adding the use of glucocorticoids for ≥ 3 months in the reimbursement database also improved the diagnosis accuracy to 92.8%. These two designed algorithms also had the benefit of reducing the number of false positive cases by 10 and 16 respectively. Finally, 589 GCA and/or PMR cases were confirmed by our two devised algorithms: 401 cases with algorithm using the specific GCA/PMR questionnaire and 188 with medication reimbursement database. The mean age at diagnosis was 70.3 (± 8.0) years [73.4 (± 6.2) years for cases detected using the specific GCA/PMR questionnaire and 68.9 (± 8.3) years for cases detected with medication reimbursement database]. Demographic and clinical data were similar between our population of validated cases by medical chart review and the cases detected by our algorithms in the cohort.

Conclusion: The accuracy of self-reported diagnosis of GCA/PMR was high in the E3N-cohort. Using additional data such as medication reimbursement and/or other self-reported data from a specific questionnaire, particularly the prolonged use of glucocorticoids led to a better accuracy with a very small number of false positive cases and seemed to be sufficient to correctly ascertained GCA and/or PMR diagnoses. With the validation of nearly 600 GCA and/or PMR cases in our cohort, we will be able to conduct epidemiological studies to identify risk factors of these diseases.

POS1430 WATCH OUT FOR THE INFLAMMATORY RESPONSE IN AUTOIMMUNE DISEASES WITH INTERSTITIAL PNEUMONIA. A RETROSPECTIVE STUDY

F. Romero Bueno[1], M. J. Rodriguez[2], M. A. Nieto[3], C. Palacios Miras[4], I. Martín Lores[5], C. Vadillo[6], M. C. Vegas Sánchez[7], L. Abasolo[6], O. Sanchez Pernaute[1]. *[1]Hospital Universitario Fundación Jiménez Díaz, Rheumatology, Madrid, Spain; [2]Hospital Universitario Fundación Jiménez Díaz, Pulmonology, Madrid, Spain; [3]Hospital Clinico Universitario San Carlos, Pulmonology, Madrid, Spain; [4]Hospital Universitario Fundación Jiménez Díaz, Clinical Imaging, Madrid, Spain; [5]Hospital Clinico Universitario San Carlos, Clinical Imaging, Madrid, Spain; [6]Hospital Clinico Universitario San Carlos, Rheumatology, Madrid, Spain; [7]Hospital Universitario Fundación Jiménez Díaz, Immunology, Madrid, Spain*

Background: Chronic interstitial pneumonia (IP) is often a feature of autoimmune rheumatic diseases (ARD). While potentially a life-threatening complication, it is however highly heterogeneous both as regards its presentation and its progression over time. Some patients may have a predominantly lung involvement, a context which hampers their classification and/or management. The recently coined concept of interstitial pneumonia with autoimmune features (IPAF) may help to identify these cases, albeit some others might remain unclassified (UAIP). Either with or without an overt underlying ARD, real-life data are regarded fundamental to shed light on the natural course of autoimmune IP (AIP) and to identify prognostic markers in order to tailor follow-up and therapeutic approaches

Objectives: To find prognostic markers in our cohort of patients with autoimmune diseases with AIP (comprising ARD-IP, IPAF and UAIP), which may guide our therapeutic strategies.

Methods: We set a retrospective study including all patients diagnosed with AIP from our Clinic with a minimum follow-up of 3 yr -or until death-. The end of the study was set at January 2020. We collected demographic data and classified the disease according to the updated criteria for the ARDs, Fischer's preliminary criteria of IPAF and Solomon's proposed criteria of anti synthetase (ARS) syndrome. We registered morphological, serological and clinical features of the disease. Besides, available laboratory parameters were recorded as dichotomous variables (absent/present; normal/increased). The dependent variable of our study was death. Student's t, Fisher's exact test and survival techniques were employed in the univariate analysis. Logistic regression analysis was done to assess death prediction models. One way ANOVA and Dunnett 2 sided t were employed in multi-group comparisons of means.

Results: A total of 118 patients (69% women), comprising 63 patients (53%) with ARD-IP, 37 (31%) with IPAF and 18 (15%) with UAIP, were included. There were 22 patients fulfilling RA criteria, 16 patients SSc criteria and 20 patients meeting criteria for IM. Twenty one patients could be diagnosed with ARS syndrome. Disease duration was not different between subgroups, with a total follow-up of 984 patient-years. Age at onset was significantly younger in ARD-IP cases (54 ± 2), than in IPAF (61,7 ± 2,7), p 0.035, and also in 2 group comparison with UAIP (72,1 ± 1,9), p < 0.001, p 0.019, respectively. Thirty one deaths occurred during follow-up. In the univariate analysis, older age at presentation (difference: -11,2 ± 3,3 y.o. [CI95: -17.9; -4.6] p 0,001), a shorter course of the disease (difference: 4,5 ± 1,1 y [CI95: 2,3; 6,8] p < 0.001) and the presence of pulmonary hypertension (OR 6,08 ± 1,69 [CI95 2,18; 16,96] p 0.001) were associated to fatal cases. On the other hand, none of clinical subgroups, morphological patterns or autoantibodies conveyed death risk. As regards laboratory parameters, increases of ferritin, triglycerides, ESR, CRP and LDH were strong predictors of death (Table 1). With logistic regression, the combination of older age, pulmonary hypertension, increased ferritin an increased ESR was the best model for death prediction (OR 14,57, p < 0.001), while the elevation of LDH and CRP could be explained by the mentioned 4-factor model.

Table 1.

Laboratory parameter	alive	dead	OR	p
increased ferritin	19p (22,9%)	16p (51,6%)	3,59 ± 1,56 [CI95 1,50; 8,58]	0,004
increased ESR	47p (55,3%)	24p (77,4%)	2,77 ± 1,62 [CI95 1,08; 7,13]	0,034
increased CRP	49p (57,6%)	27p (87,1%)	4,96 ± 1,78 [CI95 1,59: 15,43]	0,006
increased triglycerides	6p (7%)	7p (22,6%)	3,84 ± 1,83 [CI95 1,18: 12,53]	0,026
increased LDH	34p (40%)	23p (74,2%)	4,31 ± 1,59 [CI95 1,73; 10,76]	0,002

Conclusion: According to our data, markers of macrophage activation and the activation of acute phase response could be taken as risk factors of a poor outcome in patients with AIP, regardless of clinical diagnosis and process-related features. Nonetheless, due to our study design and sample, these resutls warrant replication in other cohorts.

POS1431 FISH CONSUMPTION AND RISK OF RHEUMATOID ARTHRITIS: FINDINGS FROM THE E3N COHORT STUDY

Y. Nguyen[1,2], C. Salliot[1,3], X. Mariette[4,5], M. C. Boutron-Ruault[1], R. Seror[4,5]on behalf of the authors are indebted to all participants for their continued participation. The authors would like to thank Pascale Gerbouin-Rerolle, Maxime Valdenaire and Roselyn Rima Gomes for their help on data management. The present work was performed using data from the Inserm E3N cohort and support from the MGEN, Gustave Roussy, and the Ligue contre le Cancer for setting up and maintaining the cohort..*[1]Inserm, U1018, Villejuif, France; [2]Beaujon, Internal Medicine, Clichy, France; [3]Hospital Center Régional D'orléans Hospital La Source, Rheumatology, Orléans, France; [4]Bicetre Hospital, Rheumatology, Le Kremlin-Bicêtre, France; [5]Inserm, Centre of Immunology of Viral Infections and Auto-immune Diseases (IMVA), INSERM U1184, Université Paris-Saclay, Le Kremlin Bicêtre, France*

Background: Rheumatoid arthritis (RA) is an inflammatory rheumatic disease of multifactorial aetiology, which preferentially affects women. To date, active personal smoking has been the most reproducibly reported risk factor for anti-citrullinated protein antibodies (ACPA) positive RA. Fish consumption has been thought to reduce the risk of rheumatoid arthritis (RA), but reported data were conflicting.

Objectives: To assess the association between fish consumption (overall, lean fish, and oily fish) and the risk of RA.

Methods: The E3N study (Etude Epidémiologique auprès des femmes de la Mutuelle générale de l'Education Nationale) is a French prospective cohort investigating environmental factors associated with chronic diseases. It follows 98,995 healthy French women since 1990 covered by a national health insurance primarily involving teachers. RA cases have been previously identified with specific questionnaires and medication reimbursement database. Dietary data were collected via a validated food-frequency questionnaire in 1993. Cox proportional hazards models were used to calculate HRs and 95% CIs for incident RA depending on the tertiles of consumption of overall, lean and oily fish. Models were adjusted for age and for the main potential confounders. Stratified analyses were conducted depending on the active smoking status (never or ever-smoker).

Results: Among 62,629 women, 480 incident cases of RA were identified. In the overall population, we did not find a linear association between overall fish consumption and RA risk (p for trend 0.65), but a moderate consumption of fish (16.7–31.1 g/day, roughly corresponding to 1 to 2 servings a week) was associated with a decreased risk of RA (HR 0.74; 95% CI 0.59—0.94 for tertile 2 compared with tertile 1), especially among ever smoking women (HR 0.61; 95% CI 0.44—0.85). Although not statistically significant, a trend towards an inverse association was only found with oily fish consumption (HR 0.81; 95% CI 0.65—1.02 for tertile 2), but not with lean fish.

Conclusion: In our large population-based cohort study of French women, there was a U-shaped relationship between overall fish consumption and the risk of RA, with a reduced RA risk only in moderate consumers. The inverse association was restricted to ever-smokers. When separately considering oily and lean fish, the second tertile of oily fish consumption was inversely associated with the risk of RA only in never-smokers, while there was no association with lean fish.

Table 1. Hazard ratios (95% confidence intervals) for the risk of rheumatoid arthritis (RA) by tertiles of fish consumption (N = 62,629)

Fish consumption	Non-cases	RA	Model 1	Model 2
	N (%)	N (%)	HR (95% CI)	HR (95% CI)

POS1432 ROLE OF FAT AND MUSCLE TISSUE ON QUALITY OF LIFE OUTCOMES IN OSTEOARTHRITIS: RESULTS FROM THE KHOALA COHORT

A. C. Rat[1,2,3], J. Sellam[4,5], B. Mazières[6], W. Ngueyon Sime[7], P. Fardellone[8], F. Guillemin[3,7]. *[1]Caen-Normandy University, UNICAEN, Inserm, UMR-S 1075 COMETE, PFRS, Caen, France;, Caen, France; [2]University Hospital Center Caen, Rheumatology Department, Caen, France; [3]University De Lorraine, APEMAC, Nancy, Nancy, France; [4]Sorbonne Université, Inserm UMRS_938, FHU PaCeMM, Paris, France; [5]Sorbonne Université, AP-HP, Hôpital Saint-Antoine, Department of Rheumatology, Paris, France; [6]University Hospital Center Toulouse, Rheumatology Department, Toulouse, France; [7]University De Lorraine, CHRU-Nancy, Inserm, CIC 1433 Épidémiologie clinique, Nancy, France; [8]Chu D'amiens-Picardy Site Nord, Rheumatology Department, Amiens, France*

Background: The study of associations between body composition and osteoarthritis is still incomplete. While fat-related components are associated with pain in cross-sectional studies, longitudinal studies are rare and the impact on other quality of life (QOL) dimensions is not known.

Objectives: The main objective of the study was to analyze the impact of body composition on the evolution of the perceived health of patients followed for hip and knee osteoarthritis (OA).

Methods: Longitudinal data from the Knee and Hip Osteo Arthritis Long-term Assessment (KHOALA) cohort, a multicenter cohort of 878 patients with symptomatic knee and/or hip OA, were used. Body composition measures were obtained from DXA scans at year 3. Only 3 of the 6 investigating centers with Lunar Prodigy Advance DXA equipment recruited patients for this study. The main outcome criteria were the changes in Patient-Reported Outcomes Measures (PROms) (physical functioning, pain, mental health and vitality of the SF-36 0=worst,100=best) between 3 and 7 years of follow up. Body composition variables were as follows: fat mass index (FMI (kg/m^2)), percentage of fat mass and trunk to leg fat mass ratio (TFM/LFM), skeletal muscle Mass Index (SMI (kg/m^2)) and low lean mass if SMI <7.00 kg/m^2 for men and <5.5 kg/m^2 for women. To account for the correlation of repeated measurements of the same individual, generalized estimating equation (GEE) models were used to assess the associations between body composition measurements and the 4 SF-36 scores. The GEE models were adjusted for potential confusion covariates (age, sex, education level, occupation, smoking, comorbidity, hand OA, number of painful joints, joint of inclusion and Kellgren grade (KL)) showing a significant association at the 0.2 threshold in the bivariate analysis.

Results: 290 patients with knee and 114 patients with hip OA have been included in the analysis: women 254 (66.7%), mean age 60.3 (SD 8.4) years old, IMC 29.5 (5.7), KL grade2 135 (46.6%) for knee OA, 79 (69.3%) for hip OA.

The results of the multivariate analysis of associations between anthropometric measures and quality of life dimensions are presented in Table 1.

Table 1.

	Physical functionning			Bodily pain			Mental health			Vitality		
	β	CI* 95%	p	β	CI* 95%	p	β	CI* 95%	p	β	CI* 95%	p
FMI*	-0.02	(-0.03;-0.01)	<.0001	-0.007	(-0.02;0.002)	0.14	0.0012	(-0.006;0.008)	0.76	-0.01	(-0.02;0.002)	0.02
TLF/LFM*	0.06	(-0.02;0.14)	0.12	0.03	(-0.06;0.12)	0.53	0.09	(0.02;0.15)	0.008	0.08	(0.002;0.17)	0.04
SMI*							0.01	(0.006;0.02)	<.0001	0.02	(0.01;0.02)	<.0001
Low LM	-0.21	(-0.02;0.02)	0.02									

Positive coefficients indicate that the outcome variable increased more for the observed group than for other participants. *The estimator expresses the variation of risk for an increase of 1 units of the variable. Analyses were adjusted on age, sex, education level, occupation, smoking, comorbidity, hand OA, number of painful joints

Conclusion: Increased FMI and the presence of low muscle mass (SMI) were associated with impaired functional ability, but not with pain, the associations of which disappeared after adjustment. Increased TFM/LFM and SMI were associated with improved mental health and vitality over time

POS1433 OBSTETRIC OUTCOMES OF MEXICAN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES.

L. G. Espinosa Banuelos[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], A. Cárdenas[1], F. Hernández[2], A. Y. Lujano Negrete[1], S. M. Delgado Ayala[1], A. Guzman Lopez[3], D. Á. Galarza-Delgado[1]. *[1]Hospital Universitario Dr. José Eleuterio González, Rheumatology Deparment, Monterrey, Mexico; [2]Hospital Universitario Dr. José Eleuterio González, Obstetrics and Maternal Fetal Medicine Unit, Monterrey, Mexico; [3]Hospital Universitario Dr. José Eleuterio González, Obstetrics and Gynaecology, Monterrey, Mexico*

Background: Autoimmune rheumatic diseases(ARDs) are more prevalent in women during childbearing age. These women have an increased risk of adverse pregnancy outcomes and maternal morbidity than general obstetric population(GOP)

Objectives: The objective this study was to evaluate the obstetric outcomes in Mexican women with ARDs

Methods: A retrospective and descriptive study was conducted in a pregnancy and rheumatic disease clinic of a university hospital in Northeast Mexico from Jan 2017 to Dec 2020. All data were collected from the medical records of childbearing age women with ARDs enrolled in our clinic at the time of their pregnancy and childbirth. Patients with non-inflammatory rheumatic diseases were excluded. The obstetric, maternal, and fetal outcomes were compared with the rate of adverse perinatal outcomes of the GOP (n=31,254) database from the same institution. Sociodemographic and clinical characteristics of the population are described. We used the Mann–Whitney U, Chi-square, or Kruskal–Wallis tests to analyze the differences between groups. A p<0.05 was considered statistically significant. The statistical analysis was performed with SPSS v.24 statistical software (IBM, NY).

Results: A total of 62 pregnancies in women with ARDs were included. RA (n=24, 38%) was the most frequent diagnosis followed by SLE (n=14, 22.5%) and APS (n=9, 14.5%). The median maternal age at conception was higher in pregnancies with ARDs than GOP(p<0.001). Table 1 shows the pregnancy and product outcomes between groups. Maternal age ≥ 35 years was also more frequent in the ARDs group(p<0.001). The birth weight was lower in ARDs group than GOP(p=0.007). The odds of preterm delivery were increased in ARDs group(p=0.038)

Table 1. Pregnant outcome, maternal, fetal, and neonatal adverse events

	ARD(n=62)	GOP(n=31254)	OR(CI 95%)	p
Pregnancy outcome				
Pregnancy loss[a]	6(9.68)	1560(4.99)	1.94(0.84-4.49)	0.122
Live births[a]	60(90.9)	29694(95)	0.96(0.67-1.35)	0.8

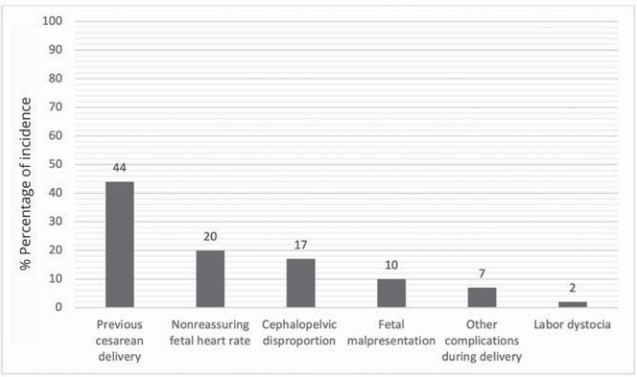
Emergency cesarean section[a]	8(12.9)	1844(5.9)	2.19(1.05-4.57)	**0.037**
Maternal death[a]	0	31(0.09)	7.94(0.48-131.2)	0.148
Fetal adverse events				
Miscarriages[a]	3(4.8)	663(2.12)	2.28(0.71-7.29)	0.164
Stillbirths[a]	3(4.8)	897(2.87)	1.69(0.53-5.38)	0.377
Congenital anomalies[a]	4(6.5)	1094(3.5)	1.84(0.67-5.08)	0.237
Neonatal adverse events				
Low birthweight (<10th percentile)[a]	7(12.3)	3782(12.1)	0.933(0.43-2.04)	0.862
Very low birthweight (<3rd percentile)[a]	3(5.3)	813(2.6)	1.86(0.58-5.93)	0.294
Low Apgar scores at 5 minutes (<7)[a]	4(7.02)	1781(5.7)	1.13(0.41-3.12)	0.81

Values in bold denote statistical significance (<0.05)[a] n, % [b] IQR, interquartile range (25th–75th percentile) [c] CI, confidence interval (95%)

The most common fetal adverse event was congenital anomalies in both groups with no significant difference(p=0.237). The most frequent neonatal adverse events were low birthweight(<10th percentile) and a low Apgar score at 5 minutes(<7pts) in both groups

The prevalence of cesarean section was higher in the ARDs group(p=0.016). The distribution of indications for cesarean sections is shown in Figure 1.



Conclusion: Pregnant women with ARDs had a higher median maternal age at conception, lower birth weight, increased preterm delivery, and more emergency cesarean sections than pregnant women without ARDs. Close monitoring and multidisciplinary care are necessary to prevent and timely treat complications in this population

POS1434 USE OF BIOLOGIC OR TARGETED SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS AND THE RISK OF LYMPHOMA IN RHEUMATOID ARTHRITIS

N. Singh[1], A. Peterson[2], A. Baraff[2], P. Bhatti[3], A. Gopal[1], N. Smith[2], J. Barton[4], J. Curtis[5], C. LI[1], N. Weiss[1]. *[1]University of Washington, Medicine, SEATTLE, United States of America; [2]VA Puget Sound, Epidemiology, SEATTLE, United States of America; [3]University of British Columbia, Epidemiology, Vancouver, Canada; [4]VA Portland, Medicine, Portland, United States of America; [5]University of Alabama at Birmingham, Medicine, Birmingham, United States of America*

Background: Epidemiologic studies suggest that disease duration and degree of inflammatory activity of rheumatoid arthritis (RA) contribute to lymphoma

development (1). Whether the decrease in inflammatory burden seen with use of biologic or targeted synthetic disease modifying anti-rheumatic drugs (bDMARDs or tsDMARDs) translates into a lower risk of lymphoma in RA needs to be studied.

Objectives: The objective of our study was to examine the effect of administration of b/tsDMARDS on the incidence of lymphoma relative to conventional synthetic DMARDs (csDMARDs) in an inception cohort of Veterans with RA.

Methods: We identified patients >18 years of age diagnosed with RA in any US Veterans Affairs (VA) facility from 1/1/2002 and 12/31/2018 using the VA Corporate Data Warehouse (CDW). To be included, each patient was required to meet the following criteria: 2+ RA diagnostic codes at least 7 days apart but no more than 365 days apart; 2) a prescription for a csDMARD within 90 days of the first RA diagnosis; and 3) an inpatient or outpatient visit 30 days to 2 years preceding first RA diagnosis (indicating they are a regular user of the VA). The csDMARDs included in these analyses were: methotrexate, sulfasalazine, leflunomide, and hydroxychloroquine. The bDMARDs included were tumor necrosis factor inhibitors (TNFi) and non-TNFi biologics such as tocilizumab, rituximab, abatacept, and biosimilars; tsDMARD was tofacitinib. Patients with prevalent lymphoma were excluded. Lymphoma diagnoses were identified using International Classification of Diseases Version 9, 10 and Oncology (ICD9, ICD10, ICDO) codes.

We used marginal structural models as described by Hernan et al (2) and time-varying Cox models to control for confounding by indication while evaluating this association. We adjusted for baseline demographics (age, sex, race, ethnicity, year of cohort entry, rheumatology visits), and time-varying CRP and time-varying Rheumatoid Disease Comorbidity Index (RDCI) (3) to control for confounding.

Results: 27,421 Veterans with RA met our eligibility criteria. Most of the Veterans (56%) were in the age range 61-80 years old; 89% male, 76% White, 14% African American. 8,225 (30%) patients were treated with a b-/tsDMARD. The crude incidence rates were 1.71 (95% CI 1.5-1.94) per 1000 person-years for those only on csDMARDs and 1.78 (95% CI 1.44-2.18) for patients during or following use of a b/tsDMARDs. After adjustment with both time-fixed and time-varying covariates using marginal structural models, the incidence of lymphoma was not different between patients who did and did not use a b/tsDMARD (hazard ratio=1.06, 95% CI= 0.82-1.37) (Table 1).

Table 1. Estimates of Effect of bDMARD or tsDMARD use on Lymphoma relative to use of csDMARDs

Marginal Structural Models; adjusted for:		
[@]Demographics	1.04	(0.80, 1.34)
[#]Demographics + CRP	1.06	(0.82, 1.37)

* per 1000 person-years [@]Demographics = age, gender, race, ethnicity, rheumatology visits, and year of cohort entry [#]Adjusts for CRP, baseline rheumatology visits (yes/no) and RDCI. CRP = C-Reactive Protein, RDCI = Rhematic Disease Comorbidity Index, CI = Confidence Interval, b/tsDMARD = biologic or targeted synthetic DMARD, csDMARD = conventional synthetic DMARD

Conclusion: In this large study using the nationwide VA data, we did not observe an association between the use of b/ts DMARDs and an increased risk of lymphoma.

POS1435 FACTORS ASSOCIATED WITH THE RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A NATIONWIDE, POPULATION-BASED CASE-CONTROL STUDY

C. M. Kao[1], H. H. Chen[1,2]. [1]*Taichung Veterans General Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Taichung City, Taiwan, Republic of China;* [2]*Taichung Veterans General Hospital, Division of General Internal Medicine, Department of Internal Medicine, Taichung City, Taiwan, Republic of China*

Background: Ankylosing spondylitis (AS) is a chronic, systemic inflammatory disease with major pharmacological treatment with long-term nonsteroidal anti-inflammatory drugs (NSAIDs). Patients with AS are notably at risk for comorbidities involving the cardiovascular system [1]. Development of a predictive chart score or algorithm for risk of major adverse cardiovascular events (MACE) in patients with incident AS requiring pharmacologic therapy based on identified risk factors is a clinical necessity for a better holistic management. The related epidemiologic studies are still lacking currently.

Objectives: To investigate factors associated with major adverse cardiovascular events (MACE) in patients with incident ankylosing spondylitis (AS) requiring medical therapy.

Methods: We conducted a population-based case-control study using the Taiwanese National Health Insurance Research Database, and 42,595 newly-diagnosed AS patients requiring medical therapy without previous MACE (the composite outcome of myocardial infarction, ischemic stroke, or patients who underwent coronary artery bypass graft or percutaneous coronary intervention) from 2004 to 2012 was identified. Totally 1,151 patients (2.7%) developed MACE during the follow-up period. We matched MACE cases with non-MACE controls at a 1:4 ratio for age, gender and AS follow-up duration and included 947 AS patients with MACE and 3896 matched controls for final analyses. Using conditional logistic regression analyses, we examined the associations of MACE with low income (≤ 21000 new Taiwan dollars per month), urbanisation, extra-articular manifestations (uveitis, psoriasis and inflammatory bowel disease), comorbidities and use of medications within a year before MACE development. We also examined the influence of NSAIDs of three categories (traditional NSAIDs, selective cyclooxygenase-2 inhibitors [COX-2i] and preferential COX-2i) with their annual cumulative defined daily dose (cDDD) on MACE risk with a Bonferroni correction of the cut-off of probability value for statistical significance. The risk was shown as adjusted odds ratio (aOR) with 95% confidence intervals (CIs).

Results: MACE development was associated with selective COX-2i use especially with annual cDDD > 132 (aOR, 1.61; 95% CI, 1.12-2.32, p = 0.011), corticosteroid use with a dose–response relationship (prednisolone equivalent dose < 5 mg/day: aOR, 1.25; 95% CI, 1.02-1.54, p = 0.028; ≥ 5 mg/day: aOR, 4.75; 95% CI, 3.51-6.43, p < 0.001), residence in rural region (aOR, 1.32; 95% CI, 1.03-1.69, p = 0.028), hypertension (aOR, 3.12; 95% CI, 2.57-3.80, p < 0.001), diabetes mellitus (aOR, 1.69; 95% CI, 1.37-2.07, p < 0.001), hyperlipidaemia (aOR, 5.00; 95% CI, 4.14-6.03, p < 0.001), chronic kidney disease (aOR, 1.98; 95% CI, 1.35-2.90, p = 0.001), heart failure (aOR, 4.04; 95% CI, 2.74-5.94, p < 0.001) and valvular heart disease (aOR, 2.06; 95% CI, 1.33-3.20, p = 0.001), but not with use of traditional NSAIDs, preferential COX-2i, biologics, methotrexate, sulfasalazine, uveitis, psoriasis or inflammatory bowel disease.

Conclusion: The risk factors of MACE in AS patients include use of selective COX-2i, corticosteroids, residence in rural region and other well-known associated comorbidities. The major limitation of this study was a lack of information on individual smoking status. The findings might aid in the development of a predictive chart score or algorithm for MACE risk in patients with AS.

POS1436 CLINICAL CHARACTERISTICS AND RISK FACTORS OF INVASIVE FUNGAL INFECTION DURING IMMUNOSUPPRESSIVE INDUCTION THERAPY IN PATIENTS WITH CONNECTIVE TISSUE DISEASE

H. Fukui[1], H. Hanaoka[1], Y. Kaneko[1]. [1]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Invasive fungal infection (IFI) is a life-threatening complication among immunosuppressed patients. Whereas intensive immunosuppressive therapy during remission induction phase in patients with connective tissue disease is a major risk of IFI, little is known about the clinical characteristics and risk factors of IFI.

Objectives: This study aims to reveal prevalence, clinical characteristics, and associated risk factors of IFI during immunosuppressive induction therapy in patients with connective tissue disease.

Methods: We reviewed consecutive patients with connective tissue diseases who underwent immunosuppressive remission induction therapy in Keio University Hospital Rheumatology Department from January 2012 to August 2020. Patients with 0.5mg/kg or more equivalent dose of daily prednisone use were included for IFI, diagnosed according to the definition of invasive fungal diseases from EORTC/MSG 2008. Infections caused by *Pneumocystis jirovecii* were not included.

Results: Among 2701 hospitalized cases, 627 patients had undergone induction or re-induction therapy. Total of 24(3.8%) patients were diagnosed as IFI,

of whom there were 8 proven cases and 16 probable cases; 14 aspergillosis, 5 candidiasis, 2 cryptococcosis, 1 phaeohyphomycosis, and 2 cases with unknown pathogen. Median duration from the start of immunosuppressive therapy to the onset of IFI was 95 days (interquartile range, 36,249 days; range, 13-1397 days) and the mean dose of daily prednisolone was 0.53±0.29 mg/kg at the onset of IFI. Total of 11 patients died; 6 patients (25.0%) due to IFI and 5 patients (20.8%) due to the exacerbation of underlying disease. Univariable analysis comparing the IFI and non-IFI groups, age (65.8±3.7 vs. 56.1±0.7; P=0.01), initial prednisolone dose (0.87±0.01 vs 0.95±0.04 mg/kg; P=0.037), the history of methylprednisolone (mPSL) pulse therapy (54.2% vs. 20.0%; P<0.001), tumor necrosis factor (TNF) inhibitor use (8.3% vs. 1.1%; P=0.039), 2 or more immunosuppressant or biologic use (33.3% vs. 12.9%; P=0.010), HbA1c 6.5% or higher (58.3% vs. 28.9%; P=0.003), lowest serum IgG during the clinical course (599.4±62.1 vs 787.7±12.4 mg/dl; P=0.003), and cytomegalovirus reactivation defined by pp65 antigen 6 or higher (33.3% vs. 11.2%; P=0.004) were significantly different, respectively. Sex, body mass index, presence of interstitial lung disease, and the use of cyclophosphamide, rituximab, or interleukin-6 inhibitors were not significantly different. Multivariable analysis revealed older age (for each 10-year increase: OR 1.40, 95% CI 1.03-1.91; P=0.023), the history of methylprednisolone pulse therapy (OR 2.60, 95% CI 1.06-6.77; P=0.049), TNF inhibitor use (OR 11.2, 95% CI 1.70-74.0; P=0.012), and serum IgG less than 550 mg/dl (OR 2.59, 95% CI 1.03-6.55; P=0.041) as the independent risk factors of IFI.

Conclusion: Patients with connective tissue disease with older age, lower serum IgG, mPSL pulse therapy, or TNF inhibitor use are at higher risk of IFI. Further studies are needed to determine the benefit of prophylactic anti-fungal treatment in such patients.

POS1437 ASSOCIATION BETWEEN BEVERAGE CONSUMPTION AND RISK OF RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY FROM THE FRENCH E3N COHORT

S. Ascione[1,2], C. Salliot[2,3], F. Artaud[2], Y. Nguyen[2,4], C. Macdonald[2], F. Barde[2], X. Mariette[5,6], M. C. Boutron-Ruault[2], R. Seror[5,6]. *[1]Hôpital Lariboisière AP-HP, Rheumatology, Paris, France; [2]Université Paris-Saclay, UVSQ, Inserm, Institut Gustave Roussy,"Exposome and Heredity"Team, CESP, 94805, Villejuif, France; [3]Centre Hospitalier Régional d'Orléans, Rheumatology, Orléans, France; [4]AP-HP.Nord, Hôpital Beaujon, Université de Paris, Internal Medicine, Clichy, France; [5]Université Paris-Saclay, France, AP-HP, Hôpital Bicêtre, National Reference Center for Rare Systemic Autoimmune Diseases, INSERM UMR1184, Le Kremlin Bicêtre, France; [6]Université Paris-Saclay, AP-HP, Hôpital Bicêtre, Rheumatology, Le Kremlin Bicêtre, France*

Background: The role of nutrition in the pathogenesis of RA has been suggested in many studies but remains controversial.

Objectives: To assess the relationship between consumption of the most frequently drinked specific beverages (coffee, tea, alcohol, and soft drinks) and the risk of RA.

Methods: The E3N Study (*Étude Épidémiologique auprès des femmes de la Mutuelle Générale de l'Éducation Nationale*) is a French prospective cohort including 98,995 women since 1990. RA cases have been previously identified with specific questionnaires and medication reimbursement database (1). Food and beverage consumption was assessed using a validated food-frequency questionnaire. Hazard ratios (HR) and their 95% confidence intervals (CI) for incident RA were estimated by Cox proportional hazards models, adjusted for age and the main potential confounders, including smoking. Tests for linear trends were performed. As smoking is a major risk factor for RA, stratified analyses were conducted according to the smoking status (ever or never-smoker) even in the absence of statistically significant interaction between the smoking status and beverage consumptions. Sensitivity analyses were performed in the subgroup of seropositive cases (positive RF and/or ACPA).

Results: During a total follow-up of 21 years (mean 20.78 (SD 2.26) years), 62,630 women contributed 1,300,874 person-years, and 481 developed RA (incidence 37/100 000 person-years). Incident RA cases were diagnosed a mean 11.7 (SD 5.9) years after baseline. Of the 179 (37.2%) RA cases with known antibody status, 153 (31.8%) were seropositive. Consumptions of total alcohol, tea and sugar-sweetened soft drinks were not associated with RA risk. Coffee consumption was associated with RA risk with a dose-effect relationship (≥4 cups/day *versus* ≤ 1cup/day, HR 1.24, 95% CI [0.94; 1.64], p_{trend} = 0.04), only in never-smokers. According to the type of coffee consumed, only high caffeinated coffee consumption was associated with an increased risk of RA among never-smokers (≥ 3.5 cups/day *versus* ≤ 1 cup/day, HR=1.62 95% CI [1.12;2.34], p_{trend} = 0.006, $p_{interaction}$ = 0.07). Decaffeinated coffee consumption was not associated with RA risk. Risk of RA was higher with artificially-sweetened soft-drinks consumption (consumers *versus* non-consumers, HR 1.66 [1.12; 2.45]), in never-smokers. No association was observed with other soft drinks. Moderate liquor (spirits or aperitifs) intake was associated with a reduced risk of RA among ever-smokers (consumption of 1 - 3 glasses/week *versus* non-consumers HR 0.63, 95% CI [0.43; 0.91]) and moderate wine consumption was associated with a decreased risk of seropositive RA (consumption of 4 -10 glasses/week *versus* ≤ 1glass/week HR 0.57, 95% CI [0.35 to 0.94], whereas no association was observed with other alcohols.

Conclusion: Consumptions of tea, total alcohol, and sugar-sweetened soft drinks were not associated with RA risk, whereas consumptions of coffee (especially caffeinated coffee), and artificially-sweetened soft drinks were associated with higher RA risk, among never-smokers. By contrast, moderate liquor consumption was associated with a decreased risk of RA in ever-smokers, and moderate wine consumption was associated with a decreased risk of seropositive RA. If further confirmed, these results could lead to novel mechanistic hypotheses and to simple prevention measures.

POS1438 FRYQ QUESTIONNAIRE DISTINGUISHES INFLAMMATORY FROM NON-INFLAMMATORY DISEASE IN NEWLY REFERRED PATIENTS

R. Bos[1], A. Al Hasan[2], F. Reimann[1], A. M. Schilder[1], D. Zhang[1], F. Wink[1], L. Hendriks[1], T. Maarseveen[2], R. Knevel[2]. *[1]Medical Center Leeuwarden, Rheumatology, Leeuwarden, Netherlands; [2]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: Inflammatory Rheumatic Diseases (IRDs) affect 5% of the general population, while 35% of the population experiences Musculoskeletal Complaints (MSCs) [1]. IRDs cause early disability, reduced life-expectancy and considerable health care costs. Early diagnosis is essential to prevent long-term damage, similarly important is the early identification of patients with MSCs without IRDs to prevent unnecessary health care expenses. Of the population referred to the rheumatologist, 60% have non-inflammatory MSCs while only 20% of patients with an IRD see a rheumatologist within three months of symptom onset [2]. The need for digital predictive (triage) tools for Rheumatic and Musculoskeletal Diseases led to the development of the Frysian Questionnaire for differentiation of MSK complaints (FRYQ).

Objectives: To assess if FRYQ questionnaire can distinguish inflammatory rheumatic disease from non-inflammatory MSCs in newly referred patients.

Methods: The Frysian Questionnaire for differentiation of MSK complaints (FRYQ) is an 87 item questionnaire (consisting of 20 open questions and 67 closed questions), which is used in regular care in the rheumatology outpatient clinic of the Medical Center Leeuwarden to triage newly referred patients. Results of FRYQ, referral work diagnosis, resulting diagnoses and demographic data of 854 patients were collected. Elastic Net regularization was used to extract the most informative questions. The data was split: 75% to construct the elastic net and 25% to perform an independent validation. The classification performance was evaluated according to the area under the ROC-curve.

Results: The group consisted of 287 males (33%) and 570 (66%) females. Table 1 shows the characteristics of the 854 studied referrals.

Table 1.

Table 1	Referral or work diagnosis Number (%)	Diagnosis by rheumatologist Number (%)	Correct work diagnosis GP Number (%)
Rheumatoid arthritis	146 (16.9)	87 (10.1)	53 (36.3)

Fibromyalgia	79 (9.2)	110 (12.7%)	57 (72.2)
Osteoarthritis	29 (3.4)	153 (17.7%)	22 (75.9)
Hypermobility syndrome	0	23 (2.7)	0 (0)
Unknown	6	0	NA
Other	33 (3.9)	127* (14.8)	NA
total	854 (100)	854 (100)	NA
Inflammatory	293 (34.3 %)*		
Non-inflammatory	560 (65.7 %)*		

*including missing data

After elastic net regularization the 87 items could be reduced to 33 items that were able to differentiate inflammatory disease from non-inflammatory disease with an AUC of 0.70 in the ROC curve below (Figure 1).

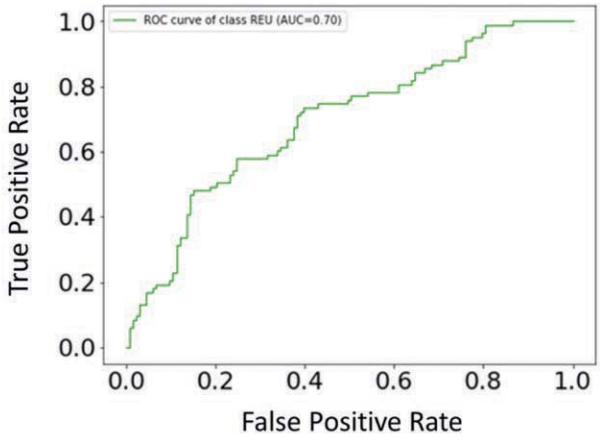

Figure 1. ROC-curve highlighting performance of FRYQ after regularization in the validation set

Conclusion: FRYQ questionnaire can differentiate inflammatory rheumatic disease from non-inflammatory musculoskeletal complaints. To officially validate FRYQ a prospective cohort study is needed.

POS1439 CANCER IN PATIENTS WITH RHEUMATIC DISEASES EXPOSED TO DIFFERENT BIOLOGIC AND TARGETED SYNTHETIC DMARDS IN REAL-WORLD CLINICAL PRACTICE: DATA FROM A MULTICENTER REGISTER

I. Castrejon[1,2], J. Molina Collada[1,2], C. Perez-Garcia[3], P. Vela-Casasempere[4], C. Diaz-Torne[5], C. Bohórquez[6], J. M. Blanco[7], F. Sánchez-Alonso[8]on behalf of BIOBADASER. *[1]Hospital General Universitario Gregorio Marañón, Rheumatology, Madrid, Spain; [2]Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Rheumatology, Madrid, Spain; [3]Hospital del Mar, Rheumatology, Barcelona, Spain; [4]Hospital General Universitario de Alicante, Rheumatology, Alicante, Spain; [5]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain; [6]Hospital Principe de Asturias, Rheumatology, Madrid, Spain; [7]Hospital de Basurto, Rheumatology, Bilbao, Spain; [8]Fundación Española de Reumatología, Rheumatology, Madrid, Spain*

Background: Extensive evidence has confirmed no increased risk of cancer associated to either conventional synthetic DMARDs or anti-TNF in patients with rheumatic diseases. The risk of cancer in biologic (bDMARDs) different to anti-TNF and targeted synthetic (tsDMARDs) is considerably less investigated. As new therapies are emerging, more data in real-world registries are needed to confirm safety in other treatment groups.

Objectives: To compare the risk of cancer of tsDMARDs and other bDMARDs versus anti-TNF in patients with rheumatic diseases.

Methods: Data of patients enrolled in BIOBADASER 3.0 up to October 2021 with the start of any bDMARD or tsDMARD were analyzed. For each group, demographic and clinical variables were estimated. Changes to therapy and occurrence of serious adverse events collected annually. Incident cancer was defined as any cancer during the exposure classified according to Meddra dictionary leading to therapy discontinuation. Incidence rate ratios of cancer per 1000 patients-year (PYs) and 95% confidence interval were estimated. Incidence rate ratio was calculated for each group versus anti-TNF.

Results: We identified 271 cancers in BIOBADASER 3.0, corresponding to a cancer incident rate of 7.4 (6.5-8.3) per 1000 PY of exposure. Patients exposed to anti-TNF and anti-IL17 were younger, with lower disease duration and comorbidity versus other groups. Proportionally more malignancies were identified in the anti-CTLA-4 group (3.4%) versus the anti-TNF group (2.9%). The rates of incident cancer ranged between 2.6 events/1000 PY in the anti-IL17 group and 15.3 events/1000 PY in the anti-CTLA-4 group. The rate of cancer did not differ significantly in patients exposed to JAKi [0.8 (95% CI 0.4-1.5)], anti CD20 [1.1 (95% CI 0.6-1.8)], or anti-IL6 [1.3 (95% CI 0.9-1.9)] versus anti-TNF; it was significantly lower in patients exposed to anti-Il17 [0.4 (95% CI 0.2-0.9)], and significantly higher in patients exposed to anti-CTLA-4 [2.2 (95% CI 1.4-3.2)]. The most frequent malignancy was non-melanoma skin cancer, followed by solid cancer (mainly breast cancer with 24 events and lung cancer with 14 events) and melanoma (13 events).

Conclusion: In this register-based study, rates of incident cancer did not differ between patients treated with anti-TNF and other bDMARDs or tsDMARDs, with the possible exception of a potential increased risk in patients treated with anti-CTLA-4.

HEMATOLOGICAL MALIGNANCIES AND ANTI-TNF IN INFLAMMATORY ARTHRITIS: THE REAL LIFE DATA FROM THE HUR-BIO REGISTRY

E. Duran[1], Z. Ö. Öztürk[2], E. Bilgin[1], E. C. Bolek[1], G. K. Yardımcı[1], B. Farisogullari[1], Z. Özsoy[1], G. Ayan[1], G. Sandal Uzun[1], M. Ekici[1], E. Unaldi[1], L. Kılıç[1], A. Akdoğan[1], O. Karadag[1], Ş. A. Bilgen[1], S. Kiraz[1], U. Kalyoncu[1], A. I. Ertenli[1]. *[1]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Rheumatology, ANKARA, Turkey; [2]Hacettepe University School of Medicine, Department of Internal Medicine, ANKARA, Turkey*

Background: TNF inhibitors (TNFi) is highly effective in inflammatory arthritis (IA) treatment. However, concerns are raised about the possible association between TNFi and hematologic malignancies (HMs).
Objectives: To assess the incidence of HMs among IA patients receiving TNFi compared with the general Turkish population.
Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a single center biological disease modifying anti-rheumatic drug (bDMARD) registry since 2005. Patients with IA including rheumatoid arthritis (RA), spondyloarthritis (SpA), and psoriatic arthritis (PsA) patients who had at least 1 visit after the TNFi usage were screened from 2005 to November 2021. HM diagnosis was determined from the each patient files according to the hematologists' decision and/or bone marrow/lymph node biopsy. Demografic data, disease characteristics, and death status were recorded. Standardized incidence rates (SIR) were calculated after adjustment for age and gender and compared with age- and gender-specific SIR values abstracted from the 2017 Turkish National Cancer Registry (TNCR).
Results: Of the 6139 patients registered in the HUR-BIO database, 5355 [3116 female (58.2%)] used any TNFi at least once. Median follow-up duration was 2.6 years for all patients receiving TNFi. 13 patients [8 (61.5%) female] had HM on follow-up. In these patients, median age at the IA onset was 38 (range 26 to 67) and the number of patients with SpA, RA, and PsA was 7, 4, and 2, respectively. The median duration of IA was 17.7 years (range 1 to 33). The median age at the HM onset was 55.5 (range 38 to 76) and the type of HM as follow: 8 lymphoma, 2 multiple myeloma, 1 large granular lymphocytic leukemia, 1 plasma cell dyscrasia, and 1 myelodysplastic syndrome. The median duration of the TNFi usage onset to HM was 36 (range 4-112) months. The TNFi was as follows: etanercept (n=8), adalimumab (n=6), infliximab (n=4), golimumab (n=1), and certolizumab (n=1). 5 patients used more than one TNFi. Patients using TNFi had an increased incidence for HMs (SIR 4.23, 95% CI 2.35-7.05). These results were also valid for both gender. 10 patients with HMs were under the age of 65. In this group, there was a higher incidence of HMs in both men (SIR 5.15, 95% CI 1.88-11.43) and women (SIR 4.76, 95% CI 1.74-10.55). 5 patients deceased on follow-up.
Conclusion: The risk of HMs in inflammatory arthritis patients receiving TNFi being four times higher in comparison with the general Turkish population. There is a plethora of information that discusses the association between HMs and rheumatic disease. To determine whether the increased risk is from rheumatic disease or from TNFi usage, it would be ideal to compare patients receiving TNFi with bDMARD naive IA patients.

Table 1. SIR for diferent age cut-ofs in both sexes for patients with hematologic malignancies

Gender	Age	Observed/expected cases	SIR	%95 confidence interval
Total	All ages*	13/3.07	4.23	2.35-7.05

INFLUENCE OF ENVIRONMENTAL AND GENETIC FACTORS ON SERUM IGG4 DURING HEALTH CHECKUPS IN NAGASAKI ISLAND STUDY

Y. Tsuji[1], M. Tamai[1], T. Koga[2], S. Morimoto[3], S. Y. Kawashiri[4], F. Nonaka[5], H. Yamanashi[6], K. Arima[7], K. Aoyagi[7], T. Maeda[4], F. Matsuda[8], A. Kawakami[1]. *[1]Nagasaki University, Department of Immunology and Rheumatology, Nagasaki, Japan; [2]Nagasaki University, Center for Bioinformatics and Molecular Medicine, Nagasaki, Japan; [3]Nagasaki University, Innovation Platform & Office for Precision Medicine, Nagasaki, Japan; [4]Nagasaki University, Department of Community Medicine, Nagasaki, Japan; [5]Nagasaki University, Department of Island and Community Medicine, Nagasaki, Japan; [6]Nagasaki University, Department of General Medicine, Nagasaki, Japan; [7]Nagasaki University, Department of Public Health, Graduate School of Biomedical Sciences, Nagasaki, Japan; [8]Kyoto University, Center for Genomic Medicine, Nagasaki, Japan*

Background: Although serum IgG4 levels are important for the diagnosis of IgG4-related diseases (IgG4-RD), few studies have validated IgG4 levels in healthy individuals in large resident medical examination cohorts and investigated background factors associated with serum IgG4.
A report on genetic factors shows that HLA loci associate with IgG4-RD found in Japanese nation-wide IgG4-RD registry[1)]. However, environmental and genetic factors related to the elevated serum IgG4 levels, which may closely associate with development of IgG4-RD, have previously been unclear in healthy subjects. The nephelometric immunoassay (NIA) is conventionally used to measure IgG4, but it requires a relatively large amount of serum. The magnetic bead panel assay (MBA), which can evaluate IgG4 levels with only a few ml of serum, has an advantage compared with NIA regarding to required sample volume, but the correlation between the two methods is unclear.
Objectives: First, we attempted to verify the accuracy of the MBA compared to the standard NIA in the first cohort. Next, we examined the relationship between IgG4 measured by the MBA and background information of healthy subjects to identify variables that correlate with serum IgG4 in the second cohort.
Methods: First, Kanazawa University collected 947 samples from the resident health examination, and IgG4 levels were measured by both MBA and NIA, and

the correlation between the two was verified using Spearman's rank correlation coefficient (first cohort). Next (second cohort), serum IgG4 of 3240 samples of Nagasaki Island Study (NaIS), which had started in 2014 collaborating among Nagasaki University and Goto City, Nagasaki Prefecture, intended for research of varying conditions and diseases including IgG4-RD, were then measured by MBA. These subjects were stratified into the two groups as IgG4-high and IgG4-within normal limit using the aforementioned cutoff values, and compared with background information such as age, gender, drinking, smoking, uric acid, serum creatinine, comorbidities and HLA typing, including *DRB1*04:06, *04:03, *04:05, *04:10* as disease-susceptibility gene, *DRB1*09:01* and *DQB1*03:03* as protective gene[1)].

Results: IgG4 by MBA correlated well with IgG4 by NIA (r=0.94, p-value<0.001) which was determined from Kanazawa samples (N=947). 1,463.6 mg/mL of IgG4 of MBA corresponded to 135 mg/dl, the normal cut-off value for IgG4 by NIA. In the analysis of NaIS samples (N=3240), the overall high IgG4 positivity rate was 6.3%. Multivariable analysis including age, gender, smoking and drinking, led by univariate analysis, showed that gender and smoking were significantly associated with high serum IgG4 positivity (male: odds ratio = 1.8, 95%CI =1.2-2.7, p = 0.009, smoking: odds ratio = 1.7, 95%CI =1.1-2.5, p = 0.012). There was no association between high serum IgG4 level and HLA genotyping.

Conclusion: We concluded that MBA is a good method to measure serum IgG4 even by the very small sample volume. In our study, the prevalence of serum IgG4 positivity was high tendency than previous report[2)]. Our data showed that male and smoking are independent factors associated with high serum IgG4 positivity. There were no association between serum IgG4 level and HLA genotyping in healthy subjects. Further comprehensive investigation is necessary to clarify high risk subjects who will develop IgG4-RD.

POS1442

THE PREVALENCE OF RHEUMATOID ARTHRITIS IN WESTERN AUSTRALIA EXTRAPOLATED FROM HOSPITALISATION AND BIOLOGICAL THERAPY USAGE DATA

K. Almutairi[1,2], C. Inderjeeth[1,3], D. Preen[4], H. Keen[1,5], J. Nossent[1,3]. *[1]The University of Western Australia, School of Medicine, Perth, Australia; [2]King Fahd Specialist Hospital, Clinical Pharmacy, Buraydah, Saudi Arabia; [3]Sir Charles Gairdner and Osborne Park Health Care Group, Rheumatology, Perth, Australia; [4]The University of Western Australia, School of Population and Global Health, Perth, Australia; [5]Fiona Stanley Hospital, Rheumatology, Murdoch, Australia*

Background: Rheumatoid arthritis (RA) is a heterogeneous chronic autoimmune disease that affects the synovial joint lining and may result in permanent joint destruction, premature death, and socio-economic burden.[1] Although RA is one of Australia's national health priority areas and gathering information about the RA burden of disease was one of the national action plans[2], no published epidemiological study adequately describes RA prevalence and risk factors for frequent hospitalisations in Western Australia (WA) to date. An accurate prevalence estimate of this disease offers a framework for predicting present and growing healthcare service requirements in the future.[3]

Objectives: We estimated RA period prevalence and identified risk factors of frequent RA hospitalisations, using linked administrative health and state-specific Australian Pharmaceutical Benefits Scheme (PBS) datasets in WA from 1995–2014.

Methods: RA prevalence was calculated per 1000 hospital separations and biological therapy users. RA patients were identified in the WA linked health dataset using ICD codes 714.0–714.9 and M05.00–M06.99. Dispensing data on biological therapy for RA were obtained from PBS records and converted to defined daily doses/1000 population/day. Multivariate logistic regression was used to analyse risk factors for frequent RA hospitalisations (>2/year), controlling for sex, age, and geographic locations.

Results: A total of 17,125 RA patients were admitted to WA hospitals between 1995–2014. The total number of RA hospital separations was 50,353, averaging three hospitalisations per patient over 20 years. The RA period prevalence was 3.4 per 1,000 separations (0.34%), while the RA period prevalence based on biological therapy use was 0.36%. The corrected RA prevalence based on biological therapy usage was 0.36% and 0.72% for the 2005–2009 and 2010–2014 periods, respectively (Table 1). Female gender, age 60–69 years, and living in rural areas were all risk factors for frequent RA hospitalisations.

Conclusion: Based on hospital and biological therapy data, the minimal prevalence of RA in Western Australia is 0.34–0.36%, which falls within the literature range. Older female RA patients in rural areas were more likely to be hospitalised, suggesting unmet needs in primary care access.

Table 1. Total number of Rheumatoid Arthritis patients in Western Australia taking a standard dose daily (DDD) of RA biological therapy from 1995 to 2014.

Year	Total RA bDMARDs utilisation (DDD/1000 population/day)	WA general population	Prevalence of RA bDMARDs use in WA population (%)	Number of RA patients use standard dose daily of bDMARDs at WA
2003	0.01	1,952,741	0.00	14
2004	0.08	1,979,542	0.01	158
2005	0.16	2,011,207	0.02	329

POS1443

IDENTIFYING THE NEW EMERGENCE OF RACIAL DISPARITIES IN GOUT OVER THE PAST 3 DECADES – US NATIONAL SURVEY AND PROSPECTIVE COHORT DATA

N. McCormick[1,2,3,4], L. Lu[1], C. Yokose[2,3,4], A. Joshi[2,3,5], Y. Zhang[2,3,4], H. Choi[1,2,3,4]. *[1]Arthritis Research Canada, Vancouver, Canada; [2]The Mongan Institute, Medicine, Boston, United States of America; [3]Harvard Medical School, Medicine, Boston, United States of America; [4]Massachusetts General Hospital, Rheumatology, Allergy, and Immunology, Boston, United States of America; [5]MGH Clinical and Translational Epidemiology Unit, Medicine, Boston, United States of America*

Background: Several studies published after 2010 reported a higher frequency of gout and hyperuricemia among US Blacks than Whites.[1-4] However, Blacks (in the US and Africa) were previously thought to suffer gout less often than Whites.[5] We hypothesized that the racial disparity in Blacks emerged over the past several decades, with flipped prevalence between the two races.

Objectives: To assess trends in racial differences in gout prevalence in the US using both national survey and cohort study data over the past 3 decades.

Methods: Using data from the NHANES (National Health and Nutrition Examination Survey) III (**1988-1994**) and latest decade (**2007-2016**), and data from 5 examination periods in the ARIC (Atherosclerosis Risk in Communities) Study between **1988 through 2013**, we compared age- and sex-adjusted prevalences and odds ratios (OR) to determine the trend of racial differences in gout prevalence between Blacks and Whites. A time-race interaction term was used to assess differences in the rate of change between the two races.

Results: Among Whites, the sex- and age-standardised prevalence of gout in the NHANES rose from 2.8% (95% CI: 2.4 to 3.2) in 1988-94 to 3.7% (3.2 to 4.1) in 2007/16. Prevalence of gout among Blacks was lower than Whites in 1988-94 (2.6% [2.2 to 3.0]) but rose more sharply over the subsequent decades (p for race-time interaction=0.003), and in 2007/16 came to exceed that of Whites (5.0% [4.4 to 5.6]). Corresponding age-sex-adjusted ORs for gout in Blacks vs. Whites were 0.93 (0.73 to 1.17) in 1988-94, increasing to 1.46 (1.22 to 1.74) in 2007/16 (**Table 1**). This disproportionate rise in gout prevalence among Blacks tended to be more prominent among women (OR 1.81 [1.29 to 2.53]) than men (OR 1.26 [1.02 to 1.55]; p for race-time interactions of 0.002 and 0.01, respectively). Similar trends were observed in the ARIC cohort, where the OR for gout among Blacks vs. Whites rose progressively from 0.82 (0.65 to 1.02) in 1987-89 to 1.81 (1.49 to 2.19) in 2011-13.

Table 1. Temporal Trend of Racial Disparity in Gout Prevalence in NHANES Survey and the ARIC Study Cohort, overall and by sex

		Odds Ratio (95% CI) for Gout Among Blacks vs. Whites				
OVERALL	NHANES	**1988-1994**			**2007-2016**	
	Age- and sex-adjusted	0.93 (0.73 to 1.17)			1.46 (1.22 to 1.74)	
	ARIC	Visit 1: **1987-89**	Visit 2: **1990-92**	Visit 3: **1993-95**	Visit 4: **1996-98**	Visit 5: **2011-13**
	Age- and sex-adjusted	0.82 (0.65 to 1.02)	0.99 (0.81 to 1.22)	1.24 (1.03 to 1.50)	1.60 (1.35 to 1.90)	1.81 (1.49 to 2.19)
WOMEN	NHANES	**1988-1994**			2007-2016	
	Age-adjusted	0.98 (0.65 to 1.47)			1.81 (1.29 to 2.53)	
	ARIC	Visit 1: **1987-89**	Visit 2: **1990-92**	Visit 3: **1993-95**	Visit 4: **1996-98**	Visit 5: **2011-13**
	Age-adjusted	0.92 (0.64 to 1.32)	1.14 (0.82 to 1.59)	1.45 (1.07 to 1.96)	1.89 (1.45 to 2.46)	2.28 (1.73 to 3.01)
MEN	NHANES	**1988-1994**			2007-2016	
	Age-adjusted	0.91 (0.68 to 1.21)			1.26 (1.02 to 1.55)	
	ARIC	Visit 1: **1987-89**	Visit 2: **1990-92**	Visit 3: **1993-95**	Visit 4: **1996-98**	Visit 5: **2011-13**
	Age-adjusted	0.73 (0.54 to 0.97)	0.87 (0.66 to 1.14)	1.03 (0.79 to 1.33)	1.29 (1.02 to 1.64)	1.34 (1.00 to 1.78)

Conclusion: Gout prevalence tended to be lower in Blacks than Whites until late 80's, then rose and surpassed that of Whites over the past several decades. These trends closely parallel the worsening obesity epidemic during this period,[6] particularly in Blacks, partly due to enhanced Western lifestyle. Gout risk genetic profile change would not contribute to this emergence of racial differences, particularly among the same individuals in ARIC, although it remains to be clarified whether Blacks carry genetic profiles that enhance the effect of lifestyle risk factors for gout.

FLT1 AND EPHB2 ARE NOVEL GENETIC MARKERS ASSOCIATED WITH PANCREATITIS IN PATIENTS TAKING AZATHIOPRINE FOR IMMUNE-MEDIATED CONDITIONS: INTEGRATING GENOME- AND TRANSCRIPTOME-WIDE ASSOCIATION STUDIES

S. Shah[1], T. Reese[2], J. Zanussi[2], A. Dickson[2], L. Daniel[2], R. Tao[3], T. Miller-Fleming[4], P. Straub[5], A. Hung[6], P. Nepal[2], W. Q. Wei[5], E. Phillips[7], N. Cox[4], C. M. Stein[8], Q. Feng[8], C. P. Chung[2]. *[1]University of California, San Diego and VA San Diego Healthcare System, Gastroenterology, San Diego, United States of America; [2]Vanderbilt University Medical Center, Division of Rheumatology, Nashville, United States of America; [3]Vanderbilt University Medical Center, Biostatistics, Nashville, United States of America; [4]Vanderbilt University Medical Center, Genetics, Nashville, United States of America; [5]Vanderbilt University Medical Center, Biomedical Informatics, Nashville, United States of America; [6]Vanderbilt University Medical Center, Nephrology, Nashville, United States of America; [7]Vanderbilt University Medical Center, Infectious Diseases, Nashville, United States of America; [8]Vanderbilt University Medical Center, Pharmacology, Nashville, United States of America*

Background: Azathioprine (AZA) is a thiopurine immunosuppressant medication used to treat a variety of immune-mediated diseases. Unfortunately, its use is limited by adverse effects. Pancreatitis, a potentially severe, life-threatening side effect is independent of dose and necessitates AZA discontinuation given the high risk of recurrent pancreatitis with continued use or re-challenge. The mechanisms driving pancreatitis are unclear. While classic thiopurine-induced acute pancreatitis (TIAP) has been associated with HLA haplotypes, most patients taking AZA and presenting with pancreatitis do not fulfill the stringent criteria for TIAP.

Objectives: To identify genetic risk factors for pancreatitis in patients taking azathioprine for immune-mediated conditions.

Methods: Using a biobank linked to electronic health records (EHR) from a tertiary center, we identified new users of AZA. Patients were excluded if the primary indication for AZA was organ transplant or if there was a history of pancreatitis prior to AZA use. The analysis was restricted to patients with EHR-reported race as White due to insufficient case counts for the non-White group. We then identified patients with amylase or lipase values that exceeded twice the upper limit of normal (">2x ULN") or with ICD-9/ICD-10 codes for acute pancreatitis. Each record was manually reviewed to confirm the timing of AZA use in relation to laboratory derangements or ICD coding, as well as to further classify patients into three increasingly strict, but not exclusive categories: 1) pancreatic injury (amylase or lipase >2x ULN); 2) acute pancreatitis[1], or 3) TIAP[2]. We completed genotyping with Illumina Infinium Expanded Multi-Ethnic Genotyping Array plus custom content data, employed Michigan Imputation servers for genetic imputation, and used PrediXcan (GTEx v8) to impute gene expression. We then conducted genome-wide association and transcriptome-wide association studies (GWAS, TWAS). Acknowledging the relatively small overall cohort, and possible imbalance of cases vs controls, we used the Firth logistic regression method, which is a penalized likelihood-based method.

Results: We studied 2127 AZA users (35.4% male; mean 44.5+/-17.2 years). The median AZA dose was 100mg/day (IQR: 50-125mg/day). Rheumatologic conditions (56.9%) and inflammatory bowel disease (40.4%) comprised the most common primary indications for AZA. Pancreatic injury, pancreatitis, and TIAP were diagnosed in 42 (2.0%), 16 (0.8%), and 9 (0.4%) patients, respectively. GWAS identified several significantly associated genes, many with overlapping TWAS findings in the pancreas and liver (Figure 1). From these, the two protein-encoding genes *Fms Related Receptor Tyrosine Kinase-1* (*FLT1*) and *Ephrin type-B receptor-2* (*EPHB2*) overlapped in two or more pancreatitis phenotypes in the TWAS and GWAS, respectively. *EPHB2* was associated with a 8.6-fold (P=1.84 x 10^{-8}) and a 31.4-fold (P=2.87x 10^{-8}) higher likelihood of pancreatic injury and TIAP, respectively.

Conclusion: *FLT1*—a gene that encodes a receptor tyrosine kinase and is a member of the vascular endothelial growth factor receptor (VEGFR) family—and *EPHB2*—a gene that encodes a member of the Eph receptor family, which is the largest subgroup of the receptor tyrosine kinase family—are novel genetic markers associated with pancreatitis in patients taking AZA. VEGF can potentiate inflammation and the pancreas microenvironment is known to promote VEGF expression, which has been linked to pancreatic cancer development; anti-VEGF treatments have been investigated both for mitigating inflammation and also anti-pancreatic cancer treatment. Future studies validating our findings in AZA-induced pancreatitis are warranted.

POS1445 EARLY DETECTION OF AXIAL PSORIATIC ARTHRITIS IN PATIENTS WITH PSORIASIS: A PROSPECTIVE, MULTICENTER STUDY.

F. Proft[1], S. Lüders[1], T. Hunter[2], G. Luna[3], V. Rios Rodriguez[1], M. Protopopov[1], K. Meier[4], G. Kokolakis[4], K. Ghoreschi[4], D. Poddubnyy[1,5]. *[1]Charité - Universitätsmedizin Berlin, Campus Benjamin Franklin, Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Berlin, Germany; [2]Eli Lilly and Company Corporate Center, Global Patient Outcomes and Real World Evidence, Indianapolis, United States of America; [3]ICON plc, Global Health Economics, Outcomes Research and Epidemiology (GHEORE), Stockholm, Sweden; [4]Charité - Universitätsmedizin Berlin, Department of Dermatology, Venereology and Allergology, Berlin, Germany; [5]German Rheumatism Research Centre, Epidemiology unit, Berlin, Germany*

Background: In the absence of reliable serological and/or imaging biomarkers that can support an early diagnosis of psoriatic arthritis (PsA) in patients with psoriasis (PsO), and considering the known diagnostic delay there is a need for screening tools for detection of early PsA. While different validated screening/referral tools focusing on peripheral manifestations of PsA exist, validated referral algorithms for PsA with axial involvement (also referred to as axial PsA - axPsA) are still missing.
Objectives: In this prospective, multicenter study we applied a dermatologist-centered screening tool and a structured rheumatologic examination including magnetic resonance imaging (MRI) of sacroiliac joints (SIJs) and spine to detect axPsA in patients with psoriasis (PsO).
Methods: Patients with PsO were systematically screened by their dermatologist for eligibility for referral to a rheumatology clinic. Eligible patients were ≥ 18 years with a confirmed diagnosis of PsO who reported having chronic back pain (≥ 3 months) with onset prior to 45 years of age and who had not been treated with any biologic or targeted synthetic DMARD 12 weeks prior to screening. For those patients who qualified for referral a rheumatologic investigation including clinical, laboratory and genetic assessments as well as imaging with conventional radiography and MRI of sacroiliac joints and spine was performed. The primary outcome of the study was the proportion of patients diagnosed with axPsA among all referred PsO patients.
Results: In total 355 patients were screened at 14 dermatology sites, of whom 151 (42.5%) qualified for referral to rheumatology clinic and 100 (28.2%) were seen by a rheumatologist. The diagnosis of axPsA was confirmed in 14 patients (3/14 with both, axial and peripheral involvement) and the diagnosis of peripheral PsA (pPsA) without axial involvement was made in five patients. The ASAS classification criteria for axSpA were fulfilled in nine (64.3%) of the patients diagnosed with axPsA. All but one patient diagnosed with PsA (13/14 with axPsA and 5/5 with pPsA) fulfilled the CASPAR criteria for PsA.
Patient characteristics are presented in Table 1. All patients diagnosed with axPsA had active inflammatory and/or structural (post)inflammatory changes in the sacroiliac joints and/or spine on imaging. In five patients (35.7%), MRI changes indicative of axial involvement were found only in the spine as illustrated in Figure 1.

Table 1. Clinical characteristics of all referred patients with PsO and suspicion of axSpA.

Patient characteristic	pPsA (N=5)	axPsA (N=14)	No PsA (N=81)	p-value[1]
Age (years) – Mean (SD)	42.8 (9.0)	46.2 (13.6)	45.7 (13.3)	0.883
Female – n (%)	2 (40.0)	9 (64.3)	45 (55.6)	0.543
PASI – Mean (SD)	3.3 (2.1)	4.3 (4.9)	4.0 (4.5)	0.971
Inflammatory back pain – n (%)	5 (100.0)	8 (57.1)	36 (44.4)	0.379
HLA-B27 positive – n (%)	0	4 (28.6)	12 (14.8)	0.204
Elevated CRP (>5 mg/L) – n (%)	1 (20.0)	5 (35.7)	11 (13.6)	0.041
Peripheral arthritis, current (last 7 days) – n (%)	5 (100.0)	3 (21.4)	3 (3.7)	0.012
Radiographic sacroiliitis as per mNY criteria – n (%)	0	4 (28.6)	1 (1.2)	<0.001
Active inflammation, sacroiliac joint (MRI) – n (%)	0	8 (57.1)	0	<0.001
Structural (post)inflammatory changes, sacroiliac joint (MRI) – n (%)	0	8 (57.1)	0	<0.001
Active inflammation, spine (MRI) – n (%)	0	13 (92.9)	0	<0.001
Structural (post)inflammatory changes, spine (MRI) – n (%)	0	8 (57.1)	0	<0.001

[1]Statistically significant differences between the axPsA and No PsA groups of patients were determined by using Mann–Whitney U test for continuous data and Chi-square test for categorical data

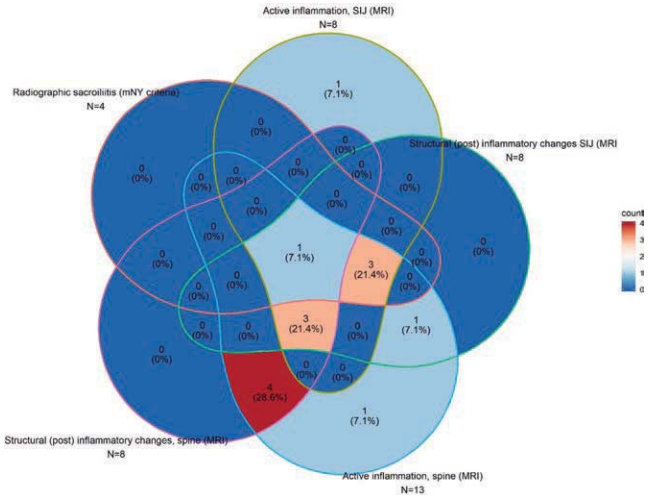

Figure 1. Imaging features of axial involvement in PsO patients diagnosed with axPsA

Conclusion: Our study revealed that applying a dermatologist-centered screening tool may be useful for the early detection of patients with a high probability of PsA (and specifically axPsA) in PsO patients. Given the high prevalence of isolated spinal involvement (without SIJs), imaging of the entire axial skeleton may be required as a part of diagnostic procedure in patients with suspected axPsA.

POS1446 CREATINE KINASE COULD BE A MARKER OF CHRONIC INFLAMMATION-INDUCED SARCOPENIA IN FRAIL PATIENTS

I. Bermejo[1], J. A. Carnicero[2], F. J. Garcia[3,4], S. Pérez-Baos[1], M. Mateos[1], J. P. Medina[1], A. Mediero[1], L. Rodríguez[3,5], R. Largo[1], G. Herrero-Beaumont[1]on behalf of Bone and Joint Research Unit. *[1]Instituto de Investigacion Sanitaria FJD, Rheumatology, Madrid, Spain; [2]Fundación para la Investigación Biomédica del Hospital Universitario de Getafe, Madrid, Data Management, Madrid, Spain; [3]CIBERFES: CIBER (Centers of the Network of Biomedical Research) Thematic Area of Frailty and Healthy Ageing, Geriatrics, Madrid, Spain; [4]Complejo Hospitalario de Toledo, Geriatrics, Toledo, Spain; [5]Hospital Universitario de Getafe, Geriatrics, Madrid, Spain*

Background: Frailty is a hallmark of unhealthy ageing characterized by a decline in the general physiological state, strength and endurance of the patient and consequently, a greater vulnerability to endogenous and/or exogenous stressors. Behind this condition there are multiple pathophysiological processes affecting different systems, such as the musculoskeletal, reflected in sarcopenia, where anabolism is reduced in turn of catabolism. Underlying these processes, chronic inflammation is a well-known but not properly dissected mechanism that contributes to frailty. Although several studies suggest an association of TNF-α, IL-6, IL1-β with systemic inflammation in frail patients, the results are not conclusive. Some authors have explored other molecules related to inflammation, including creatine kinase (CK), a muscle enzyme involved in energy metabolism. Decreased serum CK levels have been observed in chronic inflammatory diseases associated with sarcopenia such as rheumatoid arthritis. In turn, CK is increased not only after myocardial infarction and post-traumatic myolysis, but also associated with muscle mass anabolism.
Objectives: To study the clinical significance of CK levels and their association with other inflammatory and anabolic regulators in frail patients.
Methods: We randomly selected 152 individuals (76 frail and 76 robust) that were 80.86 (±5.49) years and 50% were female, from the second wave of Toledo Study of Healthy Aging cohort (1). CK was measured by routine analysis; serum TNF-α, sgp130, Growth Differentiation Factor (GDF)-15, soluble IL-6R (sIL-6R) and IGF-1 by Multiplex-Luminex. Serum C-Reactive Protein

(CRP) and Myostatin (MSTN) were assessed by ELISA. Differences between robust and frail patients were tested using Mann-Whitney and Kruskal-Wallis test for continuous variables and Chi-square test for discrete variables. For each variable, normality was tested using Shapiro-Wilk normality and Kolmogorv-Smirnov tests. Non-normal variables were natural logarithm transformed to achieve normality. The association between each biomarker and frailty was assessed using multivariate logistic models. Additionally, a sensitivity analysis was performed including a second biomarker in the model in order to detect those biomarkers that influenced the association. All analyses were done using R.

Results: Inflammatory markers CRP and GDF-15 were increased in frail patients, OR (95% CI) 1.59 (1.22-2.05; p<0,001) and OR 1.93 (1.01-3.68; p=0,006), respectively, in comparison to robust. There were no significant changes in the inflammatory parameters TNF-α, sgp130, sIL-6R between groups. The anabolic marker IGF-1 did not change significantly between groups, while the anti-anabolic mediator MSTN was reduced in frail patients, OR 0.40 (0.19-0.86; p=0.02). Finally, CK levels were decreased in frail patients when compared to robust subjects, OR 0.37 (0.18-0.76; p=0.007). In sensitivity analysis, this association remained statistically significant with ORs ranging from 0.33 to 0.40 regardless of a second biomarker.

Conclusion: We identified chronic inflammation in a cohort of frail patients given the significant increase in CRP and GDF-15, although we did not find association with other inflammation parameters such as TNF-α, sgp130 or sIL-6R, highlighting the difficulty of characterize the status of systemic inflammation. The decrease in CK levels in frailty suggest that this marker could be an indicator of cumulative muscle mass loss due to chronic inflammation. Since CRP can be sensitive and altered by a multitude of pathological conditions in frail patients, we propose CK as a more specific marker of inflammation-induced muscle impairment.

POS1447 SOCIODEMOGRAPHIC, CLINICAL AND TREATMENT DIFFERENCES OF RHEUMATIC DISEASES IN THREE MEXICAN REGIONS.

V. Rivera Teran[1], D. Vega-Morales[1], S. Sicsik[1], F. Irazoque-Palazuelos[1], M. A. Saavedra[1], J. C. Casasola[1], S. Carrilo[1], A. Peña[1], A. Castillo Ortiz[1], O. E. Muñoz-Monroy[1], S. Duran Barragan[1], A. Ramos[1], L. F. Valdés Corona[1], E. Torres Valdéz[1], A. Paz[1], E. A. Zamora-Tehozol[1], A. Torres[1], S. Mendieta[1], D. X. Xibille Friedmann[1], F. Guerrero[1], N. Santana[1], M. Vazquez[1], C. Zepeda[1], M. Rivera[1], K. Alvarado[1], D. Alpizar-Rodriguez[1]on behalf of Mexican Adverse Events Registry (BIOBADAMEX). *[1]Colegio Mexicano de Reumatología, Unidad de Investigación, Mexico City, Mexico*

Background: Rheumatic diseases prevalence and characteristics in Mexico may vary depending on the country´s region[1]. To acknowledge these differences is needed to develop focused strategies for early diagnosis and treatment[2].

Objectives: Identify the sociodemographic, clinical and treatment characteristics of the rheumatic diseases in the different regions in Mexico using data from the Mexican Adverse Events Registry (BIOBADAMEX).

Methods: In this analysis we included all patients registered from 2016 to 2021. We described the prevalence in the northern region of Mexico (NR), central (CR) and southern region (SR). We compared sociodemographic, clinical and treatment characteristics between these three regions. We used descriptive statistics, Chi square and Kruskal Wallis tests to analyze differences between the groups.

Results: A total of 780 patients were included in this study, 248 patients (32%) were from the NR, 471 (60%) were from the CR and 61 (8%) from the SR. At baseline, patients had a median (IQR) age of 50 (40-58) years and median disease duration of 7 (3-15) years. NR patients had longer disease duration (9.7 years, p <0.001) and SR patients had higher BMI (29, p 0.001). Overall, 351 (45%) had comorbidities. In CR and SR more than the half of the patient had comorbidities, while in NR only 29% (p 0.001).

The most common diagnosis was rheumatoid arthritis with 512 (66%) patients, followed by ankylosing spondylitis in 115 (15%), psoriatic arthritis in 44 (6%), systemic lupus erythematosus in 30 (4%) and idiopathic juvenile arthritis in 27 (3%), this proportions were maintained when analyzed by regions. We found SR had higher DAS 28 and higher BASDAI (Table 1).

Table 1. Baseline characteristics by region.

	Northern region n=248	Central region n=471	Southern region n=61	p
Age, median(IQR)	49.7 (42-58)	49.9 (38-58)	51.6 (43-61)	0.4
Female, n(%)	193 (78)	383 (81)	52 (85)	0.33
Body Mass Index, median (IQR)	28 (25-32)	26 (22-29)	**29 (26-32)**	0.001
Disease duration (years), median (RIC)	**9.7 (5-16)**	5.9 (2-14)	4.5 (1-10)	0.001
Diagnostic, n(%):				
Rheumatoid arthritis	**173 (70)**	300 (64)	39 (64)	0.001
Idiopathic Juvenile Arthritis	3 (1)	**23 (5)**	1 (2)

Laboratory studies, n(%)				
Rheumatoid factor	97 (39)	274 (58)	**38 (62)**	0.001
ACPA	15 (6)	68 (14)	**12 (19)**	0.001
Disease activity scores, median (IQR)				
DAS28	4.8 (3-6)	5.1 (4-6)	**5.2 (5-7)**	0.001
BASDAI	2.8 (0-7)	4.9 (2-7)	**8.0 (5-9)**	0.003
Comorbidities, n(%)	72 (29)	**247 (52)**	**32 (52)**	0.001
Previous bDMARD, n(%):	**136 (55)**	149 (32)	1 (2)	0.001
Steroids, n(%):	93 (38)	155 (33)	**42 (69)**	0.001
cDMARD, n(%)	200 (81)	373 (79)	53 (87)	0.4
Cause of bDMARD discontinuation, n(%) [a]				
Lack of efficacy	**85 (62)**	45 (33)	2 (22)	0.001
Adverse Event	4 (3)	25 (18)	**3 (33)**	
Pregnancy	1 (1)	**3 (2)**	0(0)	
Loss of patient follow up	10 (7)	0 (0)	**2 (22)**	
Remission	**23 (17)**	5 (4)	0 (0)	
Others	14 (10)	**59 (43)**	2(22)	

a) 238 patients.

Glucocorticoids were used by 290 (37%) patients, SR had the highest use rate (69%, p <0.001) and 80% of the patients used conventional DMARDs (cDMARDs) with no differences between regions. Overall, the most used bDMARDs were adalimumab, certolizumab, tocilizumab and abatacept.

At the time of the analysis 238 (36%) had discontinued bDMARDs treatment, 132 (47%) due to lack of response, being this the most frequent cause reported overall, with the highest rate in NR (62%, p <0.001). All NR patients have social security compared to 83% in CR and 79% in SR.

Conclusion: There are regional differences between patients with rheumatic diseases registered in Biobadamex. It was remarkable that all patients form NR had social security, which may impact in the access to treatment. There were differences in the treatments between regions. The data from this analysis may be useful to policy makers, pharmaceutical companies and physicians. Differences in size samples between regions could have influenced in the results, further analyses will be performed in the future including more patients.

Validation of outcome measures and biomarkers

POS1448 DICKKOPF HOMOLOG 3 (DKK3) AS A PROGNOSTIC MARKER IN LUPUS NEPHRITIS: A PROSPECTIVE MONOCENTRIC EXPERIENCE

S. Sciascia[1], M. Radin[1], A. Barinotti[1], I. Cecchi[1], D. Rossi[1], R. Fenoglio[1], D. Roccatello[1]. [1]*University of Torino, Department of Clinical and Biological Sciences of the University of Turin, Torino, Italy*

Background: Lupus nephritis (LN) is a major cause of mortality/morbidity in patients affected by systemic lupus erythematosus (SLE). Reliable prognostic markers, especially related to the degree of interstitial fibrosis, are still lacking and renal biopsy still represents the gold standard. Recent data suggests a role of Dickkopf homolog 3 (DKK3) as a marker of tissue fibrosis in different diseases, however its role in autoimmune diseases still needs to be elucidated.
Objectives: To investigate DKK3 serum levels in SLE patients with and without LN, assessing its changes in relation to kidney function, flares and interstitial renal fibrosis, as well as its association with the IFN signature.
Methods: 132 SLE patients, 57 of whom diagnosed with LN, were included in this study, as well as 50 healthy donors. DKK3 and Myxovirus resistance protein 1 (MxA) were measured in serum samples, using enzyme-linked immunosorbent assays. Biopsies were evaluated for glomerular involvement, interstitial renal fibrosis and tubular atrophy according to 2003 International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification and the revised 2018 version. Patients were followed-up for at least 36 months.
Results: DKK3 serum levels were significantly higher in patients with biopsy-proven LN when compared to those without (median[min-max]: 215ng/ml [81-341] vs 21.1ng/ml [1-69], p<0.01). When focusing on patients with LN, DKK3 levels resulted to be associated with the presence of chronic kidney disease (OR: 4.31[C.I. 2.01-6.61] per DKK3 doubling, p<0.01), higher chronicity index at biopsy (OR: 1.75[C.I. 1.59-2.13] per DKK3 doubling, p<0.01) and flares rate (OR: 1.45[C.I. 1.1-5.71] per DKK3 doubling, p<0.044). DKK3 levels correlated with the IFN signature as expressed by MxA (correlation coefficient: 0.71, p<0.037).
Conclusion: While kidney biopsy remains the gold standard for diagnostic and prognostic assessment in LN, DKK3 could represent an additional useful prognostic tool to monitor SLE patients and eventually to guide therapeutic choices.

POS1449 VALIDATION OF THE GERMAN LUPUSPRO QUESTIONNAIRE TO MEASURE LUPUS-SPECIFIC HEALTH-RELATED QUALITY OF LIFE IN LUPUS ERYTHEMATOSUS PATIENTS

V. Mevissen[1], T. Filla[1], C. Duesing[1], M. Schneider[1], J. Meenakshi[2], G. Chehab[1]. [1]*Policlinic for Rheumatology & Hiller Research Unit for Rheumatology, Medical Faculty, Heinrich Heine University Duesseldorf, University Clinic, Duesseldorf, Germany;* [2]*Medical Center, Rush University, Chicago, United States of America*

Background: To date, there is no validated lupus-specific questionnaire for health-related quality of life (HRQoL) in German language. Regular assessment of health-related quality of life is recommended for monitoring and outcome in current management guidelines [1][2]. Given that about 20% of the EU population are native German speakers, it is therefore essential to validate a Lupus-specific questionnaire in German.
Objectives: The aim of this study is to present the validity (content, construct, and criterion) and reliability (internal consistency and test-retest) of the German translation of the LupusPro questionnaire, which captures both generic and lupus-specific HRQoL domains.
Methods: The German LupusPRO was professionally translated and then administered to consecutive patients with systemic lupus erythematosus treated at our tertiary centre. At each visit, clinical and laboratory data were collected, including disease activity and damage (SLEDAI-2K resp. SLICC/SDI). Additional questionnaires were used for validity testing, including questionnaires for HRQoL (SF-36v2), fatigue (FACIT), depression (CES-D), sleep (PSQI) and health impairments (IMET).
We calculated Cronbach's alpha to test reliability. An alpha >0.70 is considered acceptable. Test-retest reliability was tested by evaluating the consistency between the LupusPro at two time points (T0 and T1 after 2-3 days). Criterion and construct validity was assessed by comparing the results of the LupusPRO with the generic HRQoL questionnaire, established clinical endpoints (disease activity, disease damage), and the domains of the additional questionnaires. The confirmatory factor analysis was performed with the Lavaan package (Ver. 0.6-9) in R using the relative fit indices, the Tucker-Lewis index (TLI) and the comparative fit index (CFI).
Results: 148 patients with confirmed SLE took part in the study of which 111 participated in the test-retest analysis. About 84% were female with a mean age of 45.5 (SD 12.0) and mean disease duration of 17.7 (SD 9.7) yrs. The mean SLEDAI-2K was 3.1 (SD 3.2) and SLICC/SDI 1.4 (SD 2.1).
The LupusPro domain's internal consistency by Cronbach's alpha exceeded >0.7 except for the domains lupus symptoms (α=0.64), lupus medication (α=0.59), procreative ability (α=0.58), and coping strategies (α=0.43). The overall test-retest correlation was excellent (ICC=0.94). The correlation of the corresponding LupusPRO and SF-36v2 domains were moderate to strong (ρ=0.54–0.78), whereas correlation with disease activity and damage (SLEDAI-2K and SLICC/SDI) was weak (ρ=-0.23 resp. -0.08). Correlation of the selected LupusPRO domains with the above mentioned other dedicated outcome measure instrument emphasized construct and criterion validity.
The results of the confirmatory factor analysis showed good construct validity of the LupusPRO. The observed model fit for the hypothesized item-scale relationships was very good (CFI = 0.98, TLI = 0.98). Items generally had loadings of >0.6 with their respective factor. Exceptions were especially the domain coping strategies where all items loaded <0.4.
Conclusion: The GermanLupusPRO is a valid instrument for measuring health-related quality of life. It shows comparable psychometric properties as the original versions. Minor difference in individual domains may be explained by sociocultural factors.

POS1450 PSYCHOMETRIC PROPERTIES OF THE CENTRAL SENSITIZATION INVENTORY IN PATIENT WITH FIBROMYALGIA

F. Salaffi[1], S. Farah[1], C. Mariani[1], P. Sarzi-Puttini[2], M. Di Carlo[1]. [1]*Università Politecnica delle Marche, Dipartimento Di Scienze Cliniche e Molecolari, Ospedale "Carlo Urbani", Jesi, Italy;* [2]*ASST Fatebenefratelli-Sacco, Rheumatology Unit, Internal Medicine Department, Milano, Italy*

Background: Patients with fibromyalgia (FM) complain many symptoms besides musculoskeletal pain: e.g. fatigue, sleep difficulties, a swollen feeling in tissues, paresthesia, cognitive dysfunction, dizziness, and symptoms of overlapping conditions such as irritable bowel syndrome, headaches and restless legs syndrome. These conditions can be grouped under the umbrella term of central sensitization (CS) syndromes.
Objectives: The goal of the present study was to explore additional evidence of convergent and discriminant validity of the Central Sensitization Inventory (CSI) in a large sample of subjects with fibromyalgia (FM).
Methods: Patients were consecutively enrolled for a cross-sectional assessment comprehensive of three FM-specific measures (the revised Fibromyalgia Impact Questionnaire [FIQR], the modified Fibromyalgia Assessment Status [modFAS], and the Polysymptomatic Distress Scale [PDS]) and of CSI. To test the convergent validity, the Spearman's rho was used to measure the degree of correlation between the variables CSI and the FM-specific measures. To assess discriminant validity, CSI scores were grouped according to FIQR disease severity states, and differences between these groups studied with the Kruskal-Wallis test. Interpretative cut-offs were established with the interquartile reconciliation approach.
Results: The study included 562 FM patients, 199 (35.4%) were classified as having central sensitization syndrome (CSI ≥40). CSI was largely correlated with modFAS (rho = 0.580; p <0.0001), FIQR (rho = 0.542; p <0.0001), and PDS (rho = 0.518; p <0.0001). The differences between the CSI scores in accordance with the FIQR were significant (p <0.000001). CSI cut-offs proposed for FM: 21 between remission and mild severity, 30 between mild and moderate severity, 37 between moderate and severe disease, and 51 between severe and very severe disease.
Conclusion: The current study successfully showed additional evidence of the convergent and discriminant validity of the CSI in FM patients.

POS1451

DISCRIMINATORY CAPACITY OF THE ASAS HEALTH INDEX IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS TREATED IN A TIGHT CONTROL SETTING VERSUS STANDARD OF CARE

U. Kiltz[1,2], A. Moltó[3], C. López-Medina[3,4], M. Dougados[3], D. Van der Heijde[5], A. Boonen[6], F. Van den Bosch[7,8], J. Braun[1,2]. [1]*Rheumazentrum Ruhrgebiet, Rheumatology, Herne, Germany;* [2]*Ruhr University Bochum Faculty of Medicine, Rheumatology, Bochum, Germany;* [3]*Cochin Hospital, Rheumatology, Paris, France;* [4]*Hospital Universitario Reina Sofía, Rheumatology, Córdoba, Spain;* [5]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands;* [6]*Maastricht University Medical Center+, Rheumatology, Maastricht, Netherlands;* [7]*Ghent University Hospital, Rheumatology, Gent, Belgium;* [8]*VIB-UGent Center for Inflammation Research, Inflammation, Gent, Belgium*

Background: Improvement in functioning and health as assessed by the ASAS Health Index (HI) is an important outcome of interventions in patients with axial spondyloarthritis (axSpA). ASAS HI thresholds for measuring improvement have been proposed but not yet tested in an independent intervention trial to study its discriminant capacity.
Objectives: To test the discriminant capacity of the ASAS HI using data from a randomized, active-controlled trial.
Methods: In this post-hoc analysis from the tight-controlled, treat-to-target (T2T) trial TICOSPA [1], data of active axSpA patients randomized to either the T2T arm (visits every 4 weeks, prespecified strategy of treatment intensification until achieving low disease activity) or standard of care (SOC; visits every 12 weeks, treatment at the rheumatologist's discretion) were compared to test whether different thresholds for improvement or achieved state of ASAS HI could discriminate between treatment arms. Week 48 effect sizes (ES) of improvement from baseline were calculated for each treatment arm as Phi Coefficient (higher means better discrimination) and OR (95% CI).
Results: The table shows the ES between treatment arms for all tested improvements and health states achieved in ASAS HI. Overall, absolute improvement outcomes performed better than percentage changes outcome followed by status outcomes. The absolute improvement of ≥2.0, ≥2.5, and ≥3.0 performed best followed by the 20% improvement. As the ASAS HI ≥3.0 is the smallest detectable change for this outcome, this seem to be the most appropriate proposed outcome.

Table 1. Thresholds by treatment groups.

	Non-responder imputation at 48 weeks		Effect size measures	
	TC/T2T	UC	Phi Coefficient*	OR [95% CI]
ASAS HI 20% improvement	56.9%	45.8%	**0.11 [0-1.0]**	0.64 [0.33-1.23]
ASAS HI 25% improvement	51.4%	41.7%	0.10 [0-1.0]	0.68 [0.35-1.30]
ASAS HI 30% improvement	43.1%	34.7%	0.09 [0-1.0]	0.70 [0.36-1.38]
ASAS HI 35% improvement	40.3%	31.9%	0.09 [0-1.0]	0.70 [0.35-1.38]
ASAS HI 40% improvement	37.5%	31.9%	0.06 [0-1.0]	0.78 [0.39-1.56]
ASAS HI 50% improvement	29.2%	22.2%	0.08 [0-1.0]	0.69 [0.33-1.47]
ASAS HI 60% improvement	26.4%	18.1%	0.10 [0-1.0]	0.61 [0.28-1.36]
ASAS HI 70% improvement	16.7%	12.5%	0.06 [0-1.0]	0.71 [0.28-1.82]
ASAS HI 80% improvement	13.9%	11.1%	0.01 [0-1.0]	0.78 [0.29-2.09]
ASAS HI 90% improvement	9.7%	9.7%	0.0[0-1.0]	1.0 [0.33-3.01]
ASAS HI improvement ≥1.0	66.7%	61.1%	0.06[0-1.0]	0.79 [0.40-1.55]
ASAS HI improvement ≥2.0	55.6%	41.7%	**0.14 [0.0-1.0]**	0.57 [0.30-1.11]
ASAS HI improvement of ≥2.5	44.4%	31.9%	**0.13 [0-1.0]**	0.59 [0.30-1.16]
ASAS HI improvement of ≥3.0	41.7%	29.2%	**0.13 [0-1.0]**	0.58 [0.29-1.15]
ASAS HI improvement of ≥ 3.5	29.2%	22.2%	0.08 [0-1.0]	0.69 [0.33-1.47]
ASAS HI improvement ≥4.0	29.2%	22.2%	0.08 [0-1.0]	0.69 [0.33-1.47]
ASAS HI improvement ≥5.0	16.7%	12.5%	0.06 [0-1.0]	0.71 [0.28-1.82]
ASASHI, end of study, ≤12.0	87.5%	80.6%	0.09 [0.0- 1.0]	0.59 [0.24, 1.47]
ASASHI, end of study, ≤5.0	37.5%	33.3%	0.04 [0.0, 1.0]	0.83 [0.42, 1.65]

A value of PHI = 0.1 is considered to be a small effect, 0.3 a medium effect, and 0.5 a large effect.

Conclusion: In this active-controlled trial an absolute improvement in the ASAS HI discriminated best between treatment arms. A similar evaluation is needed in a placebo-controlled trial to be able to propose the best outcome for the ASAS HI in a trial.

Rehabilitation

POS1452 EFFECT OF PHYSICAL ACTIVITY ON CHRONIC FATIGUE IN RHEUMATOID ARTHRITIS PATIENTS

A. Aleksandrov[1,2], M. Nikitin[3], V. Aleksandrov[1,2], N. Aleksandrova[1]. [1]*Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Department of Functional Research Methods, Volgograd, Russian Federation;* [2]*Volgograd State Medical University, Department of Hospital Therapy, Volgograd, Russian Federation;* [3]*National Medical Research Center of Rehabilitation and Balneology, Sanatorium-Resort Complex"Vulan"- Scientific and Clinical Branch, Moscow, Russian Federation*

Objectives: To evaluate the dynamics of fatigue indices in RA patients depending on the intensity of physical activity (aerobic exercise) in the short term.
Methods: The study included 111 women with RA (mean age 54.4±11.03 years old, mean disease duration 11.9±9.3 years, DAS28-ESR score 2.84 [2.32;3.05]; mean VAS fatigue score 71.6±8.93). All patients underwent a 3-week post-hospital rehabilitation program (PHRP), and aerobic exercise was the main component of this program (dosed walking, daily, up to 1 hour) and outdoor walks up to 3-3.5 hours per day [1].The level of fatigue was estimated using the British Rheumatoid Arthritis Fatigue Scale - Numerical Rating Scale (BRAF-NRS V2). The 50-meter walking test was used to assess the functional state of patients in dynamics, the 6-minute walking distance test (6MWD) - to assess patients' tolerance to physical activity. The intensity and duration of exercise were compared with serum levels of free fatty acids (FFA), triglycerides (TG), and angiopoietin-like protein type 4 (ANGPTL4), an inhibitor of lipoprotein lipase, which plays an important role in the regulation of lipid metabolism and energy balance.
Results: After completion of PHRP, RA patients showed a significant decrease in fatigue aspects of the NRS severity scale (6.83 ± 1.21 vs. 6.51 ± 1.18 points, p=0.003), NRS-effect (6.24 ± 1.07 vs. 5.95 ± 1.08 points, p=0.037); a decrease in time taken to complete the 50 m. walk test was noted (79.3 ± 8.64 vs. 78.91 ± 8.15, p=0.01) [2]. Increased concentration of ANGPTL4 (p<0.02), FFA (p<0.01) and decreased TG level (p<0.05) were also determined in serum of RA patients. There was a significant correlation between ANGPTL4 and FFA (r=0.54, p<0.02), but not with TG (r= -0.18, p>0.05). The increase in serum ANGPTL4 during exercise may be mediated by increased serum FFA content and increased lipid oxidation processes. Previously, it was shown that muscle tissue, along with liver and adipose tissue, significantly affect to the increase in circulating ANGPTL4 during exercise [3, 4].
Based on the results of the first phase of the study, patients (n=102) were retrospectively divided into two groups: Group I (n=53) included patients with < 5-6 thousand steps/day (sedentary lifestyle); Group II (n=49) included patients with ≥ 7-8 thousand steps/day (mobile lifestyle).Group II of RA patients significantly improved their physical parameters - reduction of walking time (p<0.001) and number of steps in the 50-meter test (p=0.013) at the end of PHRP. There was a reduction in fatigue severity on all scales: VAS (p<0.001), NRS severity (p<0.001), NRS effect (p<0.001), and NRS-overcoming (p=0.001). In group I, there was an increase in VAS fatigue (p=0.008) and NRS effect (p=0.01). No intergroup differences were found among lipid metabolism indices before and after PHRP (p>0.05).
Conclusion: Aerobic exercise (walking) is an effective method of increasing physical activity and reducing fatigue in patients with RA during the post-hospital rehabilitation phase. Increased physical activity during walking (≥7-8 thousand steps/day) has a positive effect on physical indices and fatigue components in the short term. Lipid metabolism markers can be used in determining the degree of activity, optimization of the duration and intensity of exercise in RA patients.

POS1453 INTERVAL HYPOXIC-HYPEROXIC TRAINING IN REHABILITATION OF PATIENTS WITH OSTEOARTHRITIS AND POST-COVID SYNDROME

E. Orlova[1], N. Lyamina[1], I. Pogonchenkova[2], N. Skorobogatykh[3]. [1]*Moscow Centre for Research & Practice in Medical Rehabilitation, Restorative and Sports Medicine, Department of Medical Rehabilitation, Moscow, Russian Federation;* [2]*Moscow Centre for Research & Practice in Medical Rehabilitation, Restorative and Sports Medicine, Director, Moscow, Russian Federation;* [3]*Moscow Centre for Research & Practice in Medical Rehabilitation, Restorative and Sports Medicine, Department of Physical Exercises, Moscow, Russian Federation*

Background: Intermittent hypoxia conditioning reduces the levels of inflammatory parameters and cytokines (C-reactive protein, TNF-α, IL-4, IL-6, IL-8), increases the tolerance to acute hypoxia, the functional capacity and improves parameters of respiratory and cardiovascular systems [1–4].
Objectives: To evaluate the efficiency of the interval hypoxic-hyperoxic training (Reoxy therapy) in the rehabilitation of patients with osteoarthritis (OA) and post-COVID syndrome.
Methods: 36 patients with OA (78% females, age of 43 to 68 years, generalized OA, OA of the knee or hip joints) where included in the randomized placebo-controlled study. Coronavirus infection COVID-19 were diagnosed from 12 to 26 weeks before the study. The main symptoms of post-COVID syndrome were dry cough, smell loss, breathlessness, weakness, fatigue, sleep disorders, cognitive symptoms, memory problems, anxiety, depression, headache, dizziness, joint and muscle pain. All patients were randomized into 3 groups. 13 study group patients received 10 Reoxy therapy procedures, 9 placebo group patients – 10 placebo procedures of Reoxy therapy, 14 control group patients – only standard rehabilitation. The patients of all groups underwent 2-week standard rehabilitation program: 10 procedures of electrostatic massage for muscles and periarticular tissues, 10 sessions of general magnetic therapy, 10 group sessions of physical exercises with elements of breathing exercises. All patients received NSAIDs and SYSADOA at standard dosages. Intra-articular corticosteroids was not used. The study group patients were breathing hypoxic (FiO2 13–15%) and hyperoxic (FiO2 up to 40%) gas mixture through the mask in the interval mode with biofeedback using device «ReOxy» (Ai Mediq S.A., Luxembourg). 10-min hypoxic test (FiO2 12–13%) was performed before the first and fourth procedures. The duration of 1–4 procedures was 30 min, 5–10 procedures – 40 min. The placebo procedures were performed using the mask with the atmospheric air hole. Joint pain and general health on 100-mm VAS, Lequesne and WOMAC indexes, Spielberger-Khanin anxiety test, Beck depression inventory and breathlessness on Modified Borg scale were evaluated at baseline and at 2 weeks.
Results: After 2 weeks in the study group pain on VAS decreased by 49,6% (p<0,05), Lequesne index – by 39,3% (p<0,05), WOMAC – by 1,4 times (p<0,01), anxiety level on Spielberger-Khanin test – by 40,9% (p<0,05), depression level on Beck depression inventory – by 64,1% (p<0,01), general health on VAS improved by 69,3% (p<0,01). The level of breathlessness on Modified Borg scale in the study group initially was 2,5±0,9 score (moderate – slight breathlessness). After rehabilitation in the study group the level of breathlessness decreased to 0,3±0,4 score (extremely slight – no breathlessness). In the study group there were statistically significant differences from the placebo group (p<0,05) and the control group (p<0,05) in all parameters.
Conclusion: 2-week complex rehabilitation program, including interval hypoxic-hyperoxic training (Reoxy therapy), reduces pain, breathlessness, depression and anxiety, improves functional status and general health in patients with OA and post-COVID syndrome.

POS1454 NEUROPLASTICITY STIMULATION-BASED REHABILITATION IMPROVES PAIN AND HAND FUNCTIONALITY IN PATIENTS DIAGNOSED WITH CARPAL TUNNEL SYNDROME: A PILOT STUDY

E. Muñoz-Gómez[1], S. Mollà-Casanova[1], N. Sempere-Rubio[1], M. Aguilar Rodríguez[1], M. Inglés[1], P. Serra-Añó[1]. [1]*Research Unit in Clinical Biomechanics (UBIC), Physiotherapy, Universitat de València, Valencia, Spain*

Background: Carpal tunnel syndrome (CTS) is the most commonly diagnosed entrapment neuropathy, characterized by sensory and motor disorders. Physiotherapy interventions based on neuroplasticity stimulation, such as mirror therapy (MT) and cross-education (CE) have been demonstrated effective in pain and impaired function. In those therapies, mirror neurons that are activated when observing an action are considered the possible underlying neural mechanism, creating organized new pathways between two cerebral hemispheres and enabling brain plasticity. However, MT and CE effects have not been widely studied on unilateral CTS.
Objectives: To analyze the effectiveness of MT and CE rehabilitation protocols in a sample of patients with CTS on pain intensity and functionality.
Methods: A randomized-controlled trial was conducted. Subjects diagnosed with unilateral CTS were enrolled in this study. MT group (MTG) (N=9)

performed a rehabilitation protocol consisting of six-weeks of MT training, five days/week. The healthy hand was trained in front of a mirror placed in the middle of the body, while the affected hand was hidden and quiet on the opposite side. CE group (CEG) (N=10) intervention was designed to perform the same training protocol, but without a mirror. Thus, the difference between interventions was the use of the mirror. Training consisted of mobility, strength and functional exercises. Minimum, maximum and average perceived pain were assessed through Visual analog scale (VAS), and upper limb function through Quick-DASH, before and after the intervention. Regarding statistical analyses, a two-factor mixed multivariate analysis of variance (MANOVA) was carried out with a between-subjects factor "treatment group" (MTG and CEG) and a within-subject factor "time measuremets" (pre and post-intervention) for all variables. (Clinical trial Id: NCT05115396).

Results: Nineteen participants (4 men and 15 women) between 30 and 60 years were included in the study. There were no statistically significant differences between groups at the beginning of the study. After treatment, there was a significant decrease in maximum pain (p<0.05), minimum pain (p<0.05) and average pain (p<0.05) of the affected hand in both groups, being larger the experienced changes of the MTG compared to that of the CEG (Table 1). Regarding hand functionality, both groups significantly improved compared with baseline (p<0.01). This study suggests that activation of mirror neurons either by MT or CE, is effective on hand pain and functionality in people with unilateral CTS.

Table 1. Pre and post-intervention results on pain and functionality.

Group		N	Pre-treatment	Post-treatment
VAS maximum	MTG	9	4.22 (2.64)	2.11 (2.26)*
	CEG	10	4.70 (2.87)	2.80 (2.15)*
VAS minimum	MTG	9	2.22 (2.22)	0.33 (0.50)*
	CEG	10	2.50 (2.64)	0.90 (1.10)*
VAS mean	MTG	9	3.22 (2.44)	1.56 (1.59)*
	CEG	10	3.80 (2.82)	2.20 (1.75)*
Quick-DASH	MTG	9	34.35 (21.36)	23.74 (21.71)**
	CEG	10	31.14 (26.48)	19.77 (19.87)**

Data are shown as mean (SD). MTG: Mirror Therapy Group; CEG: Cross-education Group; VAS: Visual Analog Scale; *: p-value <0.05 between pre and post-intervention; **p-value <0.01 between pre and post-intervention.

Conclusion: Neuroplasticity stimulation-based rehabilitation, using a MT protocol or a CE protocol, improves pain and functionality in patients with unilateral CTS.

POS1455 EFFICIENCY OF PASSIVE MECHANOTHERAPY IN COMPLEX REHABILITATION OF PATIENTS WITH OSTEOARTHRITIS

E. Orlova[1], I. Pogonchenkova[2]. [1]*Moscow Centre for Research & Practice in Medical Rehabilitation, Restorative and Sports Medicine, Department of Medical Rehabilitation, Moscow, Russian Federation;* [2]*Moscow Centre for Research & Practice in Medical Rehabilitation, Restorative and Sports Medicine, Director, Moscow, Russian Federation*

Background: Different types of physical exercises relieve pain, improve functional status and quality of life in patients with osteoarthritis (OA) in addition to drug treatment [1–4].

Objectives: To evaluate the efficiency of robotic mechanotherapy (continuous passive motion) in the complex rehabilitation of patients with OA.

Methods: 58 patients with OA of the knee, hip, wrist and hand joints (76% females, age of 49 to 65 years, disease duration of 3 to 11 years) were included in the study and randomized into 2 groups. 28 study group patients underwent robotic passive mechanotherapy (continuous passive motion) for the knee and hip joints using «ARTROMOT K1» machine (Ormed gmbh, Germany), for the wrist and hand joints using «Kinetec Maestra hand and wrist CPM» machine (Kinetec, UK) (10 sessions for 20–25 min) in addition to the standard rehabilitation program (2 weeks). 30 control group patients received only the standard rehabilitation program, which included 10 group sessions of physical exercises for the joints for 45 min under the supervision of a trainer, 10 procedures of electrostatic massage for muscles and periarticular tissues, 10 sessions of occupational therapy for 45 min (joint protection strategies, use of assistive devices and adaptive equipment). All patients received NSAIDs and SYSADOA at standard dosages. Intra-articular corticosteroids were not used. Tender joint count, joint pain on 100-mm VAS, Lequesne and WOMAC indexes, the amplitude of flexion in the knee joint measured by goniometer, the march test (passage time of 20 meters per sec), hand grip strength measured by a dynamometer were evaluated at baseline and at 2 weeks.

Results: After 2 weeks in the study group pain on VAS decreased by 40,9% (p<0,05), tender joint count – by 38,7% (p<0,05), Lequesne index – by 1,53 times (p<0,01), WOMAC – by 1,21 times (p<0,01). In the study group the amplitude of flexion in the knee joint increased by 34,2% (p<0,05), the march test decreased by 3,5±1,2 sec (28,8%) (p<0.05), the grip strength of the more affected hand enhanced by 22,3% (p<0,05), of the less affected hand – by 18,5% (p<0,05). In the study group there were statistically significant differences from the control group in all parameters (p<0,05), excluding the grip strength of the less affected hand (p>0,05).

Conclusion: 2-week complex rehabilitation program, including robotic mechanotherapy (continuous passive motion), relieves pain, improves functional ability, motor activity (march test, range of motion in the knee joint, hand grip strength) in patients with OA.

Education

POS1456 TEACHING NAILFOLD CAPILLAROSCOPY USING THE "FAST TRACK ALGORITHM" VIA AN ONLINE PLATFORM: THE ASIAN EXPERIENCE

S. A. Ng[1,2], W. H. Tan[1], E. Saffari[2], A. Low[1,2]. [1]*Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore;* [2]*Duke-National University of Singapore, Duke-National University of Singapore, Singapore, Singapore*

Background: Nailfold capillaroscopy (NFC) is being increasingly used in the early identification of systemic sclerosis (SSc) related disorders. Recent studies have shown that an optimised simple capillaroscopic definition of normal and abnormal capillary morphology is reliable and a multi-centre consensus 'fast track algorithm' was developed by the European League against Rheumatism (EULAR) Study Group on Microcirculation in Rheumatic Diseases (SG MC/RD) to allow trainees to identify scleroderma patterns from non-scleroderma patterns.

Objectives: To validate the "fast track algorithm" taught via an online teaching platform to identify scleroderma patterns from non-scleroderma patterns on NFC.

Methods: Trainees participated in the NFC teaching workshops conducted via an online platform by the same SSc expert (AL) over 3 separate sessions. In the first part of the workshop (training), all trainees attended a talk on NFC by the SSc expert (AL) whereby they were taught the fast track algorithm to identify and classify NFC image patterns using a training set of images. The "fast track algorithm" (Figure 1) consists of three easy rules: 1) Rule number 1: the presence of ≥ 7 capillaries (capillary density) AND the absence of giant capillaries (capillary dimension) allows the rater to call the capillaroscopic image a "non-scleroderma pattern (category 1)"; 2) Rule number 2: the presence of giant capillaries or the presence of an extremely lowered capillary density (≤ 3 capillaries) in combination with abnormal shapes (= "late" scleroderma pattern) allows the rater to call the capillaroscopic image a "scleroderma pattern (category 2)"; 3) Rule number 3: if the image does not meet rule number 1 or rule number 2 then the image is automatically classified as a "non-scleroderma pattern (category 1)". In the second part of the workshop (evaluation), each trainee independently rated 45 NFC images (30 seconds for each NFC image) in the same session, and submitted their answers in real time using an electronic form. The reading of the expert (AL) was considered the gold standard. AL is a SSc expert who had previously attended the EULAR workshop on NFC and has had more than 10 years of experience in NFC. Within 2-4 weeks of the initial rating exercise, trainees re-evaluated the same set of images for the intra-reader exercise under supervised conditions via the online platform. We computed the inter- and intra-rater agreement using

mean [standard deviation (SD)] Cohen's Kappa, with the following values representing the degrees of agreement: <0 –poor; 0-0.20 –slight; 0.21-0.40 –fair; 0.41-0.60 –moderate; 0.61-0.80 –substantial; and 0.81-1.00 –almost perfect agreement.

Results: Ninety-eight trainees from Singapore, Malaysia, Indonesia, Hong Kong, Philippines, Taiwan, Myanmar and Brunei included rheumatologists, rheumatology trainees, pediatric rheumatologists, internists and nurses. Fifty-four participants were novices with no prior NFC experience, 38 participants were "moderately experienced" (< 5 years of NFC experience) and 1 participant was "experienced" with more than 5 years of NFC experience. The mean (SD) inter-rater kappa of the 98 trainees was 0.71 (0.13). For the 61 trainees who participated in the re-evaluation session, mean (SD) inter-rater and intra-rater kappa were 0.74 (0.16) and 0.71 (0.15), respectively.

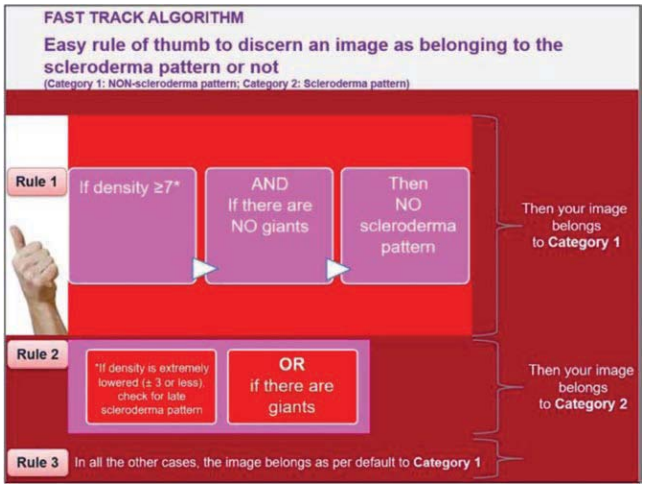

Figure 1. Fast Track algorithm

Conclusion: There was substantial inter- and intra-rater agreement. This is the first study in Asia examining NFC training using the EULAR SG MC/RD fast track algorithm and our results support the importance of standardized teaching for NFC.

POS1457

ANALYSIS OF WORLDWIDE RHEUMATOLOGY POSTGRADUATE TRAINING CURRICULA: A MAPPING EXERCISE TO INFORM THE DEVELOPMENT OF EULAR STANDARDS FOR THE TRAINING OF EUROPEAN RHEUMATOLOGISTS

A. Alunno[1], T. Avcin[2], C. Haines[3,4], F. Sivera[5,6], S. Ramiro[7,8], C. J. Edwards[9].

[1]Internal Medicine and Nephrology Unit, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy; [2]University Children's Hospital and University Medical Centre Ljubljana, Department of Allergology, Rheumatology and Clinical Immunology, Ljubljana, Slovenia; [3]University of Oxford, Centre for Teaching and Learning, Oxford, United Kingdom; [4]King's College London, Faculty of Life Sciences and Medicine, London, United Kingdom; [5]Hospital General Universitario de Elda, Department of Rheumatology, Elda, Spain; [6]Universidad Miguel Hernandez de Elche, Department of Medicina Clinica, Elche, Spain; [7]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands; [8]Zuyderland Medical Center, Department of Rheumatology, Herleen, Netherlands; [9]NIHR Southampton Clinical Research Facility, University Hospital Southampton, Musculoskeletal Research, Southampton, United Kingdom

Background: Previous work has highlighted considerable heterogeneity in the organization of postgraduate rheumatology training programs. EULAR strives to harmonise rheumatology training across Europe with defined standards of key aspects of training including knowledge, skills and professional behaviors.

Objectives: To analyse existing documents on postgraduate training in rheumatology and other related specialties available within Europe and the rest of the world.

Methods: As most documents were unpublished, key documents on specialty training in Rheumatology and 28 related specialties were retrieved by hand-search. We started with the collection of documents developed by UEMS (Europe), ACGME (USA), CanMEDS (Canada) and RACP (Australia). Then we searched for specialty training documents developed by other international Boards and we also sent emails to the boards or associations if no document could be found in their websites. Finally, we retrieved national documents from European Countries with a structured rheumatology training process, translated them into English using DeepL/Google translate and, in case of doubt, liaised with native speakers familiar with the documents. The content of all the above documents (including information about the structure of each document) was extracted into a standardized data extraction sheet.

Results: 133 documents were retrieved. UEMS, ACGME, CanMEDS documents were available for all the mapped specialties, while RACP documents were retrieved for only 18 specialties. No American or Canadian specialty board developed additional documents on training, while in Europe non-UEMS boards of 11 specialties did (Table 1). With regard to Rheumatology, 2 separate documents for adult and pediatric rheumatology training were available from UEMS and ACGME while one document

Table 1. Documents retrieved and extracted for each specialty. Rheumatology national training documents are not listed.

*2 UEMS and 2 ACGME document on adult and pediatric rheumatology

on adult rheumatology training was retrieved for CanMEDS and RACP. Upon assessment of the content of these 133 documents, we observed that their organisation could be competence-based (48%), role-based (47%), or problem-based (5%). When focusing on Rheumatology, content was fairly similar across international curricula, but several differences emerged in national curricula. These were mainly related to national regulations (e.g. rheumatology training as part of internal medicine training) and a different definition of mandatory/optional competences. The number of listed competences in the rheumatology documents ranged from 18 to 196.
Conclusion: We collected and analysed documents on specialty training in Rheumatology and other related specialties across a broad set of international sources. Most documents followed a competence-based or role-based framework; similarities and differences in the content of Rheumatology documents were detected. This mapping exercise informed the EULAR Task Force on the development of standards for the training of European rheumatologists.

POS1458 HOW EASY IS IT FOR PATIENTS TO READ AND UNDERSTAND AVAILABLE PATIENT EDUCATIONAL MATERIALS FOR LUPUS?

U. C. Nweke[1], S. Hassan[2], J. Meenakshi[2]. *[1]Rush University, Graduate College, Chicago, United States of America; [2]Rush University, Medicine, Chicago, United States of America*

Background: Health Literacy (HL) informs health behaviors such as follow-up with health care providers & management plans. Poor HL is linked to poor health outcomes & healthcare disparity. In addition to personal HL, health care providers/systems & Organizations can also empower patients by developing & providing educational resources that foster HL & support a patient's understanding of their health condition (organizational HL). Patient educational handouts are frequently provided after a physician visit to supplement instructions/education & are often obtained from online resources accessible to both physicians & patients. Lupus, a multisystem disease, preferentially effects people of color, a group at higher risk of health disparities, & poor HL. It is paramount for lupus patients to understand their disease & management to optimize health outcomes & reduce health disparities. The provision of easy to read & comprehend patient educational resources are one way to address this need.
Objectives: The Center for Disease Control (CDC) recommends the readability of patient educational material to be at eight-grade level, while the National Institute of Health (NIH) & the American Medical Association (AMA) recommend a level no higher than sixth-grade. The Readability & Comprehension (RC) of commonly available lupus-related patient educational materials are not known & may offer an opportunity to improve patient care & outcomes.
Methods: We searched for the RC of Lupus-related patient educational materials, available at the American College of Rheumatology (ACR) & Lupus Foundation of America (LFA) websites. These reputable national organizations are at the forefront of Lupus education & research. RC were evaluated using the following measures: Flesch Kincaid Readability Ease (FKRE), Flesch Kincaid Grade Level (FKGL), Gunning Fog Score (GFS), Simple Measure of Gobbledygook (SMOG) Index, Coleman Liau Index (CLI) & Automated Readability Index (ARI).
FKRE score is a widely used measure of readability with scores ranging from 0-100 & higher scores denoting greater reading ease (Goal is >60). FKGL represents the U.S. school grade needed to comprehend the text (Target is 7th grade). GFS estimates the years of formal education required to understand the text on the first reading (Goal is 7-8). SMOG index estimates the years of education needed to comprehend written materials. CLI is used to assess the U.S. grade level necessary to comprehend text material. The ARI assesses how easy a text material is to learn & estimates the U.S. grade level necessary to comprehend a passage.
Descriptives for RC were obtained & compared using t test between the two sources.
Results: There were 12 patient educational pamphlets on Lupus available (4 from ACR & 8 from LFA). Mean (SD) FKRE & FKGL were 52.73 (11.44) & 10.46 (2.14) respectively (Table 1). Mean GFS & CLI exceeded 12, while mean ARI was 18.

Table 1. Reading & Comprehension of Patient Educational Materials on Lupus

RC Test (Values are Mean (SD))	All	ACR	LFA	P
Flesch Kincaid Reading Ease	52.73 (11.44)	47.18 (4.93)	55.50 (13.00)	0.25
Flesch Kincaid Grade Level	10.46 (2.14)	10.73 (0.64)	10.33 (2.64)	0.78

There were no significant differences in the RC scores among patient educational materials from the ACR or LFA.
Conclusion: Patient educational materials on Lupus, available at the ACR & LFA websites, are not easy to read or comprehend, using standardized RC metrics. Additionally, they are not aligned with recommended reading levels suggested by leading organizations (CDC, NIH or AMA). Patient's understanding is critical in a complex disease like lupus to optimize health outcomes. Revision of patient lupus educational resources at these websites, to target 6-7th grade RC metrics, is recommended & could be overseen by the development of a new taskforce.

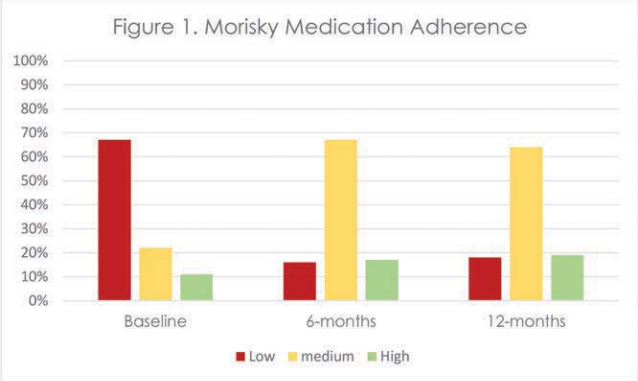
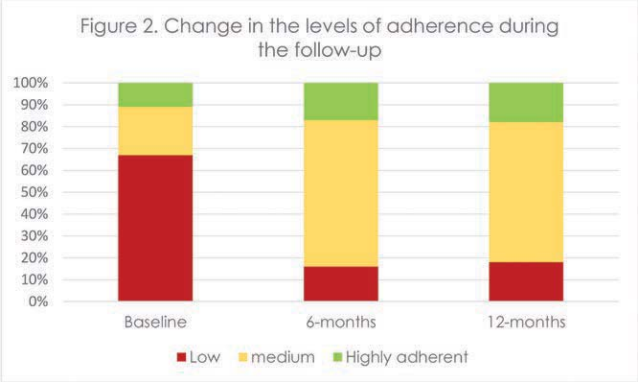
POS1459 THE IMPLEMENTATION OF AN EDUCATIONAL PROGRAM TO IMPROVE PHARMACOLOGICAL ADHERENCE IN PATIENTS WITH RHEUMATOID ARTHRITIS. RESULTS FROM A QUASI-EXPERIMENTAL STUDY

P. Santos-Moreno[1], D. Buitrago-Garcia[2], F. Rodriguez[3], G. Sánchez4. *[1]Biomab IPS, Rheumatology, Bogotá, Colombia; [2]Fundación Universitaria de Ciencias de la Salud - FUCS, Epidemiology, Bogotá, Colombia; [3]Biomab IPS, Patient Education, Administration, Bogotá, Colombia; [2]Fundación Universitaria de Ciencias de la Salud - FUCS, Epidemiology, Bogotá, Colombia*

Background: Pharmacological therapy is the principal intervention in rheumatoid arthritis (RA) patients. Currently, adherence to DMARDs therapy is a challenge that needs to be addressed[1]. On the other hand, educational programs have shown an improvement in the health status of RA patients[2].
Objectives: This study aimed to determine if a 12-month educational program developed for patients with RA can improve medication adherence.
Methods: A quasi-experimental design was conducted. Patients who attend a specialized center in RA were invited to participate in an educational program. The program was called UNIVERSITAR: PATIENT UNIVERSITY. An interdisciplinary team provided educational workshops for the patients; we included coaching sessions and leisure activities such as yoga and art lessons to avoid a conventional classroom program and provide a dynamic program. A rheumatologist with experience in centers of excellence for RA led the team. Patients attended during a year. Follow-up was planned at 6 and 12 months after enrollment. Medication adherence was assessed using the self-reported 8-item Morisky Medication Adherence Scale (MMAS-8). Patients were considered adherent when they scored 8 points, moderately adherent with a score of 6 or 7, and non-adherent with less than 6 points. The Wilcoxon signed-rank test was used to evaluate differences in MMAS-8 scores between baseline and 16 and 12-months. We also assessed if there were changes in DAS 28 in the participants who improved the level of adherence.





Results: In total, 252 patients were enrolled in the study, and 206 completed the follow-up at 6 and 12 months (82%). The median age was 60 years IQR (54-67), 94% were female. In our study, 54% of patients received conventional and 46% Biological therapy. The proportion of patients with high adherence at baseline was 11%, at 6-months was 17% and at 12-month was 19%. At the end of the follow-up, 49% of the participants moved from being non-adherent to a moderate or high adherence level. When we compared the MMAS scores at baseline and follow-up, they showed a significant improvement (P<0.05) Figures 1-2. The majority of participants (65%) were in remission at baseline, according to DAS28. Therefore, we found no differences between the level of adherence and DAS28.

Conclusion: Our educational program improved medication adherence among patients with RA. Educational interventions are helpful to sustain remission in patients with RA. Further studies focused only on patients with moderate and high disease activity are necessary to assess the impact on clinical outcomes.

POS1460 CONTRIBUTING TO THE TRAINING OF IMAGING IN RHEUMATOLOGY BY EXPERTS WORLDWIDE VIA INTERACTIVE MOBILE E-TEACHING: BERLINCASEVIEWER.

K. G. Hermann[1], M. Protopopov[2], A. Serfaty[3], I. Hmamouchi[4], F. Sommerfleck[5], F. Macori[6], K. Ziegeler[1], T. Diekhoff[1], D. Poddubnyy[2], J. Sieper[2]. *[1]Charité – Universitätsmedizin Berlin, Dept. of Radiology, Berlin, Germany; [2]Charité – Universitätsmedizin Berlin, Dept. of Rheumatology, Berlin, Germany; [3]Medscan Lagos, Radiology, Cabo Frio, Brazil; [4]Laboratoire d'Epidémiologie, Recherche Clinique, Rabat, Morocco; [5]Sanatorio Julio MendezSanatorio, Rheumatology, Buenos Aires, Argentina; [6]Ospedale Santo Spirito, Radiology, Rome, Italy*

Background: Rheumatology education today can be very diverse, and you can find everything from structured textbooks to YouTube channels to social media accounts. Peer-reviewed content is still recognized as a very high-quality source of information. App-based content has the advantage of bundling information in one place, always available on the go. However, the majority of offerings are only available in English.

Objectives: An app was to be created to learn about imaging in rheumatology in a very easy to understand way in different languages, with experts being able to create translated content very easily.

Methods: Using mySQL, Java, Objective C and JavaScript, a case database with specific structure and numerous interactive elements was created for academic teaching. Special functions for the annotation of images were provided. The development was initially for devices with the iOS operating system, and later for Android. Rheumatologists and radiologists worldwide were invited to participate via the social media channels LinkedIn, Instagram, Facebook, Twitter, and TikTok.

Results: The app, called BerlinCaseViewer, was developed for smartphones, tablets and Mac computers. All information is entered and processed in a web-based database. Using XML files and ZIP archives, the relevant data is then transferred to the mobile apps. Case of the month and learning modules on rheumatoid arthritis, psoriatic arthritis, and axial spondyloarthritis are available, many in English, Spanish, French, Italian, Portuguese, German, and other languages (Figure 1). In addition to the medical image data, the patient's medical history is also presented in an exciting way with the help of multiple-choice questions. Only when all questions are answered, the diagnosis becomes visible. Timeline functions can be used to visualize medical courses as well. Colored overlays are used to annotate images and can be placed with pixel precision. The user can decide whether these should be displayed as aids. Content is peer-reviewed before publication.

Figure 1. Multi-lingual presentation of medical training cases.

Conclusion: BerlinCaseViewer is a new approach not only to train medical professionals, but also to connect colleagues and overcome language barriers. As a platform, BerlinCaseViewer is open to all medical professionals to collaborate, whether to contribute their own cases or translate existing cases for use in the local language.

POS1461 GIANT CELL ARTERITIS-RELATED STROKE IN A MAN WITH ELDERLY-ONSET RHEUMATOID ARTHRITIS

M. Hng[1,2], M. Dey[3,4], R. Moots[1,5]. *[1]Aintree University Hospital, Rheumatology, Liverpool, United Kingdom; [2]Sultanah Fatimah Specialist Hospital, Muar, Medical, Muar, Malaysia; [3]University of Liverpool, Institute of Life Course and Medical Sciences, Liverpool, United Kingdom; [4]Countess of Chester Hospital NHS Foundation Trust, Rheumatology, Chester, United Kingdom; [5]Edge Hill University, Faculty of Health & Social Care, Liverpool, United Kingdom*

Background: Giant cell arteritis-related stroke is rare, with high early mortality and major morbidity in survivors.

Objectives: To increase the awareness of coexistence of giant cell arteritis-related stroke and rheumatoid arthritis.

Methods: A case report and discussion.

Results: A 73 year-old man with seronegative elderly-onset rheumatoid arthritis (EORA) presented to the emergency department (ED) with a one week history of frontal headache, vomiting and dizziness. He had multiple cardiovascular comorbidities and took multiple medications, including methotrexate and sulfasalazine. He also had long-standing history of thrombocytopenia without requiring any treatment. Neurological examination performed in the ED was unremarkable. His C-reactive protein (CRP) was 69mg/L and erythrocyte sedimentation rate (ESR) 82mm/hour. Computed tomography (CT) of the brain was normal. The headache settled with analgesia. A diagnosis of probable tension-type headache, with underlying active EORA, was made. One month later, he presented to an ophthalmologist with recurrence of headache associated with visual disturbance and was diagnosed with giant cell arteritis (GCA). Both CRP (77mg/L) and ESR (85mm/hour) remained raised. Neither temporal artery biopsy nor temporal artery ultrasound were possible due to the coronavirus disease 2019 (COVID-19) pandemic. The headache and visual symptoms resolved completely a week after prednisolone 60mg daily was prescribed. In parallel, the CRP dropped to 2mg/L and ESR 16mm/hour. The patient's glucocorticoid dose was then tapered. While on prednisolone 20mg daily, about 3 weeks later, he developed slurred speech and generalized weakness. Examination showed cerebellar signs and MRI brain showed acute cerebellar infarct. He was treated pragmatically as an atherosclerotic stroke with clopidogrel, and the steroid was rapidly tapered in view of absence of headache and normalization of inflammatory markers. Four weeks later, he was noted to have persistent confusion and unsteadiness of gait. CRP was elevated at 92mg/L. An urgent positron emission tomography-CT (PET-CT) scan showed inflammation in the vertebral arteries [Figure 1] and cerebellar stroke. Prednisolone 40mg daily was restarted which led to a rapid improvement in his symptoms and normalization of inflammatory markers. The glucocorticoids were tapered in a slower manner this time.

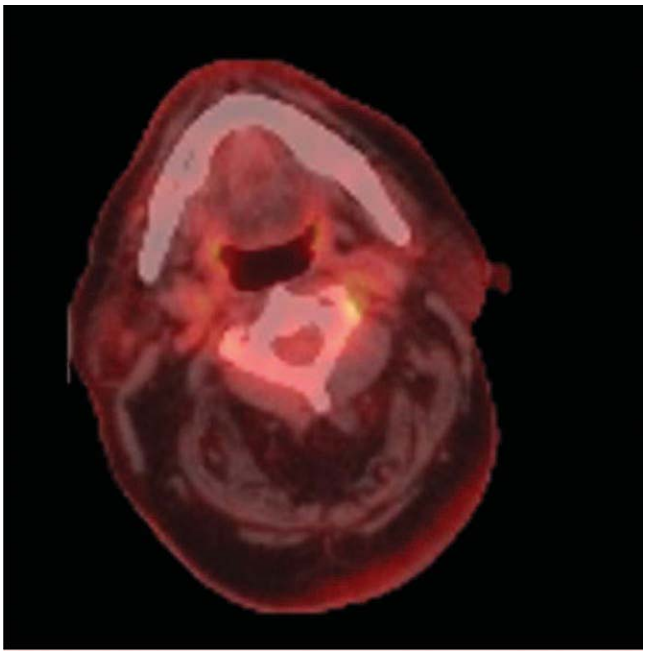

Figure 1. Fused axial image of a PET-CT scan demonstrating increased uptake in the region of the left vertebral artery within the vertebral foramen.

A diagnosis of GCA-related cerebellar stroke with vertebral vasculitis was made and, with glucocorticoids, the patient made a good clinical recovery. His inflammatory joints pain also improved in parallel.

Conclusion: Stroke or transient ischemic stroke are rare complications, reported in 2.8-16% of patients with active GCA. Most studies report strokes as occurring between the onset of GCA symptoms and 4 weeks after commencement of glucocorticoids[1-3]. Vertebrobasilar territory is involved in 60–88% of cases of GCA-related stroke[1-3]. In contrast, the vertebrobasilar territory is affected only in 15-20% of atherosclerotic strokes[1,2]. One study reported fatal outcomes in 11 out of 40 patients (28%) with GCA-related stroke, 7 within 2-13 days of stroke[2]. To conclude, this case demonstrates that high-dose glucocorticoids with slower tapering were able to control GCA-related stroke due to vertebral vasculitis in patient with EORA on background methotrexate and sulfasalazine.

POS1462 **CAUSES OF DEATH IN PATIENTS WITH RHEUMATIC AND AUTOIMMUNE DISEASES: A 15-YEAR-OLD AUTOPSY-BASED STUDY.**

M. J. Mantilla Ribero[1], J. C. Santacruz Devia[1], J. Londono[1], A. M. Santos[1], G. J. Rodriguez[1], I. Rueda[1], J. C. Mantilla[2]on behalf of Spondyloarthropathies Research Group, Universidad de La Sabana, Chía, Colombia. *[1]Universidad de la Sabana, Rheumatology, Spondyloarthropathies Research Group, Chía, Colombia; [2]Universidad Industrial de Santander, Hospital Universitario de Santander, Pathology, Bucaramanga, Colombia*

Background: Patients with rheumatic and autoimmune diseases have susceptibility to fatal outcomes and may seem less deadly than they actually are.
Objectives: To describe the main causes of death as determined by autopsy findings, in patients with rheumatic and autoimmune diseases in a central hospital of the Colombian north-east. Stress the importance of autopsy as a teaching, research tool and education in medicine.
Methods: A retrospective, descriptive study of the database from the Pathology Department at UIS in Bucaramanga, Colombia. A total of 4,430 autopsies were performed between January 2004 and December 2019 in patients whose death occurred at Hospital Universitario de Santander or other hospitals in the Bucaramanga metropolitan area. Perinatal autopsy cases were excluded (2,181) and 2,249 autopsy protocols were analyzed, of which 47 corresponded to patients with a rheumatic and autoimmune disease (Figure 1).

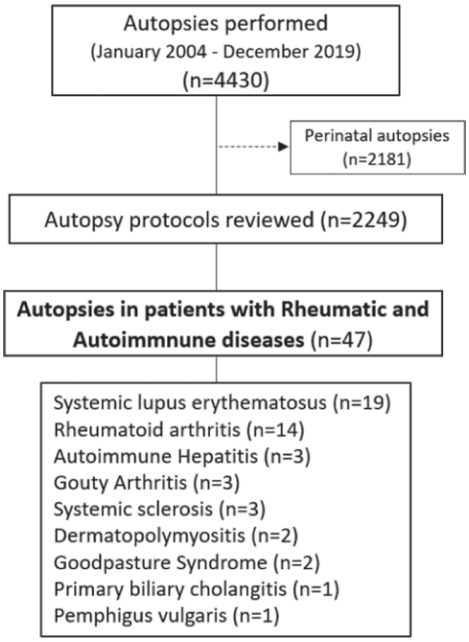

Figure 1. Flowchart of case selection

Results: A total of 47 cases were included, 27 (57.5%) were female and 20 (42.5%) were male. The mean age was 39 years old with a range from 13 to 69 years old. The most common disease was systemic lupus erythematosus (40.5%) and rheumatoid arthritis (29.8%), followed by autoimmune hepatitis and gouty arthritis with 3 cases (6.4%) each one. The most common cause of death determined by the autopsy findings was infections (66%) of which more than half were due to opportunistic pathogens, with tuberculosis being the predominant cause with 12 cases. The second cause was organic compromise due to disease activity (23.4%), and lastly other causes (10.6%) such as pulmonary embolism or myocardial infarction, which conditions more likely to present in patients with a rheumatic and autoimmune disease. A detailed description of the case series is displayed in Table 1. Almost all patients were receiving immunosuppressive therapy. The most used agents were prednisone (85%), methotrexate (19%), and azathioprine (15%). The other immunosuppressive medications were cyclophosphamide and tumor necrosis factor inhibitors in 2 cases each one.

Table 1. Causes of death determined at autopsies findings.

Disease n (%)	SLE	RA	AH	GA	SSc	DMPM	GS	Others*
Cause of death	19 (40,5)	14 (29,8)	3 (6,4)	3 (6,4)	2 (4,2)	2 (4,2)	2 (4,2)	2 (4,2)
Pneumonia (CAP)	5 (26,2)	3 (21,4)	1 (33,3)	-	1 (50)	-	-	-
Septic shock	2 (10,5)	2 (14,3)	-	-	-	-	-	-
Opportunistic Infection	5 (26,2)	6 (42,9)	-	2 (66,6)	1 (50)	2 (100)	-	1 (50)
Renal failure	3 (16)	-	-	-	-	-	2 (100)	-
Respiratory failure	-	-	-	-	-	-	-	-
Hepatic failure	-	-	2 (66,6)	-	-	-	-	1 (50)
MODS	3 (16)	-	-	-	-	-	-	-
Pulmonary embolism	1 (5,1)	1 (7)	-	-	-	-	-	-
Myocardial infarction	-	2 (14,3)	-	1 (33,3)	-	-	-	-

*Others: Primary biliary cholangitis 1 case and Pemphigus vulgaris 1 case. SLE= Systemic lupus erythematosus; RA= Rheumatoid arthritis; AH= Autoimmune Hepatitis; GA= Gouty Arthritis; SSc= Systemic sclerosis; DMPM= Dermatopolymyositis; GS= Goodpasture Syndrome; CAP= Community-acquired Pneumonia; OI= opportunistic infections; MODS= Multiple organ dysfunction syndrome.

Conclusion: The causes of death in our autopsy series match previous studies in these population. The leading cause of death were infections and most cases occurred in young and middle-aged women. These results support previous reports regarding the importance of infections as a cause of death in patients with rheumatic and autoimmune diseases and the fatal outcomes of a severe activity of the uncontrolled disease. It is a challenge for the clinician to treat patients with these conditions and to achieve a balance between obtaining an effective treatment (usually high doses of immunosuppressive drugs) and minimizing the risks of adverse events related to the medications, such as infections.

POS1463 TUBERCULOSIS AS A FATAL OUTCOME IN PATIENTS WITH RHEUMATIC DISEASES: AN AUTOPSY-BASED STUDY

M. J. Mantilla Ribero[1], J. C. Santacruz Devia[1], J. Londono[1], A. M. Santos[1], S. A. Serrato[2], J. C. Mantilla[2]on behalf of Spondyloarthropathies Research Group, Universidad de La Sabana, Chía, Colombia. *[1]Universidad de la Sabana, Rheumatology, Spondyloarthropathies Research Group, Chía, Colombia; [2]Universidad Industrial de Santander, Hospital Universitario de Santander, Pathology, Bucaramanga, Colombia*

Background: Tuberculosis (TB) is still a worldwide health problem and patients with rheumatic disease (RD) have an increased risk of this infection and fatal outcomes.

Objectives: We aim to report an autopsy case series in patients with an RD whose deaths were caused by TB in a high-level hospital of the Colombian north-east and stress the importance of autopsy as a teaching and research tool.

Methods: A retrospective, descriptive study of the database from the Pathology Department at UIS in Bucaramanga, Colombia. A total of 3390 autopsies were performed between January 2009 and December 2019 in patients whose death occurred at Hospital Universitario de Santander. A total of 1713 autopsy reports were analyzed, of which 10 corresponded to patients with RD whose deaths were caused by Mycobacterium tuberculosis.

Results: A total of 12 patients with a premortem diagnosis of RD were included who additionally had autopsy findings consistent with a mortal infection by a Mycobacterium tuberculosis. Nine cases (75%) were male and 3 were female (25%). The mean age was 49 years old with a range from 32 to 69 years old. The most common RD was rheumatoid arthritis (33,3%) followed by systemic lupus erythematosus, dermatopolymyositis and gouty arthritis with 2 cases (16,6%) each one. In 9 cases the autopsy findings were extrapulmonary TB, of which more than half were disseminated and only 3 cases were exclusively pulmonary TB. All patients were receiving immunosuppressive therapy. The most commonly used therapies were prednisone (100%), methotrexate (25%), and anti-TNF agents (16,6%). A detailed description of the reported cases is displayed in Table 1 and Figure 1.

Table 1. Description of the reported cases

Case	Sex	Age	RD	IST	Autopsy findings
1	Male	32	RA	PRED, MTX, Anti-TNF	Disseminated tuberculosis
2	Male	37	DMPM	PRED	Disseminated tuberculosis
3	Female	42	SLE	PRED	Disseminated tuberculosis
4	Male	43	DMPM	PRED, MTX	Pulmonary tuberculosis
5	Male	45	GA	PRED	Meningeal tuberculosis
6	Male	45	RA	PRED	Meningeal tuberculosis
7	Male	49	GA	PRED	Pulmonary tuberculosis
8	Male	53	PV	PRED, AZA	Pulmonary tuberculosis
9	Female	56	RA	PRED, Anti-TNF	Miliary tuberculosis
10	Male	57	SLE	PRED	Disseminated tuberculosis
11	Male	60	RA	PRED, MTX	Pulmonary tuberculosis and tuberculous endocarditis
12	Female	69	SSc	PRED	Pulmonary and meningeal tuberculosis

RD= Rheumatic Disease; RA= Rheumatoid Arthritis; DMPM= Dermatopolymyositis; SLE= Systemic Lupus Erythematosus; GA= Gouty Arthritis; PV= Pemphigus Vulgaris; SSc= Systemic Sclerosis; IST= Immunosuppressive therapy; PRED= Prednisone; MTX= Methotrexate; Anti-TNF= Tumor Necrosis Factor Inhibitor; AZA= Azathioprine.

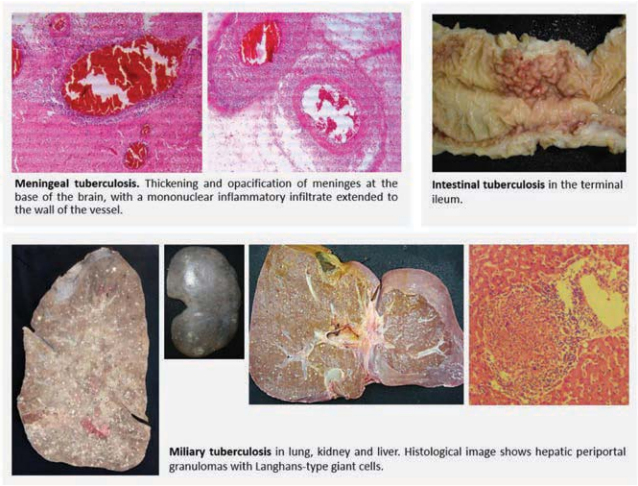

Figure 1. Pictures of some autopsy findings of the reported cases

Conclusion: TB remains one of the leading causes of death worldwide and patients with RD have an increased risk of TB as compared to the general population. In patients with rheumatic conditions, TB most commonly presents in its extrapulmonary form likely from the reactivation of latent infection, hence we stress the importance of screening for the most prevalent infections before the initiation of immunosuppressive therapy. The diagnosis and early treatment of latent TB infection are vital to preventing the progression of the disease and avoid fatal outcomes related to this infection.

POS1464 TOXOPLASMOTIC CHORIORETINITIS IN A PATIENT WITH RHEUMATOID ARTHRITIS

O. Nesmeyanova[1], E. Bogdanova[1], G. Khusainova[2], E. Tur[3,4]. *[1]Chelyabinsk Regional Clinical Hospital, Rheumatology, Chelyabinsk, Russian Federation; [2]South Ural State Medical University, Hospital Therapy, Chelyabinsk, Russian Federation; [3]South Ural State Medical University, Ophthalmology, Chelyabinsk, Russian Federation; [4]Medical Organization Optic-Center, Ophthalmology, Chelyabinsk, Russian Federation*

Background: Biological disease-modifying antirheumatic drugs (bDMARD) are one of the most effective in the treatment of rheumatoid arthritis. Infectious complications are one of the most common complications of this type of therapy. Before the therapy is started, patients are examined for tuberculosis, human immunodeficiency virus and hepatitis B and C, but the spectrum of chronic infections is much wider, for example toxoplasmosis infection is widespread. Toxoplasma gondii mainly affects the brain, lungs, liver and organ of vision.

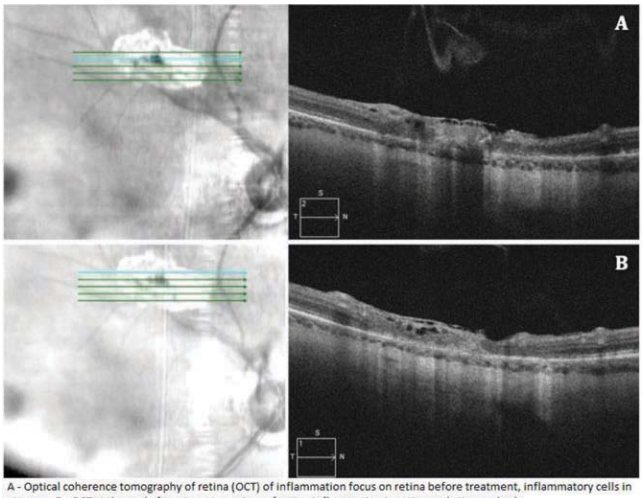
Objectives: To present a clinical case of toxoplasma chorioretinitis in a patient with rheumatoid arthritis.

Methods: Case report. The patient was treated and examined based on real clinical practice.

Results: A 59-year-old woman was admitted to the rheumatology department with symmetric arthritis of the hand joints, long morning stiffness duration (up to 4 hours). The diagnosis of rheumatoid arthritis was previously verified according to the ACR / EULAR 2010 criteria (three years ago). She received treatment in accordance with the clinical guidelines of the Ministry of Health of the Russian Federation: methotrexate 12.5 mg per week with a subsequent increase in dosage to 20 mg per week. Due to the increase in transaminases, the dosage of methotrexate was reduced to 17.5 mg per week, the daily intake of glucocorticosteroids (prednisone 7.5 mg per day). Nevertheless she had high disease activity (Disease Activity Score (DAS28) 5.54, Clinical Disease Activity Index (CDAI) 26.6, Simplied Disease Activity Index (SDAI) 30.12). Considering the continued high activity of the disease against the background of ongoing therapy lasting more than 6 months,

infliximab was added to the treatment at a dose of 3 mg per kg of body weight. A good clinical response was achieved (DAS28 2.67, CDAI 4.0, SDAI 9.4, prednisone canceled). After 4 months, there were complaints of acute decrease in vision in the right eye. Referred to an ophthalmologist. Visual Acuity: best corrected visual acuity (BCVA) on right eye is 0.4 (Snellen Chart), BCVA on left eye is 0.9 (Snellen Chart), intraocular pressure: right eye - 18 mmHg (non-contact), left eye - 19 mmHg (non-contact). Right eye: palpation is painful; cornea and anterior chamber humor are transparent; mild cataract in lens; inflammation cells in vitreous body (3+). Fundus (right eye): disc of optic nerve is normal; edema along upper-temporal vessels in macular region, exudates with pigmentation; periphery is normal. Left eye: findings are not clinical significant. Optical coherence tomography of retina (OCT): macular depression is normal; in paramacular region is epiretinal membrane, no traction; along upper-temporal vessels in macular region is chorioretinal focus with retina layer disorganization and tractions. Laboratory: Diaskintest is negative; Toxoplasma IgG = 170 ME / ml (positive is> 8 ME / ml). Diagnosis: Toxoplasma chorioretinitis, infiltration phase of right eye. Topical therapy: dexamethasone 0.1% - 1 x 6 times / day - 20 days, nepafenac 0.1% - 1 x 3 TID - 20 days. Oral: rovamycine 3 mil. ME - 2 TID - 20 days. Infliximab and methotrexate were canceled for the entire period of toxoplasma chorioretinitis treatment. Ophthalmologist's follow-up after 20 days: no complaints on visual acuity, BCVA on right eye is 1.0 (Snellen Chart). No cells in vitreous body. Fundus: decrease evidence of edema. OCT: decrease evidence of edema. Taking into account the presence of chronic toxoplasmosis infection, the patient was prescribed sulfasalazine 3 g per day as a basic therapy.

Conclusion: In this clinical case we demonstrated the possibility of activating chronic infections such as toxoplasmosis during therapy with bDMARD infliximab. To avoid risk of activating toxoplasmosis patients with rheumatoid arthritis should be screened for this infection before start bDMARD therapy.



A - Optical coherence tomography of retina (OCT) of inflammation focus on retina before treatment, inflammatory cells in vitreous. B - OCT at the end of treatment: no signs of active inflammation in retina and vitreous body

POS1465 **COMPLICATED QUESTIONS YET SIMPLE ANSWERS. A CASE OF THIAMIN DEFICIENCY MISTAKEN FOR SJOGREN'S SYNDROME.**

Y. Abbas[1,2], A. Mahdi[3], S. Hammadi[4,5]. *[1]College of Medicine / Al-Nahrain University, Internal Medicine, Al-Kadhimia, Iraq; [2]Baghdad Teaching Hospital, Rheumatology, Baghdad, Iraq; [3]College Of Medicine / Al-Nahrain University, Pathology and Forensic Medicine, Al-Kadhimia, Iraq; [4]College Of Medicine / Al-Nahrain University, Surgery, Al-Kadhimia, Iraq; [5]MOH, Otolaryngology, Al-Kadhimia, Iraq*

Background: Sialosis is a non inflammatory nor neoplastic expansion of the salivary glands. it is a common mimicker for obstructive, inflammatory and malignant salivary gland disorders.(1) It had been described in acromegaly, vitamin A, and Thiamin deficiency and in amylophagia and bulimia.(2-5) Imaging should be normal in Sialosis(6) Here we describe a case of Sialosis due to Vitamin deficiency who was treated for a few months with anti-tuberculous and anti inflammatory drugs.

Objectives: To raise awareness about this cause of parotid swelling and encourage practice of exclusion prior to treatment.

Methods: A 30 year old lady with no significant past medical history presented to us with 2 years of slowly progressive, non tender bilateral facial swellings, with no excess or reduced salivation and no pain upon eating, she had negative history of preceding upper respiratory tract infection. the condition was associated with feeling a lump in her right axilla, and cervical region, there was no fever or systemic manifestations. she consulted a surgeon during that period, an exisional biopsy of the lump revealed the presence of fatty lumps, she was then prescribed antituberculosis medications since her symptoms were vague and because TB is quite common in Iraq. She denied any improvement with these medications. She then was prescribed treatment with hydroxyChloroquin and prednisolone by another physician assuming she had sjogren's syndrome. When we saw the patient she was extremely distressed and depressed, had bilateral diffused parotid swellings, along with submandibular swelling, no mass could be felt during the exam, her mandibles and neck appeared large, she had normal tear film production and negative eye test, with no articular or muscular abnormalities.

Results: Her Labs were negative, and ultrasound for the parotids revealed enlarged glands with normal texture, MRI showed enlarged both parotids and submandibular glands with no other abnormality, minor salivary gland biopsy showed normal tissue with no inflammatory cell infiltrates. she had normal thyroid, parathyroid and growth hormone levels, normal metabolic panel and denied history of Alcohol consumption of Bulimia, but rarely consumed meat. a trial of Vitamin A, Thiamin and pilocarpine was started, the patient reported regression in the size of the swellings after 2 weeks of therapy but then developed mucosal dryness, afterwards, Vitamin A was stopped, she developed bone pain with normal bone markers and for that reason, pilocarpine was stopped. despite stopping these medicines, the size continued to regress on thiamin supplement alone, and she was prescribed anxiolytics and antidepressants by a Neurologist.

Figure 1. Showing the appearance A, before and B after one month of treatment.

Conclusion: Sialosis can be a manifestation of variable metabolic and endocrine conditions and it should be kept in mind when facing a patient with parotid swelling being a potentially treatable cause.

POS1466 A CASE REPORT OF IRAQI CHILD WITH MONA SYNDROME AND GALACTOSEMIA

Y. Abbas[1,2], N. Ihsan[2], F. I. Gorial[2,3], G. Saleh[2]. *[1]Al-Nahrain University, College / of Medicine, Internal Medicine, Al-Kadhimia, Iraq; [2]Baghdad Teaching Hospital, Rheumatology, Baghdad, Iraq; [3]College of Medicine, University of Baghdad, Internal Medicine, Baghdad, Iraq*

Background: MONA) Multicentric Osteolysis, subcutaneous Nodulosis and Athropathy(is a rare autosomal recessive disorder caused by inactivating mutations in the matrix metallopeptidase 2 (MMP2) gene.It is manifested by osteolysis of the carpal and tarsal bones, progressive joint contractures, and fibrocollagenous nodules (1,2). In addition, there are reports of gingival hypertrophy, pigmented skin lesions, coarse face, corneal opacities, and cardiac defects (1,3). Because of joint contractures and dysmorphic features and radiological findings, it can be misdiagnosed as juvenile idiopathic arthritis and mucopolysaccharidoses respectively(4). Most affected children are apparently normal at birth with symptoms' onset usually between six months and six years of age (5); the range is from birth to 11 years (2).To date, 51 individuals have been identified with biallelic pathogenic variants in MMP2 (3,6).Here we report a case of child MONA and galactosemia which is not known before.
Objectives: To share this interesting extremely rare presentation and new association
Methods: An eight year old Iraqi boy with Galactosemia at the 4th month of life presented with 4 years history of fractures of his long and short bones after trivial traumas with progressive painful deformities in hands and feet with limitation motion He has seizures, and Atrial septal defects. Intellect is normal, He had coarse facial features, hypertelorism, gum hypertrophy with high arched palate and hirsutism. Painful subcutaneous nodules involving both palms and soles (Figure 1).

Figure 1.

Results: The immunological, hematological and ultrasound were normal. The X-rays showed osteopenia, decrease in joint space and resorption of phalanges with cortical thinning and expansion of the phalangeal and metacarpal bones was a distinct finding (Figure 1). Genetic study revealed Homozygous *MMP2* mutation.
Conclusion: Diagnosis of MONA Combined with galactosemia was made.

POS1467 SEPTAL PANNICULITIS AS A MANIFESTATION OF COVID-19 INFECTION

O. Egorova[1], G. Tarasova[1], A. Datsina[2]. *[1]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Thromboinflammation, Moscow, Russian Federation; [2]Pirogov Russian National Research Medical University, Pirogov Russian National Research Medical University, Moscow, Russian Federation*

Objectives: to study the clinical and laboratory features of septal panniculitis in the form of erythema nodosum (EN) in a cohort of patients with COVID-19 referred to a rheumatological center.

Methods: In 2020–2021 we examined 21 patients (18 women and 3 men, average age 43.2±11.4 years) with EN and polyarthralgia/arthritis. Depending on the time of EN and articular syndrome associated with COVID-19 development, patients were divided into three groups: 1) up to 4 weeks – acute COVID (symptoms potentially associated with infection); 2) from 4 to 12 weeks – ongoing symptomatic COVID and 3) more than 12 weeks – post-COVID syndrome (persistent symptoms not associated with an alternative diagnosis). All patients underwent a comprehensive clinical, laboratory and instrumental examination, including ultrasound of the joints and chest computed tomography (CT), as well as pathomorphological examination of skin and subcutaneous adipose tissue from the node area (in 9 cases).

Results: Based on the history data, COVID-19 in the study cohort had mild (in 3 patients), moderate (12) and severe (6) severity. Two patients (21 and 23 years old) with a mild severity of the disease on the 2nd-3rd day of the development of the respiratory symptom for the first time noted red painful (45 mm on a visual analogue scale) nodes on the legs and polyarthralgia. In 9 patients (52.3%), similar skin changes were detected 24.5 ± 7.6 days after stopping active COVID-19, i.e. during the period of ongoing symptomatic COVID. In 8 patients (38%), including 6 with moderate severity of the disease, nodules appeared after 85.6 ± 12.3 days, which corresponded to post-COVID syndrome. At the time of examination, 100 and 71.4% of patients complained of skin rashes and joint pain, respectively. Shortness of breath, weakness, cough, sweating and myalgia disturbed 67% of patients. An increase in body temperature to subfebrile was observed in 43% of cases, mainly with ongoing symptomatic COVID. In the overwhelming majority of cases (86%), UE was located on the anterior and lateral surfaces of the legs, less often on the posterior and medial surfaces. It is noteworthy that the lesion of more than 50% of the surface of the lower and upper extremities was associated with the number of nodes ($p < 0.02$), CRP level ($p < 0.03$) and post-COVID syndrome ($p < 0.2$). Sixteen patients (76.1%) had signs of arthralgia, mainly ankle (81%) and knee (56%) joints. In a laboratory study, the median ESR was 39 [14; 62] mm/h, the level of CRP was 17 [2; 79] mg/l. The results of the polymerase chain reaction for SARS-CoV-2 were negative in 90.4 % of patients. In 90.4 % of cases, IgG antibodies were detected and in 52.3% - IgM to the SARS-CoV-2 virus. At CT of the chest, ≤25% of lung lesions were detected in 51% of patients, from 25 to 50% - in 33% and from 50% to 75% - in 9.5 % of cases. Pathomorphological examination of the nodes showed signs of septal panniculitis.

Conclusion: When EN associated with SARS-CoV-2 appears it is important to timely suspect a post-infectious manifestation, based on the clinical picture of the disease and to determine the scope of further examination and adequate treatment

POS1468

PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY IN A PATIENT WITH A BACKGROUND OF LUPUS NEPHRITIS AND CEREBRAL LUPUS

H. Johnsson[1], R. Hunter[2], S. Boyle[1]. [1]*Western General Hospital, Rheumatology, Edinburgh, United Kingdom;* [2]*Royal Infirmary of Edinburgh, Renal Medicine, Edinburgh, United Kingdom*

Background: Progressive multifocal leukocencephalopathy (PML) is a potentially fatal degenerative condition caused by reactivation of the human polyomavirus 2 (JC virus) in immunodeficient individuals. It is well recognised in individuals who have received Rituximab, but patients treated with other immunosuppressants are at risk also (1). Moreover, patients with SLE may be at increased risk, even when they are not taking immunosuppressants (1, 2).
Objectives: Describe the case of a patient with a history of lupus nephritis and cerebral lupus, on long-term Mycophenolate mofetil (MMF) and Prednisolone, diagnosed with PML complicated by immune reconstitution inflammatory syndrome (IRIS).
Methods: Case report.
Results: This patient first presented in 2010 at the age of 18 with ankle swelling and proteinuria. She had high ANA and anti-dsDNA titres, and renal biopsy showed class IV lupus nephritis. She went into remission on high dose Prednisolone and MMF and elected to stop her MMF. Four months later, she developed behaviour changes and worsening proteinuria. MRI showed a mild high signal lesion in the right cerebral hemisphere, and she was diagnosed with cerebral lupus. She recovered after treatment with IV methylprednisolone and MMF. Over the subsequent eight years, she had three flares of her lupus nephritis, with repeat biopsies in 2013 and 2018 showing active proliferative (class IVA) glomerulonephritis. Consequently she was treated with varying doses of oral Prednisolone and MMF for most of this period. She never received any B-cell depleting therapies. In October 2020, she presented to A&E with numbness in her left face and down her left arm and leg. MRI demonstrated signal abnormalities in her right hemisphere, involving the cortex, white matter and leptomeninges. She was lymphopenic (0.58x10^9/L) with a low CD4 count of 136 cells/uL (normal range 620-1990 cells/uL). A recent dsDNA had risen to 70 IU/ml. Her cerebrospinal fluid revealed mildly raised white cells and a weakly positive JC virus PCR. The differential diagnoses included cerebral lupus, opportunistic infection and malignancy. During this period of diagnostic uncertainty, she was treated with an increased dose of oral Prednisolone and plasma exchange. She went on to have a brain biopsy that showed peri-vascular lymphocytic infiltration and JC virus was present in high copy numbers in the brain tissue (49221.8 IU/mL), confirming a diagnosis of PML. Her MMF was stopped but she continued a low dose Prednisolone with the addition of Hydroxychloroquine. She was re-admitted two weeks after discharge in December 2020 with a right-sided headache, left facial weakness and loss of dexterity in her left hand. MRI showed evidence of IRIS in the right hemisphere with cerebral oedema causing midline shift. She was treated with IV Dexamethasone then Prednisolone 30 mg daily, with a gradual taper over a year.She has made a good recovery with minimal neurological deficit; she had recurrent seizures which responded well to anticonvulsant therapy. Her SLE has not flared.
Conclusion: This describes a case of PML in the context of longstanding lupus nephritis, treated with prednisolone and MMF. Her longstanding lymphopenia with low CD4 counts were attributed to the combined consequences of active lupus and her cumulative immunosuppressive burden. CD4 lymphopenia is associated with PML in the HIV population, and may provide information about which patients on immunosuppressive treatments are at risk of developing PML (3). However, not enough is known to routinely screen patients and the counts of other lymphocyte subsets are likely to be important too. The case highlights that PML can be associated with different immunosuppressants, other than B-cell depletion. The prompt diagnosis, facilitated by brain biopsy, and appropriate management led to a good medium-term outcome for this patient, showing that PML is eminently survivable.

POS1469

POLYAUTOIMMUNITY AS THE PRESENTING FEATURE OF LIPOPOLYSACCHARIDE RESPONSIVE BEIGE-LIKE ANCHOR PROTEIN DEFICIENCY IN A YOUNG INDIAN BOY

D. B. Pandya[1]. [1]*Dev Paediatric Rheumatology & Immunology Center, Pediatric, Rajkot, India*

Background: LPS-responsive beige-like anchor protein(LRBA) deficiency is an autosomal recessive disorder caused by biallelic mutations in the LRBA gene leading to a syndrome of autoimmunity, lymphoproliferation and humoral immune deficiency.LRBA protein plays a major immuno-regulatory role in the expression, function and trafficking of cytotoxic T lymphocyte-associated protein 4 (CTLA4) in Tregs which is an immune effector molecule that acts as an inhibitory checkpoint for the immune response.[1,2,3]
Objectives: We report a 7 years old boy with LRBA deficiency who was presented with polyautoimmuity primarily affecting gut, pancreas & joints with recurrent infections.
Methods: He was born to a non-consanguineous Indian parents with uneventful birth, development and vaccination history.He had been unwell from the age of one with multiple episodes of lower respiratory tract infections warranting usage of prolonged antibiotics. 2.5 years of age, he had been diagnosed as Type 1 Diabetes Mellitus and he was commenced on insulin therapy. 3.5 years, he developed chronic diarrhoea.Evaluation revealed sterile blood, urine and stool cultures with normal abdominal imaging(USG & CT scan), elevated TTg-IgA & HTTP/DGP screen and negative HLADQ2-DQ8. He failed gluten-free diet. Gastrointestinal endoscopy showed duodenum and terminal ileum nodularity & biopsy was suggestive of non-celiac autoimmune enteropathy. 4 years, he developed two episodes of stridor, tetany and breathing difficulty which were promptly reversed by IV calcium infusion. He had low serum calcium, low parathyroid hormone with normal vitamin D level, serum phosphorous, magnesium, thyroid profile, anti-thyroid antibodies, renal and liver functions. 5.5 years, he first presented to us with chronic unexplained polyarthritis involving small and large joints in an additive pattern. Family history was significant for a death of the previous male sibling at 7 months of age due to chronic unexplained diarrhoea. Examination revealed facial dysmorphism and failure to thrive with no systmic findings.
Results: Investigations showed HB 8.1gm%,TLC6700/cumm with normal differential counts and platelet counts 233000/ul. ESR was 39mm/hr and CRP was negative. Direct coomb's test, RF, ANA were negative. He had a mild elevation in IgG levels with normal B-T cells populations. Genetic evaluation revelaed pathogenic homozygous splice site mutation in intron 11 of *LRBA* gene. Both the parents are heterozygous carriers. A largest systematic review[3] of 212 cases of LRBA deficiency showed autoimmunity(70%), non malignanat lymphoproliferation(54%), enteropathy(41%), endocrinopathy(41%) and lower respiratory tract infections(41%) as the most common clinical manifestations with normal or abnormal immunoglobulin level and B-T cells populations. Arthritis(8%) was amongst the rare manifestations. Hypoparathyroidism was the rarest endocrine manifestations. No data available regarding prevalence of positive celiac disease antibodies. There was no haematological manifestations in our case.
Conclusion: LRBA deficiency should be strongly considered in a child recurrent infection and polyautoimmunity including arthritis. Abatacept could be used as a steroid sparing agent and as a bridging agent awaiting transplant.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

POS1470-HPR KNOWING WHAT TO DO WITH THE DATA - A QUALITATIVE STUDY ON CHALLENGES OF USING SMARTPHONE-BASED EPROS IN RHEUMATOID ARTHRITIS

Y. Seidler[1], T. S. Jørgensen[2], P. Studenic[3,4], H. Radner[3], T. Nygaard[5], N. Weibrecht[6], N. Popper[7], L. E. Kristensen8, T. C. Wilhelmer[9,10], J. Rickmann[11], E. Mosor[12], V. Ritschl[1], T. Stamm[1]. *[1]Medical University of Vienna, Section for Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Vienna, Austria; [2]Copenhagen University Hospital, Frederiksberg and Bispebjerg, Parker Institute, Department of Rheumatology, Copenhagen, Denmark; [3]Medical University of Vienna, Division of Rheumatology, Department of Internal Medicine III, Vienna, Austria; [4]Karolinska Institutet, Division of Rheumatology, Department of Medicine (Solna), Stockholm, Sweden; [5]Daman, P/S, Copenhagen, Denmark; [6]dwh, GmbH, Vienna, Austria; [7]Vienna University of Technology, Institute for Information Systems Engineering, Vienna, Austria; [2]Copenhagen University Hospital, Frederiksberg and Bispebjerg, Parker Institute, Department of Rheumatology, Copenhagen, Denmark; [9]EULAR, Young PARE, Zurich, Switzerland; [10]Austrian Rheumatism League, None, Maria Alm, Austria; [11]The Parker Institute´s Patient Association, Department of Rheumatology, Copenhagen, Denmark; [12]Medical University of Vienna, Section for Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Wien, Austria*

Background: Using patient-reported outcomes (PROs) has a long tradition in rheumatology, and PRO measurement is included in many composite indices evaluating disease progression and treatment response [1]. However, little is known about patients´ and health professionals´ (HPs) perceptions of using digitally collected PROs, the so-called ePROs, with a personal smartphone app.

Objectives: To identify main challenges in utilising ePROs for management and treatment of rheumatoid arthritis from patients' and HPs' perspectives.

Methods: We interviewed 25 people with rheumatoid arthritis (RA) and 17 HPs (nurses, rheumatologists, and physiotherapists) from Austria and Denmark. We used the RheumaBuddy app as a practical example to illustrate the digital data collection and the feedback that patients would get from entering their self-reported outcomes. Interviews were recorded and transcribed. We applied a qualitative thematic analysis to identify major themes using a procedure of rigorous coding. Analysis was done by two researchers, and conflicts were solved by consensus. Ethical approval was obtained in both countries.

Results: Three main themes emerged: 1) Being simple yet comprehensive; 2) Resources to interpret, use and act upon the collected data; and 3) Being reminded of the disease. Within the first theme, many valued the intuitiveness and simplicity of ePROs, especially when used as a monitoring tool in between clinical visits. HPs were concerned about not to overwhelm the patients with too many questions. On the other hand, the short ePROs asked in the app were not comprehensive enough to capture psychosocial and lifestyle aspects of the disease which were considered important both by patients and HPs. Within the second theme, patients and HPs expressed that ePROs could be the basis for shared decision making. Nevertheless, some patients had clearer ideas on making use of the feedback they could get from their self-reported data than the others. Participants from Denmark, who experienced a higher level of digital health maturity in official institutions, expressed more proactive use of the data than participants from Austria who were on average younger than their Danish counterparts. One patient in Austria even asserted having no idea what to do with the collected data but believed that the "doctor will make good use of it". HPs in both countries, however, indicated that they needed more resources, skills, and time to make sense of the ePRO data and act accordingly. Under the third theme, patients considered the collection of ePROs to be very important when pain and disease activity were high. HPs, on the other hand, were more concerned that the regular collection of ePROs might constantly remind patients that they are living with the disease.

Conclusion: The potential adoption of ePROs in practice depends on both patients and HPs' motivations and ideas to use the feedback they would get from the collected data. This might be influenced by the level of digital health maturity of a country, as well as available resources. In addition, ePROs need to be intuitive and simple, but at the same time comprehensive and reliable enough so that they can be used for shared decision making. Challenges remain for the ePROs to be used as supporting and empowering tools, and not as reminders of the disease and pain.

Table 1. Demographic data of the participants (N=42)

POS1471-HPR PAIN CATASTROPHIZING AND ITS ASSOCIATION WITH PAIN OF PATIENTS WITH RHEUMATOID ARTHRITIS IN A NON-INFLAMMATORY CONDITION.

T. Abe[1]. *[1]Hyogo College of Medicine, Division of Diabetes, Endocrinology and Clinical Immunology, Nishinomiya, Japan*

Background: Pain in rheumatoid arthritis (RA) is considered to be linked with non-inflammatory factors, including physical disabilities, psychiatric disorders, and pain catastrophizing (PC) [1].

Objectives: We investigated the role of PC in the possible link between physical disabilities and psychiatric disorders in RA patients in a non-inflammatory condition.

Methods: In this cross-sectional study, a total of 81 RA patients in a non-inflammatory condition were included; all patients had serum C-reactive protein levels <0.5 mg/dL, without any inflammatory joints. We examined the demographic and clinical data and administered the pain visual analog scale (VAS), the pain catastrophizing scale (PCS), the Health Assessment Questionnaire Disability Index (HAQ-DI), and the patient version of the Brief Scale for Psychiatric Problems in Orthopedic Patients (pBS-POP). A series of multivariate-adjusted multiple regression analyses were performed to examine the associations between PC and pain intensity, physical disabilities, and psychiatric disorders.

Results: We found associations between all the above-mentioned variables in separate models associated with HAQ-DI, pBS-POP, and PCS scores. However, in the model associated with pain VAS, the PCS score (β=0.34, p=0.0073) emerged as the only variable showing statistically significant association.

Conclusion: PC is associated with pain in RA patients in a non-inflammatory condition, and this association may be mediated through pathways involving physical disabilities and psychiatric disorders.

POS1472-HPR

CONSTRUCT VALIDITY OF THE PROMIS PHYSICAL FUNCTION 10-ITEM SHORT FORM IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES AND SEVERE LIMITATIONS IN PHYSICAL FUNCTIONING

B. Straathof[1], M. Van Wissen[1], T. P. M. Vliet Vlieland[1], C. Van den Ende[2,3], M. Teuwen[1], W. Peter[1], A. Den Broeder[2,3], W. Van den Hout[4], D. Van Schaardenburg[5], A. Van Tubergen[6,7], M. G. J. Gademan[1,8], S. Van Weely[1]. *[1]Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; [2]Sint Maartenskliniek, Research, Nijmegen, Netherlands; [3]Radboud University Medical Center, Rheumatic Diseases, Nijmegen, Netherlands; [4]Leiden University Medical Center (LUMC), Biomedical Data Sciences, Leiden, Netherlands; [5]Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands; [6]Maastricht University Medical Center, Rheumatology, Maastricht, Netherlands; [7]Maastricht University, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands; [8]Leiden University Medical Center (LUMC), Clinical epidemiology, Leiden, Netherlands*

Background: Physical functioning in patients with inflammatory arthritis (IA) can be severely affected and is often measured using the disease-specific questionnaires Health Assessment Questionnaire-Disability Index (HAQ-DI) or Bath Ankylosing Spondylitis Functional Index (BASFI). Also, the Patient Reported Outcome Measurement Information System (PROMIS) Physical Function Item Bank[1] has been increasingly used. This is a generic instrument to assess physical functioning and compare health status across conditions. Several short forms can be derived, including the PROMIS PF 10-Item Short Form (PROMIS PF-10). To date, experience with this PROMIS PF-10 in research with IA is limited and more insight is needed in its construct validity in specific IA populations.
Objectives: To assess the construct validity of the PROMIS PF-10 in patients with rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA) and severe limitations in physical functioning.
Methods: Baseline data from patients with RA or axSpA and severe limitations in physical functioning participating in two randomized controlled trials on the effectiveness of longstanding physical therapy[2] were used. Patients completed the PROMIS PF-10 (score range 13.5-61.9 worst-best, standardized to the Dutch population) and several measures of physical functioning and quality of life: i.e. the 36-item Short Form Health Survey (SF-36) (Physical and Mental Component summary Scores (PCS and MCS) were calculated), the EuroQol 5-dimensions 5-levels (EQ5D5L; index and VAS) and the 6 Minute Walk Test (6MWT). In addition, RA patients completed the HAQ-DI and axSpA patients the BASFI. Spearman rho correlation coefficients were computed between the PROMIS PF-10 and the other measures. Correlations were considered 0.3<r<0.5 weak, 0.5 <r<0.75 moderate to good, r >0.75 good to excellent. The PROMIS PF-10 was expected to correlate moderately to good with instruments measuring physical functioning and weak with other instruments (e.g. SF-36 MCS). All analyses were stratified for RA and axSpA.
Results: Data from 181 patients with RA and 139 with axSpA (92% and 48% female, mean (SD) age 59 (13.1) and 54 (11.4) years, respectively) were analyzed. The mean score of the measures of physical functioning and quality of life are summarized in the Table 1. The PROMIS PF-10 correlated moderately to good with HAQ-DI, BASFI, SF-36 PCS and EQ5D5L-index (Spearman r >0.5, all p-values <0.001). The PROMIS PF-10 correlated weak with the 6MWT, EQ-VAS and the SF-36 MCS (Spearman r <0.5).

Table 1. Mean score and Spearman r correlation coefficients of PROMIS PF-10 with measures of physical functioning and quality of life

	PROMIS PF-10	HAQ-DI (RA) BASFI (axSpA)	SF-36 PCS	SF-36 MCS	EQ5D5L index	EQ-VAS	6MWT
RA Mean(SD)	34.1 (5.0)	1.6 (0.5)	39.4 (19.7)	46.8 (12.0)	0.5 (0.3)	56.4 (18.7)	300 (100)
Spearman r	-	-0.724*	0.611*	0.101	0.617*	0.450*	0.469*
AxSpA Mean(SD)	35.4 (4.2)	6.2 (1.8)	44.4 (17.6)	45.5 (11.6)	0.5 (0.3)	54.5 (19.0)	390 (108)
Spearman r	-	-0.686*	0.539*	-0.014	0.598*	0.438*	0.434*

*Correlation is significant at <0.001 level

Conclusion: The moderately to good correlations of the PROMIS PF-10 with measures of physical functioning support the construct validity in RA and axSpA patients with severe limitations in physical functioning. However, the correlation of the quality of life questionnaire EQ5D5L was also moderately to good. Future research is needed to better understand this relatively high correlation. Also clinimetric properties (responsiveness to change and ability to discriminate between intervention and control conditions) in this population should be determined in future.

POS1473-HPR

THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY LEVEL AND EXERCISE SELF-EFFICACY, BODY AWARENESS, AND FATIGUE SEVERITY IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL AND PILOT STUDY

M. Köprülüoğlu[1], İ. Naz[1], B. Dağ[2], G. Alp[3], D. Solmaz[3], S. Akar[3]. *[1]Izmir Katip Celebi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [2]Izmir Katip Celebi University Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [3]Izmir Katip Celebi University Ataturk Training and Research Hospital, Department of Internal Diseases, Rheumatology, Izmir, Turkey*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease in which, for many reasons of the nature of the disease, patients tend to perform less physical activity (PA) than recommended in the guidelines (1). Many variables associated with a level of PA in patients have been described (2). However, there are limited studies about related factors with PA in RA patients.
Objectives: To investigate the relationship between PA level and exercise self-efficacy, body awareness, and fatigue severity in RA patients.
Methods: A total of 80 RA patients (women/men=61/19, age=56.83±11.56 years) who were diagnosed according to the ACR 2010 criteria and followed in university outpatient clinic were included in our study. All patients were assessed regarding physical characteristics (age, body-mass index), exercise status (yes/no), and occupational status (working/not working/retired). Physical activity level by International Physical Activity Questionnaire, exercise self-efficacy by Exercise Self-Efficacy Scale, body awareness by Body Awareness Questionnaire, and fatigue by Bristol Rheumatoid Arthritis Multidimensional Scale was assessed.
Results: Patients' characteristics are presented in Table 1. It was observed that patients have low PA levels. Significant correlation was found between PA and exercise self-efficacy (r=0.410, p<0.001), body awareness (r=0.374, p=0.001), and fatigue (r=-0.482, p<0.001).

Table 1. The characteristics of patients

	Mean ± SD, median (25/75 quartiles) or n (%)
Age, years	56.83 ±11.56
Body mass index, kg/m^2	27.84 ±5.57
Time of diagnosis, years	11.49 ±10.92
Exercise status	
Yes	53 (66.3)
No	27 (33.8)
Occupational status	
Working	16 (20.0)
Not working	30 (37.5)
Retired	34 (,42.5)
IPAQ	
Walking, MET-min/week	371 (198/693)
Moderate, MET-min/week	270 (0/840)
Vigorous, MET-min/week	0 (0/0)
Total, MET-min/week	693 (268/ 1533)
IPAQ sub-group	
Inactive	55 (68.8)
Minimal Active	19 (23.8)
Very Active	6 (7.4)
Exercise self-efficacy score, 0-1800	646.62 ±339.40
Body awareness score, 18-126	84.77 ±16.41
Bristol rheumatoid arthritis multidimentional fatigue score, 0-70	19.06 ±12.83

IPAQ: International Physical Activity Questionnaire.

Conclusion: Our study showed that RA patients had low PA and PA was related to exercise self-efficacy and fatigue moderately and body awareness weakly. We think that it may be important to assess these variables and to plan interventions to improve these variables while planning PA programs of the patients.

POS1474-HPR FATIGUE IS AN IMPORTANT COMORBIDITY FOR RA PATIENTS. HOW CAN WE MEASURE IT EASILY IN CLINICAL PRACTICE?

B. Frade-Sosa[1], R. Morlà[1], N. Sapena[1], R. Sanmartí[1], J. A. Gómez-Puerta[1].
[1]*Hospital Clinic de Barcelona, Rhematology, Barcelona, Spain*

Background: Fatigue is highly prevalent (40-70%) in Rheumatoid Arthritis (RA)[1]. Patients describe fatigue as an important symptom, in discrepancy with rheumatologist´s perception. Different validated questionnaires are available to measure fatigue, without any standarised preference in their use. In randomized controlled trials, FACIT-F is a unidimensional tool for fatigue widely used. MDHAQ is a multidimensional tool exploring different dimensions of RA, providing a VAS 0-10 for fatigue as a simple scale to measure it[2].

Objectives: We studied fatigue in RA patients with two different questionnaires, FACIT-F and VAS 0-10 included in MDHAQ, and evaluated their utility in clinical practice.

Methods: Patients with RA (ACR/EULAR criteria, 2010) who agreed to participate in this study were included consecutively in the Arthritis Unit for 3 months. They fulfilled 2 questionnaires to evaluate fatigue: 1. FACIT-F(FS)=FACIT-Fatigue, 13 questions (0-4 score) with a global score of 0-52 (lower scores indicate worse fatigue). 2. VAS 0-10 of fatigue (=VAS-Fatigue) included in the question 9 in MDHAQ. Other self-reported queries of the MDHAQ were collected: 1-10 physical function (FN) according to modified HAQ (0-10), VAS 1-10 for pain (PN) and patient global assessment (PATGL) to calculate RAPID3, a review of 60 symptoms (ROS60) and self-assessment 48 joint count (RADAI48). Physical articular examination (TJC 0-28, SJC 0-28), laboratory test (CRP, ESR), composite EULAR disease activity indices (DAS28-ESR, SDAI), demographic (sex, age, BMI) and patient´s disease characteristics, also screened for depression with Patient Health Questionnaire 9= PHQ9≥10) were collected. A descriptive analysis of the variables was done, and Pearson´s correlation between FACIT-Fatigue and VAS-Fatigue scores, and between each questionnaire (FACIT-Fatigue and VAS-Fatigue) and the rest of variables was performed.

Results: A total of 75 patients (84% females) with RA were recruited, with a mean age of 62 (±11.6) years, a mean disease duration of 14.6 (± 5) years, a mean BMI of 22.8 (± 8.0), 64% with bDMARD and 45.3% with glucocorticoids treatment. Depression (PHQ9≥10) was observed in 16%. Correlation between the two studied questionnaires (FACIT-Fatigue and VAS-Fatigue) was almost very good (-0.79, p<0.001). Statistically significant (p<0.05) similar correlation ~0.70 were obtained between VAS-Fatigue (range: 0.60, 0.76) and ~0.80 between FACIT-Fatigue (range:-0.70,-0.87) and self-reported MDHAQ queries (FN, PN, PATGL, RAPID3, ROS60, and RADAI48). Similar but moderate correlation~0.50 (range:0.42,-0.61) was obtained in both questionnaires with TJC and EULAR indices of disease activity (DAS28-ESR, SDAI), and similar but lower ~0.20 (range:0.24, -0.29) with inflammatory variables (CRP, ESR, SJC) except for ESR and FACIT-Fatigue, no correlation was observed. Depression (PHQ9≥10) obtained the highest correlation with -0.92, p<0.001 in FACIT-Fatigue, and less for VAS-Fatigue 0.66, p<0.001 (Table 1).

Table 1. Correlation between VAS-Fatigue and FACIT-Fatigue and the different disease activity variables.

	VAS-Fatigue (0-10)	p-value	FACIT- Fatigue (0-52)	p-value
FACIT-Fatigue (0-52)	-0.79	<0.001	1	
VAS-Fatigue (0-10)	1		-0.79	
TJC (0-28)	0.42	<0.001	-0.58	<0.001
SJC (0-28)	0.24	0.040	-0.29	0.014
CRP	0.27	0.021	-0.28	0.017
ESR	0.25	0.032	-0.20	0.096
DAS28-ESR	0.52	<0.001	-0.61	<0.001
SDAI (0-86)	0.49	<0.001	-0.58	<0.001
FN (0-10)	0.76	<0.001	-0.87	<0.001
PN (0-10)	0.70	<0.001	-0.62	<0.001
PATGL (0-10)	0.75	<0.001	-0.73	<0.001
RAPID3 (0-30)	0.77	<0.001	-0.75	<0.001
ROS60 (0-60)	0.66	<0.001	-0.77	<0.001
RADAI48 (0-48)	0.60	<0.001	-0.70	<0.001
PHQ9 (0-27)	0.66	<0.001	-0.92	<0.001

Conclusion: VAS (1-10) is a good tool compared to FACIT to easily measure of fatigue in daily routine for RA patients. The use of this simple scale integrated in the MDHAQ allows capturing important clinical information for the disease.

Background: The minimally important difference (MID) required to interpret the magnitude of changes in lupus patient-reported outcome (LupusPRO), which is a widely used outcome measure of quality of life in SLE patients, remains unclear.

Objectives: We report preliminary results of an ongoing prospective observational study that assesses the MID as the interpretability of emotional health (EH) domain in Japanese version of LupusPRO.

Methods: We recruited subjects at three university hospitals in Japan participating in an ongoing multidisciplinary cohort study (the Lupus registry of Nationwide institutions (LUNA). Of a total of 210 SLE patients enrolled during the 17-month recruitment period, patients with low disease activity, defined as SLE Disease Activity Index 2000 (SLEDAI-2K) ≤ 4, and who were seen at least twice of three months'

duration and responded to both the LupusPRO and health status change questions were included in this subcohort. The second questionnaire was given an allowance period of 30 days before or after the three months from starting date. Descriptive statistics were presented as means and standard deviations (SD) or counts and percentages (%). The emotional health score ranges from 0 to 100; a higher score indicates less frequent presence of symptoms. The change in health status was assessed using the 7-point Global Rating of Change [1], and the score = 0 and the score ≥ +1 were considered in the 'unchanged' and the minimal 'improved' category, respectively. MID was mainly estimated using the mean change of the groups with the score ≥ +1 as the anchor-based method, and the area under the curve (AUC) was also calculated as a sensitivity analysis to estimate MID thresholds [2] and 95% confidence intervals (CI) were constructed using 1000 bootstrapping.

Results: The mean age of the 24 eligible patients was 48 (SD 14), and 88% were female. The glucocorticoid dose, SLEDAI-2K, and Systemic Lupus International Collaborating Clinics /American College of Rheumatology Damage Index were 3.4 (2.1) mg, 1.0 (1.1) and 1.1 (1.9), respectively. The mean EH score was 67.5 (30.3), five patients (21%) had the maximum EH score at baseline, 73.4 (25.0) after three months, 7.2 (18.0) for the change in EH. The correlation coefficient and the AUC for the change in health status and the EH were 0.23 and 0.60. The mean changes were 4.1 (18.4) of the groups with 'unchanged' health status and 12.3 (17.1) of the groups with 'improved' health status. The MID for improvement was estimated at 12.3 using the anchor-based method, and the cutoff point corresponded to 9.3 [95%CI -6.7 to 25.3]) of the EH change score by the receiver operating curve method.

Conclusion: In this study, the MID (3 months) for the EH domain in the Japanese version of LupusPRO was estimated to be between 9 and 12, which was similar to the results of the previous cross-sectional study [3]. The challenge in estimating the MID in our setting was the low correlation with external anchors, even though the study population was limited to patients with low disease activity, because disease activity at baseline can generally influence 'improved' health status.

POS1476-HPR FEASIBILITY OF USING OPTOELECTRONIC MEASUREMENT OF HAND MOVEMENT FOR CHARACTERIZING HAND FUNCTION IN RHEUMATOID ARTHRITIS

B. Coppers[1,2], S. Heinrich[3], U. Phutane[3], D. Berisha[3], K. Tascilar[1,2], A. Kleyer[1,2], D. Simon[1,2], J. Bräunig[4], J. Penner[3], M. Vossiek[4], V. Schönau[1,2], S. Bayat[1,2], G. Schett[1,2], S. Leyendecker[3], A. M. Liphardt[1,2]. *[1]Friedrich-Alexander-Universität Erlangen-Nürnberg and University Hospital Erlangen, Department of Internal Medicine 3—Rheumatology and Immunology, Erlangen, Germany; [2]Friedrich-Alexander-Universität Erlangen-Nürnberg and University Hospital Erlangen, Deutsches Zentrum für Immuntherapie, Erlangen, Germany; [3]Friedrich-Alexander-Universität Erlangen-Nürnberg, Chair of Applied Dynamics, Erlangen, Germany; [4]Friedrich-Alexander-Universität Erlangen-Nürnberg, Institute of Microwaves and Photonics, Erlangen, Germany*

Background: Physical function is an important factor determining disease burden in arthritis. Monitoring function in rheumatoid arthritis (RA) patients is essential for effective treatment [1]. The currently used tools to assess physical function (e.g. patient reported outcomes) have limitations with respect to sensitivity and specificity to measure functional impairment in RA [2,3]. A marker-based optoelectronic measurement of hand function enables detailed analysis of hand movements such as spatial-temporal parameters and joint angles [4]. This may provide new possibilities to quantitatively and qualitatively analyze the changes of hand function in patients with RA in so far unprecedented way.

Objectives: To test the feasibility of optoelectronic measurement of hand function in RA patients and healthy controls (HC) when performing standard functional tests such as the Moberg Pick-Up-Test (MPUT) as well as standard movements such as finger flexing and to detect disease specific patterns.

Methods: RA patients (ACR/EULAR 2010 criteria [1]) recruited from the Internal Medicine 3 outpatient clinic, Erlangen, Germany and HC were included (Ethics #125_16B). Participants were asked to perform the MPUT and a simple movement of flexing the interphalangeal (DIP) and proximal interphalangeal joint (PIP). Spatial-temporal data of hand movements and hand segment kinematics were captured using an optoelectronic measurement system (Qualisys AB, Sweden) with 29 retroreflective markers (Figure 1). Transport time for each of the 12 MPUT objects was divided into a grasping phase (GP) (first touch to safe grip) and a manipulation phase (MP) (safe grip to drop) using the video recording or marker trajectories. For the flexing movement, the ratios between the flexion angle of the DIP and PIP joint (DIPPIP) were calculated. We used linear mixed-effects models accounting for within-participant clustering of hands and adjusting for age and sex differences to compare RA with controls.

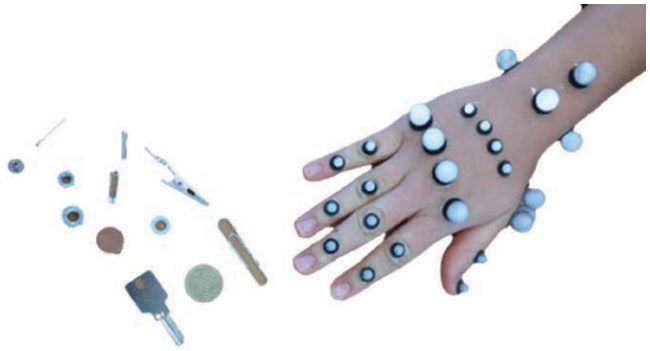

Figure 1. Marker setup and the 12 objects transported during the MPUT.

Results: Twenty-four RA patients and 23 healthy controls were evaluated (Table 1). Mean GP times across all objects showed higher absolute differences between the groups (RA 0.43 [0.35-0.52]; HC 0.33 [0.27-0.40] sec) while MP times were identical (RA 0.36 [0.30-0.44]; HC 0.36 [0.30-0.44] sec) showing a significant group-phase interaction ($p<0.001$). Objects safety pin, key, and paper clip showed the highest absolute between-group mean differences for unadjusted time data (0.41, 0.36, 0.34 sec respectively). Measured angle ratios (RA 0.60±0.15; HC 0.68±0.17 (DIPPIP)) and their linear fit (RA 0.96±0.05; HC 0.97±0.03 R^2) were similar for RA and controls ($p>0.05$).

Table 1. Subject characteristics; mean (SD)

	RA	HC
male: female [N]	7: 17	11: 12
Age [years]	62.3 (9.1)	50.2 (16.1)
Disease duration [years]	11.8 (10.8)	
Disease Activity Score (DAS28)	2.5 (1.3)	

Conclusion: Optoelectronic measurement of hand function is feasible and allows to gain a more detailed picture of impairment in hand function in RA patients. For instance, tasks like reaching for an object are significantly impaired. Further, objects causing the greatest difficulty for RA patients in the GP were identified. The previously described linear relationship of angle ratios for the distal finger joints in healthy individuals [5] seems also valid for RA patients in our cohort and no significant group differences for the ratio could be observed. This may reflect that DIP and PIP joints are less affected in RA compared to e.g. psoriasis arthritis [6]. In conclusion, optoelectronic hand movement analysis allows a more accurate and differentiated analysis of hand function in RA patients.

Background: Researchers are increasingly using echo-intensity (EI) as an index of muscle quality or fatty and fibrous tissue infiltration. EI is moderately associated with muscle strength and/or power and a better predictor of muscle performance than measures of muscle mass. In this regard, ultrasound-derived EI may be a promising skeletal muscle assessment tool for monitoring the progression of physical performance. However, there has been no study that investigated the relationship between muscle EI and physical performance in women with knee osteoarthritis (OA).
Objectives: The aim of our study is to investigate the relationship between the physical performance and muscle echo-intensity in women with knee OA.
Methods: Ninety-six women with radiological and clinical knee OA participated in this cross-sectional observational study. Quadriceps femoris (Rectus Femoris-RF, Vastus Intermedius-VIM, Vastus Medialis-VM, Vastus Lateralis-VL) and hamstring (Biceps Femoris-BF, semitendinosus-STT and semimembranosus-SMM) muscles were evaluated using B-Mode ultrasonography. Ultrasound images were analysed offline using an image analysis software (Image J) program and EI of muscles was determined the same researcher. All patients completed Knee Injury and Osteoarthritis Outcome Score (KOOS) that is a knee related disorder-specific questionnaire. Physical performance measures included the Five times Sit to Stand test (FTSS), the Twenty-meter Walk Test (20WT), and the Stair Climbing Test (SCT).
Results: The mean age of patients participating in the study was 58.73±9.42 years. A positive correlation was found between EI of quadriceps femoris and hamstring muscles and the total KOOS scores. EI of RF, VIM, VM, VL and BF presented a significant negative correlation with FTSS, 20WT and SCT (Table 1).

Table 1. Correlation coefficients between Echo-Intensity of Quadriceps Femoris And Hamstring Muscles and KOOS, Physical Performance Parameters (n=96)

Knee Injury and Osteoarthritis Outcome Score Subscales					
EI (au)	Pain	Symptoms	Function in daily living	Function in Sport and Recreation	Quality of Life
RF	0.129	0.237	0.443*	0.365*	0.186
VI	0.220	0.94	0.210	0.162	0.201
VL	0.071	0.116	0.444*	0.482*	0.312
VM	0.105	0,191	0.432*	0,454*	0.112
BF	0.456*	0.227*	0.436*	0.402*	0.502
SMM	0.070	0.239	0.078	0.015	0.357
STT	0.224	0.179	0.456	0.312	0.522

Physical Performance Parameters			
EI (au)	**Five times Sit to Stand test**	**Twenty-meter Walk Test**	**Stair Climbing Test**
RF	0.439*	0.454*	0.643**
VI	0.322*	0.435*	0.432*
VL	0.444*	0.623**	0.556**
VM	0.431*	0.584**	0,571**
BF	0.448*	0.419*	0.433**
SMM	0.126	0.414*	0.125
STT	0.145	0.315*	0.319**

EI, Echo-intensity; au, Arbitrary Unit; RF, Rectus femoris; VIM, Vastus Intermedius; VM, Vastus Medialis; VL, Vastus Lateralis; BF, Biceps Femoris; STT, Semitendinosus; SMM, Semimembranosus; *P < 0.05; **P < 0.001

Conclusion: We concluded that muscle EI may be an important predictor of functional performance in women with knee OA.

POS1478-HPR INCREMENTAL SHUTTLE WALK TEST IN ANKYLOSING SPONDYLITIS PATIENTS

Y. Acar[1], N. Ilcin[2], İ. Sari[3], F. Onen[3], S. Savci[2]. [1]*Dokuz Eylül University Institute of Health Sciences, Physical Therapy and Rehabilitation, Izmir, Turkey;* [2]*Dokuz Eylül Üniversite Fizik Tedavi ve Rehabilitasyon Yüksek Okulu, Physical Therapy and Rehabilitation, Izmir, Turkey;* [3]*Dokuz Eylül Üniversitesi Hastanesi, Rheumatology and Immunology, Izmir, Turkey*

Background: Functional exercise capacity might be affected in ankylosing spondylitis (AS) patients due to factors such as pulmonary function impairment, reduced physical activity, peripheral arthritis, fatigue, muscle weakness and systemic inflammation. In addition to laboratory-based exercise tests, field tests are also used to measure functional exercise capacity. The six-minute walk test (6MWT) which is the most frequently used field test, is valid, reliable, and cost-effective. However, the main disadvantage of the 6MWT is that it allows the patient to set the walking speed. The incremental shuttle walk test (ISWT) is a valid field exercise test of functional capacity. The test requires patients to walk at increasing speeds up and down a 10 m course. The walking speed, which increases every minute, is controlled by audio signals. Performance on the test relates strongly to $VO2_{max}$, the traditional indicator of cardiorespiratory capacity [1]. Although there are studies evaluating functional exercise capacity in AS patients, no study using ISWT has been found.
Objectives: The aim of this study was to investigate the ISWT results and factors associated with this test in patients with AS.
Methods: Fifty AS patients aged between 25-58 years (27 males,23 females,) participated in the study. Age, height, weight, body mass index (BMI) were recorded. Disease-specific indices such as Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI), Bath AS Metrology Index (BASMI) were used. Sit-up test and push-up test were used to measure muscular endurance. Incremental Shuttle Walk Test (ISWT) was used to assess functional exercise capacity The test was performed in a 10 m course defined by two cones placed 0.5 m from each endpoint. The test was terminated if the patient was unable to maintain the required speed and failed to complete a shuttle in the time allowed for the second time. The total number of shuttles was recorded and distance calculated. Heart rate (HR), blood pressure, perceived dyspnea and leg fatigue (modified Borg Scale) were assessed before and after the test. Age-predicted maximal heart rate (HR_{max}) was calculated as 220 minus age. Spearman's correlation coefficients were used to examine the relationship between the ISWT distance and the variables.
Results: The mean incremental shuttle walk distance (ISWD) of the patients was 458.40± 98.63 m (min 290 m-max 710 m). Subjects reached 50% of the predicted ISWD according to the reference equation for healthy people [2]. The maximal heart rates were lower than predicted values anticipated for the patients' age. At the end of the test, subjects reached 57.97±8.62 % of HR_{max}. ISWD showed significant correlations ($p<0.05$) with gender ($r = 0.488$), height ($r = 0.474$), BASFI ($r = -0.313$), BASMI ($r = -0.397$), sit-up test ($r = 0.620$), push-up test($r = 0.476$). However, no relationship was found between ISWD and age, weight, BMI, BASDAI, dyspnea, fatique. Dyspnea and fatigue were not limiting factors for the test. The most common reason for stopping the test was the inability of the patients to maintain the set pace. ISWD has been reported to be associated with age [2], but in our study, unlike the literature, no relationship was found between ISWD and age in AS patients.
Conclusion: According to the results of our study, we found that the incremetal shuttle walk test distance in AS patients decreased compared to the reference values reported for healthy individuals. ISWT is associated with factors such as gender, height, functionality, spinal mobility and muscular endurance. ISWT may be appropriate for measuring exercise capacity of AS patients, however, more research is needed.

Background: Although the hand involvement is one of the first manifestations in the disease course of Systemic Sclerosis (SSc), hand functions are generally inquired by using patient-reported tools. Sollerman Hand Function Test (SHFT) is developed to evaluate the performance-based hand functions.
Objectives: The aim of this study was to investigate the reliability of the SHFT and the associations with disease- and hand-related parameters in patients with SSc.
Methods: Thirty-six patients (30 females) were included in the study. SHFT includes 20 different hand functions which are scored between 0 (unable to perform) and 4 (performed within 20 seconds with normal quality) (1). In the present study, item 12 'put on Tubigrip stocking on the other hand' was not evaluated, thus, the SHFT was scored over a total score of 76. Inter-rater reliability was investigated by comparing the scores of two different investigators, and test-retest reliability was investigated by assessing the scores obtained at 2-hour intervals. Modified Hand Mobility in Scleroderma Test (mHAMIS), modified Rodnan skin score (mRSS), grip and pinch strengths were measured to evaluate hand-related physical characteristics. Duruoz Hand Index, Disability of Arm, Shoulder and Hand Questionnaire (DASH), Health Assessment Questionnaire (HAQ), and Scleroderma Health Assessment Questionnaire (SHAQ) were used as patient-reported outcomes.

Table 1. Associations between the Sollerman Hand Function Test scores and disease- and hand-related parameters

n= 36	Median (IQR 25/75)	rho	*p*
mHAMIS (score 0-4)	0 (0/0)	-0.366	0.072
mRSS-Fingers (score 0-3)	2.5 (2/3)	-0.070	0.684
mRSS-Hands (score 0-3)	1.5 (1/2)	-0.056	0.747
mRSS-Forearms (score 0-3)	1 (0/2)	-0.032	0.855
mRSS-Upper Arms (score 0-3)	0 (0/1)	0.008	0.962
mRSS-Total (0-51)	10 (6/27.5)	-0.158	0.356
Hand Grip Strength (kg)	19.9 (12.0/24.9)	**0.612**	**<0.001***
Tip to Tip Pinch Strength (kg)	3.1 (2.3/3.9)	**0.517**	**0.001***
Three Jaw Pinch Strength (kg)	2.7 (1.9/3.4)	**0.554**	**<0.001***
Lateral Pinch Strength (kg)	3.9 (3.3/5.3)	**0.461**	**0.005***
Duruoz Hand Index (score 0-90)	5.5 (0/17)	**-0.751**	**<0.001***
DASH (score 30-150)	61.5 (47/84)	**-0.645**	**<0.001***
HAQ (score 0-3)	0.3 (0.1/0.9)	**-0.632**	**<0.001***
SHAQ-Raynaud's Phenomenon (score 0-3)	0.9 (0.1/1.4)	-0.246	0.161
SHAQ-Digital Ulcers (score 0-3)	0.1 (0/1.2)	**-0.372**	**0.030***
SHAQ-Gastrointestinal (score 0-3)	0.2 (0/1.5)	-0.177	0.315
SHAQ-Pulmonary (score 0-3)	0.6 (0.1/1.5)	-0.270	0.123
SHAQ-Patient Global Assessment (score 0-3)	1.4 (0.1/2.1)	**-0.547**	**0.001***

p<0.05, rho: Spearman correlation coefficient, mHAMIS: modified Hand Mobility in Scleroderma Test, mRSS: modified Rodnan skin score, lcSSc: limited cutaneous Systemic Sclerosis, dcSSc: diffuse cutaneous Systemic Sclerosis, DASH: Disability of Arm, Shoulder, and Hand Questionnaire; HAQ: Health Assessment Questionnaire; SHAQ: Scleroderma Health Assessment Questionnaire

Results: SHFT demonstrated excellent inter-rater reliability (75 (72/76) vs. 75 (72/76), ICC: 0.987) and moderate test-retest reliability (75 (72/76) vs. 76 (75/76), ICC: 0.645). SHFT scores correlated significantly with grip and pinch strengths, Duruoz Hand Index scores, HAQ scores, SHAQ-Patient Global Assessment scores, and SHAQ-Digital Ulcer Scores ($p<0.05$). No significant correlations were observed between other parameters and SHFT ($p>0.05$). The hardest task was determined as 'do up buttons' which cannot be completed within 20 seconds by the half of the patients. All the patients completed 'put key into Yale lock, turn 90°', 'lift iron over edge 5 cm in height', and 'lift telephone receiver, put to ear' tasks within 20 seconds with normal quality.
Conclusion: The results of the present study suggest that SHFT is a reliable tool to evaluate hand functions in patients with SSc.

POS1480-HPR SCREENING WITH THE ROUTINE ASSESSMENT OF PATIENT INDEX DATA 3 QUESTIONNAIRE CAN REDUCE THE NUMBER OF CLINIC VISITS

J. Wiegel[1], B. Seppen[1], M. Ter Wee[2], M. Boers[2], M. Nurmohamed[1,3], W. H. Bos[1]. *[1]Amsterdam Rheumatology & immunology Center, Reade, Rheumatology, Amsterdam, Netherlands; [2]Amsterdam UMC location VUmc, Department of Epidemiology & Data Science, Amsterdam, Netherlands; [3]. Amsterdam Rheumatology & immunology Center, Amsterdam UMC location VUmc, Rheumatology, Amsterdam, Netherlands*

Background: The long-term and frequent evaluation of disease activity in patients with rheumatoid arthritis (RA) leads to a large burden of planned consultations at outpatient clinics. It might be possible to reduce that burden by prescreening to identify patients with low disease activity with the electronic Routine Assessment of Patient Index Data 3 (RAPID3), with the aim to let them skip their visits. For this purpose, accurate classification of patients in the low category with the RAPID3 is required.
Objectives: To evaluate the test characteristics and agreement between the Disease Activity Score 28 (DAS28) and the RAPID3 in patients with RA and low disease activity.
Methods: We performed a retrospective database study with clinical data collected as part of usual care from the electronic medical record at Reade Amsterdam, a secondary care center for rheumatology patients. The dataset comprised each completed RAPID3 between June 2014 and March 2021, that was followed by a DAS28 within 2 weeks in patients with RA. We dichotomized the disease activity for both the RAPID3 and DAS28 into 'low' and 'high', with cutoffs at 2.0 for RAPID3 and 3.2 for DAS28. We report test characteristics and agreement (Cohen's kappa).
Results: The dataset comprises 5009 combined RAPID3 and DAS28 measurements recorded in 1681 unique RA patients. Mean age was 60 years, 76% of patients were female with a median disease duration of 4 years. Overall agreement was 0,58, ƙ was fair at 0.26, with 1426 (28%) of the RAPID3 measurements in the 'low' category (Table 1). Sensitivity to detect low disease activity was 0.39, specificity 0.94 and positive predicted value 0.92.

Table 1. Crosstabulation of dichotomised RAPID3 and DAS28* results.

		DAS28		Total
		Low (<3,2)	**High (>3,2)**	
RAPID3	**Low (≤2,0)**	1309 (26%)	117 (2%)	1426 (28%)
	High (>2,1)	2005 (40%)	1578 (32%)	3583 (72%)
Total		3314 (66%)	1695 (34%)	5009 (100%)

*Disease activity score 28 (DAS28), Routine Assessment of Patient Index Data 3 (RAPID3).

Conclusion: With a positive predictive value of 0.92 for low disease activity, a RAPID3 score of 2.0 or lower is a good threshold to propose a postponement of the consultation and substantially reduce the clinic burden. Such a proposal is safe if the patient can overrule it.
REFERENCES:

POS1481-HPR CROSS-CULTURAL ADAPTATION, VALIDITY AND RELIABILITY OF THE QUIPA TOOL: TURKISH VERSION

N. G. Tore[1], D. Oskay[1], H. Satış[2], S. Haznedaroglu[3]. *[1]Gazi University, Physiotherapy and Rehabilitation, Ankara, Turkey; [2]Abdurrahman Yurtaslan Training and Research Hospital, Rheumatology, Ankara, Turkey; [3]Gazi University, Rheumatology, Ankara, Turkey*

Background: The Quality Indicators for Physiotherapy Management of Hip and Knee Osteoarthritis (QUIPA) is the only patient-reported outcome measure assessing the quality indicators of physiotherapy management of hip/knee osteoarthritis (OA). It consists of 3 subscales and a total of 18 questions.
Objectives: The purpose of this research was to translate and cross-culturally adapt the QUIPA into the Turkish language and test its validity and reliability in Turkish-speaking patients with hip/knee OA.
Methods: Ninety-two patients with hip/knee OA were enrolled in the research. The QUIPA was cross-culturally adapted according to guidelines defined by Beaton et al. Participants completed QUIPA tool twice, with an interval of 7 days. Construct validity was tested via Exploratory Factor Analysis. Test-retest reliability and internal consistency were determined interpreting Intraclass Correlation Coefficient (ICC) and Cronbach's alpha coefficient, respectively.
Results: The Exploratory Factor Analysis demonstrated that QUIPA has 3 factors. For the first, second and third subscales and total score of QUIPA, ICC was found to be as 0.895, 0.947, 0.665, and 0.925, respectively. Cronbach's alpha coefficient was determined to be as 0.682, 0.797, 0.593, and 0.812, respectively for the first, second and third subscales and total score of QUIPA. These results indicate that Turkish version of QUIPA has excellent test-retest reliability and good internal consistency.
Conclusion: Turkish version of the QUIPA determined to be a valid and reliable tool to assess the quality indicators of physiotherapy management of hip/knee OA in Turkish-speaking patients. It is suggested to be used in clinical settings and researchs.

POS1482-HPR ASYNCHRONOUS TELECONSULTATION BY WHATSAPP CHATBOT IN CONTROLLED AXIAL SPONDYLOARTHRITIS (SPA) PATIENTS UNDER BIOLOGICAL THERAPY: 10 MONTHS EXPERIENCE AT A SINGLE CENTRE

M. L. García-Vivar[1], N. Rivera[2], E. Galíndez-Agirregoikoa[1], E. Cuende[1], A. R. Intxaurbe Pellejero[1], J. M. Blanco Madrigal[1], L. Vega[1], C. García[1], M. Enjuanes[1], M. J. Allande[2], O. B. Fernandez Berrizbeitia[1], R. Exposito[1], M. E. Ruiz Lucea[1], I. Torre-Salaberri[1]on behalf of INNOBIDE working group.
[1]BASURTO UNIVERSITY HOSPITAL, RHEUMATOLOGY, BILBAO, Spain; [2]BIOCRUCES BIZKAIA, RHEUMATOLOGY, BILBAO, Spain

Background: The use of telehealth in the control of rheumatic diseases had been scarce, but COVID pandemic forced rheumatologists to try alternatives to classic face-to-face consultation. In times of lockdown phone calls and video calls were easy to perform, but later on an asynchronous model of teleconsultation would probably fit better. The purpose of this study is to prove that asynchronous whatsapp teleconsultation is an effective alternative to classic healthcare consultation models out of pandemic. So, we selected axial spondyloarthritis (SPA) patients with stable controlled disease under biological therapy and we offered teleconsultation with a whatsapp platform chatbot, that´s been created for this purpose as a way to send PROMS (BASDAI, VAS for patient global disease assesment, ASDAS, and 3 questions for extraarticular disease), and receive feedback and schedule for the following visits
Objectives: To prove that teleconsultation through whatsapp platform was not inferior to face-to-face consultation in terms of mantaining axial SPA patients disease under control. And to prove that teleconsultation model was less time and resources consuming for the patient and the system, and probably preferred by a group of patients.
Methods: Prospective study with retrospective control of patients diagnosed of Axial SPA, fullfilling ASAS criteria and with stable disease under biological therapy for the previous year, recruited from 01 jan to 30 nov 2021. We offered them two teleconsultation visits using their personal mobile device, once every four months and a face-to-face visit at the end of the study (one year since inclusion). If there is a deviation in the lab test or PROMs or if the patient asks for contact (via whatsapp) he is called up by the person in charge (nurse/doctor) that solves the question and arranges an aditional presential visit when needed. We consider disease controlled if BASDAI <4, ASDAS < 2,1 or if in rheumatologist´s opinion there is no need to change treatment. We collect patient and disease information (age, gender, employment, use of mobile devices, duration and characteristics of the disease, previous and actual treatment), activity (BASDAI, PCR, ASDAS), physical function (BASFI), Quality of life (AsQol) ansd productivity (WAPAI), and we also check number of face-to-face and phone consultations and patient´s preferences.
Results: 62 patients (52 men and 10 women) were recruited, mean aged 47,7 years (range 26-72), 36% were under 45 years at the time of inclusion. They were mostly Ankylosing Spondylitis (AS) (90%; only 6 non radiographic SPA), positive HLA B27 (90%) and with longstading disease (mean 24 years), and only 6 patients less than five years. 16% had peripheral involvement (arthritis/dactylitis), and 40% presented extraarticular manifestations, mainly uveitis (20%). 70% were under their first biological (TNF inhbitor, mostly adalimumab), 24% were refractory to the first, 3 patients to 2 previous biologicals and just 1 patient was refractoy to 5. 50% of patients were treated with tapered dose of TNF inhibitors. We have now a mean followup of 10 months, in which we have had 109 scheduled teleconsultations with aditional need of 36 phone calls and 10 aditional presential visits for the whole group. To date, 3 patients with reduced dose increased to standard dose of biological drug and none change of biological was required.
Conclusion: Asynchronous teleconsultation seems promising, specially for followup in patients with stable rheumatic disease, less interfering with daily activities, less time consuming for the patient and less resource consuming for healthcare systems, with no impairment of disease control and quailty of healthcare. This study will also show patient´s preference, and we´ll try to describe a profile of patient more prone to teleconsultation.

Meyer-Olson[1,2]. *[1]Medizinische Hochschule Hannover, Klinik für Rheumatologie und Immunologie, Hannover, Germany; [2]m&i Fachklinik Bad Pyrmont, Rheumatologie/Innere Medizin, Bad Pyrmont, Germany; [3]University Medicine Göttingen, Institut für medizinische Statistik, Göttingen, Germany*

Background: Disease flares of rheumatoid arthritis (RA) are important stressors for patients (pts) who may use coping for disease management. Some coping styles are thought to be beneficial and may help to improve disease outcome whereas others are thought to be harmful.
Objectives: We investigate the frequency and intensity of different coping styles in pts with an acute flare of seropositive RA and its impact on disease outcomes after 12 month of therapy.
Methods: Coping was analysed with the Brief-COPE (1) using a 4 point Likert scale in 222 pts participating in the ERFASS study (2). Coping styles were analysed by confirmatory and exploratory factor analysis (CFA, EFA). Disease activity was measured via DAS28 (CRP), depression and/or anxiety using Hospital Anxiety and Depression Scale (HADS) and Patient Health Questionnaire 9 (PHQ-9). Repeated measures ANOVA was used to identify the effect of different coping strategies on disease activity and Spearman-Rho to identify correlations.
Results: Factor analysis revealed five dominant coping styles (problem oriented, emotion oriented, dysfunctional, religion, alcohol/drugs) which were consistent during 6 and 12 months follow up. When analysing the relative intensity of each coping strategy over time there was no significant change during treatment (Table 1). The usage of only a single coping style at baseline ("I am doing this a medium amount" or "a lot") was reported by 70 pts (31,5%). 65 pts (29,3%) reported the use of 2 coping styles simultaneously, 25 pts (11,3%) 3 coping styles and 4 pts (1,8%) four coping styles. Problem oriented coping was used by 125 pts (56,3%), emotional coping by 97 pts (43,7%), dysfunctional coping by 41 pts (18,5%), religion by 24 pts (10,8%) and alcohol/drugs by only 4 pts (1,8%). 58 pts (26,1%) reported not to use any of the coping styles ("I am doing this not at all" or "only a little bit") and these pts had a lower DAS28 during the course of the study (p=0.036) as compared to pts who use one or more coping strategies. When analysing the group with high disease activity (DAS28 >5.1) at baseline (n=60), pts with medium or high dysfunctional coping had a significantly higher disease activity after 12 months as compared to those with no or little dysfunctional coping (U = 187,00, Z = -2.025, p = 0.043) (Figure 1). The other coping styles did not significantly predict the outcome of disease activity. We observed a strong correlation between dysfunctional coping and depression (PHQ9 r = 0.590; HADS depression r = 0.569) as well as anxiety (HADS anxiety r = 0.639) but not for the other coping strategies at baseline.

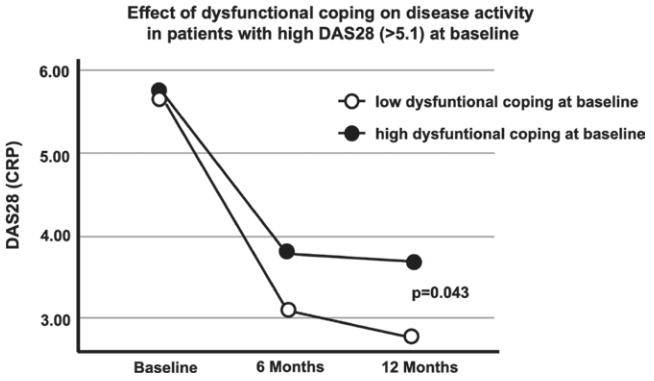

Figure 1.

Table 1. Development of disease activity (DAS28) and coping strategies over time

	Time		
	Baseline mean (SD)	Month 6 mean (SD)	Month 12 mean (SD)
DAS28	4.32 (1.14)	2.79 (1.23)	2.47 (1.05)
Problem oriented	53.10 (14.93)	49.69 (14.10)	47.43 (14.00)
Emotion oriented	49.94 (13.00)	50.73 (12.76)	50.46 (13.45)
Dysfunctional	40.25 (14.59)	36.44 (11.76)	36.00 (12.26)
Religion	36.15 (18.30)	35.53 (17.02)	34.68 (16.64)
Alcohol / Drugs	27.03 (7.81)	27.15 (8.75)	26.53 (6.07)

Conclusion: Different ways of coping may be used simultaneously during an acute flare of seropositive RA. In pts with high disease activity dysfunctional coping is the only coping strategy predicting a worse disease outcome after 12 months and dysfunctional coping correlates with depression and anxiety.

POS1484-HPR LUMBOPELVIC STABILITY, TRUNK POSITION SENSE, AND SPINE POSTURE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Y. Akkubak[1], T. Duger[2], A. Kucuk[3]. *[1]Necmettin Erbakan University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, KONYA, Turkey; [2]Hacettepe University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; [3]Necmettin Erbakan University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Konya, Turkey*

Background: Axial Spondyloarthritis (ax-SpA) are chronic systemic inflammatory rheumatological diseases characterized by axial skeletal involvement and enthesitis. The trunk is the central key point of the body, playing an essential role for postural control, the coordination of the extremities, and functional activities. The systemic, inflammatory nature of ax-SpA, chronic pain, inflammatory cytokines, changes in the bone and ligaments of the spine may affect lumbopelvic stability, trunk position sense, and spine posture.

Objectives: We aimed to investigate lumbopelvıc stability, trunk position sense, and spine posture in patients with ax-SpA.

Methods: Twenty ax-SpA patients (mean age; 33.65± 5.72, 75% female) and 20 age- and gender-matched healty controls were included in the study. In ax-SpA patients, mean time since symptom onset was 9.75±4.82 years and mean time since diagnosis was 6±3.97 years. Lumbopelvic stabilization was evaluated by a pressure biofeedback unit (Stabilizer Pressure Biofeedback Unit, Chattanooga Group Inc., Hixson, TN, USA). Trunk position sense, as indicated by trunk reposition errors (TRE), was assessed with a digital inclinometer. Thoracic and lumbar curvature tests werw performed with a digital inclinometer.

Results: Comparisons of lumbopelvıc stability, trunk position sense and posture were shown in Table 1. Lumbopelvic stabilization values were significantly lower in the ax-SpA group when compared to the control group (p<0,001). TRE, in which higher scores indicate poorer trunk position sense, was higher in the ax-SpA group compared to the control group (p<0,001). The degree of thoracic curvature was higher (p = 0.001) in the ax-SpA group compared to controls whereas the degree of lumbar lordosis was not significantly different between the groups (p = 0.444).

Table 1. Comparison of lumbopelvıc stability trunk position sense, and posture of the groups

Characteristics	AxSpA group (n=20)	Control group (*n* = 20)	p
Lumbopelvic stabilization (mmHg, median; min–max)	43.65 (41.3;51.3)	48,6 (46;62,6)	p<0.001[*b]
Trunk position sense (TRE) (°,median; min–max)	3.6 (0.66; 8.6)	1.3 (0.66; 2)	p<0.001[*b]
Spine posture			
Thoracic curvature (°,median; min–max)	39,95 (29.3;53.3)	34.3 (29.6;3)	p = 0.001[*b]
Lumbar curvature (°, mean ± SD)	39,78 ± 7,60	37,9 ± 7,82	p = 0.444[a]

TRE trunk reposition error, AxSpA Axial Spondyloarthritis, SD standard deviation*p < 0.05. *a Independent samples t test. b Mann–Whitney U test.*

Conclusion: According to our results, patients with ax-SpA had poor lumbopelvic stability, trunk position sense, and spine posture. The multiplicity and complexity of the symptoms of patients with ax-SpA require multifaceted symptom management interventions. For this purpose, consideration of the training of lumbopelvıc stability, trunk position sense, and spine posture might be beneficial in optimal treatment planning.

POS1485-HPR DIGITALLY ENHANCED TREAT-TO-TARGET AND SHARED DECISION-MAKING APPROACH WITH A DIGITAL HEALTH APPLICATION: INTERIM RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

J. Knitza[1,2], M. Grahammer[3], S. Boeltz[1,2], J. Lang[1,2], M. Detert[4], M. Bader[3], A. Kleyer[1,2], D. Simon[1,2], G. Krönke[1,2], G. Schett[1,2], J. Detert[4]. *[1]Friedrich-Alexander- University Erlangen-Nürnberg (FAU), Universitätsklinikum Erlangen, Department of Internal Medicine Rheumatology and Immunology, Erlangen, Germany; [2]FAU Erlangen-Nuremberg and Universitätsklinikum, Deutsches Zentrum fuer Immuntherapie (DZI), Erlangen, Germany; [3]ABATON GmbH, ABATON, Berlin, Germany; [4]Rheumatologisch-immunologische Arztpraxis Templin, Rheuma - Templin, Templin, Germany*

Background: Digital health applications (DHA) became indispensable patient companions accelerated by the current COVID pandemic [1]. In 2020, for the first time worldwide, a regulatory framework to reimburse DHA was established in Germany. To get listed as a DHA, preliminary evidence needs to be generated – next to fulfilling highest standards in quality and safety. The DHA ABATON RA consists of two parts; 1) digital shared-decision-making (SDM) including choosing an appropriate electronic patient reported outcome (ePRO) instrument and the respective ePRO target for the next visit, 2) remote patient monitoring and ePRO tracking by the patient. Hereby, ABATON RA supports a digitally guided Treat-to-Target (T2T) approach.

Objectives: The objective of this study is to evaluate a potentially beneficial effect for the patient by using ABATON RA.

Methods: Three-armed, partially blinded multicenter trial (RCT) including RA patients who regularly use a smartphone. Patients attend 3 visits, 3 months apart (T0, T3, T6), with one follow-up visit (T9). Intervention group (IG): Patients use ABATON RA. Via SDM patients and rheumatologists choose a specific ePRO and respective treatment target for the next visit in three months, e.g. RAID ≤4. Control group (CG): Standard of care treatment (no DHA). Placebo group (PG): Usage of a placebo version of ABATON RA providing only Regensburger Insomnie Skala (RIS) and Epworth Sleepiness Scale (ESS) as ePROs. No SDM is conducted and ePRO results are not presented to HCP.

Results: This interim analysis evaluated the first 38 patients that completed T3. IG: 13 patients (Av. age 55.9, 61.5% females); PG: 12 (Av. age 50.7, 66.7% females); CG: 13 (Av. age 56.1, 76.9% females). We observe a significant improvement in the mean over time in a pairwise comparison within the intervention group for the following: Pt-GA mean difference of 2.98 (p = 0.025, partial η^2

= 0.353), pain mean difference of 1.46 (p = 0.049, partial η^2 = 0.286) whereas all pairwise comparisons for the two parameters were non-significant in PG and CG. The patient reactions assessment (PRA) score, measuring patient perceived quality of the patient-provider relationship, increased by a mean of 4.15 points in IG, compared to a slight decrease of 1.92 for PG and 2.77 for CG.

Conclusion: These preliminary findings show beneficial differences among the groups in favor of IG: 1) for quality of life and 2) the physician-patient-relationship. A digitally enhanced therapy is non-inferior to the gold-standard of exclusive in-person treatment. Patients seem willing and able to get involved in an enhanced treat-to-target and shared decision-making approach.

POS1486-HPR DETECTION OF ASSOCIATED FIBROMYALGIA IN PATIENTS WITH OSTEOARTHRITIS OF THE KNEE ACCORDING TO THE MULTIDIMENSIONAL HEALTH ASSESSMENT QUESTIONNAIRE/ FIBROMYALGIA ASSESSMENT SCREENING TOOLS (MDHAQ/FAST4).

Y. Ponce[1], O. Rillo2, A. Brigante[3], O. Leonardi[1], E. Raad[1], M. C. Lunic[4]. *[1]Hospital General de Agudos Dr. Ignacio Pirovano, Reumatologia, Ciudad Autónoma de Buenos Aires, Argentina; [1]Hospital General de Agudos Dr. Ignacio Pirovano, Reumatologia, Ciudad Autónoma de Buenos Aires, Argentina; [3]Sanatorio Güemes, Reumatologia, AAF, Argentina; [4]Hospital de Clínicas José de San Martín, Reumatologia, Ciudad Autónoma de Buenos Aires, Argentina*

Background: Osteoarthritis is the most prevalent joint pathology. knee Osteoarthritis is one of the most frequent locations and has the greatest impact on the health of patients. It can be associated up to 11% with depression and 23% with neuropathic pain. It has also been reported that it can coincide with fibromyalgia (FM) between 6% and 22.83%. This difference may be attributed to some factors, e.g., sample size and/or socioeconomic status. Therefore, the clinical interpretation of symptoms in knee osteoarthritis may be overestimated by the presence of FM. Pincus T. et al. used the FAST4 to identify the coexistence of FM in patients with various rheumatic pathologies. The FAST4 consists of using the MDHAQ (symptom checklist, painful joint count, fatigue and pain). A FAST4 score ≥ 3 allows the association of FM to be considered. The authors demonstrated good concordance with the 2011 FM criteria according to the ACR (with a sensitivity of 70.4% and a specificity of 97.1%)

Objectives: To detect the presence of associated FM in patients with early and established knee osteoarthritis employing the MDHAQ/FAST4

Methods: Patients ≥18 years, of both sexes, from our community with early and established knee osteoarthritis (Luyten, FP 2018 and Altman, R 1986 Classification Criteria respectively). All answered the MDHAQ/FAST3-F questionnaire, in addition to the Patient Health Questionnaire (PHQ9) and the Neuropathic Pain 4 Questions (DN4). Depression was considered respectively with a score ≥3 of the PHQ9 and neuropathic pain with 4 points of the DN4

Results: 100 patients (96 with a diagnosis of early knee osteoarthritis and 4 with established knee osteoarthritis [Luyten - ACR]) with a median age of 58 (RIC 16) and female sex were included 72%.We observed associated FM (FAST4-F) in 31% of patients (27 with early knee osteoarthritis and 4 with established knee osteoarthritis). Median VAS pain, patient and physician global assessment of the disease was higher in patients with FM (p<0.0001). Disease activity by RAPID 3 was low in 4%, moderate in 38% and high in 58% of patients. The cohort had a median pain score of 60 (RIC 60) with absence of neuropathic pain (DN4) in 90% of patients. Depression (PHQ9) was observed in 29% of cases.OA evolution time in months in patients with FM 48 (RIC 12) vs. 36 (RIC 24) without FM (p< 0.0001).Binary logistic regression was performed. In the bivariate analysis, it was observed that the presence of early OA by Luyten's criteria (p=0.002), the presence of depression by PHQ9 (p=0.001), patients of white ethnicity (p=0.03), sobrepeso (p=0.002), low RAPID 3 disease activity (p=0.001), kellgren and lawrence grades II and III (p=0.001), were significant in the bivariate model, although none were statistically significant in the multivariate model

Conclusion: The evaluation of knee osteoarthritis can be complicated in those patients who coexist with FM. In our study 31% met criteria for this entity according to MDHAQ/FAST4. We consider this questionnaire to be single and practical for detecting associated FM. The results obtained give hierarchy to the use of PROMs (Patient Reported Outcomes Measures) that can recognize clues of associated diseases such as FM and/or depression. And thus be able to establish a timely and appropriate treatment when these pathologies are overlapping, in order to change the patient's prognosis and improve their quality of life

POS1487-HPR THE RELATIONSHIP BETWEEN SEXUAL QUALITY OF LIFE AND CLINICAL FEATURES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Y. Akkubak[1], A. Kucuk[2]. *[1]Necmettin Erbakan University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, KONYA, Turkey; [2]Necmettin Erbakan University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Konya, Turkey*

Background: Axial spondyloarthritis (axSpA) is associated to a significant economic and social burden, due to the fact that it affects young individuals during their most productive years of life. Sexuality is one of the health areas affected by axSpA, owed to pain and inflammation, loss of axial and peripheral mobility, joint deformity, joint replacement surgeries, and adverse events secondary to therapy.

Objectives: To assess the relationship between disease related variables, treatment and sexual quality of life in patients with ax-SpA.

Methods: Thirty-nine ax-SpA patients (69.2% female) were included in the study. Median age was 36.0 (IQR 25/75: 25.32/41.7) years, mean body mass index was 26.34±4.64 kg/m^2, median time since symptom onset was 10.0 (IQR 25/75: 9.59/14.72) years, median time since diagnosis was 6.0 (IQR 25/75: 5.70/8.66) years, and treatment with anti-TNF alpha was 64.1%. All the patients completed the Qualisex questionnaire to assess the quality of sexual life. Axial mobility according to the Bath Ankylosing Spondylitis Metrology Index (BASMI) was calculated. All the patients completed the questionnaires Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and, to evaluate disease activity and functional status respectively. Furthermore, patients fulfilled Ankylosing Spondylitis Quality of Life (AsQoL) and Musculoskeletal Health Questionnaire (MSK-HQ) to evaluate quality of life and musculoskeletal health respectively. Spearman's rank-order correlation test was used to analyse the relationships between sexual quality of life and clinical features.

Results: The results of BASMI and the self-reported questionnaires Qualisex, BASDAI, BASFI, AsQoL and MSK-HQ scores of patients with ax-SpA were summarized in Table 1. Moderate relationships were found between Qualisex questionnaire and BASMI, MSK-HQ (Table 1, p<0.05). Qualisex questionnaire has the strongest association with BASFI (rho: .703, p<0.001) and average association with BASDAI (rho: .648, p<0.001) and AsQoL (rho: -.612, p<0.001).

Table 1. The relationships between Qualisex questionnaire and BASMI, self-reported questionnaires BASFI, BASDAI, AsQoL, MSK-HQ in patient with axSpA

Characteristics	Median (IQR 25/75) (n:39)	The correlation results, rho, p values
		Qualisex questionnaire
BASFI	3.1 (2.87/3.9)	.703* p<0.001
BASDAI	4.3 (3.67/4.74)	.648* p<0.001
AsQoL	10 (8.88/11.18)	-.612* p<0.001
BASMI	2.2 (2.26/3.15)	.403* p=0.016
MSK-HQ	30 (30.18/34.5)	-.522* p=0.001
Qualisexquestionnaire	3.7 (2.69/3.73)	

IQR 25/75: Interquartile range between 25th and 75th percentiles; axSpA, Axial spondyloarthritis; BASMI, Bath Ankylosing Spondylitis Metrology Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; AsQoL, Ankylosing Spondylitis Quality of Life; MSK-HQ, Musculoskeletal Health Questionnaire
*Spearman's rank-order correlation test, p<0.05.

Conclusion: According to our results; especially high disease activity and lower functional status were highly associated with worse sexual health in axSpA patients. Improving disease activity, funnctional status and axial mobility may help to improve sexual health in those patients.

POS1488-HPR DETERMINANTS OF PATIENT AND PHYSICIAN GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN LARGE VESSEL VASCULITIS.

A. Kernder[1], M. Rohde[1], H. Acar[1], O. Sander[1], J. Richter[1], R. Fischer-Betz[1], M. Schneider[1], G. Chehab[1]. [1]*Heinrich-Heine-University Düsseldorf, Medical Faculty, Department Rheumatology & Hiller-Research Unit Rheumatology, Düsseldorf, Germany*

Background: Factors influencing disease activity assessment by patients and physicians are unknown, but are highly relevant in the context of PROs development.
Objectives: To compare the patients' and physicians' global assessment of disease activity in large vessel vasculitis and investigate factors influencing the assessment of disease activity.
Methods: Between 2010 and 2020, patients with large vessel vasculitis and their routine caring physicians assessed a global disease activity score (numerical rating scale 0 – 10) in our outpatient clinic. We compared these global scores of disease activity. In a multiple linear regression analysis we examined the influence of potential demographical and clinical factors on the disease activity assessment.
Results: 138 Patients with 866 assessments were available for analysis. At timepoint of assessment they had a mean age of 76 (± 9) years and a mean disease duration of 5 years (± 5). The median global score of patient-reported disease activity was 3 points, the median physicians' disease activity assessment was 2 points. In 28,2% (n=244) there was a deviation of more than 2 points between the patients' and physicians' assessment of disease activity. Only 5 times the physicians, but 232 times the patients rated their disease activity higher than 5 points. In this group the patient-reported disease activity was associated with the patients age (β 0.025), the patients BMI (β 0.071) and the extent of pain (β 0.19), p<0.05. The disease duration, CRP level and the psychological well-being of the patient showed no association.
Conclusion: In our cohort, physicians and patients showed greater divergence in disease activity assessment with higher disease activity. Age, BMI and the extent of pain were associated with higher disease activity ratings by the patients. This results are relevant for the development and interpretation of PROs for activity assessment in large vessel vasculitides.

POS1489-HPR ASSESSMENT OF TREATMENT ADHERENCE IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH SUBCUTANEOUS ANTI-TNF WHO WERE EXPOSED TO A COMPREHENSIVE CARE MODEL

W. Rivero[1], G. Sánchez[2], F. Rodriguez[3], L. Villarreal[4], D. Buitrago-Garcia[2], C. Castro[5], P. Santos-Moreno[6]. [1]*Biomab IPS, Pharmaceutical Chemist, Bogotá, Colombia;* [2]*Fundación Universitaria de Ciencias de la Salud - FUCS, Epidemiology, Bogotá, Colombia;* [3]*Biomab IPS, Administration, Bogotá, Colombia;* [4]*Biomab IPS, Medical services, Bogotá, Colombia;* [5]*SIIES Consultants, Epidemiology, Bogotá, Colombia;* [6]*Biomab IPS, Rheumatology, Bogotá, Colombia*

Background: Rheumatoid arthritis (RA) is an autoimmune, chronic, and inflammatory disease, which can be treated with effective medications, but requires a high level of adherence to treatment. Offering a comprehensive care model by a multidisciplinary team could increase the adherence levels of these patients and improves disease outcomes.
Objectives: Compare the level of adherence to treatment before and after the implementation of a comprehensive care model in a cohort of patients with RA, treated with subcutaneous anti-TNF, in a reference center in Bogotá-Colombia.
Methods: An analytical study was conducted before and after the implementation of a comprehensive care model on a cohort of patients over 18 years of age, diagnosed with RA, who have been prescribed management with a subcutaneous anti-TNF by their doctor during the last 12 months. Convenience sequential sampling was performed to reach a defined sample size of 130 patients to estimate a baseline versus final adherence difference of 20%, at an alpha value of 5% and a beta value of 20%. The comprehensive care model (CCM) consisted of the approach by a multidisciplinary team, offering a comprehensive care not fragmented, based on evidence (guidelines and protocols) and proposing a treatment by objectives (T2T). Adherence was measured using the CQR-19 scale, with a cut-off point ≥80.7 to consider an adherent patient.
Results: The cohort consisted of 131 patients who were followed semiannually for 24 months, and who were incorporated into the CCM. 83.9% were women (n=110), in an age range between 30 and 84 years (Average: 62; DS: 9.9 years). 37.4% of patients were treated with etanercept (n=49), 29% with golimumab (n=38) and 33.6% with adalimumab (n=44). The median baseline of CQR-19 was 87.7 points (RIQ:84.2-91.2); while at month 24 it reached 91.2 points (RIQ: 87.7-94.7). The difference between the distributions was statistically significant (p<0.00). According to the cut-off point for CQR-19, the baseline percentage of adherent patients was 87.8% (n=115) and increased to a percentage of 96.2% at 24 months of follow-up (n=126). The difference between these two percentages of adherence was 8.39% (95% CI: 1.9-14.9%) (p: 0.012). The results of a generalized linear model binomial family, for the outcome of difference in proportions (PD) of basal and final adherence, are presented in Table 1. The estimator is adjusted for activity level (DAS28), disability level (HAQ) and anti-TNF. Golimumab appears to have an effect that increases adherence by 4.5% compared to adalimumab and etanercept, adjusting for the other predictors.

Table 1. Model of the effect of MAI on adherence to treatment.

Dependent variable: Adhesion according to cut-off point CQR-19(≥80.7). Proportion Difference (DP) Estimator

Variable	DP	CI 95%	P-value
Intervention: MAI	9,4%	3,2-15,5%	0,003
Golimumab vs. Etanercept-Adalimumab	4,5%	0,5-8,5%	0,024
DAS28	(-)0,85%	(-)3.2% to 14.9%	0,47
HAQ	0,00	(-)0.03% to 0.045%	0,85

MLG-Binomial family. Identity function.

Conclusion: The CCM, after a follow-up of 24 months in patients with RA in treatment with subcutaneous anti-TNF increases the percentage of adherence by 9.4%, adjusting for treatment, activity level and degree of disability. Golimumab appears to have an effect that increases adherence by 4.5% compared to adalimumab and etanercept, adjusting for the other predictors.

POS1490-HPR INVESTIGATION OF THE RELATIONSHIP BETWEEN EXERCISE CAPACITY AND PSYCHOSOCIAL VARIABLES IN WOMEN WITH FIBROMYALGIA: A PRELIMINARY STUDY

B. Beyrek[1], M. Köprülüoğlu[2], K. Nas[3], İ. Naz[2]. [1]*Izmir Katip Celebi University Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, İzmir, Turkey;* [2]*Izmir Katip Celebi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, İzmir, Turkey;* [3]*Sakarya University School of Medicine, Department of Physical Medicine and Rehabilitation, Division of Rheumatology and Immunology, Sakarya, Turkey*

Background: Various studies have showed that patients with fibromyalgia have lower exercise capacity than healthy individuals (1, 2). This reduced exercise capacity affects these patients' independence in performing daily activities (3). Although it was shown that exercise capacity related physical status, it is not quite clear that relationship between exercise capacity and patients' psychosocial variables in patients with fibromyalgia.
Objectives: To identify whether there is any direct link between the exercise capacity of women with fibromyalgia and their psychosocial status.
Methods: Nineteen women with fibromyalgia meeting the criteria of the American College of Rheumatology were included in the preliminary cross-sectional study (age=46.26±6.25 years, BMI=27.64±3.86 kg/m^2). Exercise capacity was assessed by 6-min walking test. For psychosocial variables, alexithymia, fatigue, self-efficacy, and social support were measured by Toronto Alexithymia Scale, Multidimensional Fatigue Index, General Self-Efficiacy Scale, and MOS Social Support Survey, respectively. Spearman' correlation was used to investigate the relationship.
Results: The average distance walked was 468.15± 57.50 m. It was found that a significant correlation between 6-min walking test and alexithymia (r=-.517, p=.023), fatigue (r=-.475, p=.040), and self-efficacy scores (r=.607, p<.001). However, no link was observed between 6-min walking test and social support scores (r=.170, p=.486).
Conclusion: As a result of our study, the exercise capacity of fibromyalgia patients was reduced as in other studies. there was a strong positive correlation between exercise capacity and self-efficacy in patients with fibromyalgia. Furthermore, exercise capacity was negatively associated with multidimensional fatigue scores and alexithymia. In the light of all this, it may be said that exercise capacity is related to patients' psychosocial status in women with fibromyalgia. We think that the structure of exercise programs aimed at improving the exercise capacity of patients should include strategies that also improve psychosocial factors.

POS1491-HPR THE USEFULNESS OF THE PATIENT ACTIVITY SCORE-PASS-II TO ASSESS DISEASE ACTIVITY DURING THE COVID-19 LOCKDOWN IN PATIENTS WITH RHEUMATOID ARTHRITIS

F. Rodriguez[1], D. Buitrago-Garcia[2], G. Sánchez[2], P. Santos-Moreno[3].
[1]Biomab IPS, Administrative, Bogotá, Colombia; [2]Fundación Universitaria de Ciencias de la Salud - FUCS, Epidemiology, Bogotá, Colombia; [3]Biomab IPS, Rheumatology, Bogotá, Colombia

Background: Many measurement tools are designed to assess disease activity for Rheumatoid Arthritis (RA) patients. One of the most used tools is the Disease Activity Score- DAS28 which assesses the number of painful joints, erythrocyte sedimentation, and a patient's global assessment. The assessment is performed by a clinician and requires laboratory exams. Unfortunately, from March to August 2019, Colombia had one of the strictest responses to the COVID-19 pandemic according to the COVID-19 stringency Index(1). One of the main restrictions was the preventive isolation of older populations, especially those with comorbidities. These restrictions challenged the rheumatology practice because face-to-face consultations were not possible. Due to the above, measurements like the PAS-II score should be used to assess disease activity during the pandemic.
Objectives: To describe disease activity according to the Patient Activity Score-PAS-II score patients with RA and compare its results to the most recent DAS28 assessment before the COVID-19 pandemic.
Methods: We conducted a descriptive study; patients were followed during the COVID-19- lockdown in a video consultation. The PAS-II score was applied to assess disease activity as an alternative to the DAS28 assessment. The patients were part of an educational program, clinical charts were reviewed to collect the study variables. We collected demographic data and DAS28 before the pandemic started. We present a descriptive analysis of DAS28 severity and the results obtained by the PASS-II score.
Results: The educational program enrolled 250 participants; 196 patients had complete data. 93% of participants were women, mean age was 64 years IQR (54-67). 43% of participants were married or had a civil union, 26% were single, 20% divorced, and 11% were widowed. Regarding educational level, 25% had finished elementary school and 39% high school; the remaining 36% had higher education. When we compared the last DAS28 assessed by a rheumatologist between January, and March 2019, 67% of patients were in remission, while in July 2019, the PASS-II score reported that 7% of patients were in remission and 75% had low or minimal activity. Figure 1- Table 1.
Figure 1.

Table 1.

DISEASE ACTIVITIY	DAS28	PASS-II
Remission	67%	6%
Low (Minimal)	14%	75%
Moderate	15%	18.5%
High/Severe	4%	0.5%

Conclusion: The PASS score is a helpful tool to assess disease activity in patients with RA, especially in situations where the patient cannot see a rheumatologist in a face-to-face consultation; however, patients in severe disease activity should not delay the consultation with a clinician. As other studies have demonstrated, patient-reported outcome measures should be adopted in clinical practice as an alternative for treat- to- targe strategies(2). Further studies should be conducted to assess the impact of the pandemic in countries with high levels of restrictions in the course of RA.

POS1492-HPR PSYCHOMETRIC PROPERTIES OF THE FIBROMYALGIA IMPACT QUESTIONNAIRE – REVISED IN FIBROMYALGIA AND CHRONIC WIDESPREAD PAIN: A RASCH ANALYSIS

P. H. Duhn[1,2], K. Amris[1,2], H. Bliddal[1,3], E. E. Wæhrens[1,4]. *[1]Bispebjerg-Frederiksberg Hospital, The Parker Institute, Frederiksberg, Denmark; [2]Bispebjerg-Frederiksberg Hospital, Department of Rheumatology, Frederiksberg, Denmark; [3]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [4]University of Southern Denmark, Occupational Science, User Perspectives and Community-based Research, Department of Public Health, Odense, Denmark*

Background: The Fibromyalgia Impact Questionnaire - Revised (FIQR) is one of the most commonly used self-rating instruments developed to quantify the severity of disease burden and impact of disease on functional ability and social participation in patients with fibromyalgia (FM) [1]. The FIQR consists of 21 individual items categorized within three different domains; 'function', 'overall impact' and 'symptoms' [2]. The FIQR that has been translated into several languages, has mainly been validated based on classical test theory (CCT) - except for the Italian version [3]. The psychometric properties of the Italian version of the FIQR was evaluated by Salafi et al. based on item response theory using Rasch analysis [3]. The benefit of using Rasch measurement models, is that it allows for a detailed analyses of an instrument's rating scale properties and aspects of validity, including fit of individual scale items to a unidimensional model [4]. Although the FIQR demonstrated adequate psychometric properties in the original studies based on CCT, the Rasch analysis in the Italian study revealed problems with the rating scale properties [2,3]. The FIQR is a frequently used questionnaire when assessing patients with FM in Denmark, but the Danish version of the FIQR has not yet been validated.
Objectives: The aim of this study was to evaluate the psychometric properties of the Danish version of the Fibromyalgia Impact Questionnaire Revised (FIQR), when used to quantify the severity of disease burden in a Danish population of patients with Chronic widespread pain (CWP) including Fibromyalgia (FM).
Methods: A total of 924 participants diagnosed with CWP and/or FM completed an electronic version of the FIQR via touchscreens in the clinic at referral for specialist care. Data was collected from January 1st, 2018 to September 3rd, 2020. Rasch measurement methods were applied.
Results: Rating scale analysis suggested multiple threshold disordering in the 0 to 10-category rating scale. A principal component analysis suggested assessment of a multidimensional construct. Thus, the Rasch analysis of the full FIQR was discontinued. Instead Rasch analyses were performed on the two subscales: 'function' and 'symptoms'. By collapsing the rating scale to a 0 to 4-category scale, the remaining threshold disordering of both subscale was solved. Only the symptom subscale indicated a multidimensionality. There was underfitting misfit of item 21 and overfitting misfit of item 12. No significant Differential Item Functioning was found defined by sex, ethnicity, or education.
Conclusion: The FIQR should be considered as an instrument consisting of three separate subscales representing 'function', 'overall impact' and 'symptoms'. We recommend calculating and reporting on both a 0 to 10- and a 0 to 4-category scale. Also, if using the total FIQR score as an outcome measure, this should be done with caution, until revision of the rating scale.

HPR Epidemiology and public health (including prevention)

POS1493-HPR FACTORS ASSOCIATED WITH THE OCCURRENCE OF MENTAL DISORDERS IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES DURING THE COVID-19 PANDEMIC.

R. V. Gamboa Cárdenas[1,2], J. Huarcaya-Victoria[3,4], M. F. Ugarte-Gil[1,2], C. Reategui Sokolova[2,5], V. Pimentel-Quiroz[1,2], F. Zevallos Miranda[2], M. Medina[2], Z. Rodriguez Bellido[2], R. Perich Campos[2], C. Pastor Asurza[2], G. S. Alarcon[6]. *[1]School of Medicine, Universidad Científica del Sur. Lima, Peru, Rheumatology, Lima, Peru; [2]Hospital Guillermo Almenara Irigoyen. EsSalud. Lima, Peru, Rheumatology, Lima, Peru; [3]School of Medicine, Universidad Particular de San Martín de Porres, Psychiatry, Lima, Peru; [4]Hospital Guillermo Almenara Irigoyen. EsSalud. Lima, Peru, Psychiatry, Lima, Peru; [5]Unidad de Investigación para la Generación y Síntesis de Evidencias en Salud, Universidad San Ignacio de Loyola, Lima, Peru, Rheumatology, Lima, Peru; [6]University of Alabama at Birmingham, Rheumatology, Birmingham, United States of America*

Background: Mental disorders constitute a serious and underestimated problem in Latin America and they could have worse features in comparison with Europe or North America [(1)]; that was the case even before the COVID-19 epidemic ensued in 2020.
Objectives: The objective of this study was to determine the factors associated with the occurrence of mental health disorders (MHD) in patients with autoimmune rheumatic disease (ARD) from Perú, a high COVID-19 incidence country.
Methods: Patients with ARD from a single center (Hospital Guillermo Almenara -EsSalud, Lima-Perú) were included during the first and second waves of the COVID-19 pandemic (March to November 2020). Interviews, medical records reviews, and an electronic survey were performed. MHD explored were depression (assessed with the Patient Health Questionnaire 9: PHQ-9), anxiety (ascertained with the Generalized Anxiety Disorder-7: GAD-7) and post-traumatic stress disorder: PTSD (evaluated with the Event Scale-Revised: IES-R). Variables examined were sociodemographic (age, gender, educational level, marital status, living alone, job status, religiosity), previous diagnosis and treatment for mental disorders, living with a COVID-19 patient, COVID-19 diagnosis (current or past), fear of COVID-19 (assessed with the COVID-19 Scale: FCV-19S) and the ARD type. Multivariable logistic regression models using backward elimination procedure were performed to determine the variables associated with depression, anxiety, and PTSD. (See Table 1).

Table 1. Variables associated with depression, anxiety an PSTD on ARD patients: Multivariable analysis.

	Depression		Anxiety		PTSD	
variables	OR (CI=95%)	p value	OR (CI95%)	p value	OR (CI95%)	p value
Previous treatment for mental disorders	2.35 (1.37-4.0)3	0.002	2.42 (1.37-4.26)	0.002	2.42 1.39-4.21	0.002
Fear for COVID-19	1.07 (1.05-1.10)	<0.001	1.09 (1.06-1.12)	<0.001	1.41 1.11-1.17	<0.001
COVID-19 diagnosis		NS		NS	1.75 1.06-2.89	0.028
Educational level						
University/ postgraduate						
High School		NS	0.43 (0.82-0.21)	0.009		NS
Elementary		NS	0.52 (0.28-0,95) Ref.	0.032		NS
Marital status						
Single		NS		NS	0.57 (0.34-0.96)	0.033
Divorced/ separate		NS		NS	1.02 (0.73-1.41)	0.919

Results: Nine hundred and thirteen ARD patients were evaluated. The most frequent diagnosis was rheumatoid arthritis in 446(48.8%) patients followed by systemic lupus erythematosus in 279 (30.6%). Depression, anxiety, and PTSD were observed in 128 (14.0%), 112 (12.30%) and 485 (53.1%) patients, respectively. In the multivariable analyses, previous treatment for mental disorders and fear of COVID-19 were associated with depression: OR=2.35 (95% CI 1.37-4.03; p=0.002) and OR=1.07 (95% CI 1.05-1.10; p<0.001) respectively; also with anxiety: OR= 2.42 (95% CI 1.37-4.26; p=0.002) and OR=1.09 (95% CI 1.06-1.12; p <0.01) and with PSTD: OR=2.42 (95% CI 1.39-4.21;p=0.002) and OR=1.41 (95% CI=1.11-1.17; p<0.001). A diagnosis of COVID-19 was associated with PTSD: OR=1.75 (95% CI 1.06-2.89, p=0.028), while being single was associated with a decreased probability of PTSD occurrence: OR=0.57 (95% CI=0.35-0.96; p=0.03). Finally, having a high educational level was associated with less anxiety: OR=0.43 (95% CI=0.82-0.21; p=0.009), for university /postgraduate studies and OR=0.52 (CI 95%=0.28-0.95; p=0.032) for secondary studies.
Conclusion: Fear of COVID-19 and previous treatment for mental disorder were associated with all MHD explored on our ARD patients during the COVID-19 pandemic.

POS1494-HPR INCIDENCE OF PSYCHIATRIC DISORDERS AND FIBROMYALGIA IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS DURING COVID 19 PANDEMIC: THE ROLE OF TELEMEDICINE.

R. Foti[1], G. Amato[1], Y. Dal Bosco[1], C. Gagliano[2], A. Longo[2], R. Falsaperla[3], R. Foti[1], F. De Lucia[1], S. Speranza[1], E. Visalli[1]. *[1]AOU Policlinico San Marco, Rheumatology Unit, Catania, Italy; [2]AOU Policlinico San Marco, EYE Clinic, Catania, Italy; [3]AOU Policlinico San Marco, Pediatric Unit, Catania, Italy*

Background: The management of patients with immuno-rheumatological diseases has profoundly changed during the COVID 19 pandemic and telemedicine has played an important role in the disease follow-up.
In addition to monitoring disease activity and any adverse events, especially infectious events, assessing the psychological situation of the patient can be fundamental in particular considering that COVID-19 has also a serious impact on mental health and it has been demonstrated a significantly higher incidence of anxiety disorders and depressive symptoms especially in younger people
Objectives: The aim of this study is to evaluate the incidence of depressive disorders, anxiety and fibromyalgia in our patients with rheumatoid arthritis and psoriatic arthritis during the lockdown period due to the COVID 19 pandemic and validate the use of telemedicine in the clinical management of these patients.
Methods: Patients affected by rheumatoid and psoriatic arthritis treated with biological disease-modifying drugs were contacted to evaluate the state of health and the presence of any adverse events and a nurse administered the clinimetric questionnaires assessment to evaluate the disease activity, the impact of rheumatic disease on the health status and the presence of anxiety, depression and fibromyalgia. In particular the following scales have been used: The Rheumatoid Arthritis Impact of Disease (RAID), the Psoriatic arthritis impact of disease (PsAID), Beck Depression Inventory BDI-II, State-Trait Anxiety Inventory (STAI) and The Fibromyalgia Rapid Screening Tool questionnaire (FIRST), The VAS scale for the assessment of pain. Patients who reported disease flare-up or adverse events underwent an outpatient visit and during visit Disease Activity Score (DAS 28) and Disease Activity Index for Psoriatic Arthritis (DAPSA) were used.
Results: 171 patients with rheumatoid arthritis (RA) and 129 patients with psoriatic arthritis were enrolled. The incidence of fibromyalgia was increased in the two groups during the lockdown compared to the previous evaluations and in particular in patients with psoriatic arthritis (AR p =0.013, AP p= 0.001).Our analysis did not report significant differences between the two groups for the presence of fibromyalgia and anxiety-related disorders during lockdown, but a prevalence of depressive disorders in patients with rheumatoid arthritis was observed.During lockdown in RA patients, (n=50), no correlation was found between DAS28 and RAID score (r=0.112, p=0.438) and in PsA patients (n=34), no correlation was found between DAPSA and PSAID score (r=0.131, p=0.459) while median value of RAID was higher in STAI I and II positive and median value of PSAID was higher in STAI I and II positive. Patients positive at BDI had higher RAID score (median 6.28 vs 1.14) and PSAID (median 4.95 vs 2.85) score (Mann Whitney p<0.001 and p=0.003)
Conclusion: In conclusion, mental and physical stress during COVID-19 pandemic can greatly worsen FM symptoms and intensify the patients' suffering without a clinical flare of the inflammatory disease for patients affected by rheumatoid arthritis. Telemedicine has allowed us to identify patients who needed a face-to-face approach for therapeutic reevaluation even if not related to a flare of the disease.

POS1495-HPR COVID-19, INFLUENZA AND PNEUMOCOCCUS VACCINATION UPTAKE IN PATIENTS WITH RHEUMATIC DISEASE: A PROSPECTIVE AUDIT

R. Mazumder[1], R. Yamin[1], M. Roberts[1], K. Afridi[1], E. Ntatsaki[1]. *[1]Ipswich Hospital, Rheumatology, Ipswich, United Kingdom*

Background: Patients with autoimmune inflammatory rheumatic diseases are susceptible to infections. This could be attributed to theimmunosuppressive effect of the underlying condition or the use of immunomodulatory medications. According to the Department of Health guidelines inthe UK and the European League Against Rheumatism (EULAR), patients who are immunosuppressed should be vaccinated against influenza and pneumococcal infection, as well as COVID-19 infection.
Objectives: Our aim was to explore the Pneumococcal, Influenza and COVID-19 vaccination uptake of our patients with different autoimmune inflammatory rheumatological conditions. In addition, to assess the side effects profile and the status of their underlying rheumatological diseases following COVID-19 vaccination.
Methods: We undertook a prospective audit of consecutive patients with regards to their vaccination update for influenza, pneumococcus, and COVID-19, utilizing a standard questionnaire and compared the results to our 2017 data.
Results: Some 81% of patients received the influenza vaccination (compared to 47% in 2017) representing a 172% improvement, p<0.001. Some 53% received the pneumococcus vaccination compared to 28% in 2017, indicating a 185% improvement, p=0.003. With regards to COVID-19 vaccination, 98/101(97%) of eligible patients received at least one dose and 66% received two doses. 47% received Astra Zeneca, 52% Pfizer and 1% unsure. 46% of patients mentioned, no one specifically discussed the COVID vaccine with them - got information via SMS/ from media, However, 37% of patients were informed by GP Doctor/ Nurse, 14% from the person giving the vaccine, and 7% from specialist hospital doctor. Safety concerns were indicated by all 3 patients who deferred vaccination.
Most side-effects were observed following the first dose (74 patients) vs. the second dose (13 patients) and were mainly mild (66%), but also moderate (19%) and severe (15%). The sore arm was the commonest side-effect, whilst the majority of side-effects resolved within two days. Crucially, 28% reported a flare of the rheumatological condition following the vaccination. No patients receiving at least one dose were diagnosed with COVID-19 infection subsequently.
Conclusion: Vaccination rates for influenza and pneumococcus have improved substantially since 2017, although the population with rheumatic diseases still has low uptake in pneumococcal vaccination. The COVID-19 vaccination uptake has been extremely high in this cohort.

HPR Interventions (educational, physical, social and psychological)

POS1496-HPR HARD TIMES: ADAPTING A FATIGUE MANAGEMENT PROGRAMME IN A PANDEMIC

J. Dobson[1], D. Dockrell[1], K. Berg[2], H. Harris[3]. *[1]University of Edinburgh, CGEM, Institute of Genetics and Cancer, Rheumatic Diseases, Edinburgh, United Kingdom; [1]University of Edinburgh, CGEM, Institute of Genetics and Cancer, Rheumatic Diseases, Edinburgh, United Kingdom; [3]NHS Lothian, Rheumatic Diseases, Edinburgh, United Kingdom*

Background: Fatigue is a symptom of many Rheumatology Conditions (1). Hewlett et al have shown that a Fatigue Management programme (FMP) is effective in reducing fatigue in Rheumatoid Arthritis patients (2). In 2019, a 7-week group-based FMP was developed using a cognitive behavioural approach for Rheumatology patients in NHS Lothian (Scotland). In 2020, due to COVID-19, the in person FMP was adapted for virtual delivery. Referral criteria included Visual Analogue Scale-Fatigue (VAS-F) of ≥6/10 and an inflammatory rheumatic disease diagnosis. The FMP participants recorded Patient Reported Outcome Measures (PROMs) prior to and on completion of the FMP. In August 2021 demand for the FMP far outweighed the capacity of the delivery team and therefore the original 7-week FMP was further adapted to a 4-week programme. This was achieved by focusing on four core elements (i) sleep, (ii) thoughts, emotions and behaviours, (iii) energy conservation, (iv) setbacks.
Objectives: The primary objective was to evaluate whether the 4-week programme produced comparable PROMs results to the 7-week programme. In doing so, the aim was to maintain efficacy of the programme and provide increased capacity by offering more groups in the same timeframe.
Methods: Fatigue Severity Scale (FSS) and VAS-F were selected for comparison between pre and post FMP PROMs results, these being the main indicators of improvement in fatigue management. Fisher's exact test was used to determine any difference between the PROMs results reported at the end of both programmes. Participants who reported that their PROMs result were the same, worse or who did not respond, were all placed into the category "Other". The FMP team recorded the average waiting time for those attending each group. The length of the waiting list at any one time was calculated by removing those who were not interested, had been referred elsewhere, or who did not respond to the invitation, from the total number of referrals received by the FMP team.
Results: There was no significant difference in FSS and VAS-F results reported by the participants in both groups at the end of the FMPs as determined by Fisher's exact test (Table 1). Waiting list times reduced from 24 weeks in August 2021 to 6 weeks in December 2021 as a result of the adaptation of the FMP from a 7-week programme to a 4-week programme (Figure 1).

Table 1. Reported differences between pre-FMP and post-FMP PROMs.

		7 Week FMP (n = 25)	4 Week FMP (n = 13)	Fischer Exact
FSS	Improved	72%	77%	p = 1.000
	Other	28%	23%	
VAS	Improved	80%	69%	p = 0.689
	Other	20%	31%	

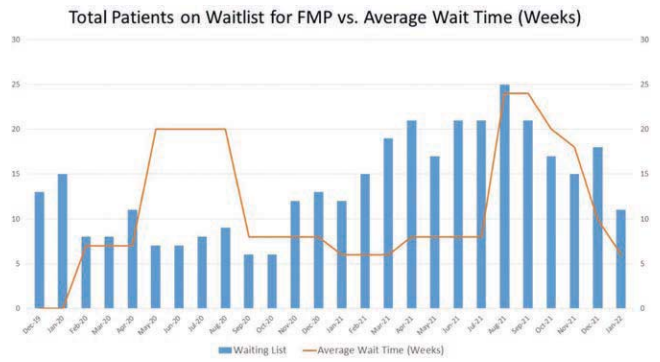

Figure 1. *- Review of average waiting times experienced by each group. In August 2021, the decision was made to trial a 4-week FMP to counter large increases in average waiting times.*

Conclusion: A 4-week FMP is as effective at improving the management of fatigue in Rheumatology patients as a 7-week FMP and reduces patient waiting times. More research is required to bolster the evidence base to support this novel approach.

POS1497-HPR FEASIBILITY OF A PHYSIOTHERAPIST LED, BEHAVIOUR CHANGE INTERVENTION TO IMPROVE PHYSICAL ACTIVITY IN PEOPLE WITH RHEUMATOID ARTHRITIS

L. Larkin[1], S. Mckenna[1], T. Pyne[1], S. Gallagher[2,3], L. Glynn[3,4], A. Fraser[4,5], B. A. Esbensen[6,7], N. Kennedy[1,3]. *[1]University of Limerick, School of Allied Health, Limerick, Ireland; [2]University of Limerick, Department of Psychology, Limerick, Ireland; [3]Health Research Institute, University of Limerick, Limerick, Ireland; [4]University of Limerick, School of Medicine, Limerick, Ireland; [5]University Hospital Limerick, Department of Rheumatology, Limerick, Ireland; [6]Copenhagen Centre for Arthritis Research, Rigshospitalet, Copenhagen, Denmark; [7]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*

Background: Physical activity (PA) is an important component in the management of people with rheumatoid arthritis (RA) (1). Interventions incorporating Behaviour Change (BC) theory are needed to target physically inactive people with RA. The study Physiotherapist-led Intervention to Promote Physical Activity in Rheumatoid Arthritis (PIPPRA) was designed using the Behaviour Change Wheel (BCW) and a pilot study of feasibility undertaken (ClinicalTrials.gov Identifier: NCT03644160).
Objectives: To obtain reliable estimates regarding recruitment rates; participant retention; protocol adherence and possible adverse events, and to producing estimates of the potential effect sizes of the BC intervention on changes in outcomes of physical activity; fatigue; disability and quality of life.
Methods: Participants were recruited at University Hospital (UH) rheumatology clinics and randomly assigned to control group (physical activity information leaflet) or intervention group (four BC physiotherapy sessions in eight weeks). Inclusion criteria were diagnosis of RA (ACR/EULAR 2010 classification criteria), aged

Table 1. Mean (sd) for secondary outcome measures in PIPPRA feasibility study

	Intervention			Control		
Outcomes and instruments	Baseline Mean (sd)	Time 1 Mean (sd)	Time 2 Mean (sd)	Baseline Mean (sd)	Time 1 Mean (sd)	Time 2 Mean (sd)
Physical Activity – self report (YPAS[1])	146.27 (193.73)	120.88 (70.80)	132.00 (70.65)	91.75 (85.86)	58.03 (50.61)	124.31 (69.75)

[1]YPAS – Yale Physical Activity Scale [2]VAS – Visual Analogue Scale [3]HAQDI – Health Assessment Questionnaire Disability Index [4]BRAF MDQ - Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire [5]TPB – Theory of Planned Behaviour Questionnaire [6]RA QoL – Rheumatoid Arthritis Quality of Life Scale [7]PSQI – Pittsburgh Sleep Quality Index

18+ years and classified as insufficiently physically active. Ethical approval was obtained from the UH research ethics committee. Participants were assessed at baseline (T0), 8-weeks (T1), and 24-weeks (T2). Descriptive statistics and t-tests were used to analyse the data with SPSS v22.

Results: 320 participants were identified through chart review with direct contact then with people meeting the inclusion criteria at rheumatology clinics. Of the clinic attendees n=183 (57%) were eligible to participate and n=58 (55%) of those consented to participate. The recruitment rate was 6.4 per month and refusal rate was 59%. Due to impact of COVID-19 on the study n=25 (43%) participants completed the study (n=11 (44%) in intervention and n=14 (56%) in control). Of the 25, n= 23 (92%) were female, mean age was 60 years (sd 11.5). Intervention group participants completed 100% of BC sessions 1 & 2, 88% session 3 and 81% session 4. No serious adverse events were reported. Secondary outcome measures data is Table 1.

Conclusion: The PIPPRA study designed using the BCW to improve promote physical activity was feasible and safe. This pilot study provides a framework for larger intervention studies and based on these findings a fully powered trial is recommended.

POS1498-HPR NEWLY DIAGNOSED WITH INFLAMMATORY ARTHRITIS – DEVELOPMENT OF A COMPLEX SELF-MANAGEMENT INTERVENTION

L. Lindgren[1], T. Thomsen[1,2], M. Aadahl[2], A. De Thurah[3,4], M. L. Hetland[1,5], S. Kristensen[1], B. A. Esbensen[1,5]on behalf of NISMA - a part of the TASEMA-Programme.. *[1]Rigshospitalet Glostrup, DHC, Copenhagen Center for Arthritis Research, Glostrup, Denmark; [2]Frederiksberg Hospital, Center for Clinical Research and Prevention, Frederiksberg, Denmark; [3]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark; [4]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [5]The University of Copenhagen, Faculty of Health and Medical Sciences, København, Denmark*

Background: People newly diagnosed with inflammatory arthritis (IA) request regular consultations and support from health professionals (HPRs) in rheumatology to manage physiological, emotional, and social challenges. Evidence suggests that providing a tailored tailormade multi-component self-management program may benefit disease management (1). However, there is a lack of evidence in interventions with multiple components targeting people newly diagnosed with IA.

Objectives: To develop a complex evidence- and theory-based intervention in co-creation with patients and HPRs for better self-management in newly diagnosed people with IA in a rheumatology out-patient clinic.

Methods: This study followed the Medical Research Council (MRC) Framework (2,3) for developing a complex intervention. The development phase comprised 1) identifying the evidence base, 2) identifying theory, 3) modelling process and outcomes, resulting in 4) a final description of all components and outcomes of the intervention.

1) Identifying the evidence base

We conducted two literature reviews, on which, we described a preliminary nurse-led intervention.

2) Identifying theory

Given the fact that the theory of Self-management is built upon Social Cognitive Theory (4) this was chosen as the underlying theory along with Acceptance and Commitment Theory (5) to support our communication strategy.

3) Modelling process and outcomes

The preliminary intervention was discussed and further developed in seven workshops to ensure that the intervention was in accordance with patients' needs and feasible in clinical practice. Three patients and 38 HPRs (nine therapists, 10 rheumatologists, one psychologist, one social worker, and 17 registered nurses) attended. During the workshops we identified the competencies needed in the HPRs delivering the intervention. In addition, relevant outcomes to measure self-management in a subsequent feasibility study were discussed. Discussions were digitally recorded and analysed using Thematic Analysis (6). Subsequently, the project group discussed the analysis and consensus was reached.

Results: *4) Description of all components and outcomes of the intervention*

Our intervention, ready for testing in a feasibility study, was a 9-month nurse-led intervention, and consisted of four individual and two group sessions. A physiotherapist and an occupational therapist should attend the group sessions along with the nurse (Figure 1). All sessions should target inflammatory arthritis-specific self-management.

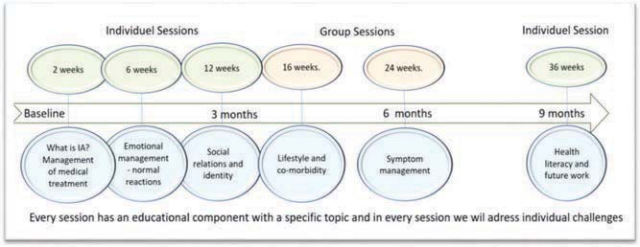

Figure 1. Intervention activities and

A comprehensive intervention manual has been developed. Our patient research partner and experts in rheumatology and self-management commented on the content to secure content validity. Subsequently, we conducted cognitive interviews with the HPRs to determine the face validity of the manual. In addition, we completed a two-day competence program to train HPRs in delivering the intervention. The selected patient reported outcomes were: Physical activity levels, Health assessment, Fatigue, Quality of life, Anxiety and depression, Illness intrusiveness, Illness perception, and Self-efficacy, supplemented with objective measures for diseases activity.

Conclusion: NISMA - a nurse-led complex self-management intervention embedded in a multidisciplinary team has been developed and described based on MRC's framework for the development of complex interventions. The intervention is currently being tested in a feasibility study.

POS1499-HPR ANKYLOSING SPONDYLITIS AND TELE-YOGA DURING COVID-19 PANDEMIC: PRELİMİNARY RESULTS OF A RANDOMIZED CONTROLLED TRIAL

Y. Acar[1], N. Ilcin[2], İ. Sari[3]. *[1]Dokuz Eylül University Institute of Health Sciences, Physical Therapy and Rehabilitation, İzmir, Turkey; [2]Dokuz Eylül Üniversite Fizik Tedavi ve Rehabilitasyon Yüksek Okulu, Physical Therapy and Rehabilitation, İzmir, Turkey; [3]Dokuz Eylül Üniversitesi Hastanesi, Rheumatology and Immunology, İzmir, Turkey*

Background: Yoga is an ancient discipline that emerged thousandans of years ago in India to unite the mind, body and spirit. Yoga is widely used by patients with various rheumatic diseases. Although it is recommended for ankylosing spondylitis (AS) patients, there is no randomized controlled study on this subject in the literature. Due to Covid-19, which has changed the world and the people's lifestyle, tele-yoga practice can be considered as an alternative to traditional face-to-face yoga classes. The use of online platforms provides a safe environment for yoga training at home.
Objectives: The aim of this study was to investigate the effects of tele-yoga on disease activity, functional status, spinal mobility, sleep quality, depression, anxiety, stress and quality of life in ankylosing spondylitis patients.
Methods: Thirty-six volunteer AS patients (21 male, 15 female) who applied to Dokuz Eylül University, Department of Internal Medicine, Division of Rheumatology and Immunology were included in the study. Participants were randomly assigned to a tele-yoga (n=18, mean age 43.22 ±8.54 years) or waiting-list control group (n=18, mean age 44.9 ±8.01 years) by block randomization method. Patients in the tele-yoga group participated in 1-hour tele- yoga sessions with a maximum of 5 people in each group using Zoom (online video-conference method) 3 days a week for 8 weeks. Assessments were performed before and after 8 weeks of yoga training. The waiting list control group did not receive any intervention, participants were advised to maintain their usual activities and continue their routine medical treatments. Assessments were performed at baseline and after an 8-week waiting period. After assessments, patients who wished participated the tele-yoga program. The following inventory was used for assessment: Bath AS Disease Activity Index (BASDAI) for disease activity, Bath AS Functional Index (BASFI) for functionality, Bath AS Mobility Index (BASMI) for spinal mobility, ASAS Health Index, Pittsburgh Sleep Quality Index (PSQI), Short Form-36 (SF-36), Hospital Anxiety and Depression Scale (HADS), Perceived Stress Scale (PSS).
Results: The groups were similar at baseline in terms of age, height, weight, body mass index, gender and physical activity level ($p>0.05$). While all parameters improved significantly in the tele-yoga group ($p<0.05$), no change was observed in the control group after 8 weeks ($p>0.05$). When the changes in the tele-yoga group and the control group were compared, the improvements in the BASDAI, BASFI, BASMI, ASAS Health Index, SF-36 Physical Function, SF-36 Role Physical, SF-36-Bodily Pain, PSQI and PSS were found to be statistically significant in the tele-yoga group ($p<0.05$).
Conclusion: According to our preliminary results, tele-yoga is beneficial in reducing disease activity and stress, improving functional level, spinal mobility, sleep quality and quality of life. Due to its therapeutic effects, tele-yoga can be considered as an alternative approach for AS patients.

POS1500-HPR BABS ON A MISSION: AN EXPERIMENTAL STUDY ON THE EFFECTS OF MESSAGE FRAMING AND THE USE OF A PATIENT TESTIMONIAL ON BELIEFS AND INTENTIONS OF OSTEOARTHRITIS PATIENTS

J. Oomen[1], C. Van den Ende2, H. Das[3]. *[1]Sint Maartenskliniek, Department of Research and Innovation, Ubbergen, Netherlands; [1]Sint Maartenskliniek, Department of Research and Innovation, Ubbergen, Netherlands; [3]Radboud University, Department of Language and Communication, Nijmegen, Netherlands*

Background: It is important that patients receive appropriate and reliable information that effectively targets beliefs in order for them to adhere to health behaviors. Framing (focusing on either gains or losses; [1]) is one of the most commonly used techniques in health communication to influence beliefs. In addition, the use of a testimonial in educational material might strengthen effects as intentions to adhere to health behaviors seem to rely strongly on testimonies of other patients. However, little is known about the potential of framing and patient testimonies to impact beliefs and change in health behaviors in osteoarthritis (OA).
Objectives: To study the effects of 1) message framing and 2) patient testimonies on beliefs about and intentions to be physically active and use pain medication.
Methods: We conducted an experiment consisting of a 2 (gain-frame vs loss-frame) x 2 (testimonial versus informative message) factorial design. Members of a research panel (n=639) with a self-reported diagnosis of knee OA were invited to participate. Participants were randomized into one of four video messages applying framing and the use of either a testimonial or facts. The messages (mean (SD) words 1073 (129)) were audiotaped by the same female speaker, subtitled, and complemented with images (duration of ~10 minutes). The four different combinations were: informative-loss ("If you are not physically active, this can lead to more pain[…]."), informative-gain ("If you are physically active, this can lead to less pain[…]."), testimonial-loss ("When I wasn't physically active, I experienced more pain[…]."), testimonial-gain ("When I was physically active, I experienced less pain[…]."). After this video, participants filled out a questionnaire on socio-demographic and disease characteristics, and rated 3 statements concerning beliefs on a 7-point Likert scale (completely disagree – completely agree), and one 7-point Likert scale item on intentions (I do not do this now and am not planning doing this – I am doing this already for more than 6 months) each for both physical activity and pain medication based on the Theory of Planned behavior questionnaire [2]. ANOVA was used to assess the main and interaction effects of framing and the use of a testimonial on mean beliefs and intentions.
Results: A total of 154 respondents completed the questionnaire (Table 1). Framing nor the use of a testimonial impacted beliefs and intentions on physical activity. Loss framing resulted in more positive beliefs about pain medication (mean (SD) 5.5 (1.6)) than gain framing (mean (SD) 4.9 (1.9), p=.04, 95% CI [0.0, 0.1]). Within the loss frame, the patient testimonial scored significantly more positive on pain medication beliefs (mean (SD) 5.0 (1.7)) than the informative message (mean (SD) 6.0 (1.1), p=.02, 95% CI [0.1, 1.6]) (Figure 1).

Table 1. Characteristics of participants (n=154)

Female, n (%)	110 (71)
Age (in years), mean (SD)	62.3 (7.9)
BMI, mean [kg/m^2], (SD)	27.3 (4.4)
Daily functioning (KOOS[a]; 0-100), mean (SD)	64.5 (18.0)
Pain VAS (0-10), mean (SD)	4.6 (2.2)
Symptoms for more than five years, n (%)	96 (62.3)
Presence of OA in other joints, n (%)	85 (55.2)
Knee replacement, n (%)	32 (20.8)
Presence of comorbidities, n (%)	111 (72.0)

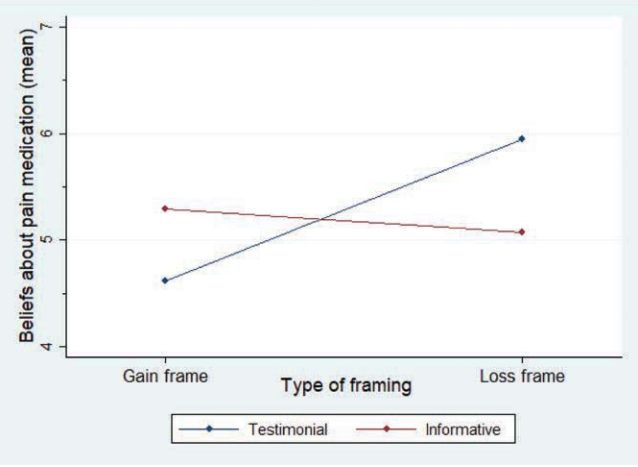

Figure 1. Interaction of framing and the use of a patient testimonial on beliefs about pain medication

Conclusion: This study showed that stating the disadvantages of nonadherence to pain medication resulted in more positive beliefs about pain medication than stating the advantages of adherence. The use of a patient testimonial within this loss frame strengthened the effect. Our findings indicate that health care providers should be aware of the potential effects of emphasising either gains or losses in educational messages to their patients.

POS1501-HPR ADDRESSING THE VOCATIONAL DEVELOPMENT OF YOUNG PEOPLE WITH LONG-TERM HEALTH CONDITIONS IN HEALTH CARE SETTINGS: A SYSTEMATIC REVIEW AND MIXED METHODS SYNTHESIS

A. Farre[1], L. Lunt[2,3], R. Lee[2,3], S. Verstappen[2,3], J. Mcdonagh[2,3,4]. [1]*University of Dundee, School of Health Sciences, Dundee, United Kingdom;* [2]*University of Manchester, Manchester Academic Health Centre, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom;* [3]*Manchester University Hospitals NHS Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom;* [4]*Royal Manchester Children's Hospital, Manchester University Hospitals NHS Trust, Department of Paediatric and Adolescent Rheumatology, Manchester, United Kingdom*

Background: Long term health conditions (LTHC) such as rheumatic conditions have significant impact on the biopsychosocial development of young people (YP) including vocational development. Educational transitions are prominent during adolescence and young adulthood yet not all transitional care programmes in rheumatology address this area [1].

Objectives: To identify and synthesise the benefits and experiences of addressing the vocational development of YP with LTHC in health care settings.

Methods: A mixed methods synthesis approach [2] was employed. We systematically searched 10 bibliographic databases. Restrictions were applied on publication date (1996-2020) and publication language (English). Articles reporting quantitative and/or qualitative primary research on addressing vocational needs/issues of YP with LTHC in health care settings were included. YP was defined as 10-24 years [3]. Two reviewers independently screened records using predetermined inclusion/exclusion criteria [4]. Quality appraisal was undertaken following study selection. Qualitative data were synthesised thematically. Quantitative data were synthesised narratively, given that a pooled synthesis was not considered appropriate. A cross-study synthesis integrated findings from both the qualitative and quantitative syntheses.

Results: 43 articles were included. The quality of qualitative evidence was generally good; but the quality of quantitative evidence was generally poor. The thematic synthesis of stakeholders' perspectives (n=23 qualitative studies) resulted in seven recommendations for interventions: provide skills training; provide psychological support; offer to liaise with key stakeholders in educational/workplace settings; provide specialist career advice; provide information, signposting and facilitate access to supporting services; provide/facilitate access to social support; provide flexible care and optimal disease management to support education/employment transitions. The narrative synthesis summarised results of 17 interventions (n=20 quantitative studies). The cross-study synthesis mapped interventions against recommendations arising from stakeholders' perspectives: Four interventions met five recommendations; two interventions met four recommendations; five interventions met three recommendations; six interventions met two recommendations. Transitional care interventions were the type of intervention that most comprehensively met the recommendations. The way in which interventions addressed vocational issues was not always clear, with some interventions addressing them explicitly/directly (reporting vocational intervention components) and others implicitly/indirectly (reporting vocational outcomes only). Interventions where vocational issues were the core, defining component of the intervention were lacking.

Conclusion: Stakeholder evidence suggests vocational development is an important area to address in the care of YP with LTHC such as rheumatic diseases. The resulting set of recommendations provides guidance for future research in this area and transitional care developments in rheumatology. Further work in this area should address these aspects to enable better quality evidence and ensure consistency.

POS1502-HPR A PHYSICAL EXERCISE PROGRAM FOR THE MANAGEMENT OF FATIGUE IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AT THE TIME OF PANDEMIC: A PILOT STUDY

E. Elefante[1], C. Tani[1], V. Signorini[1], C. Stagnaro[1], L. Lunardi[1], D. Zucchi[1], F. Trentin[1], L. Carli[1], F. Ferro[1], M. Mosca[1]. [1]*Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: Fatigue in SLE has a multifactorial origin and disease activity seems to contribute only minimally to its genesis. Therefore, non-pharmacological therapeutic strategies should also be considered in the management of fatigue. There is some evidence on the effectiveness of aerobic exercise programs in improving fatigue, without a negative impact on disease manifestations.

Objectives: the aim of this study was to analyze fatigue and Health Related Quality of Life (HRQoL) in a monocentric cohort of patients with SLE, in a condition of stable remission or low disease activity, before and after a program of physical exercise, through the administration of validated Patient Reported Outcomes (PROs).

Methods: this is a cross-sectional interventional study which included patients with SLE, aged between 18 and 55 years, in a condition of stable (≥12 months) remission (DORIS)[1] or low disease activity (LLDAS)[2]. Patients enrolled had a FACIT score ≤40 in the previous 6 months. Patients with other possible causes of fatigue (e.g.: anemia, hypothyroidism, severe vitamin D deficiency), active arthritis or physical disabilities were excluded. For each patient, demographics, comorbidities, treatment, clinical and laboratory data were collected. Disease activity was evaluated with the SELENA-SLEDAI and organ damage with the SLICC/DI. Each patient completed the following PROs before and after the interventional program: SF-36, FACIT-Fatigue, LIT, HADS. Due to the limitations related to the COVID-19 pandemic, the physical exercise sessions were carried out using the Google Meet digital platform. Patients were asked to participate to at least 70% of the lessons. The physical exercise program included moderate intensity aerobic exercises (muscle strengthening, joint mobility, breathing, static and dynamic stretching, balance and neuro-dynamics); workouts were performed 3 times a week, consisting of 60 minutes each. The program lasted for 12 weeks.

Results: we enrolled 12 female patients, regularly followed at the Rheumatology Unit of Pisa; only 9 of them completed the study (mean age 38.56 ± 9.1 years; median disease duration 7 years (IQR 5,25-9,75)). 8/9 were in stable remission, while 1/9 was in LLDAS for the presence of leukopenia. 2/9 patients presented organ damage, one for cataract and one for renal insufficiency, while none presented damage in the musculoskeletal system. 33.3% of patients had fibromyalgia. 88.8% was on treatment with Hydroxychloroquine, 55.5% was on low dose steroids (2±1.9 mg/daily), 33.3% was on Mycophenolate Mofetil; only 1 patient was on Belimumab. All PROs showed a trend to improvement at the end of the 12-week program of physical activity (Table 1). We demonstrated a statistically significant improvement of: FACIT, LIT, depression score of the HADS and MCS of the SF-36. The items of role physical (RP), vitality (VT) and mental health (MH) of the SF-36 also showed a significant improvement.

Table 1. Scores of PROs before and after the physical exercise program.

PROs	Mean scores at baseline	Mean scores after the 12-week exercise program	p
FACIT	30.2 ± 4.9	39.3 ± 7.2	0.01
PF	73.18 ± 10.9	78.9 ± 10.5	0.18
RP	50 ± 13.2	67.4 ± 18.6	0.03
BP	52 ± 12.1	54.1 ± 11.1	0.73
GH	41.7 ± 11.1	48.4 ± 11.1	0.07
VT	34.7 ± 12.5	59.0 ± 14.2	0.002
SF	58.3 ± 15.6	66.7 ± 16.7	0.3
RE	55.5 ± 21.5	69.4 ± 18.0	0.13
MH	58.3 ± 15.8	67.2 ± 16.2	0.03
PCS	43.8 ± 4.0	46.1 ± 4.8	0.19
MCS	38.6 ± 8.8	45.6 ± 8.7	0.03
LIT	36.9 ± 14.2	27.5 ± 14.1	0.05
HADS (A)	9 ± 4.4	7.7 ± 3.2	0.4
HADS (D)	7.9 ± 4.4	5.1 ± 2.96	0.05

Conclusion: In a small cohort of SLE patients in remission but with severe fatigue, in the difficult context of COVID-19 pandemic, we demonstrated that an online program of physical exercise may determine a significant improvement of fatigue, perception of disease burden and mental health. In the context of a multidisciplinary management, finding effective intervention programs to improve fatigue and HRQoL in SLE patients appears of utmost importance, with the final aim of improving patients' health status.

POS1503-HPR **THE VALUE OF REMOTE CONSULTATIONS WITH A PHYSIOTHERAPIST, SPECIALISED IN AXIAL SPONDYLOARTHRITIS DURING THE COVID 19 PANDEMIC: EVALUATION OF A MEMBER-SUPPORT PROJECT WITH THE NATIONAL AXIAL SPONDYLOARTHRITIS SOCIETY.**

E. Clarke[1], J. Hamilton[2], S. Dickinson[3]. *[1]AStretch, Committee Member, Bath, United Kingdom; [2]National Axial Spondyloarthritis Society, Policy and Health Services, London, United Kingdom; [3]National Axial Spondyloarthritis Society, Member Support Services, London, United Kingdom*

Background: COVID-19 caused significant disruption to Axial Spondyloarthritis (AxSpA) services during the intial 2020 lockdown[1]. In response, The National Axial Spondyloarthritis Society (NASS) piloted provision of remote consultations with a physiotherapist specialised in the management of AxSpA to their members in urgent need. This project was funded by the UK National Lottery Fund
Objectives: To provide a total of 130 hrs of remote consultation to members of NASS, unable to access specialist care and in need of self-management advice for their condition
Methods: Remote consultations were offered to NASS members from Sept 2020 to Feb 2021. The preferred format being 1hr assessment and 2 x 30 min at 1 and 3 weeks from assessment. Participants consented to video consultations via Zoom and the inclusion of anonymised outcomes and comments in the project evaluation. Patient Reported Outcomes (BASDAI and BASFI) were collected immediately prior to assessment, at final consultation and in April 2021, between 8- 16 weeks from final consultContent was individually tailored, centring on self-management (pacing, sleep management), education (AxSpA pathology, medication) and individualised exercise plans. Exercise plans were formulated through "Rehab My Patient" software, including links to YouTube video references and daily exercise log sheets.
Results: 67 members received online consultations, 63 receiving the full 3 sessions. Missed appointment rate = 2.5%
Participants represented a wide geographical area across England and a spread in time since diagnosis.
Patient Reported Outcomes Measures (PROMs) on assessment:

- Mean BASDAI score (n=55) on assessment = 5.8
- Mean BASFI score on assessment (n=56) = 5.5

24 participants returned PROMS at final consultation, 10 at longer follow-up (8-16 weeks). Results for complete data set (n=10):

Table 1.

PROMS	Assessment	Final consultation	Follow-up
Mean BASDAI	5.0	4.3	4.0
Mean BASFI	5.1	4.0	4.1

Satisfaction:
60 members completed an online feedback survey provided by NASS:
9 Feedback to questions were asked, with a satisfaction scale of 1-5 (ascending positivity)
99.6% of all scores were 3 or above.
Example responses:

- How would you rate the overall experience: 92% = 5, 100% = 3-5
- To what extent do you feel more confident to manage your condition: 40% = 5, 100% = 3-5
- How useful was it to be in direct contact with a Physiotherapist: 93% = 5, 100% = 3-5

46 members chose to leave additional, overwhelmingly positive comments, with 2 obvious themes arising:
1)The **value of the experience and knowledge of the therapist**. "was great to have the guidance and support of a professional who knows what they are talking about when it comes to AxSpA"
2)The **value of education in condition management** "set me back on track", "very helpful for my mental strength in dealing with this enduring disease", "I learned so much about my AS and ways to keep mobile"
Conclusion: A set of 1-3 sessions per person achieved desirable patient reported outcomes with modest and enduring improvements seen in disease activity and function. This pilot project enabled those living with Axial SpA across England access to a Physiotherapist highly experienced in treatment of their condition. The majority of participants reported having no previous experience of seeing a therapist with specialised knowledge of their condition. The knowledge and experience of the clinician was a key theme in the positive nature of feedback linking to another key theme of improved confidence to manage their condition. These results highlight the value to patients of specialised knowledge amongst health professionals. Remote consultations may provide access to specialist knowledge "out of area" and may be an efficient method of delivering self-management advice

POS1504-HPR **THE EFFECT OF REMOTE AND FACE-TO-FACE STABILIZATION EXERCISES ON FUNCTIONAL CAPACITY OF ASYMPTOMATIC INDIVIDUALS**

Y. Özel Aslıyüce[1], O. Ulger[1]. *[1]Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: In recent years, it has been emphasized that preventive rehabilitation approaches for problems such as low back and neck pain, which are very high in health expenditures, are more cost-effective than treating them. Due to the Covid-19 pandemic, risk factors for individuals' spinal health have increased and access to health care has become difficult (1). Therefore, interest in tele-rehabilitation, which is an important part of telehealth, has increased recently.
Objectives: This study aims to investigate the effectiveness of remote and face-to-face spinal stabilization exercise training on functional capacity tests in asymptomatic individuals.
Methods: Individuals who did not have chronic low back and neck pain and between the ages of 18-55 were included in the study. While the face-to-face group traditionally exercised under the supervision of a physiotherapist, the tele-rehabilitation group exercised with videoconferencing and asynchronous video recordings. Both groups performed progressive spinal stabilization exercises 3 days a week for 8 weeks (2). Before and after the training functional capacity tests (repetitive reaching, lifting object overhead, and sustained overhead work) were performed (3).
Results: Twenty (11 female, 9 male) individuals with a mean age of 30,252±9.06 and a mean body mass index of 24.36±4.09 were included in the study. There was no difference between the baseline values of functional capacity test scores of both groups ($p>0.05$). There were significant improvements in the repetitive reaching and sustained overhead work tests after the exercise program in both groups ($p< 0.05$), while there was no difference in the lifting object overhead test ($p> 0.05$). There was no difference between the changes in functional capacity test scores between the groups after the training ($p> 0.05$).
Conclusion: According to our preliminary results, face-to-face and remote spinal stabilization exercise programs caused similarly positive changes in functional capacity test scores (repetitive reaching, sustained overhead tests) of asymptomatic individuals. These exercises are known to improve deep muscle activation. This development may have led to improvements in tests, which mostly evaluate speed, coordination and endurance. Weight lifting capacities have not changed. This may be because stabilization exercises focus more on deep muscle activation and not on developing superficial muscle strength like upper extremity strength(2). Success of exercise training with telerehabilitation may have contributed to the younger population and possibly better adaptation to technology. It is planned that these preliminary results will be extended and make greater contributions to the current literature.

POS1505-HPR **FEASIBILITY OF AN ONLINE "FATIGUE AND ACTIVITY MANAGEMENT EDUCATION IN WORK" (FAME-W) INTERVENTION FOR INDIVIDUALS WITH INFLAMMATORY ARTHRITIS**

S. Karkon[1], M. Doran[2], F. B. O'shea[2], A. O' Gorman[3], H. Mccormack[3], D. Connolly[1]. *[1]Trinity College Dublin, Occupational Therapy, Dublin, Ireland;*

[2]St James's Hospital, Rheumatology, Dublin, Ireland; [3]St James's Hospital, Occupational Therapy, Dublin, Ireland

Background: A **FA**tigue **M**anagement **E**ducation in **W**ork (FAME-W) programme was developed for individuals with inflammatory arthritis to manage fatigue in work (McCormack et al, 2018).
Objectives: This study tested the feasibility and acceptability of an online format of FAME-W for a future definitive intervention trial.
Methods: This was a mixed methods study. Participants were randomly allocated to intervention (IG) or control group (CG). The IG received a four-week online FAME-W. The CG received a FAME-W handbook. Participants were required to complete questionnaires on work presenteeism, fatigue, mood, Health Related Quality of Life (HRQOL) and pain at baseline (T0), and two weeks following intervention (T1). They also attended a focus group and individual interviews. Data were analysed using descriptive statistics
Results: Seven of ten individuals recruited participated in the study (intervention = 3, control =4). The majority of participants in both groups had Rheumatoid Arthritis and were working full-time in non-manual jobs. The mean age of intervention participants was 53 ± 10.4 and 56.5 ± 3.7 for the controls. Most of the intervention group were males and the majority of controls were female. Disease activity at baseline was similar for both groups: 3.33 ±2.5 intervention; 3.0 ± 1.8 control. At follow-up, disease activity did not change for intervention group (3.3 ±.57) and reduced slightly for CG (2.7 ±2.4). Slight improvements were noted for both groups in presenteeism and fatigue between T0 and T1 (Table 1). There was no change in anxiety levels of the intervention group, with improvements noted for controls. Greater improvements were noted for the intervention group for depression and HRQOL. Pain measures showed increased pain for controls at T1 in comparison to the intervention group.

Table 1.

Measure	Intervention (n=3) Median (min-max)		Control (n=4) Median (min-max)	
	T0	T1	T0	T 1
Work Role Function	84.1 (81.9-92.1)	85.7 (83.4-97.2)	84.8 (63.7-93.9)	84.9(72.9-94.5)
Fatigue	13.0 (8.0-14.0)	10.0 (10.0-14.0)	14.0 (12.0-17.0)	12.5 (12.0-17.0)
HADS Anxiety	5.0 (3.0-6.0)	5.0 (3.0-6.0)	10.0 (7.0-14.0)	8.0 (6.0-12.0)
HADS Depression	5.0 (3.0-5.0)	3.0 (2.0-4.00)	5.0 (3.0-11.0)	6.0 (3.0-9.0)
HRQOL	68.0 (47.0-90.0)	75.0 (65.0-90.0)	70.00 (50.00-95.00)	66.5 (50.0-95.0)
Pain Level	4.0 (100-5.0)	2.0 (2.0-4.0)	1.5 (1.0-4.0)	4.5 (200-10.0)
Pain Intensity	1.0 (1.0-2.0)	1.0 (1.0-2.0)	0.5 (0.0-1.0)	1.5 (0.0-2.0)

Those allocated to FAME-W attended all four sessions. FAME-W participants reported that the programme content was comprehensive and relevant. They stated that the occupational therapist facilitator was able to "*see things from a different perspective for managing symptoms*". Participants also reported a better understanding of fatigue: "*It helped me understand my fatigue. If you understand it you can manage it better*". The online delivery format was favored over attending a centre-based programme. Control participants reported the handbook content as "*informative and reassuring*". All participants fully completed all study questionnaires and attended focus groups and interviews.
Conclusion: This feasibility study showed that an online programme to improve work ability was feasible and acceptable to individuals with Rheumatic Diseases. Study measures were completed in full and adherence rate was 100% for the intervention. The findings support a definitive intervention trial of FAME-W.

POS1506-HPR **SYSTEMATIC LITERATURE REVIEW TO INFORM THE EULAR TASK FORCE FOR RECOMMENDATIONS/ POINTS TO CONSIDER FOR THE NON-PHARMACOLOGICAL MANAGEMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS AND SYSTEMIC SCLEROSIS**

I. Parodis[1,2], A. Gomez[1], A. Tsoi[1], J. Weng Chow[1], D. Pezzella[1], C. Girard[3], T. Stamm[4,5], C. Boström[6]on behalf of EULAR Task Force for Recommendations/ Points to Consider for the Non-Pharmacological Management of Systemic Lupus Erythematosus and Systemic Sclerosis. *[1]Karolinska Institutet, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden; [2]Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden; [3]University Hospital of Geneva and University of Geneva, Division of Rheumatology, Department of Medicine, Geneva, Switzerland; [4]Medical University of Vienna, Section for Outcomes Research, Center for Medical Statistics, Informatics and Intelligent Systems, Vienna, Austria; [5]Ludwig Boltzmann Institute, Cluster Arthritis and Rehabilitation, Vienna, Austria; [6]Karolinska Institutet, Division of Physiotherapy, Department of Neurobiology, Care sciences and Society, Stockholm, Sweden*

Background: The heterogeneity and complexity of the chronic autoimmune diseases systemic lupus erythematosus (SLE) and systemic sclerosis (SSc) necessitate comprehensive person-centred management, including non-pharmacological approaches. Recommendations for non-pharmacological management are currently lacking.
Objectives: To perform a systematic literature review to inform the EULAR task force for recommendations/points to consider for the non-pharmacological management of adult patients with SLE and SSc. Among research questions formulated by the task force, we aimed at identifying (i) non-pharmacological interventions that have been evaluated and (ii) their target health domains or organ systems.
Methods: We searched the Medline, Embase, Web of Science Core Collection and CINAHL for articles published between January 2000 and June 2021. From the initial search (n=15,803), 2 researchers independently performed the article selection. Conflicts were discussed until consensus with 2 additional researchers. Subsequent data extraction from the selected articles was performed by 4 researchers, with an overarching guidance by 2 additional researchers. Risk of bias assessment was performed according to Joanna Briggs Institute Critical Appraisal Checklists.
Results: A total of 111 articles for SLE and 75 for SSc were selected for analysis. Non-pharmacological interventions identified for SLE included physical exercise (n=34), psychological support (n=21), dietary therapy and nutrition (n=15), patient education and self-management (n=14), photoprotection (n=5), medication adherence interventions (n=5), complementary and alternative medicine (CAM) e.g., Chinese medicine (n=5), multidisciplinary care (n=4), and phototherapy/laser modalities (n=4). Interventions identified for SSc included physical exercise e.g., hand, oral and general exercise (n=21), phototherapy/laser modalities or shockwave therapy (n=15), patient education and self-management (n=10), CAM (n=8), hand-bathing e.g., in paraffin (n=5), manual therapy e.g., osteopathic manipulative treatment (n=5), dietary therapy and nutrition (n=5), oral hygiene (n=2), hyperbaric oxygen or ozone therapy (n=2) and multidisciplinary care (n=2). Target health domains and organ systems identified within SLE included (in descending order) (i) disease activity, (ii) health-related quality of life (HRQoL), (iii) depression/anxiety, (iv) fatigue, (v) organ damage, (vi) inflammatory markers, (vii) psychological stress, (viii) pain, (ix) body composition/ anthropometry, and (x) aerobic capacity. Intervention targets in SSc included (i) functional impairment e.g., hand mobility, (ii) skin sclerosis including microstomia, (iii) HRQoL, (iv) pain, (v) circulation e.g., Raynaud's phenomena and telangiectasias, (vi) skin ulcers, (vii) oral hygiene, (viii) fatigue, (ix) digestion, and (x) depression/anxiety.
Conclusion: Physical exercise was a frequently researched non-pharmacological intervention within both SLE and SSc. While psychological support and dietary therapy/nutrition were frequently investigated in SLE, phototherapy modalities were common in SSc. Patient education and self-management was advocated in both SLE and SSc literature. HRQoL was a frequent target domain in both diseases; while disease activity and psychosocial domains emerged as important targets in SLE, functional impairment and skin-related aspects constituted predominant targets in SSc. Efficacy of interventions varied considerably across studies. Current evidence is limited by the overall small study populations, and the lack of large RCTs.

Table 1. Studies categorised by design.

Study design	SLE	SSc
Meta-analysis of RCTs	5	1
RCT (including long-term follow-up or post-hoc analysis)	41	28
Non-randomised longitudinal controlled/cohort studies	28	7
Retrospective cohort study, cross-sectional or case-control study	16	2
Case series or open pilot studies	21	37

Acknowledgements: The authors would like to thank the members of the EULAR task force for recommendations/points to consider for the non-pharmacological management of systemic lupus erythematosus and systemic

sclerosis (in alphabetical order by family name) i.e., Helene Alexanderson, Laurent Arnaud, Oliver Distler, Andrea Domján, Els van den Ende, Kim Fligelstone, Agnes Kocher, Maddalena Larosa, Martin Lau, Alexandros Mitropoulos, Mwidimi Ndosi, Gunilla von Perner, Janet Poole, Anthony Redmond, Valentin Ritschl, Yvonne Sjöberg, Tillmann Uhlig, Cecília Varjú, Joke Vriezekolk, Elisabet Welin, and Rene Westhovens, for their contribution to the formulation of the research questions together with IP, CG, TS and CB.

POS1507-HPR INVESTIGATION OF THE EFFECTS OF PELVIC FLOOR TRAINING ON PAIN, SEXUAL DYSFUNCTION, AND QUALITY OF LIFE IN FEMALE PATIENTS WITH SJOGREN

K. T. Aydın[1], S. Y. Cetin[2], A. Ayan[3]. *[1]Turkey, Physiotherapy and Rehabilitation, Antalya, Turkey; [2]Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey; [3]Antalya Health Sciences University, Rheumatology, Antalya, Turkey*

Background: Sjogren's syndrome is a chronic systemic inflammatory disorder (classified as an autoimmune disorder) characterized by lymphocyte infiltrates in exocrine organs. This syndrome is classified as primary sjogren's or secondary sjogren's. Dryness of the eyes, oral cavity, larynx, pharynx and vagina is common in primary sjogren's syndrome. Although vaginal dryness is a symptom seen after menopause in the healthy population, it often occurs at a young age in cases with primary sjogren's. The presence of urogynecological complaints in women with pSS adversely affected the health-related quality of life of pelvic floor function. However, it has been shown that the sexual functions of women with pSS are also negatively affected. Sexual dysfunction and increased pain were seen with increasing pelvic floor dysfunctions. Many studies showing that pelvic floor training has been accepted in the literature as the first step in the treatment of pelvic floor dysfunctions to increase pelvic floor strength and effectiveness. In addition, the positive effects of pelvic floor exercises on sexual functions have been supported by studies.

Objectives: The aim of this study was to investigate the effects of pelvic floor training on pain, sexual dysfunction and quality of life in female patients with pSS and determine whether pelvic floor training was superior to education program.

Methods: 46 pSS patients (46 female) with an average age of 47.78±9.18 were included in the study. Patients were divided into two groups by block randomization method. Group 1 received 30 minutes of pelvic floor training program every day as a home exercise for 8 weeks. Group 2 received education about pelvic floor muscles and daily living activities. Health Assessment Questionnare (HAQ) was used to evaluate the quality of life, Visual Analog Scale (VAS) and Pelvic Pain Impact Questionnaire (PPIQ) was used to evaluate degree of pelvic pain, Pelvic Floor Disability Index-20 (PFDI-20) was used to evaluate the degree of certain discomfort caused by pelvic symptoms in women, Female Sexual Function Scale (FSFI) was used to evaluate the sexual dysfunction, Pelvic Floor Impact Questionnaire (PFIQ-7) was used to evaluate the effect of bladder, bowel, and pelvic symptoms on the individual's activities of daily living, social relationships, and emotions. All evaluations were performed at baseline and at the end of the 8th week.

Results: When the groups were compared before training, there was no significant difference (p> 0.05). In post-training comparisons, there was a significant difference in FSFI, VAS, PPIQ, PFIQ-7, PFDI-20 in pelvic floor training group (p:0.02-0.00); in FSFI-lubrication, PFIQ-7 and PFDI-20 (p:0.00-0.03) in education group. In addition, after post-training, pelvic floor training group was found to be superior in terms of FSFI total (Z: -3.40, p: 0.01), FSFI-orgasm (Z: -3.13, p: 0.02), FSFI-satisfaction (Z: -2.27,p: 0.02), FSFI-pain (Z: -2.42, p: 0.01), PFDI-20 (Z: -3.42, p: 0.00), POPDI-6 (Z: -3.00, p: 0.00), CRADI-8 (Z: -2.18, p: 0.02), UDI-6 (Z: -3.64, p: 0.00) compared with education group.

Conclusion: As a result of our study, pelvic floor training has a positive effect on sexual dysfunction and discomfort caused by pelvic symptoms in patients with pSS. Pelvic floor training should be included in rehabilitation programs as a home exercise to improve sexual function and pelvic floor dysfunctions for patients with pSS.

POS1508-HPR USE OF PHYSICAL THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS OR AXIAL SPONDYLOARTHRITIS: THE PATIENT´S PERSPECTIVE

M. Van Wissen[1], B. Straathof[1], T. P. M. Vliet Vlieland[1], M. Teuwen[1], C. Van den Ende[2,3], W. Peter[1], M. G. J. Gademan[1,4], S. Van Weely[1]. *[1]Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands; [2]Sint Maartenskliniek, Research, Nijmegen, Netherlands; [3]Radboud University Medical Center, Rheumatic Diseases, Nijmegen, Netherlands; [4]Leiden University Medical Center (LUMC), Clinical epidemiology, Leiden, Netherlands*

Background: In national and international management guidelines physical therapy (PT) is a recommended treatment for people with inflammatory arthritis (IA). Based on multiple systematic reviews, concluding that supervised exercise therapy and exercise promotion is an effective and safe PT treatment option in patients with IA, recommendations in particular endorse active PT treatment. In order to monitor and enhance the quality of PT in clinical practice, knowledge about its delivery, including its active content, is needed.

Objectives: To assess the use, frequency, duration and content of PT in patients with IA.

Methods: In this cross-sectional, national study a link to an electronic questionnaire addressing people with rheumatic and musculoskeletal diseases was published between December 2020-July 2021 by the Dutch Arthritis Foundation via their website, newsletter and various social media. It comprised questions on demographic and health characteristics, the EuroQol 5-Dimensions 5-Levels (EQ5D5L) and 29 questions on the usage of PT currently and/or in the past 12 months and, if applicable, the duration, frequency and content of the PT treatment. The content of PT was categorized into exercises (active aerobic, muscle strengthening, range of motion and/or functional exercises), manual treatment, physical modalities and counseling/education. Only data from patients self-identifying as diagnosed with rheumatoid arthritis (RA) and/or axial spondyloarthritis (axSpA) were used for the current study.

Results: A total of 267 people with RA (mean (SD) age 54 (12) years, 96% female) and 104 people with axSpA (age 47 (13) years, 88% female) (10 patients with both diagnoses) completed the questionnaire. More than 90% were treated by a rheumatologist; the mean (SD) EQ5D5L of people with RA was 0.62 (0.2) and of axSpA 0.59 (0.2). 172 RA respondents (64%) reported the use of PT related to their RA (162 individual PT, 1 group PT, 9 both individual and group PT). In axSpA, the rate was 87 (84%; 77 individual PT, 2 group PT, 8 both individual and group PT). Of those reporting individual PT treatment, the duration was long-term (> 3 months) in 134 (89%) and 70 (89%) of the respondents with RA and axSpA respectively, with a duration of more than 2 years in 67 (44%) and 38 (48%). In all users of individual PT, the mean frequency was once per week or less in 116 (77%) of the RA and 63 (80%) of the axSpA patients. Proportions were based on number of respondents to questions on individual PT. Concerning the content of individual PT, and taking into account both short-term and long-term use, for active exercises, the proportion of patients reporting aerobic, muscle strengthening, range of motion or functional exercises ranged from 40-66% in RA and 24-73% in axSpA patients. Regarding manual treatment, the proportions were 61% and 58%, in RA and 73% and 72% in axSpA for massage and passive mobilizations, respectively. With respect to physical modalities (passive), the modality most frequently mentioned were kinesiotaping and dry needling (40 and 25% and 43 and 32% in RA and axSpA). For counseling/education, exercises to perform at home (70 and 78%) and physical activity (PA) promotion (48 and 49%) were most often reported in both RA and AxSpA.

Conclusion: Long-term use of PT is common in patients with RA and AxSpA. Apart from active treatment modalities (exercises) and promoting recommended PA, passive treatment options appear to be relatively often used. The results must be interpreted with caution, as the respondents may not constitute a representative sample of the IA population, yet warrant further research.

POS1509-HPR CHANGES IN SELF-EFFICACY AND USE OF ENERGY CONSERVATION STRATEGIES FOLLOWING PARTICIPATION IN THE FATIGUE MANAGEMENT EDUCATION FOR INDIVIDUALS WITH SYSTEMIC SCLEROSIS (FAME-ISS)

J. L. Poole[1], D. Connolly[2], K. Carandang[3]. *[1]University of New Mexico, Occupational Therapy Graduate Program, Albuquerque, United States of America; [2]Trinity College, Discipline of Occupational Therapy, Dublin, Ireland; [3]University of Wisconsin-River Falls, Young Patients'Autoimmune Research & Empowerment Alliance, River Falls, United States of America*

Background: Fatigue is one of the most prevalent and disabling symptom of systemic sclerosis (SSc). No fatigue specific programs exist for people with SSc despite the negative impact on daily life activities. However, recent literature has shown that using pacing and other energy conservation strategies, has been associated with reduction in fatigue.
Objectives: The purpose of this pilot study was to evaluate changes in self-efficacy and use of energy conservation strategies after participation in Fatigue and Activity Management Education for Individuals with Systemic Sclerosis (FAME-iSS).
Methods: Adult participants were recruited from the Scleroderma Foundation chapters and social media to participate in a 6-week, virtual group program focused on SSc-related fatigue. Inclusion criteria: ≥18 years of age, access to device with videoconferencing capabilities, and at least moderate fatigue determined by degree, severity, and distress (scales: 1-10). The program, led by occupational therapists included sessions on factors related to fatigue, management of energy, pain, stress, physical activity and nutrition. At baseline, participants completed a demographic questionnaire, the Self-Efficacy for Performing Energy Conservation Strategies Assessment (SEPESCA) to measure confidence using energy conservation strategies. At post-intervention and 3-month follow-up, participants also completed the Energy Conservation Strategies Survey (ECSS) to identify use and effectiveness of 14 energy conservation strategies (e.g. changing body positions, planning and prioritizing, communicating needs) and a qualitative interview to contextualize their responses. Descriptive statistics (means, standard deviations) were used to analyze quantitative data.
Results: The sample for the pilot study included 18 participants (89% women; age 52 ± 11.6 years) with established SSc (disease duration= 13.7 ± 14.5 years). 83% participants completed 100% of FAME-iSS sessions. Directly following the program all 14 energy conservation strategies were used by at least seven (39%) participants. The most frequently used strategy was "*planned day to balance rest and activity*" which was used by 17 participants post-intervention. (see Table 1). At the three-month follow-up the there was a decline in use for 50% of the strategies and an increase in use for the other 50%. Of those who reported not using energy conservation strategies, the most frequent reason provided by participants was that they were already using the strategy prior to attending FAME-iSS. The mean strategy effectiveness scores varied at both time points with "*adjusting priorities*" the most effective strategy at T2 and "*delegating activities*" the most effective at T3. While not statistically significant, participants trended towards improved self-efficacy scores for energy conservation strategies (baseline: 6.8 (2) post-intervention: 8.1 (1.4); 3-month follow-up: 8.4 (2.8) Participants qualitatively reported that FAME-iSS led to the sharing of new fatigue management strategies and increased attention to their daily activities.
Conclusion: This pilot study showed that FAME-iSS resulted in increased self-efficacy in use of energy conservation strategies in participants with established SSc. New behaviors were adapted that participants felt reduced their fatigue. The virtual format allowed for sharing of strategies and availability to more people.

POS1510-HPR IDENTIFYING THEORY-DRIVEN THERAPEUTIC CONTENT FOR A SMARTPHONE APP FOR THE SELF-MANAGEMENT OF SJOGREN'S SYNDROME

M. Campbell[1], C. Mccallum[2], V. Deary[3], J. Ellis[4], T. Rapley[5], J. Vines[6], K. Hackett[5]. *[1]Teesside University, School of Social Sciences, Humanities, and Law, Middlesbrough, United Kingdom; [2]University of Bristol, School of Computer Science, Electrical and Electronic Engineering and Engineering Maths, Bristol, United Kingdom; [3]Northumbria University Newcastle, Faculty of Health and Life Sciences, Northumberland Building, United Kingdom; [4]Northumbria University Newcastle, Faculty of Health and Life Sciences, Newcastle upon Tyne, United Kingdom; [5]Northumbria University Newcastle, Social Work, Education and Community Wellbeing, Newcastle upon Tyne, United Kingdom; [6]University of Edinburgh, School of Informatics Institute of Language, Cognition and Computation Design Informatics, Edinburgh, United Kingdom*

Background: Technology-supported self-management of long-term conditions (e.g., through the use of smartphone apps) provides easily accessible support. However, currently there are no systematically developed, evidence-based smartphone apps for Sjogren's Syndrome. We took an agile approach to developing such an app: instead of starting "from scratch" we deemed it more efficient and scientifically sound to digitalise relevant components from existing, evidence-based interventions for the symptoms of SS.
Objectives: The present study was desk research, which aimed to deconstruct interventions and resources down to units of theory-driven therapeutic content, to then select from, for the inclusion in an app for the self-management of SS.
Methods: We used deductive and inductive content analysis, to identify behaviour change techniques (BCTs)[1] and behaviour change methods (BCMs)[2]. The materials consisted of published fatigue, pain and sleep interventions (e.g. [3] and [4]), as well as private-facing clinician notes and public facing resources on self-management from Versus Arthritis and the UK NHS's CRESTA fatigue clinic.
Results: We found 38 active ingredients from the BCT Taxonomy and the BCM intervention mapping approach frameworks, of which at least 14 were overlapping in function. Importantly we noted that BCTs and BCMs were formulated in various ways pertaining to how the interventions should be delivered (form of delivery-FoD) [5]. Further qualitative analysis revealed 6 themes relating to FoD. The theme *Interactivity* involved presenting information in ways that would involve the reader in actively responding to it in various ways. The theme *Reflection* was about engaging the recipient in in-depth consideration of their own experience with symptoms and self-management processes. The theme *Validation* encompassed all the ways in which the illness and management experience was socialised and normalised to remove stigma and sense of isolation. The theme *Treatment Rationale* was about providing an a-priory transparent, sound, and compelling justification for the self-management actions required from recipients. The theme *Discourse* pertained to how information was being communicated, e.g., with language that is warm, simple, assertive, etc. Finally, the theme *Approaches* was about the therapeutic origins of the active ingredients, e.g. Second and Third Wave CBT. These themes indicate that meaningful therapeutic content is missing from commonly used theoretical frameworks for the development of interventions.
Conclusion: Our findings indicate that meaningful therapeutic content is missing from commonly used theoretical frameworks for the development of interventions. Interventions should not just include BCTs and methods, but also active ingredients pertaining to how these techniques and methods are delivered, i.e., active ingredients relating to FoD. Reflection deserves particular attention in self-management, as it is unclear empirically in apps what is the most effective way to produce the most useful psychological and behavioural insight, and for whom. FoD is a component of intervention development that requires systematising and the present findings can contribute to such efforts.

HPR Patients- perspectives, functioning and health (descriptive: qualitative or quantitative)

POS1511-HPR "I LEARNT SO MUCH ABOUT MY APPROACH TO BEING ACTIVE": EXPERIENCES OF PEOPLE WITH RHEUMATOID ARTHRITIS ON THE IMPACT OF A PHYSIOTHERAPIST LED INTERVENTION TO PROMOTE PHYSICAL ACTIVITY

S. Mckenna[1,2], L. Larkin3, T. Pyne3, S. Gallagher[4,5], L. Glynn[5,6], A. Fraser[6,7], B. A. Esbensen[8,9], N. Kennedy[5,10]. [1]*Health Service Executive, Department of Physiotherapy, Croom, Ireland;* [2]*University of Limerick, School of Allied Health, Limerick, Ireland;* [2]*University of Limerick, School of Allied Health, Limerick, Ireland;* [4]*University of Limerick, Department of Psychology, Limerick, Ireland;* [5]*University of Limerick, Health Research Institute, Limerick, Ireland;* [6]*University of Limerick, School of Medicine, Limerick, Ireland;* [7]*University Hospitals Limerick Group, Department of Rheumatology, Limerick, Ireland;* [8]*Copenhagen Center for Arthritis Research, Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark;* [9]*University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark;* [10]*University of Limerick, Office of Vice President of Research, Limerick, Ireland*

Background: Physical activity is an important component in the management of people with rheumatoid arthritis (RA) [1]. A Physiotherapist-led Intervention to Promote Physical Activity in people with RA (PIPPRA) was undertaken using the Behaviour Change Wheel, with the aim of examining the feasibility of promoting physical activity in RA. This qualitative study involved participants and health care professionals who participated and were involved in a behaviour change pilot RCT intervention.
Objectives: To determine, qualitatively, the acceptability of PIPPRA to participants with RA and health care professionals, in order to capture their reality.
Methods: A qualitative study design of face-to-face semi-structured interviews was undertaken. The interview schedule explored the following areas: experience of the intervention; unintended consequences; experience and suitability of outcome measures used; views regarding the intervention; perceptions of behaviour change and physical activity. Interviews were transcribed verbatim by a professional transcriber. Thematic analysis was used as an analytical approach [2]. The research team searched for patterns, analysed and coded the data, and generated themes and sub-themes. Themes were reviewed by the research team to check if they worked in relation to the coded extracts and the entire data set. The COREQ checklist provided guidance throughout [3].
Results: Fourteen participants [13 female/1 male; mean age of 59 (SD 6.3); mean RA diagnosis of 8.6 (SD 6.8) years; moderate to severe disability (HAQ-DI: 1.4 (SD 0.50)] and 8 healthcare staff [4 female/4 male; mean age of 41 (SD 5.6)] participated. Three main themes were generated from participants:- 1) Positive experience of behaviour change intervention - *"I found it very knowledgeable to help you get stronger"*; 2) Improvement in self-management - *"…….motivate me maybe to go back to doing a little bit more exercise"*; 3) Negative impact of COVID-19 on intervention – *"I don't think doing it online again would be really good at all"*. Two main themes from health care professionals:- 1) Positive learning experience of behaviour change delivery – *"Really made me realise the importance of discussing physical activity with patients"*; 2) Positive approach to recruitment – *"Very professional team showing the importance of having a study member on site"*.
Conclusion: The findings demonstrated that participants had a positive experience of being involved in a behaviour change intervention in order to improve their physical activity and found it acceptable as an intervention. However, if given the choice they would prefer the intervention delivery face to face rather than telehealth. Healthcare professionals also had a positive experience and in particular found it beneficial to their own development, in particular the importance of recommending PA to patients.

POS1512-HPR FATIGUE AND MOOD DISORDERS AS DETERMINANTS OF QUALITY OF LIFE IN PATIENTS WITH RA TREATED WITH BIOLOGICS

W. Tański[1], N. Świątoniowska-Lonc[2], B. Jankowska-Polańska3. [1]*4th Military Teaching Hospital, Department of Internal Diseases, Wroclaw, Poland;* [2]*4th Military Teaching Hospital, Research and Innovation Center, Wroclaw, Poland;* [2]*4th Military Teaching Hospital, Research and Innovation Center, Wroclaw, Poland*

Background: Rheumatoid arthritis (RA) includes many conditions that affect joints, the tissues surrounding the joints, and other connective tissues.[1] In 2012, the prevalence of RA in the USA was estimated to be 22.7% (52.5 million adults over 18 years of age) and projected to increase to 49% (about 78 million Americans) by 2040.[2] The disease causes pain and limits physical function.[3] It is accompanied by fatigue, anxiety and even depression, which may not be considered important by those around the patient, but may be crucial for the patient.[4] Research on the impact of psychosocial factors on the quality of life (QoL) of patients receiving biologic therapy is still limited. There is a need to identify new psychological determinants affecting the course of treatment of patients with RA and their quality of life and perception of health.
Objectives: The aim of the study was to assess the level of QoL and the association of selected psychosocial (depression, anxiety, fatigue) and clinical (pain) factors with the quality of life of patients with RA treated with biologics.
Methods: Standardized questionnaires were used in the study to assess the level of anxiety and depression (Hospital Anxiety and Depression Scale), quality of life (WHOQoL-BREF), pain (Visual Analogue Scale) and fatigue (Modified Fatigue Impact Scale).
Results: A total of 63 RA patients (61.9% women) aged 52.38±16.97 years treated with biologics were enrolled in the study. Mean disease duration in the study group was 13.54±9.51 years. The level of fatigue in MFIS questionnaire was 25.96±16.14, the level of depression and anxiety assessed by HADS, respectively was (17.1±2.2 vs (20.0±2.3)). In QoL assessment, the highest scores were obtained in psychological (16.5±1.86) and environmental (14.47±- 2.22) domains, and the lowest in physical domain (11.4±-2.41). In regression analysis, pain negatively affected the psychological domain (5.11±2.55) and social life of 6.03% of patients. Patients assessed their QoL as average and almost half of the respondents (42.86%) were dissatisfied with their health. In correlation analysis, anxiety ($r=-0.472$, $p<0.001$), depression ($r=-0.322$, $p=0.01$) and mental fatigue ($r=-0.271$, $p=0.047$) significantly decreased patients' QoL in psychological domain. In multivariate analysis, depression ($R=-0.126$,$p=0.002$) was a significant independent determinant of QoL perception, disease duration ($R=-0.104$, $p=0.001$) was a significant determinant of QoL in the psychological domain, and obesity ($R=-2.427$, $p=0.013$) and depression ($R=-0.244$, $p=0.008$) were significant in the physical QoL domain.
Conclusion: The quality of life of RA patients treated with biologics is moderate. The independent determinants of QoL are obesity, depression and disease duration. There is a need to introduce diagnostics recognizing mood disorders in order to implement individual remedial projects aimed at prevention and re-education of depression and improvement of QoL.

POS1513-HPR ASSESSMENT OF WORK CAPACITY AND PRODUCTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Fominykh[1]. [1]*Ural State Medical University, Internal Disease and Geriatrics, Yekaterinburg, Russian Federation*

Background: The main task of rheumatologists in the treatment of SLE was to reduce mortality and increase patient survival. At the same time, insufficient attention was paid to improving the quality of life, which includes getting an education, building a career and starting a family.
Objectives: Study the effect of SLE on the ability to work and productivity of patients.
Methods: 110 patients with SLE participated in a one-time anonymous survey conducted using Google Forms. A mean age of the patients included in the study was 32.8 ± 7.97 years. A mean duration of SLE was 4 years. 95.45% of patients received glucocorticoids as monotherapy or in combination with immunosuppressive medications: 63.64% hydroxychloroquine, 2.73% methotrexate, 10% azathioprine, 10% cyclosporine, 1.82% mycophenolate mofetil, and 6.36% biological therapy. Work capacity and labor productivity were assessed using the Work Productivity and Activity Improvement (WPAI) questionnaire.

Results: 110 respondents of working age took part, including 105 women (95.45%) and 5 men (4.55%). A mean age of the study participants was 32.8 ± 7.97 years, women were a mean age 32.6 ± 7.80, and men - 36.4 ± 11.44. The men surveyed have experience of SLE a mean experience of 6.8 ± 4.08 and women 6.4 ± 5.77. High activity disease was observed in 37 people (35.2%), and mild and moderate activity - in 73 (64.8%). 59 women (56%) and 2 men (40%) responded positively to the question about the availability of paid work. Ehe activity of the majority of working patients was associated with mental labor - 58 people (95%). Among the unemployed group of respondents, which made up 44.5% of the total number of survey participants, 76% of respondents associate the lack of paid work with the presence of SLE. Absenteeism was zero in 38 patients (62.3%), which indicates that more than half of the patients did not miss work during all the analyzed days. 6 out of 38 (15.8%) had a high activity disease. 5 people (8.2%) with paid work were absent from the workplace for the entire week under study (absenteeism 100%), of which 4 people had a high activity disease. A mean value of presenteeism in the group of actual workers during the study period was 50.45 ± 28.60% of working time. A mean value of absenteeism was 41.78 ± 36.73%. Work productivty loss in 61 patients with a job was 52.73 ± 30.55%. activity impairment, which was determined in all patients included in the study, was reduced by 51.68 ± 28.44%. In the course of our study, it was revealed that 44.5% of the surveyed patients with SLE of working age do not have a paid job. The absolute majority associate this fact with the influence of the disease on their ability to work. It is also important to say that 23 (37.7%) people out of 61 employees missed work due to their illness. Damage to the musculoskeletal system during the progression of SLE affects the ability to work, labor productivity and daily activity of the adult population is confirmed by the above indicators (presenteeism 50.45 ± 28.60%, absenteeism 41.78 ± 36.73%, work productivty loss 52.73 ± 30.55%, activity impairment 51.68 ± 28.44%).

Conclusion: Activity disease, functional insufficiency and damage developing as a result of the progression of SLE and ongoing therapy have a direct relationship with a decrease in labor productivity, disability and disability, which is confirmed by the values of presenteeism, absenteeism, work productivty loss and activity impairment.

POS1514-HPR UNDERSTANDING AND CHARACTERISING PATIENT PATHWAYS TO TREATMENT FOR VERTEBRAL FRACTURES: A QUALITATIVE STUDY

S. E. Bennett[1], R. Gooberman-Hill[1,2], E. Clark[1], Z. Paskins[3,4], N. Walsh[5], S. Drew[1]. *[1]University of Bristol, Bristol Medical School, Bristol, United Kingdom; [2]NIHR Bristol Biomedical Research Centre, Bristol, Bristol, United Kingdom; [3]Arthritis Research UK Primary Care Centre, Research Institute for Primary Care and Health Sciences, Keele University, Keele, United Kingdom; [4]Haywood Academic Rheumatology Centre, Midlands Partnership NHS Foundation Trust, Stoke-on-Trent, United Kingdom; [5]University of the West of England - UWE Bristol, Centre for Health and Clinical Research, Bristol, United Kingdom*

Background: Osteoporosis involves thinning of the bones, making them more prone to break. The most common osteoporotic fracture is a vertebral fracture (OVF). People with OVFs are at high risk of further fractures. To reduce this risk, guidelines recommend prescription of bone protection therapies to people who have experienced a fracture. However, many patients do not receive diagnosis. Understanding patient pathways to treatment for OVFs will provide information to improve practice and aid in effective identification and management.

Objectives: To understand and characterise patient pathways to treatment for OVFs.

Methods: Twenty-three semi-structured qualitative interviews were conducted with patients aged ≥50 years with diagnosis of OVF. Patients were recruited through two hospitals in England and were purposively sampled to capture variation in pathways to diagnosis, sex, age, comorbidities and other relevant characteristics. Interviews were audio-recorded, transcribed and analysed thematically, with themes transposed onto key stages of the patient pathway.

Results: Several factors influenced patient pathways to treatment: *Patient appraisal and self-management*: Characteristics and attitudes towards back pain impacted treatment-seeking behaviour. Patients who appraised their pain as 'different', severe or disruptive, or associated with an injury such as a fall, were more likely to seek help. Limited availability of information about OVFs and risk factors meant most patients did not associate symptoms with a potential OVF. Factors contributing to delayed consultation included the normalisation of back pain and prioritisation of comorbid conditions. Several misappraised their symptoms as a "pulled muscle" or other minor injury. Many adopted strategies to manage pain, including use of painkillers, lying flat or resting. For some, a lack of improvement in symptoms over time, combined with worsening pain, created a '*tipping point'* in seeking care. There was a moral dimension for some patients who did not want to "bother" healthcare professionals.

Healthcare professional appraisal: Differential diagnosis was a barrier to treatment and healthcare professionals interpreted OVF pain as broken ribs, muscular pain, kidney pain or sciatica. GPs tended to instigate watchful waiting, in which patients were asked to re-consult if pain did not improve. Feeling disbelieved caused some patients to become disillusioned and reluctant to re-consult and a small number of patients presented at Accident and Emergency. Those already having treatment for musculoskeletal conditions with access to specialist care, were more likely to receive timely diagnosis.

Communication of diagnosis: Patients discussed multiple methods of communication, including written communication and clinical conversations. Several expressed confusion around the use of unfamiliar medical terminology, the implications of OVFs, how many OVFs they had experienced and how they had been identified.

Treatment initiation: Bone protection therapies were not consistently prescribed after diagnosis. Patients who were familiar with these therapies were unsure whether treatment should be initiated in primary or secondary care. Patients described how they felt a need to be proactive by arranging appointments and asking for treatment.

Conclusion: The study provides novel findings about patient pathways to treatment and will be used to identify targeted solutions to improve management of OVFs. This work addresses stages of the Model of Pathways to Treatment[1] and provides detailed understanding of patients' experiences of these stages. Further work with healthcare professionals in primary care is underway to identify additional system-level factors that may impact patients' journeys to treatment.

POS1515-HPR CONJUGAL RELATIONSHIPS IN MARRIED PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISMS

O. Hamdi[1], S. Jemmali[1], S. Boussaid[1], S. Rahmouni[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]. *[1]La Rabta hospital, Rheumatology, Tunisia, Tunisia*

Background: The consequences of chronic inflammatory rheumatisms (CIR) on the sexuality and the relationships between the subject and his/her partner are still underestimated and insufficiently studied.

Objectives: The aim of this study was to investigate the impact of CIR on conjugal relationships.

Methods: We conducted a cross-sectional study involving patients with rheumatoid arthritis (RA) (2010 ACR/EULAR criteria) and spondyloarthritis (SpA) (2009 ASAS criteria). All the patients included in the study were married. We collected demographic data, and participants were asked to complete a questionnaire on their conjugal relationships.

Results: We enrolled 75 patients (40 RA and 35 SpA) with a sex ratio of 0.4 and a mean age of 55.35 ± 9.81 years [22-85]. The mean chronic CIR duration was 11.85 ± 3.4 years. The mean duration of marriage was 9.5 ± 2.6 years. The mean age at marriage was 27 ± 6.41 years [19-33]. The mean number of off-springs was 4. Forty-nine percent of patients and 22.3% of the partners had a profession, respectively. Forty one percent of the partners had a chronic disease: diabetes (n=12), hypertension (n=10), dyslipidemia (n=7), CIR (n=7), coronary disease (n=3), and other conditions (n=5). A psychiatric illness was noted in 22.6% of cases: depression (n=9), anxiety (n=6), and bipolar disorder (n=2). Sixty-four percent of patients consider their spouses sympathetic to their illness. Eighty-nine percent of participants have noticed a change in their life as a couple before and after the CIR onset. According to 64% of participants, the CIR had a negative impact on their married lives. The spouses' emotional reactions to the disease were as follows: indifference (30.6%), denial (29.3%), anger (26.6%), and fear (13.6%). Patients reported being accompanied by their spouses to their medical appointments in 36% of cases, and 40% of them were asked questions by their spouses about their disease and treatment. The CIR has resulted in the termination of the marriage in 2.6% of cases.

Conclusion: Patients suffering from chronic diseases such as CIR are more frequently exposed to difficulties in their conjugal relationships. The disease has thus important consequences on the subject's quality of life, emotional and interpersonal state. A better compliance with the chronic disease and its treatment may improve the couples' relationships.

DOI: 10.1136/annrheumdis-2022-eular.428

POS1516-HPR CHRONIC INFLAMMATORY RHEUMATISMS: DOES PERIODIC FASTING REDUCE THE DISEASE ACTIVITY?

O. Hamdi[1], S. Jemmali[1], W. Kammoun[2], S. Boussaid[1], S. Rahmouni[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta hospital, Rheumatology, Tunisia, Tunisia;* [2]*Pasteur Institute, Immunology, Tunis, Tunisia*

Background: Many experimental studies have emphasized the role of periodic fasting in the adaptive responses that reduce inflammation.
Objectives: Our purpose was to assess the impact of periodic fasting on the activity of chronic inflammatory rheumatisms (CIR).
Methods: We conducted a cross-sectional study involving patients with rheumatoid arthritis (RA) (2010 ACR/EULAR criteria) and spondyloarthritis (SpA) (2009 ASAS criteria). CIR activity was assessed during the period of Ramadan (periodic fasting) and three months following Ramadan using clinical parameters including the Patient's Global Assessment of disease activity (PGA), 10-cm Visual Analog Scale (VAS) pain score, morning stiffness, nocturnal awakenings, and joint count for RA (tender joint count (TJC) and swollen joint count (SJC)); biological parameters including C-reactive protein (CRP); disease activity scores including the SDAI, CDAI and $DAS_{28\ CRP}$ for RA, BASDAI and $ASDAS_{CRP}$ for SpA. An analysis of variance (ANOVA) was used to assess the statistical relationship between fasting and CIR activity.
Results: We enrolled 75 patients (40 RA and 35 SpA) with a sex ratio of 0.4 and a mean age of 55.35 ± 9.81 years [22-85]. The mean chronic CIR duration was 11.85 ± 3.4 years. RA was erosive in 92% of cases. Rheumatoid factor and anti-citrullinated peptides antibodies were positive respectively in 82% and 84% of cases. Seventy-five percent of RA patients were on corticosteroids with a mean dose of 10.20 mg/day of prednisone equivalent, and 81% of SpA patients were on non-steroidal anti-inflammatory drugs. Eighty-three percent of our patients were treated with conventional synthetic DMARD, and 40% with biological DMARD. The following parameters were lower in the month of Ramadan compared to the period following Ramadan in RA patients: mean PGA 4.3 vs 4.6 (p=0.01); mean morning stiffness 1.1 vs 1.5 (p=0.01); mean SJC 4.7 vs 8.5 (p=0.01); mean $DAS_{28\ CRP}$ 3.56 vs 4.25 (p= 0.05); mean CDAI 17.5 vs 20.35 (p= 0.01), and mean SDAI 13.87 vs 18.44 (p=0.01). As for SpA, the following parameters were lower in the month of Ramadan compared to the period following Ramadan: mean morning stiffness 1.3 vs 2.1 (p= 0.01); mean $ASDAS_{CRP}$ 2.9 vs 3.3 (p= 0.01), and mean BASDAI 3.6 vs 4.9 (p= 0.05). However, we found no statistically significant correlation between periodic fasting and VAS pain score, nocturnal awakenings, TJC, and CRP.
Conclusion: Our study concluded that periodic fasting was associated to a lower CIR activity. The incorporation of periodic fasting may promote optimal health and reduce the activity of some chronic inflammatory diseases.

POS1517-HPR PATIENT AND CLINICIAN PERSPECTIVES ON IMPLEMENTING THE RADAI-F5 TOOL TO HELP INFORM THE ASSESSMENT AND MANAGEMENT OF FOOT DISEASE IN RA: A QUALITATIVE STUDY

A. Hoque[1], D. Dickson[1], M. Steultjens[1], G. Hendry[1] on behalf of Glasgow Caledonian University MSK group. [1]*Glasgow Caledonian University, Podiatry, Glasgow, United Kingdom*

Background: While patient-reported outcome measures (PROMs) are widely recommended in clinical care, their application is limited [1]. The RADAI-F5 is a validated PROM to determine RA foot disease activity [2]. Patients' and clinicians' perceptions of the RADAI-F5's clinical utility have yet to be captured.
Objectives: This study aims to explore patient and clinician opinions and perceptions of the clinical utility of the RADAI- F5's in managing rheumatoid foot disease.
Methods: A 60-minute semi-structured interview using video conference calls with adult RA patients and rheumatologists, physiotherapists, and podiatrists was conducted as part of the interpretive phenomenological analysis research. The interviews included open-ended questions about the effect of foot disease, current clinical utilization of PROMS, and barriers and facilitators to the clinical application of the RADAI-F5. Inductive thematic data analysis with Nvivo12 identified emerging themes.
Results: Eight participants with rheumatoid arthritis: seven females; mean [standard deviation, SD] age 52.4 [9.5] years; mean [SD] disease duration 16.1 [16.4] years; eight clinicians; mean [SD] age 46.75 [5.3] years; mean [SD] years of clinical experience 19.5 [2.21] years. Four main themes were identified (Table 1); 'Feet are a priority' as the impact of RA on the feet was substantial and had a negative impact on quality of life. The second theme was 'Need for a clinically feasible foot PROM' as clinicians and patients recognised the lack of a clinically feasible tool that can determine RA foot disease. The third emerging theme was 'RADAI-F5 facilitators' as the tool can promote communication, guide management, help screen foot symptoms, monitor foot disease status and treatments longitudinally, and promote patient education. The final theme was 'RADAI-F5 barriers' as there were associated practical difficulties, including lack of appointment time, administrative burdens associated with PROM use, lack of trust in the RADAI-F5's validity and IT barriers since there is no universal electronic system for reporting RADAI-F5 results.

Table 1. Themes with respective quotes that emerged as part of the individual interviews to understand the clinical utility of the RADAI-F5

Theme	Quotations
Theme 1: Feet are important	*"Foot disease is common and it's troublesome for patients" (C16)* *"I couldn't see my friends because I was always so tired and in pain. It is very lonely." (P07)*
Theme 2: Existing methods for measuring foot disease activity are inadequate	*"The feet are under-represented in the clinical tools for assessing disease activity, and clinicians don't look at feet enough." (C11)* *"We've tried numerous PROMS. Historically, I think probably it's time-consuming for our clinical consultation". (C12)*
Theme 3: RADAI-F5 facilitators	*"I think [The RADAI-F5] improves the clinician-patient relationship" (C15)* *"Using the RADAI-F5 could measure the success of the treatments that we are implicating." (C12)*
Theme 4: RADAI-F5 barriers	*"I mean, this (RADAI-F5) will obviously go along with other tools. You know, the blood tests and things as well." (P01)*

Conclusion: The RADAI-F5 has significant potential as a therapeutic tool to aid in managing foot disease in RA. However, several implementation barriers need to be overcome before widespread use in rheumatology clinics can occur.

POS1518-HPR BELIEFS ABOUT MEDICATION IN A POPULATION OF PATIENTS WITH INFLAMMATORY ARTHROPATHY

A. M. Gomes Correia[1], C. Campinho Ferreira[1], E. Costa[1], D. Esperança Almeida[1], J. Silva[1], J. Neves[1], A. R. Ribeiro[1], M. Cerqueira[1]. [1]*Hospital de Braga, Rheumatology, Braga, Portugal*

Background: The beliefs that patients have regarding their medication, namely about its need and concerns regarding possible adverse effects, are a determining factor for adherence and therapeutic success[1].
Objectives: Determine which sociodemographic and clinical factors are associated with beliefs related to medication, either in terms of necessity or concerns about medication, in patients with Rheumatoid Arthritis (RA) or Psoriatic Arthritis (PsA).
Methods: Observational study, with a sample consisting of 58 patients (female 72,4%, male 27,6%; mean age = 51,0 ± 13,2 years; education < 9 years 39,7%, ≥ 9 years 60,3%). Of these, 33 had a diagnosis of RA and 25 of PsA (mean years of disease duration = 8,2 ± 7,3 years; mean disease activity by DAS28-PCR or DAS28-PCR 3 variables = 2,32 ± 0,95). Between March 2021 and June 2021, a brief questionnaire was applied with sociodemographic and clinical variables, such as the use of classic or biological DMARDs and their administration´s route. The Specific Beliefs About Medication Scale (BMQ) was anonymously applied, adapted from the Beliefs About Medicines Questionnaire, comprising 2 sections: section 1 – Specific Needs, patients beliefs about the need for medication;

section 2 – Specific Concerns, beliefs related to the dangers of addiction and long-term toxicity or side effects. Higher scores (scale from 5 to 25 points), in sections 1 and 2, reflect the belief of greater need and greater concern regarding medication, respectively. The average scores in section 1 and in section 2 of the BMQ were 9 and 15,7 points, respectively. Statistics: descriptive, Student t-Test, Pearson Correlation and ANOVA, p<0,05.

Results: Patients with PsA and younger age had a higher mean score in section 2 of the BMQ (p= 0,049 e p<0,01, respectively). The variables male gender, education ≥ 9 years and shorter duration of the disease also showed a tendency to be associated with the higher score in section 2 of the BMQ, with p-values close to statistical significance (p=0,091, p=0,074 and p=0,094, respectively). In the multivariate analysis with the above variables, only the diagnosis of PsA showed a statistically significant association with the score in section 2 of the BMQ (B=4,269; p<0,001; CI 95%=[2,060-6,477]). There was also a statistically significant correlation (p=0,007) between the scores in section 1 and section 2 of the BMQ. Regarding analysis of the sample by diagnosis, there was an association between the subcutaneous route of drug administration in individuals with RA and greater concern with the adverse effects of the medication (p=0,007), and between low disease activity and greater belief in the specific need for medication for the disease (p=0,006).

Conclusion: In this study, patients with PsA were more concerned about the possible adverse effects of medication than patients with RA. RA patients who take subcutaneous drugs are more afraid of the drug's toxic potential, and those with lower disease activity have a greater need to comply with the prescribed therapy, which can be explained by the previous effectiveness of the drug in disease control. It was also found that the greater the belief in the need for medication, the greater the concern with its possible long-term harmful effects.

POS1519-HPR IMPACT OF SYSTEMIC LUPUS ERYTHEMATOSUS ON FOOT FUNCTION, PAIN, AND ASSOCIATED DISABILITY.

L. Cano Garcia[1], J. Marco-Lledó[2], N. Al Mashhadani[1], A. M. Cabezas-Lucena[1], M. Morales-Águila[1], J. García-Campos[2]. *[1]Instituto de Investigación Biomédica de Málaga (IBIMA); Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain; [2]Universidad Miguel Hernández; Instituto de Investigación Sanitaria y Biomédica de Alicante, Ciencias del Comportamiento y Salud, Alicante, Spain*

Background: Systemic lupus erythematosus (SLE) is an inflammatory pathology of autoimmune origin with high morbidity and a great impact on daily life. Hindfoot pain is often an area of the musculoskeletal system that is severely affected and causes walking difficulties. The alterations in the structure and posture of the foot can contribute to altered gait patterns in people with SLE, reducing health-related quality of life.

Objectives: This work's objective was to know the impact of SLE on pain, disability, activity limitation, foot function in activities of daily living and life quality.

Methods: The study of the population included people with SLE. A cross-sectional observational study was carried out. 47 subjects with a diagnosis of SLE recruited in a Rheumatology Unit between March and May 2021 were included. The inclusion criteria were: patients with a diagnosis of SLE according to the EULAR / ACR 2019 criteria11, and a diagnosis of at least one year of evolution and age equal to or greater than 18 years. Sociodemographic, clinical and therapeutic data were collected. Cumulative damage was measured using the Systemic Lupus International Collaborating Clinics Damage Index (SLICC) and disease activity using the Systemic Lupus Erythematosus Disease Activity Measure (SLEDAI). Pain, disability and activity limitation were assessed using the Foot Function Index (FFI) scale where higher scores indicate greater pain, disability, and activity limitation and therefore poorer foot health. Pain nowadays was also measured using the Visual Analog Pain Scale (EVAD), foot function was assessed using the Foot and Ankle Ability Measures (FAAM) scale for activities of daily living (FAAM-ADL) and for physical activity (FAAM-S) where higher scores indicate higher levels of function, and perceived health-related quality of life was evaluated through the EUROQoL-5D scale where higher scores indicates poorer quality of life.

Results: 47 subjects participated (93.6% women) with a mean age (SD) of 49.2 (10.8) years (range 23-66). The mean (SD) SLICC and SLEDAI scores were 0.74 (1.33) and 1.17 (1.80), respectively. Mean foot pain was 4.38 (SD 2.97) on a VAS of 10 at the current time. The mean overall score (SD) on the FFI was 37.08 (26.41). The FAAM score on the ADL subscale was 0.64 (0.234). Of a total of 31 subjects who reported that they practiced some type of physical activity, the mean score (SD) on the Sport subscale of the FAAM was 0.51 (0.30). Regarding the quality of life measured through the EQ5D, a mean score (SD) of 0.56 (0.25) was obtained. In addition, a mean score (SD) of 63.76 (23.40) was obtained on the EVAEQ5D. A significant association was only obtained between SLICC and the overall value of the FFI (r = 0.305; p = 0.037), where the less accumulated damage, the less impact of foot problems on pain, disability and activity limitation. There was no significant correlation between the SLEDAI and the FFI, FAAM and ED5D.

Conclusion: The foot's function is moderately affected and a third of the patients evaluated are unable to carry out any physical activity, despite having low activity of the disease measured by SLEDAI. Furthermore, we found a direct correlation of the damage measured by SLICC-DI with problems of pain, disability and limitation in activity related with the foot.

POS1520-HPR RHEUMATOLOGY PATIENTS TREATED WITH A BDMARD PERSPECTIVE TOWARDS THERAPEUTIC DRUG MONITORING

M. Leeuw[1], S. Atiqi[1], F. De Vries[2], L. Boekel[1], F. Hooijberg[1], M. Nurmohamed[1,3], G. J. Wolbink[1,4,5], C. Krieckaert[1]. *[1]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology, Amsterdam, Netherlands; [2]OLVG, Location East, Pharmacology, Amsterdam, Netherlands; [3]Amsterdam UMC, Locatie VUmc, Rheumatology, Amsterdam, Netherlands; [4]Sanquin Blood Supply, Immunopathology, Amsterdam, Netherlands; [5]OLVG, Location East, Rheumatology, Amsterdam, Netherlands*

Background: Therapeutic Drug Monitoring (TDM) is a tool to determine the optimal dose of a drug for individual patients using measurement of blood concentrations and, optionally, anti-drug antibodies (ADA). In the field of rheumatology interest in applying TDM is increasing. A recent study by *Syversen et al.,* the NOR-DRUM B trail, supports TDM as a treatment strategy. This study showed that treatment with proactive TDM was more effective then treatment without TDM. Applying TDM creates a more personalized treatment for individual patients, therefore it is relevant to understand the patients perspective towards TDM.

Objectives: To study the perspective of rheumatology patients treated with a bDMARD in a personalized fashion using TDM.

Methods: Adult rheumatology patients from the Amsterdam Rheumatology and immunology Center who participate in the COVID-19 prospective cohort study (Nederlands Trial Register, trial ID NL8513) received a digital questionnaire which comprised, in addition to demographic items, of three TDM topics: familiarity, attitude and risk assessment.

Results: Participants were selected based on the following criteria: treatment with a bDMARD and a fully completed questionnaire (n=888). Table 1 shows characteristics of study population.

Table 1. Characteristics of study population

	Total N= 888	
Age, yr Mean (SD)	55	(13)
Gender, female - N (%)	575	(65)
Diagnosis* - N (%)		
RA	511	(58)
PSA	172	(19)
AS	203	(23)
Axial and peripheral SpA	21	(3)
Other	17	(2)
bDMARD** - N (%)		
Adalimumab	242	(27)
Etanercept	352	(40)
Other	297	(33)

* Some patients reported more than one diagnosis** Three patients reported more than one bDMARD

Sixty-six percent (n=582) of the participants had never heard of the concept 'personalized dosing, using TDM'. After explaining the concept 60% (n=535) of the participants answered they have a positive attitude towards the concept (Figure 1). Participants with a positive attitude received a follow-up question. They were asked which of the following related aspects: individual dosing, costs, safety and other, they thought was most relevant regarding the concept. Multiple answers were possible. Ninety-four percent (n=502) reported as the main reason for having a positive attitude, that the treatment can be personally adjusted. The second and third reasons, respectively, were safety 43% (n=230) and costs 27% (n=142) of the treatment.

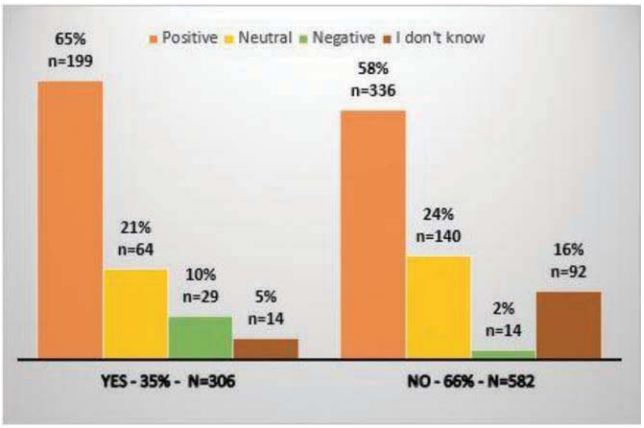

Figure 1. ***Attitude towards concept of TDM against being familiar with concept of TDM***

Five percent (n=43) of the participants had a negative attitude towards the concept. Main reasons were; previous experience with unsuccessful dose reduction and unwillingness to change current treatment due to the fact that several previous treatments were ineffective. Participants were also asked what amount of risk they are willing to take when presented with five different situations; worsening rheumatologically symptoms: e.g. pain and swelling, increased fatigability, necessary treatment with prednisone, switching to another bDMARD or more frequent visits to rheumatologist. Majority of the patients reported for each of the five situations, respectively: 37% (n=330), 40% (n=359), 51% (n=453), 48% (n= 426) and 29% (n=262) that they would only be willing to take a negligible risk, < 0.1%.

Conclusion: Majority of participants was not familiar with the concept of personalized dosing using TDM. However, the majority had a positive attitude towards the concept. The main reason for a positive attitude is that the treatment can be personally adjusted. On the other hand, patients who are currently being treated with a bDMARD were only willing to take a negligible risk when it comes to their own treatment.

POS1521-HPR

UNDERSTANDING AND IDENTIFYING KEY CONTEXTUAL FACTORS THAT INFLUENCE THE PRACTITIONER-PATIENT ENCOUNTER IN THE MANAGEMENT OF OSTEOARTHRITIS: A QUALITATIVE SYSTEMATIC REVIEW

A. Ismail[1,2], C. Evans[3,4], K. Yaseen[2,3], M. Hall[3], M. Doherty[1,5,6], W. Zhang[1,5,6].
[1]University of Nottingham, School of Medicine, Division of Rheumatology, Orthopaedics and Dermatology, Nottingham, United Kingdom; [2]King Abdulaziz University, Faculty of Medical Rehabilitation Sciences, Jeddah, Saudi Arabia; [3]University of Nottingham, Health Sciences, Nottingham, United Kingdom; [4]The Nottingham Centre for Evidence Based Healthcare: A JBI Centre of Excellence, Health Sciences, Nottingham, United Kingdom; [5]University of Nottingham, Arthritis Research UK Pain Centre, Nottingham, United Kingdom; [6]National Institute for Health Research, Nottingham Biomedical Research Centre, Nottingham, United Kingdom

Background: Contextual factors (CFs) related to the patient, healthcare practitioners, and their therapeutic relationship are integral to the overall treatment effect of any given intervention (1). In osteoarthritis (OA), around 75% of the treatment effect is directly attributable to CFs (2). Identifying and understanding the role of CFs may encourage healthcare practitioners to develop and enhance the contextual aspects of care.

Objectives: To explore and understand the experience and perspectives of patients and health practitioners regarding CFs in consultations for OA.

Methods: A systematic search was conducted between March 15 and May 18, 2020, on the following databases: MEDLINE via Ovid, EMBASE, AMED, PsycINFO and CINAHL. The search for unpublished studies included ProQuest Dissertations and Google Scholar. The search was not limited to any language or publication year. The Joanna Briggs Institute (JBI) methodology for quality assessment, study selection, data extraction and synthesis were used. Findings were assessed for credibility, categorised based on similarity in meaning and subjected to a meta-aggregation. The ConQual approach was used to assess the confidence of the synthesised findings (3).

Results: Of 1808 records generated from the systematic search of databases and grey literature, eight studies were included in the meta-aggregation (Figure 1). All included papers were moderate to high quality based on the JBI qualitative critical appraisal tool. Meta-aggregation generated three synthesised findings. According to the ConQual criteria, all the synthesised findings' level of evidence was rated as moderate (Table 1). The key, potentially modifiable, factors identified were positive communication; clear and relevant information provided by the health practitioner; patient expectation concerning their outcome and the consultation experience; sufficient consultation time; and easy access to consultations.

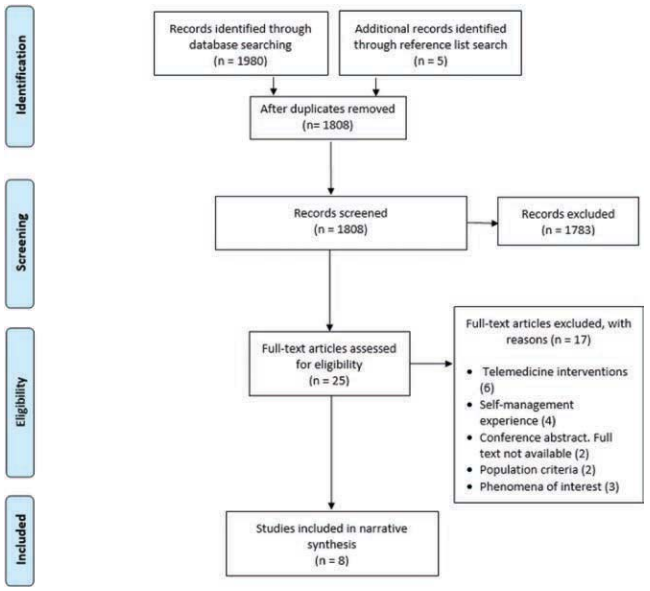

Figure 1. PRISMA flowchart of the study selection and inclusion process

Table 1. ConQual summary of findings

Synthesized finding	Type of research	Dependability	Credibility	ConQual score
I. People with OA will likely experience comprehensive and satisfactory management of their condition if the key contextual enhancers are implemented.	Qualitative	Unchanged*	Downgrade 1 level**	Moderate
II. Health providers acknowledged that information provision and efficient communication skills are likely to enhance management during consultations for OA.	Qualitative	Unchanged*	Downgrade 1 level**	Moderate
III. Effective consultations are affected by an intersection of organizational challenges and patient and provider characteristics. Limited experience with OA of some practitioners, unrealistic patients' expectations, and short consultation duration are barriers that need to be adjusted for better management.	Qualitative	Unchanged*	Downgrade 1 level**	Moderate

* The average score was (4/5) for dependability.** Downgraded one level due to a mix of unequivocal and credible findings.

Conclusion: This qualitative systematic review has defined three synthesized findings. Identification of modifiable CFs that are deemed important by both patients and health practitioners can inform the development of a training package for healthcare professional.

POS1522-HPR COMPARISON OF EDUCATIONAL NEEDS AMONG PATIENTS WITH ANCA ASSOCIATED VASCULITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS – A PILOT STUDY USING THE EDUCATIONAL NEEDS ASSESSMENT TOOL.

S. Brolin[1,2], E. Svenungsson[1,2], I. Gunnarsson[1,2], S. Pettersson[1,2]. [1]*Karolinska University Hospital, Department of Rheumatology, Stockholm, Sweden;* [2]*Karolinska Institute, Medicine, Stockholm, Sweden*

Background: Patients with chronic disease need to learn and adapt to symptoms, treatment, and the impact of disease. Knowledge about the specific disease is one way to empower the patients to cope. We previously reported that disease duration and sex, rather than disease characteristics associate with an increased need of educational support in ANCA associated vasculitis (AAV) (1). Data on how specific educational needs vary between different inflammatory rheumatic diseases are lacking.
Objectives: The aim of the study was to compare educational needs among two chronic systemic inflammatory diseases, AAV and Systemic lupus erythematosus (SLE) using the Educational Needs Assessment Tool (ENAT).
Methods: This pilot study included cross-sectional data from two separate cohorts, AVV and SLE, from the Rheumatology clinic at Karolinska University Hospital in Sweden during 2009-2022. Inclusion criteria were minimum age of 18 years and literate in Swedish. Exclusion criterion was cognitive impairment interfering with literate capabilities. Educational needs were captured by patients' answers to the questionnaire ENAT. The ENAT consists of 39 questions, presented as total ENAT and seven domains (managing pain, movement, feelings, disease process, treatment, self-management and, support systems) each containing 4-7 items (from 'not at all important' = 0, to 'extremely important' = 3). The participants' responses were presented as "mean % of the domain score", from 0 interpreted as no educational need to 100 as highest educational need. Participants with AAV and SLE respectively were individually matched for disease duration, sex, and education. For comparisons paired samples t-test were used.
Results: Twenty-two matched pairs (86% female), mean (SD) disease duration 5.7 (8) years, were included. The mean age were 43 (14.0) years for AAV 61 and (14.7) years for SLE (p=0.001). Educational length was reported as mean 14 (3.6) years among SLE patients and 13 (2.9) years among AAV patients (p=0.111).
In all patients, the mean total ENAT was 60.4% (range 23-100%) and did not differ between the two cohorts (p=0.2) (Table 1). In the pooled group the highest educational need was found in the domains 'Disease process' (mean 78.3%) and 'Self-management' (mean 75.9%). Lowest educational need was found in the domains 'Movement' (mean 46.7%) and 'Managing pain' (mean 51.6%).

Table 1. Comparison of ENAT scores (mean % of max) (SD) between patient with SLE and AAV

ENAT domain	All *n=44*	SLE *n=22*	AAV *n=22*	p
Managing pain	51.6 (29.8)	50.8 (28.7)	52.4 (32.2)	0.867
Movement	46.7 (35.1)	41.9 (34.2)	49.2 (35.7)	0.500
Feelings	63.1 (31.0)	54.6 (30.6)	70.4 (30.3)	0.087
Disease process	78.3 (22.1)	73.9 (23.0)	83.4 (20.9)	0.130
Treatments	60.7 (35.1)	46.4 (36.0)	74.2 (30.4)	**0.021**
Self-management	75.9 (21.1)	75.8 (18.8)	76.9 (24.3)	0.886
Support systems	54.0 (30.2)	49.2 (31.4)	58.7 (28.8)	0.302
Total ENAT	60.4 (24.0)	55.7 (22.8)	65.0 (24.8)	0.216

Patients with AAV report a higher educational need in total ENAT as well as in all individual domains, compared to SLE (Table 1), but only significantly in the domain 'Treatments' where the educational need among AAV was mean 74.2% (30.4) and for SLE mean 46.4% (SD 36.0) (p = 0.02).
Conclusion: In this pilot study with SLE and AAV, we found educational needs regarding 'Treatments' to be substantially increased among the participants with AAV, compared to SLE, despite that the participants were matched for disease duration and sex, two variables previously found to be indicators of increased educational needs. AAV patients with higher educational needs were older, this result needs to be further explored in a larger sample.

POS1523-HPR PATIENT SATISFACTION SURVEY OF A SPECIALIST PHARMACIST RUN RHEUMATOLOGY BIOLOGIC AND JAK INHIBITOR CLINIC

C. Jones[1], J. Trickey[1]. [1]*Wye Valley NHS Trust, Rheumatology, Hereford, United Kingdom*

Background: Hereford Rheumatology Department, UK, treats over 850 patients on biologic disease-modifying anti-rheumatic drugs (bDMARDs) and JAK inhibitors (JAKi). The multidisciplinary team (MDT) includes a Specialist Rheumatology Pharmacist running clinics for all adult Rheumatology patients who have been identified for bDMARD or JAKi initiation or switch by their responsible Consultant. Patients can feel anxious during the pre-treatment screening process and require reassurance about medication safety. This innovative role has been a well-received asset to the Rheumatology MDT, but patients' perceptions of the role are unknown. To our knowledge, there is no similar study within British Rheumatology practice.
Objectives: The survey aims to gauge patient satisfaction of the consultation from a pharmacist-run bDMARD and JAKi initiation and switch clinic.
Methods: A generic patient satisfaction survey was piloted with positive results. Following this, a bespoke survey was developed, specifically enquiring about patients' perceptions of the consultation skills, clarity, education and reassurance provided by the pharmacist. A Likert scale was used where appropriate and a space for free text was included. The Trust's Patient Experience Team was consulted to ensure clarity for patients. In consecutive weekly clinics from July 2021 to January 2022, the survey was given to all patients immediately following Specialist Rheumatology Pharmacist clinic. The majority of patients were seen face-to-face however the survey was posted to the patient if telephone consultation was necessary. Clinic staff collected the completed surveys to ensure patient anonymity.
Results: 57 of 58 patients completed the survey, with 100% stating they were pleased to receive counselling from a pharmacist. Patients were asked to score their knowledge of the medication out of 10, before and after the consultation; they reported a mean increase in knowledge of 3.9/10. The remaining survey results show mostly positive feedback (Table 1).

Table 1. Patient rating of experience in pharmacist clinic.

Statement	No answer	Strongly disagree	Disagree	Neither	Agree	Strongly agree
The pharmacist put me at ease	0	0	0	0	**11**	**46**
The information provided was easy for me to understand.	**1**	0	0	**1**	**13**	**42**
The pharmacist listened to what I had to say.	0	0	0	0	**9**	**48**
The pharmacist showed care and sensitivity to my Rheumatological condition.	0	0	0	0	**11**	**46**
The pharmacist appeared knowledgeable about the medication to be started.	0	0	0	0	**8**	**49**
I feel that the medication I am starting has been chosen for me as an individual.	**1**	0	0	**1**	**17**	**38**
I understand why we are starting the new medication.	0	0	0	**2**	**10**	**45**
I have been told about the side effects the medication could cause.	0	0	0	0	**11**	**46**
I feel that it is safe to start the new medication.	**1**	0	**1**	**6**	**15**	**34**
I was able to discuss my concerns and ask questions about the new medication.	0	0	0	0	**11**	**46**
I felt included in the decision to start or change to new medication.	**1**	0	0	**2**	**11**	**43**
Overall, my experience in the pharmacist clinic today was a positive one*	**4**	0	0	0	**10**	**43**

*Statement excludes results from 4 patients who did not complete the second page of the survey.

Conclusion: The results demonstrate the high level of patient satisfaction attained from the Specialist Pharmacist clinic. A small number of patients remain sceptical about medication safety, despite discussion. Inclusion of a pharmacist is especially useful to manage the increasing number of patients starting these medications, maintaining excellent patient experience, reducing the workload for other Rheumatology staff, and ensuring a robust MDT.

POS1524-HPR HPR 2020 GRANT. AWARENESS OF NON-PHARMACOLOGICAL AND NON-SURGICAL TREATMENTS FOR OSTEOARTHRITIS: A SURVEY OF PEOPLE WITH OSTEOARTHRITIS IN SWEDEN.

S. Battista[1,2], A. Dell'isola[2], P. Pchelnikova[3], M. Ndosi[4], M. Englund[2], M. Manoni[1], M. Testa[1]. [1]*University of Genova, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Savona, Italy;* [2]*Lund University, Clinical Epidemiology Unit, Orthopedics, Department of Clinical Sciences Lund, Lund, Sweden;* [3]*European Alliance of Associations for Rheumatology, Standing Committee of People with Arthritis/Rheumatism in Europe (PARE), Zurich, Switzerland;* [4]*University of the West of England, School of Health and Social Wellbeing, Bristol, United Kingdom*

Background: International clinical practice guidelines for the management of osteoarthritis (OA)[1 2] recommend exercise, education and diet as first-line interventions since they are safe, low cost and reported to be effective, in reducing OA pain and disability, regardless of the severity of the disease. However, these treatments require high levels of adherence, which may be difficult to achieve. One of the possible reasons that can jeopardise patients' adherence with first-line interventions for OA is the lack of awareness of the role that these treatments play in their care.

Objectives: To investigate the level of awareness of non-pharmacological and non-surgical treatments for hip and knee OA in a cohort of people with this disease in Sweden.

Methods: A cross-sectional, online survey-based study was conducted in Sweden. People with diagnosed knee or hip OA were recruited through social media outlets and patients' associations. The survey was divided into two sections: (i) participants' demographic and clinical characteristics (e.g. gender, age, income, work, height, weight, level of physical activity, previous surgeries, pain, level of disability) and (ii) a set of items with 22 treatments (e.g., weight advice, physical activity, drugs, supplements etc) where participants were asked to report whether each treatment was 'recommended', 'optional', 'not recommended', or 'I don't know' - for the management of knee or hip OA. In the analyses, we grouped the 22 proposed treatments into 'recommended', 'optional', and 'not recommended' according to existing international guidelines.[1 2] Based on the responses, participants were categorised as "aware" if they correctly identified all the treatments, "partially aware" if they correctly identified at least one treatment, and "not aware" if they did not correctly identify any of the treatments.

Results: Participants comprised 123 people with OA of the knee, hip or both (N=65, 22%; N=27, 22% and N= 33, 26% respectively). Their mean (SD) age was 60.3 (8.8) and 108 (88%) were women. Forty-eight (39%) were "aware" of the recommended treatments, 63 (50%) "partially aware" and 14 (11%) were "not aware". Regarding the optional treatments, 2 (2%) were "aware", 103 (82%) "partially aware" and 20 (16%) were "not aware". For the treatments that were not-recommended, none was "aware", while 69 (55%) and 56 (45%) were considered "partially aware" and "not aware", respectively. Figure 1 summarises the responses of the participants to each treatment item.

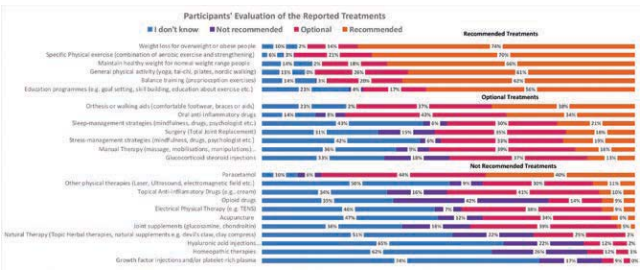

Figure 1. Participants' responses to each treatment

Conclusion: Survey participants seem to be more aware of the recommended treatments than the optional and not-recommended ones. A more holistic approach in the education of people with OA should be pursued, providing them with a complete overview of the possible OA treatments. This would help patients identify the most appropriate treatment option for their OA and facilitate a shared decision-making with their health professionals.

POS1525-HPR BODY SELF-ESTEEM AND SEXUAL FUNCTION IN IMMUNE-MEDIATED INFLAMMATORY DISEASES

C. Heredia Coca[1], L. Castiblanco[2], C. Aragón-Benedí[3], P. Oliver-Forniés[4], J. M. Martín Martín[5], L. Leon Mateos[1,6]. [1]*Camilo Jose Cela University, Department of Psychology, Madrid, Spain;* [2]*Universidad Autónoma de Madrid, Department of Psychology, Madrid, Spain;* [3]*San Jorge General University Hospital, Department of Anesthesiology, Huesca, Spain;* [4]*Mostoles General University Hospital, Department of Anesthesiology, Madrid, Spain;* [5]*Nuestra Señora de la Candelaria University Hospital, Department of Nursing, Tenerife, Spain;* [6]*Hospital Clinico San Carlos, Rheumatology and IdISSC, Madrid, Spain*

Background: The Immune-Mediated Inflammatory Diseases (IMID) are a group of pathologies that have in common an altered immune system causing a chronic inflammatory process. IMIDs usually have a significant impairment of quality of life, including affective and sexual components.

Objectives: To describe body self-esteem and sexual function in patients with IMIDs. Secondly, to compare outcomes between rheumatic IMIDs patients and those with other IMIDs.

Methods: A cross-sectional comparative study was performed including 38 patients with rheumatic IMIDs (including rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis), compared to 34 patients with other IMIDs (psoriasis and inflammatory bowel disease). All participants fulfilled the Body Self-Esteem Scale (EAC) to measure body self-esteem, and also the International Index of Erectile Function (IIEF-15) for men, and the Female Sexual Function Index (FSFI) for women.

Results: The prevalence of sexual dysfunction in our study was 66.7%. A trend of greater impairment in sexual function was observed in women. There was a higher percentage of sexual dysfunction in the gastrointestinal IMIDs group (79.2%), compared to rheumatic diseases (60.5%) and dermatological diseases (60%), but no significant differences were found regarding the sexual dysfunction between groups ($\chi^2 = 2.53$, $p = 0.28$). Our results showed a significant inverse relationship between body self-esteem and sexual function ($p = 0.012$), i.e., the lower the body self-esteem, the higher the probability of presenting sexual dysfunction.

Conclusion: Sexual function was impaired in all IMIDs. Body self-esteem problems were an important factor of sexual dysfunction in IMIDs. Healthcare professionals should be aware of these potential problems, promote self-care, and address sexual issues.

POS1526-HPR WHICH FACTORS INFLUENCE PATIENTS' PREFERENCES FOR TELEHEALTH APPLICATIONS IN RHEUMATIC DISEASES? A QUALITATIVE STUDY

L. Haegens[1], J. Van der Ven[1], V. Huiskes[2], C. Bekker[3], B. Van den Bemt[2,3]. [1]*Sint Maartenskliniek, Department of Research, Ubbergen, Netherlands;* [2]*Sint Maartenskliniek, Department of Pharmacy, Ubbergen, Netherlands;* [3]*Radboud University Medical Center, Department of Pharmacy, Nijmegen, Netherlands*

Background: Telehealth has the potential to improve patients' health outcomes and patient empowerment by increasing access to care and medical information.[1,2] As patients with rheumatic diseases are known to experience drug-related

problems at various moments along their patient journey,[3] this population can benefit from more continuous information about their medication and healthcare provider support to manage drug-related problems. To most effectively employ telehealth for this purpose, it is important that offered technologies match with patients' needs and preferences.

Objectives: Identify factors influencing the preference of patients with rheumatic diseases regarding telehealth applications.

Methods: A qualitative descriptive study was performed in the Netherlands between May and June 2021. Using a semi-structured interview guide, patients with a rheumatic disease were interviewed face-to-face. First, patients were presented four telehealth applications (frequently asked questions page, digital human, and chatting and video calling with healthcare providers). Second, patients were asked to use each application to answer one medication-related question predefined by the research team. During the process of finding an answer to the question, patients were asked to think aloud and were questioned on which factors influenced their experience and preference for each application. Third, patients were given additional hypothetical questions after which they were asked to explain their preferred application for answering the question, to elicit additional factors influencing preference. Interviews were audio recorded, transcribed verbatim and analysed thematically.

Results: Fifteen patients (aged 19 – 73 years, 53% female) participated. Three domains influenced patients' preference for telehealth applications. First, preference for telehealth applications was influenced by *factors related to individual patients* such as medication-related information needs, literacy, and skills with digital applications. Second, preference was influenced by *factors related to the specific applications* such as speed of answer, level of interaction, extent of privacy, the perceived usefulness of an application, and usability of the application. Third, preference was influenced by *factors related to the context* in which telehealth applications are offered, such as the support from healthcare providers in using telehealth applications, reliability of information source, and potential of telehealth to save time for healthcare providers.

Conclusion: Patients' preference for telehealth applications is influenced by patient-related, application-related and context-related factors. To effectively support patients with rheumatic diseases, telehealth applications should match with these patients' preferences. Furthermore, it is important to offer a variety of telehealth applications as preferences differ among patients and circumstances.

POS1527-HPR HEALTH PROMOTION IN INDIVIDUALS WITH KNEE PAIN – DIFFERENT WAYS TO ENABLE AND MAINTAIN A BALANCE IN EVERYDAY LIFE BASED ON THE ABILITIES

C. Sylwander[1,2], M. Andersson[1,3], E. Haglund[1,3,4], E. Sunesson[1], I. Larsson[1,2,3]. *[1]Spenshult Research and Development Centre, Halmstad, Sweden; [2]Halmstad University, School of Health and Welfare, Halmstad, Sweden; [3]Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden; [4]Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden*

Background: Most individuals with knee pain develop radiographic knee osteoarthritis over time [1], and up to 30% develop chronic widespread pain (CWP) [2]. Many studies only focus on physical activity or weight loss when it comes to managing knee osteoarthritis (KOA) and chronic pain. There is a challenge to get more individuals to follow the existing recommendations for KOA, including physical activity and weight loss [3]. However, the interaction between the various physical, mental, and social factors regarding health promotion is complex. More research is needed to understand health-promoting activities applied amongst individuals with knee pain.

Objectives: To explore health-promoting activities in individuals with knee pain.

Methods: The study was a part of the Halland Osteoarthritis cohort (ClinicalTrials.gov NCT04928170), including 306 individuals with knee pain without earlier diagnosed KOA, cruciate ligament injury or other rheumatological disorder. A purposeful sample of 22 individuals (13 women, 9 men; median age 52 years) participated in the study. Ten had radiographic KOA, 12 had chronic regional pain, 9 reported CWP, 16 were overweight, and 13 met the WHO recommendations for physical activity with moderate intensity. Semi-structured interviews were conducted and followed a pilot-tested interview guide initiated with open-ended questions such as "What do you do to maintain your health?" and "What enables you to keep health?". The interviewers followed the participants reasoning, and to obtain depth in the data, the participant received follow-up questions such as "Please, can you tell me more about…?". The interviews were audio-recorded and transcribed verbatim. Data analysis was performed by latent qualitative content analysis and revealed an overall theme including two categories and six sub-categories.

Results: Health-promoting activities in individuals with knee pain were interpreted in the overall theme; *enabling and maintaining a balance in everyday life based on abilities*. Two categories explored the content in health-promoting activities as 1) *Using facilitators to take care of the body* with the sub-categories: being physically active, having a healthy diet, and using external resources. For example, the participants took care of the body by being physically active to decrease pain, reducing sugar intake and using external resources such as online workouts or help from health care. 2) *Managing stressors of everyday life* with the sub-categories: promoting vitality, allowing for recovery, and safeguarding healthy relationships. The participants managed stressors of life by, for example, being in nature, planning their work- and private life and spending time with friends and family. See Table 1.

Table 1. Overview of the results exploring health-promotion activities in individuals with knee pain.

Theme	**Enabling and maintaining a balance in everyday life based on abilities**					
Category	**Using facilitators to take care of the body**			**Managing stressors of everyday life**		
Sub-categories	Being physically active	Having a healthy diet	Using external resources	Promoting vitality	Allows for recovery	Safeguarding healthy relationship

Conclusion: Individuals with knee pain described various health-promoting activities, ranging from physical activity to social interactions, included in the theme of enabling and maintaining a balance in everyday life based on abilities. We suggest that a broader approach to everyday life can be helpful in treatment plans and health promotion to manage and prevent KOA and chronic pain while maintaining a healthy lifestyle.

POS1528-HPR FACTORS ASSOCIATED WITH FRAILTY STATUS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Ö. Öztürk[1], Ö. Feyzioğlu[1]. *[1]Acıbadem Mehmet Ali Aydınlar University, Physiotherapy and Rehabilitation, Istanbul, Turkey*

Background: Frailty is characterized by increased fatigue and vulnerability which leads to adverse health outcomes. Recent studies have reported the increased prevalence of frailty in various rheumatological diseases regardless of age. However, information about the prevalence of frailty in patients with axial spondyloarthritis (axSpA) is limited.

Objectives: This study aims to determine prevalence of frailty and its assocaited factors in patients with axial spondyloarthritis (axSpA).

Methods: In this monocentric cross-sectional study 50 patients (26 women) with axSpA aged between 40 to 65 were included. Frailty status was determined using Kihon checklist. Patients were groups as pre-frail, frail and robust according to the Kihon Checklist and <4 was accepted as robust, ≥4 pre-frail, 8≥ frail. Nutritional status, disease activity, functional level and quality of life were assessed using Mini Nutritional Assessment (MNA), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankilozan Spondylitis Functional Index (BASFI), Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) respectively. Analysis of variance and multivariate linear regression analyses were used to assess group differences and factors associated with frailty status.

Results: The mean age of the patients was 51.78±6.77, the mean disease duration was 7.8±8.41 years, the mean body mass index was 29.98 ±4.72 kg/m^2. Twenty-one patients were classified as frail, 16 was pre-frail and 13 was robust. Compared to robust patients, pre-frail and frail individuals had significantly higher BASFI, BASDAI and ASQoL scores. There was a significant high correlation between the Kihon chekclist score and worse BASFI ($r=0.62$, $p<0.001$), BASDAI (0.69, $p<0.001$), ASQoL scores (0.73, $p<0.001$). Poor nutritional status was moderately correlated with frailty index score ($r=-0.53$, $p<0.001$). In multivariable linear regression analysis, nutrition status and level of quality of life were independently associated with frailty index score ($p<0.001$).

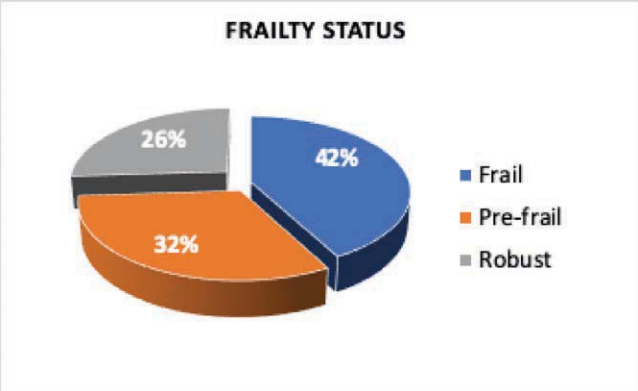

Figure 1. Percentages of patients according to their frailty status.

Table 1. Comparison of patients according to their frailty status

	Robust (n= 13)	Pre-frail (n=16)	Frail (n=21)	P_1	P_2	P_3
Age (years)	53.84±7.27	49.75±6.22	52.04±6.74	.24	.73	.56
Sex, women/men (n)	2/11	10/6	14/7	-	-	-
BMI (kg/m^2)	27.86±5.61	28.31±3.15	30.19±5.07	.96	.35	.46
BASDAI	2.39±1.81	4.83±1.60	5.93±1.83	.00	.00	.15
BASFI	1.96±2.01	2.87±2.10	5.41±2.19	.48	.00	.00
ASQoL	4.23±3.94	7.75±4.76	12.61±4.22	.08	.00	.00
Mini Nutritional Assessment	25.61±1.47	24.59±2.13	23.59±2.16	.36	.01	.29

BMI; body mass index, BASDAI; Bath Ankylosing Spondylitis Disease Activity Index, BASFI; Bath Ankilozan Spondylitis Functional Index, ASQoL; Ankylosing Spondylitis Quality of Life Questionnaire. P_1; P value between robust and pre-frail individuals, P_2; P value between robust and frail individuals, P3; P value between robust and frail individuals.

Conclusion: Frailty or pre-frailty is common in patients with axSpA and the main factors associated with frailty status were poor nutritional status and level of quality of life. Since it is a reversible condition, identifying the frailty status and its associated factors may help to prevent further decline in functional level and to design appropriate treatment interventions. Further studies are needed to determine frailty prevalence and its predictors in patients with axSpA.

POS1529-HPR SEXUAL DYSFUNCTION AND QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS

W. Tański[1], K. Dudek[2], N. Świątoniowska-Lonc[3]. [1]*4th Military Teaching Hospital, Department of Internal Diseases, Wroclaw, Poland;* [2]*Wroclaw University of Science and Technology, Department of Logistic and Transportation Systems, Wroclaw, Poland;* [3]*4th Military Teaching Hospital, Research and Innovation Center, Wrocław, Poland*

Background: Sexual health is a major component of human well-being. The World Health Organization (WHO) defines sexual health as "a state of physical, mental, emotional, and social well-being in relation to sexuality". Sexuality is a very important, inherent part of human functioning. As repeatedly shown in research, satisfaction with sex life and sexual fulfillment correlate positively with quality of life (QoL) in most of its aspects. It is thus true that a reduced quality of one's sex life and lack of sexual fulfillment can contribute to poorer QoL overall. As poor sex life quality and sexual dissatisfaction result from sexual dysfunction, effective treatment of such a dysfunction can be assumed to contribute significantly to a better QoL.

Objectives: To describe an assessment of sexual problem among RA patients as a part of patient-reported outcome measures assessment.

Methods: 171 consecutive RA patients (mean age 48.3±14.6) attending the rheumatology outpatients clinic over 6 months in 2021. Standardized questionnaires were used in the study: The Sexological Questionnaire to assess self-assessment of the incidence of sexual disorders, WHOQOL-BREF to assess QoL level, Disease Acceptance Scale and VAS scale to assess pain intensity.

Results: The mean duration of the disease in the study group was 13±9 years. The mean score of subjective assessment of mobility was 6.2 ± 1.6, and the mean score of the DAS-28 disease activity index was 4.0±1.9. The study group presented a mean level of disease acceptance (AIS 29.6 ± 11.6). The comparative analysis showed significant differences in reaching orgasm and declared sexual dysfunctions. These problems occurred more often in women than in men (34.2% vs. 18% and 43% vs. 40% respectively p=0.002). In univariate analysis, factors correlating positively with the frequency of declaring sexual dysfunction were: subjective motor score less than 6 points, AIS<36 points, WHOQOL-BREF<59 points, disease activity ≥3.5 points and VAS>3. In multivariate logistic regression analysis independent factors positively correlating with frequency of sexual dysfunction declaration were: general QoL (β=1.255; p=0.035) and pain limiting social life (β=1.564; p=0.030). The absence of comorbidities correlated negatively and reduced the prevalence of sexual dysfunction (β=-1.030, p=0.043). Patients with reduced QoL had 3.5 times and patients with pain limiting social life had 4.8 times higher risk of sexual dysfunction than other patients. In contrast, those without comorbidities were 2.8 times more likely to be free of sexual dysfunction than those diagnosed with other chronic diseases besides RA.

Conclusion: Sexual dysfunction is a problem found both in women and in men with RA. The most common problems include lack of orgasm, vaginal dryness in women, and erectile dysfunction in men. Psychological factors that contribute to sexual dysfunction include low or no illness acceptance and poor QoL. The absence of comorbidities is an independent determinant of lower sexual dysfunction incidence, whereas low QoL and pain limiting the patient's social life are independent determinants of increased incidence of sexual dysfunction in both sexes.

POS1530-HPR RHEUMATIC MUSCULOSKELETAL DISEASES (RMDS) DURING THE FIRST WAVE OF THE COVID19 PANDEMIC: PATIENTS' POINT OF VIEW ON THE ROLE OF TELEMEDICINE

K. El Aoufy[1,2], M. R. Melis[1,2], M. Balzani[1], S. Guiducci[1,2], S. Bellando Randone[1,2], S. Bambi[3], L. Rasero[3], M. Matucci-Cerinic[1,4]. [1]*University of Florence, Department of Clinical and Exeperimental Medicine, Florence, Italy;* [2]*Careggi Hospital, Department of Geriatric Medicine, Division of Rheumatology, Florence, Italy;* [3]*University of Florence, Department of Health Science, Florence, Italy;* [4]*IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), Milan, Italy*

Background: The COVID19 pandemic has caused health problems in people's daily lives with a significant psychological impact. In fact, patients with RMDs have experienced diseases' flare and also psychological problems. The lockdown and the "social quality changes" have impacted the life and the well-being of RMDs patients, influencing directly the implementation of telemedicine during daily practice.

Objectives: A descriptive observational study was designed to analyse the short-term effect of the first wave on RMDs patients on social quality changes and the usefulness of telemedicine.

Methods: The survey was carried out by administering a questionnaire consisting of 30 questions, developed *ad hoc* using Likert scales. Items such as family and work environment, access to healthcare facilities, healthcare provided to the patient, disease activity and the mental health status of individuals (anxiety / depressive symptoms) were investigated. Preliminary data on the first wave were collected between September and November 2021 through patient associations and social networks.

Results: 40 RMDs patients (Rheumatoid Arthritis 57.5%, Psoriatic Arthritis 35%, Fibromyalgia and others 7.5%) prevalently women (97.5%) were included in the survey. During the pandemic, 72% of respondents reported cancellation or delays in scheduled appointments and 50% did not have alternative contacts (telephone consultations, e-mail prescriptions, telematics training) with the hospital. 40.5% of patients reported difficulty in finding DMARDs and material for the treatment of ulcers, 28.2% reported difficulties in accessing the health facilities. In particular, 34.2% reported the total closure of the hospital facilities.

Moreover, our data show a worsening of health status due to an increased anxiety concerning the management of their RMDs, an increased stress within the

family, a reduced access to care facilities due to their closure or travel restrictions. In 57% of patients, a worsening of health status was reported, while in 90% stress and a feeling of abandonment was developed since the beginning of the pandemic. In this context, telemedicine was considered useful by 97.5% of patients, although patients felt that an improvement was necessary with an integration with the regular follow up.

Conclusion: Patients with RMDs reported that the significant delays or cancellation of the outpatient visits provoked an increase of stress, worry and anxiety for their health. The majority was very concerned about the overall management of their RMDs. The worsening of symptoms in more than half of the patients was the most worrisome observation. Almost all patients agreed that Telemedicine might help the clinical evaluation of their RMDs, also providing a significant support to their psychological condition because of the direct contact with the caring physician and health professionals.

POS1531-HPR PATIENT-REPORTED ADVERSE DRUG REACTIONS ATTRIBUTED TO THE USE OF ETANERCEPT: DISTINCTION BASED ON NATURE, FREQUENCY AND BURDEN

L. Van Boxem[1], H. Gosselt[1], S. Tas[2], B. Van den Bemt[3], H. Vonkeman[4], F. Hoentjen[5], M. Nurmohamed[6], M. Van Doorn[7], N. Jessurun[1]. *[1]Netherlands Pharmacovigilance Centre Lareb, Dutch Biologic Monitor,'s-Hertogenbosch, Netherlands; [2]Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; [3]Sint Maartenskliniek, Pharmacy, Research and Innovation, Ubbergen, Netherlands; [4]Medisch spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands; [5]University of Alberta Hospital, Division of Gastroenterology, Edmonton, Netherlands; [6]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; [7]Erasmus MC, Dermatology, Rotterdam, Netherlands*

Background: Research regarding adverse drug reactions (ADRs) associated with the use of etanercept in patients with inflammatory rheumatic diseases (IRDs) usually focuses on the nature and frequency of ADRs without considering the burden of the ADRs. However, not every ADR causes the same burden for patients. Information is lacking about the degree of experienced burden per ADR by patients with IRDs.

Objectives: First, to describe ADRs of etanercept based on nature, frequency and burden, and second, to propose a new model for identification of relevant ADRs for health care professionals.

Methods: Data of the Dutch Biologic Monitor (DBM) was used to categorize patient-reported ADRs into high and low burden. In this prospective cohort event monitoring system patients were asked to fill out bimonthly questionnaires on experienced ADRs that they attributed to the use of a biological DMARD. The questionnaire included a quantification of the burden of the reported ADRs using a five-point Likert scale ranging from 1 (no burden) to 5 (very high burden). The nature of the reported ADRs were grouped into preferred terms (PTs) according to the Medical Dictionary for Regulatory Activities (MedDRA). Inclusion criteria for this study were patients with IRDs using etanercept and who reported an ADR with at least one burden score. For every patient, the mean burden scores per ADR (MedDRA PT) were analyzed. The burden was classified in two categories: 'high' when the mean burden score was equal to or more than 2.5, and 'low' when it was less than 2.5. Text analytics of the reported ADRs (MedDRA PTs) and a comparison word cloud were used to visualize ADRs that were more often reported with high burden or more often reported with low burden. For this, the relative ADR frequencies of the low burden classes were subtracted from the relative frequencies of the high burden class, resulting in a percentual difference between the high and low burden class for every ADR. Therefore, the highest percentual difference corresponds to the ADRs that are experienced as most burdensome.

Results: A total of 187 patients (70% female) met the inclusion criteria and reported 905 ADRs, of which 373 (41%) were reported with high burden (see Table 1). The word cloud (Figure 1) visualizes which ADRs were more often reported with high or low burden. These ADRs correspond to the greatest difference in relative class frequency. Patients experienced the burden of headache, pneumonia and pruritis mainly as high, and the burden of injection site pruritus and injection site erythema as low.

Table 1. Characteristics of patients and reported adverse drug reactions (ADRs)

Characteristics	Total		
Patients (n = 187)			
Gender (female, %)	130 (70)		
Age (years) (mean ± SD)	58.1 ± 14.1		
Indication[a]			
Rheumatoid arthritis (%)	132 (71)		
Ankylosing spondylitis/axial spondyloarthritis (%)	19 (10)		
Psoriatic arthritis (%)	46 (25)		
Adverse drug reactions	Total	High burden	Low burden
Adverse drug reactions (ADRs) (%)	905 (100)	373 (40)	532 (60)
Drug-induced ADR burden (mean ± SD)	2.5 ± 0.9	3.3 ± 0.7	1.9 ± 0.5
High burden ADRs:			
Headache	30	22	8
Pruritus	23	17	6
Pneumonia	20	15	5
Feeling cold	11	11	0
Skin atrophy	11	11	0

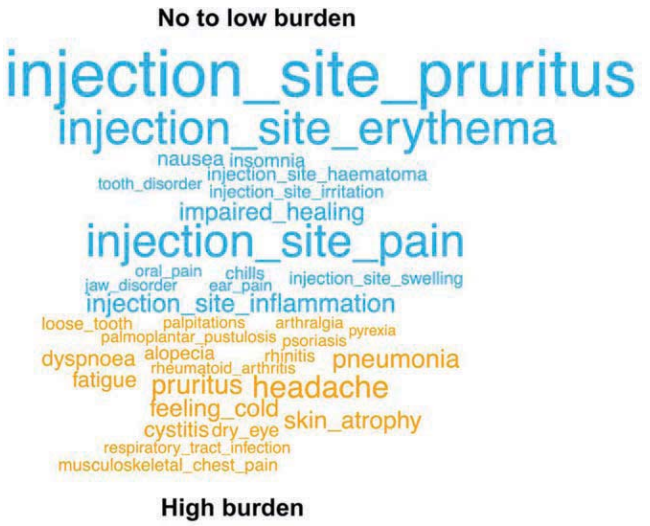

Figure 1. Comparison word cloud visualizing adverse drug reactions (ADRs) that patients reported more often with high burden (orange) and with no to low burden (blue). An ADR increases in size if the relative difference in frequency between classes increases.

Conclusion: The outcomes of the word cloud reveal that headache is more often experienced as burdensome which is an unexpected outcome. Visualizing the nature, the frequency and the burden of ADRs in one picture, provides simple guidance to the degree of relevance for the reported ADRs in clinical practice.

SEX DIFFERENCES IN THE EXPERIENCED BURDEN OF ADVERSE DRUG REACTIONS ATTRIBUTED TO ADALIMUMAB AND ETANERCEPT BY PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES

H. Gosselt[1], J. Van Lint[1], L. Kosse[1], S. Tas[2], P. Spuls[3], H. Vonkeman[4], M. Nurmohamed[5], M. Van Doorn[6], B. Van den Bemt[7], N. Jessurun[1].
[1]Netherlands Pharmacovigilance Centre Lareb, Dutch Biologic Monitor, 's-Hertogenbosch, Netherlands; [2]Amsterdam UMC, locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; [3]Amsterdam UMC, locatie AMC, Dermatology, Amsterdam, Netherlands; [4]Medisch Spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands; [5]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; [6]Erasmus MC, Dermatology, Rotterdam, Netherlands; [7]Sint Maartenskliniek, Pharmacy, Research and Innovation, Ubbergen, Netherlands

Background: Patients experience burden of adverse drug reactions.[1] So far, it is not known whether men and women experience adverse drug reactions (ADRs) with the same burden.

Objectives: To examine sex differences in regard to the burden of mutually reported ADRs in patients with immune-mediated inflammatory diseases (IMIDs) treated with adalimumab or etanercept.

Methods: Patients with rheumatoid arthritis (RA), psoriatic arthritis or (axial) spondyloarthritis using etanercept or adalimumab were included from the Dutch Biologic Monitor (DBM).[1] In the DBM, questionnaires concerning experienced ADRs and corresponding burden were filled out bimonthly. ADRs were coded according to Medical Dictionary for Regulatory Activities (MedDRA) terminology. The burden of ADRs (Preferred term level, PT) was reported on a five-point Likert scale ranging from no burden (1) to very high burden (5). If ADRs were present over multiple questionnaires, burden was only assessed the first time the ADR was mentioned. Likert scales reported for burden were compared between male and female patients for mutually reported ADRs that were reported at least four times by both male and female patients, using the Cochran-Armitage test for trend, which considers the ordinal nature of Likert scales.

Results: In total 748 consecutive patients participated, of which 55% were female (Table 1). Almost half (48%) reported at least one ADR during the study. More than half of female patients (55%) reported at least one ADR as compared to 38% of male patients. In total 882 ADRs were reported comprising 264 distinct ADRs, of which the majority (74%) was reported by female patients. 71 (27%) distinct ADRs were mutually reported by male and female patients and 12 (5%) distinct ADRs were reported at least four times by females and males. Pneumonia and headache impose the highest burden of the mutually reported adverse drug reactions. 'Arthralgia' (p=0.052) showed the largest differences burden Likert scale scores between male and female patients. Even though male patients experienced higher burden, these differences were not statistically significant (Figure 1).

Table 1. Demographics of females and males that reported at least one of the 12 distinct adverse drug reactions (ADRs) that are included in the analysis of sex-specific burden of ADRs.

Participants	Female	Male
N	138	70
Age, mean ± SD[a]	53.7 ± 13.5	57.6 ± 11.8
Indication for bDMARD therapy[b], N (%)		
Ankylosing spondylitis/axial spondyloarthritis	15 (10.9)	14 (20.0)
Ankylosing spondylitis/axial spondyloarthritis and Psoriatic arthritis	1 (0.7)	-
Ankylosing spondylitis/axial spondyloarthritis and Rheumatoid arthritis	1 (0.7)	3 (4.3)
Psoriatic arthritis	26 (18.8)	25 (35.7)
Rheumatoid arthritis	95 (68.8)	28 (40.0)
bDMARDs, N (%)		
Adalimumab	60 (43.5)	32 (45.7)
Etanercept	77 (55.8)	38 (54.3)
Switched adalimumab/etanercept	1 (0.7)	-
Comedication, N (%)[c]		
Methotrexate	55 (39.1)	21 (30.0)
Corticosteroids	17 (12.3)	11 (15.7)
Thiopurines	3 (2.2)	1 (1.4)
Sulfasalazine	9 (6.5)	3 (4.3)

[a]Age was missing for 1 male and 1 female patient. [b]Patients could report multiple indications. 5 male and 14 female participants also reported other indications. [c]Reported comedication at the moment of inclusion. Eleven patients (male=3, female=8) did not start with etanercept or adalimumab at the moment they were included. In these cases, comedication is counted from the moment they reported the start of adalimumab or etanercept treatment.

Conclusion: Although women reported the majority of the ADRs, there was a trend that that men experienced certain ADRs as more burdensome in comparison to women, albeit this did not reach statistical significance.

COMPARISON OF HAND FUNCTIONS AND FUNCTIONAL STATUS IN PATIENTS WITH LIMITED CUTANEOUS SYSTEMIC SCLEROSIS AND DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS

E. A. Akataly[1], D. Bayraktar[2], E. Otman Akad[3], O. Ustun[1], İ. Kurut Aysin[3], D. C. Saraç[2], B. Atalay[2], I. Ramazanoglu[2], I. Tekin[2], T. Kurum[2], S. Gucenmez[4], M. Ozmen[3], S. Akar[3]. *[1]Izmir Katip Celebi University, Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [2]Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [3]Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey; [4]Izmir Katip Celebi University, Ataturk Training and Research Hospital, Department of Rheumatology, Izmir, Turkey*

Background: Systemic Sclerosis (SSc) is an autoimmune connective tissue disorder which is characterised by the fibrotic changes in the skin effecting especially fingers and hands. Regarding skin manifestations, SSc is classified into two different subtypes as limited cutaneous SSc (lcSSc) and diffuse cutaneous SSc (dcSSc).

Objectives: The aim of the present study was to compare hand functions and functional status in patients with lcSSc and dcSSc.

Methods: Twenty-three patients with lcSSc and thirteen patients with dcSSc were included in the study. Modified Hand Mobility in Scleroderma Test (mHAMIS), modified Rodnan skin score (mRSS), grip and pinch strengths were measured to evaluate hand-related physical characteristics. Duruoz Hand Index, Disability of Arm, Shoulder and Hand Questionnaire (DASH), Health Assessment Questionnaire (HAQ), and Scleroderma Health Assessment Questionnaire (SHAQ) were used as the outcomes.

Results: While differences were detected in mRSS scores between disease subtypes ($p<0.05$), hand functions and functional status were comparable between groups ($p>0.05$).

Table 1. Comparison of the groups

	lcSSc Group Median (IQR 25/75) (n= 23)	dcSSc Group Median (IQR 25/75) (n=13)	p*
mHAMIS (score 0-4)	0 (0/1)	0 (0/0)	0.745

POS1534-HPR **WRIST JOINT POSITION SENSE AND MANUAL DEXTERITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS**

G. Duran[1], D. Bayraktar[2], A. C. Kalkan[3], S. Turkucar[4], B. Makay[4], E. Unsal[4], A. Genc[3]. *[1]Dokuz Eylul University, Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [2]Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [3]Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, Izmir, Turkey; [4]Dokuz Eylul University, Faculty of Medicine, Department of Pediatrics, Division pf Pediatric Rheumatology, Izmir, Turkey*

Background: Joint position sense is a marker of proprioception and is defined as being aware of the body position and individual body parts in the space. Position sense in the wrist joint is especially important for the manual dexterity. A possible damage due to arthritis may lead a decrease in joint position sense. However, the status of joint position sense was not investigated in children with juvenile idiopathic arthritis (JIA).

Objectives: To compare the wrist position sense and a motor performance test related to manual dexterity among children with JIA with wrist arthritis history (JIAWrist+), children with JIA without wrist arthritis history (JIAWrist-), and healthy controls.

Methods: A total of sixty children (20 children for each group) were included in the study. Wrist joint position sense was evaluated by measuring joint re-position error. The wrist was passively placed in a pre-determined position (30° for flexion, 30° for extension, 10° for radial deviation, and 15° for ulnar deviation). Then passively was returned to baseline position. The patient was asked to reposition their wrist into the target degree actively. The absolute error in degrees between each position and reposition was calculated. Manual dexterity was evaluated by using Purdue Pegboard Test. The test was repeated three times and the average number of the correctly placed pines was used in the analysis.

Results: Joint position sense (in all directions except radial deviation) and manual dexterity (except assembly) was found negatively affected in JIAWrist+ patients compared to healthy controls. No differences (except radial deviation) were observed between JIAWrist- patients and healthy controls.

Conclusion: Joint position sense and related manual dexterity is diminished in JIA patients with wrist involvement. The results of this study suggested that children with wrist arthritis should be followed with special attention focusing on manual abilities. Hand therapy programs might help improving joint position sense acuity.

THE RELATIONSHIP BETWEEN SCAPULAR STABILIZATION AND HAND FUNCTIONS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

G. Duran[1], D. Bayraktar[2], A. C. Kalkan[3], S. Turkucar[4], B. Makay[4], E. Unsal[4], A. Genc[3]. *[1]Dokuz Eylul University, Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [2]Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [3]Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, Izmir, Turkey; [4]Dokuz Eylul University, Faculty of Medicine, Department of Pediatrics, Division pf Pediatric Rheumatology, Izmir, Turkey*

Background: Distal stabilization is an essential component for high quality proximal movement. In this regard, scapular stabilization is important for upper extremity and hand functions. Moreover, scapular stabilization might have a role as a support point for hand functions in patients with joint problems. However, the relationships between scapular stabilization and hand functions were not investigated in children with juvenile idiopathic arthritis (JIA).
Objectives: To investigate the relationship between scapular stabilization and hand function in children with JIA with wrist arthritis history (JIAWrist+), and children with JIA without wrist arthritis history (JIAWrist-).
Methods: A total of forty children (20 children for each group) were included in the study. Scapular stabilization was measured by using scapular muscle endurance test. General functional status, subjective hand functions, and objective hand functions were assessed by using Childhood Health Assessment Questionnaire (CHAQ), Duruoz Hand Index, and Purdue Pegboard Test, respectively.
Results: JIAWrist+ patients reported poorer hand functions compared to JIAWrist- patients. No significant differences were detected for other parameters. Scapular muscle endurance was moderately related to CHAQ Disability Index score, Purdue Pegboard Test (single hand score and assembly score) in JIAWrist+ patients, while there was only a significant relationship between scapular muscle endurance and Purdue Pegboard Test both hand score in JIAWrist- patients.

Table 1. Comparison of the Groups and Relationships between Scapular Muscle Endurance and Hand Functions

	JIAWrist+ (n:20)	JIAWrist- (n:20)	
	Median (IQR 25/75)	Median (IQR 25/75)	p*
Age (years)	14.0 (10.5/16.0)	12.5 (11.0/14.5)	0.512

Purdue Pegboard Test Single Hand (score)	rho: 0.503, p: 0.024	rho: 0.313, p: 0.179	
Purdue Pegboard Test Both Hands (score)	rho: 0.400, p: 0.081	rho: 0.459, p: 0.042	
Purdue Pegboard Test Assembly (score)	rho: 0.594, p: 0.006	rho: 0.218, p: 0.355	

*Mann-Whitney-U Test, p<0.05, CHAQ: Childhood Health Assessment Questionnarie, JIAWrist+: children with JIA with wrist arthritis history; JIAWrist-: children with JIA without wrist arthritis history, rho: Spearman's Rank Correlatio

Conclusion: According to our results, scapular endurance was found more related to hand functions in wrist involved JIA patients. It seems that scapular stabilization contributes to hand functions differently related to joint involvement in JIA patients. It might be a beneficial strategy to work on scapular muscles in JIA patients with wrist involvement and poor hand functions.

POS1536-HPR

THE RELATIONSHIP BETWEEN POSTURAL CHANGES AND TRUNK MUSCLE ENDURANCE IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

A. C. Kalkan[1], G. Duran[2], S. Ozyurek[1], D. Bayraktar[3], H. Adiguzel Dundar[4], E. Unsal[4], A. Genc[1]. *[1]Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, Izmir, Turkey; [2]Dokuz Eylul University, Institute of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [3]Izmir Katip Celebi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir, Turkey; [4]Dokuz Eylul University, Faculty of Medicine, Department of Pediatrics, Division pf Pediatric Rheumatology, Izmir, Turkey*

Background: Body posture is defined as relative biomechanical alignment of body's head, trunk, and extremities as well as position of the body in the space. Body posture might be altered due to different musculoskeletal pathologies. Juvenile Idiopathic Arthritis (JIA) is a chronic inflammatory disease characterized by musculoskeletal problems including bone and muscle geometry alterations which may lead a deteriorated posture. However, it is not known whether trunk muscle endurance is associated with body posture in children with JIA.
Objectives: To investigate the relationship between postural changes and trunk muscle endurance in children with JIA.
Methods: Thirty-four children (eighteen female, sixteen male) were included in the study. Postural changes were assessed by a three-dimensional evaluation system (PosturePrint System, Biotonix, Canada). The system provides Posture Index (PI) score which is a composite score from three postural regions including head, ribcage, and pelvis. Higher PI scores indicate a more deteriorated posture. Biering–Sørensen Test (BST), Flexor Endurance Test (FET), Lateral Endurance Test (LET) were used to assess trunk muscle endurance, and Static Scapular Endurance Test (SSET) were used to assess scapular muscle endurance. Spearman Rank Correlation test was employed to determine the possible relationships.
Results: Enthesitis related arthritis was the most common JIA subtype in the study (38.2%) followed by oligoarthritis (26.5%), polyarthritis (20.6%), and systemic arthritis (14.7%). Significant negative correlations were detected between SSET and PI-head score (rho= -0.467, p=0.005), SSET and PI-ribcage score (rho= -0.381, p=0.026); FET and PI-head score (rho= -0.469, p=0.005); LET and PI-head score (rho= -0.441, p=0.009).

Table 1. Demographics, muscle endurance and Posture Index scores of children

Variable	Median (IQR 25^{th}/75^{th})
Age (years)	12.0 (10.0/14.0)
Height (cm)	145.50 (140.00/158.25)
Weight (kg)	42.75 (33.00/49.50)
Body mass index (kg/m^2)	19.17 (16.09/21.42)
Biering– Sørensen Test (sec)	49.70 (28.42/80-78)
Flexor Endurance Test (sec)	38.91 (30.59/60.19)
Lateral Endurance Test (sec)	32.52 (19.99/59.68)
Static Scapular Endurance Test (sec)	23.19 (15.93/44.74)
Posture Index-Head (score)	7.0 (5.0/8.0)
Posture Index-Ribcage (score)	5.0 (4.0/6.0)
Posture Index-Pelvis (score)	6.0 (3.0/8.0)

IQR: Interquartile range

Conclusion: These results indicated that postural displacements of head and ribcage are linked with decreased trunk and scapular muscle endurance in children with JIA. Exercise and physical activity programs targeting muscle endurance may result improvements in posture in these children.

POS1537-HPR

PERCEIVED BARRIERS AND FACILITATORS TO PHYSICAL ACTIVITY AND ITS ASSOCIATED FACTORS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Ö. Öztürk[1], Ö. Feyzioğlu[1]. *[1]Acıbadem Mehmet Ali Aydınlar University, Physiotherapy and Rehabilitation, Istanbul, Turkey*

Background: Physical activity is a core treatment method in the management of axial spondyloarthritis (axSpA). Barriers to physical activity including high disease activity, symptoms such as pain, stiffness and fatigue and lack of time have been reported in qualitative and quantitative studies in patients with axial spondyloarthritis (axSpA). Inflammatory Arthritis FAcilitators and Barriers (IFAB) questionnaire has been developed to assess perceived barriers and facilitators to physical activity in patients with inflammatory arthritis. Identifying barriers and facilitators to physical activity using a rheumatic-specific tool may help to plan better patient management strategies in clinical practice.
Objectives: To determine barriers and facilitators of physical activity in patients with axSpA and explore associations between perceived barriers and facilitators to physical activity and education level, disease duration, functional status, anxiety, depression.
Methods: Between September and December 2021, 93 patients with axSpA were included in this study. Besides demographic and clinical variables, patients completed the IFAB questionnaire to determine the perceived barriers and facilitators to physical activity or exercise. Also, anxiety and depression status was determined with Hospital Anxiety and Depression

Scale (HADS) and functionality was measured with Health Assessment Questionnaire (HAQ). Physical activity level was assessed using the International Physical Activity Questionnaire Short-Form (IPAQ-SF). Multiple linear regression analysis was used to investigate the association of HADS score, HAQ score, disease duration, educational status and the IFAB score.

Results: Of the 102 patients included, 93 were analyzed, 46 % were women. The mean age was 44.81±10.71 and the mean disease duration was 6.91 ± 6.92 months. According to the IPAQ-SF scores, 47.3 % of the patients were inactive, 49.5 % were moderately active and 3.2 % were active. The mean IFAB score was 4.61 ± 22.22, and 26 % of patients' score was below -5. One level increase in educational status resulted in an increase of 3,55±1,77 points in the IFAB score and a one-point increase in HADS-Depression score lead to a 2,00±0,57 decrease in the IFAB score.

Conclusion: In this axSPA population, 26 % scored below -5, indicating significant barriers and a need for a physical activity intervention. IFAB score was independently associated with education status and level of depression. Our results may propose that a comprehensive physical activity program should be designed considering psychological factors and should be prepared according to the educational status of the patients.

POS1538-HPR INVESTIGATION OF BALANCE FUNCTIONS IN INDIVIDUALS WITH NEURO-BEHCET: A PILOT STUDY

S. Yenil[1], E. Gur Kabul[2], F. Ulutas[3], B. Basakci Calik[1], V. Cobankara[3].
[1]Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey; [2]Usak University Faculty of Health Sciences, Physiotherapy and Rehabilitation, Usak, Turkey; [3]Pamukkale University Faculty of Medicine, Department of Rheumatology, Denizli, Turkey

Background: Behcet's disease is a vasculitis, causing multisystem inflammation and resulting in oral and genital ulcers and eye and skin lesions (1). A proportion of patients also have neurological involvement, termed Neuro-behcet's disease (2). We think about that Neuro-behçet's disease can impact balance functions in patients due to neurological involvement. However, there is no study investigating the balance functions in patients with Neuro-behcet.

Objectives: To investigate the balance functions in individual with Neuro-behçet's disease.

Methods: In this study 8 Neuro-behcet patients with a mean age of 38.37±16.96 who were followed in the PAU Rheumatology outpatient clinic and diagnosed by a rheumatologist according to the criteria of the International Behcet Study Group and 8 healthy control with a mean age of 42.62±13.94 with similar demographic characteristics were included. Exclusion criteria for the study were age <18 years old, having any disease which mimics BD (including systemic lupus erythematosus, vasculitis of central nervous system). Demographic data of the participants were recorded. Then, balance functions were evaluated with a balance board (Sensamove Mini-Board, NL) in Neuro-behcet and control groups. This assesment included static balance, proprioception, and reaction. Results were analyzed with Mann Whitney U Test.

Results: Participants were similar in terms of age and gender ($p>0.05$). Neuro-behcet group showed a significant decrease in static balance in all directions except the right side compared to the control group ($p<0.05$). A significant decrease was observed in the right and left reaction times in Neuro-behcet group compared to control group ($p<0.05$). There was no significant difference between the two groups in proprioception assesment ($p>0.05$).

Conclusion: This results show that patients with Neuro-behcet may experience disturbances in static balance and reaction time. Balance and reaction exercises should be included in rehabilitation. Further research is needed on the effect of balance functions and the effectiveness of balance exercises in Neuro-behcet's disease.

POS1539-HPR EXPLORING TASK- SHIFTING IN HAND OSTEOARTHRITIS CARE FROM THE PERSPECTIVE OF THE SERVICE USER.

H. J. Magnussen[1,2], M. Feiring[2,3], I. Pinxsterhuis[1], T. A. Sjøvold[4], I. Kjeken[1,2].
[1]Oslo Metropolitan University, Department of Occupational Therapy, Oslo, Norway; [2]Diakonhjemmet Hospital, National Advisory Unit on Rehabilitation in Rheumatology, Oslo, Norway; [3]Oslo Metropolitan University, Department of Physiotherapy, Oslo, Norway; [4]Martina Hansens Hospital, -, Sandvika, Norway

Background: The demand for and provision of health care is in constant change. People live longer and have more complex health requirements, challenging the functioning of the health care system in responding adequately to present and future needs. For persons with hand osteoarthritis (HOA), access to recommended treatment is poor (1) and what can be offered in primary health care is not optimal. A reorganization of the workforce through task-shifting can be a solution where the aim is to use existing human resources in health in more efficient ways. Through task- shifting, tasks and knowledge can be shifted between health professionals, between levels of the health care system, and from health professionals to service users, changing the current division of labor (2).

Objectives: The aim of this study is to gain a broader understanding of the distribution of tasks among health professionals and service users in HOA care from the perspective of service users to guide future task- shifting initiatives.

Methods: In- depth interviews with 21 service users with HOA were conducted, including 15 women and six men from 47 to 86 years of age. All had received services from primary and specialized health care services. A theme based semi- structured interview guide was used. All interviews were audio- recorded and subsequently transcribed verbatim. Reflexive thematic analysis was used to generate codes and develop three main themes.

Results: *Tasks by different professionals*: service users describe general practitioners (GPs) as entry points to health service provision. Contact is initiated with

the aim to have signs and symptoms recognized for referrals to diagnostic tests and specialized services. As such, tasks beyond referrals are not expected by service users in primary health care in their encounters with GPs. Upon entering specialized health care services, service users describe diagnostics and prescription of medication for pain as key tasks of the rheumatologists, highlighting the role of the rheumatologists in ruling out severe pathology. Service users attribute the tasks of providing information about the condition, exercises, and assistive devices to occupational therapists (OTs). A lack of familiarity with the OT- profession prior to consultations is also expressed. This shows how patients attribute different tasks to GPs, rheumatologists, and OTs based on experiences in consultations.

Profession secondary to competence about HOA and interpersonal skills: service users say they do not have preferences related to who executes what professional tasks in addressing their needs. On the contrary, service users highlight competence about HOA as a key factor independent of whether the health professional is a GP, rheumatologist, or OT, saying professional orientation is secondary to professional knowledge about HOA. At the same time, service users underline interpersonal skills of health professionals as another key element, further downplaying the specific professional background of health professionals and levels of the health care system in meeting service user needs.

Transfer of tasks to service users: service users experience that they are presented with few treatment options beyond self- management in encounters with health professionals, leaving service users to cater for their own needs through the self- administration of exercises, medicines, and assistive devices.

Conclusion: In the division of labor, service users highlight the importance of professional knowledge and skills within the field and interpersonal skills independent of professional background and levels of the health care system. They also underline few treatment opportunities beyond self- management resulting in task- shifting to service users.

POS1540-HPR CENTRAL SENSITIZATION PLAYS A PROMINENT ROLE IN DISEASE ACTIVITY, FUNCTIONAL IMPAIRMENT AND QUALITY OF LIFE IN PATIENTS WITH SPONDYLOARTHRITIS.

A. Ben Tekaya[1], C. Ines[1], A. Gharbi[1], O. Saidane[1], R. Leila[1], S. Bouden[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicole Hospital, Rheumatology, Tunis, Tunisia*

Background: Pain in rheumatic diseases is substantially due to an excess of nociception in response to chronic inflammation. However, the share of nociplastic pain in these disorders shouldn't be overlooked. Different tests have been evaluated but some of them require expensive equipment.

Objectives: to assess The Central Sensitization in young patients with spondyloarthritis (SpA) using a simple and validated tool: The Central Sensitization Inventory (CSI).

Methods: We conducted a cross-sectional study including patients with SpA, fulfilling the Assessment of SpondyloArthritis International Society (ASAS) 2009 criteria. For all patients, we collected the following data: age, age at onset of SpA, disease duration, the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing spondylitis quality of life score (ASQOL) and functional statement by Bath ankylosing spondylitis functional index (BASFI). Nociceptive pain was assessed by VAS pain, neuropathic pain was assessed by DN4 and nociplastic pain was assessed by CSI.

Univariable and multivariable linear regression analyses were used to investigate the association between CSI scores, patient-related parameters and disease characteristics.

Results: Sixteen SpA patients (50 axial SpA, 8 axial and peripheral SpA, 1 psoriatic arthritis and 1 SpA associated with inflammatory bowel disease) were enrolled. There were 22 females and 38 males. Mean age was 39,4 years ± 11,08, mean age at onset was 23,61 years± 8,5 and mean disease duration was 11,37 years ±7,23. Mean night awakenings was 0,92 [0, 3], mean VAS pain was 5,27 [1, 9]. Mean BASDAI was 3,53 ± 3,34, mean BASFI was 4,01 ± 2,53, mean ASQOL was 6,3 ± 5,128 and mean DN4 was 1,72 [0, 7].

Mean CSI score was 20,38 ± 18,657. Six patients (10%) had a CSI score≥ 40, which indicates a central sensitization. CSI score>40 was not associated with the gender (p=0,659), nor axial presentation of SpA (p=0,644), nor the presence of coxitis (p=0,217). CSI score was not correlated with disease duration (p=0,306) nor age at onset (p=0,376). It was however associated with a BASDAI>4 (p=0,039).

A positive correlation was found between higher CSI score and higher ASQOL (p<0,001, r=0,744), VAS pain (p=0,061, r=0,282), more frequent night awakenings (p=0,009, r=0,433), higher BASDAI (p=0,006, r=0,379) and higher BASFI (p=0,055, r=0,270).

Conclusion: Higher CSI score was associated with higher disease activity, more frequent night awakenings, poorer quality of life and greater functional impairment. A global and comprehensive management including these factors as well as nociplastic pain should help the patient achieve better outcomes.

POS1541-HPR PAIN CATASTROPHIZING IS FREQUENT AND IMPACTS THE LIFE AND FUNCTION OF PATIENTS WITH SPONDYLOARTHRITIS

A. Ben Tekaya[1], C. Ines[1], A. Gharbi[1], O. Saidane[1], R. Leila[1], S. Bouden[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicole Hospital, Rheumatology, Tunis, Tunisia*

Background: Psychological care for patients with spondyloarthritis (SpA) should be standard practice if we aim to achieve better outcomes. In fact, pain catastrophizing, anxiety, and depression are to look for when the patient remains unsatisfied despite the clinicobiological control of the disease.

Objectives: To assess the presence of pain catastrophizing among patients with SpA.

Methods: We conducted a cross-sectional study including patients with SpA, fulfilling the Assessment of SpondyloArthritis International Society (ASAS) 2009 criteria. For all patients, we collected the socio-demographic data and disease characteristics, the following scores: the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), the Bath ankylosing spondylitis functional index (BASFI), the Ankylosing spondylitis quality of life score (ASQOL) were used to evaluate respectively disease activity, functional status and quality of life. The presence of pain catastrophizing was assessed by the arabic validated version of Pain catastrophizing score (PCS) and nociplastic pain by Central Sensitization Inventory (CSI).

Results: We included 60 SpA patients (sex ratio=1,72). Mean age was 39,4 years ± 11,08. Mean disease duration was 11,37 years ±7,23. Mean BASDAI score was 3,53± 3,34, mean BASFI was 4,01 ±2,53 and mean ASQOL score was 6,3 ±5,12. Mean PCS was 15,73 ± 13,893. thirteen patients (21,7%) had PCS >30 which indicates clinically relevant level of catastrophizing. PCS was significantly higher in men (mean PCS was 19,29 in men versus 9,59 in females), p=0,003. Clinically relevant level of catastrophizing (PCS>30) was significantly associated with age: mean age was 45,61 years in patients with PCS>30 compared to 37,47 in patients with lower PCS (p=0,022). Higher PCS was correlated with greater central sensitization assessed by the CSI (p<0,0001, r=0,621), poorer quality of life assessed by the ASQOL (p<0,0001, r=0,818) and greater functional impairment appraised by BASFI (p=0,009, r=0,347). No correlation was shown between PCS and age (p=0,640, r=0,062), age at disease onset (p=0,580, r=-0,84), disease duration (p=0,805, r=0,037), patient's global assessment (p=0,211, r=0,197), CRP value (p= 0,425, r=-0,130) and BASDAI score (p=0,073, r=0,244).

Conclusion: Pain catastrophizing was not influenced by inflammation parameters. PCS was correlated with greater central sensitization, poorer quality of life and greater functional impairment. Therefore, psycho-education should be investigated among patients with SpA.

POS1542-HPR QUALITY OF LIFE AND PHYSICAL FUNCTIONING OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS FAST TRANSLATE ICON TRANSLATE FAST TRANSLATE ICON TRANSLATE

L. Bohmat[1], N. Shevchenko[2], A. Fadieieva[1], V. Nikonova[1]. [1]*SI "Institute for Children and Adolescents Health Care of the NAMS of Ukraine", The Department Of Cardiorheumatology and Comorbid Conditions, Kharkiv, Ukraine;* [2]*VN Karazin Kharkiv National University, Department of Pediatrics № 2, Kharkiv, Ukraine*

Background: Quality of life (QoL) due to World Health Organization (WHO) is an individual's perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns. QoL can be decreased during chronic illnesses, including juvenile idiopathic arthritis (JIA). This severe chronic disease of childhood afflicts both joints and body`s system inducing various comorbid conditions, among which eye damage (uveitis) is the most common[1]. Considering the fact of involved joints it was set up that physical functioning (PF) shows the lowest values in some studies, which is associated with joint damage, activity, and duration of the disease[2].

Objectives: To establish the overall level of QoL and physical functioning in patients with JIA, considering the subtype of the disease, duration and the therapy complex.

Methods: The study involved 118 patients with JIA, among which 47 had polyarticular subtype, 43 had oligoarticular one, 28 were with uveitis-associated (JIA-u) subtype. The investigation included 77 girls and 41 boys in age from 2 till 18 years old. The therapy by methotrexate was provided in 112 patients, among them 30 had MTX with immunobiological therapy (29 adalimumab, 1 – tocilizumab), 6 – sulfasalazine. The disease duration due to disease subtype in polyarthritis was (49,2±6,7), oligoarthritis – (35,4±4,2), JIA-u – (76,8±10,2) months. Disease activity was assessed using the JADAS27 questionnaire, functional state (FS) according to CHAQ and QoL according to PedsQLTM 4.0 Generic Core Scales.

Results: It was found that high JIA activity was observed in 31 (26.2%) patients, equally often in all subgroups of children. FS did not show a significant decrease either in the whole group or in each of the arthritis subgroups. The overall indicator of QoL in children with JIA was reduced in the whole group (71.2±1.4 and 72.9±1.4 per week and month). There was no significant difference between the QoL indicators of boys and girls. The polyarticular subtype showed the lowest results in QoL and PF, especially in children in the first year of the disease. They also turned out to be worse in children with JIA-u with the disease from one to three years (QoL – 63,3±2,6*; PF – 66,6±3,9) The highest level of the physical component of QoL was observed in children with oligoarthritis older than 14 years (84,9±4,7) and in children under 8 years of age in the JIA-u group (96,8±1,8). There was no significant effect on the physical indicators of QoL of the start treatment timing. ($p \leq 0,05$). Finally, the strong correlation was determined between QoL and PF ($r=-0,842$; $p \leq 0,05$).

Conclusion: A decrease in QOL and its physical component is typical for children with different types of JIA (oligoarticular, polyarticular, and JIA-y). It has been established that children with polyarticular subtype of arthritis have the greatest decrease in QoL and physical functioning.

POS1543-HPR **JOINING TELEMEDICINE SERVICES IN RHEUMATOLOGY: THE ROLE PLAYED BY PERSONALIZED EXPERIENCE FROM PATIENTS' PERSPECTIVE**

E. Listorti[1], L. Ferrara[1], A. Adinolfi[2], M. C. Gerardi[2], N. Ughi[2], V. Tozzi[1], O. M. Epis[2]. *[1]CERGAS SDA Bocconi, Bocconi University, Government, Health & Not for Profit, Milan, Italy; [2]ASST Grande Ospedale Metropolitano Niguarda, Rheumatology Unit, Milan, Italy*

Background: With the beginning of the Covid-19 pandemic, many hospital departments worldwide, including rheumatology ones, were forced to implement telemedicine strategies. Telemedicine revealed to be an umbrella term, with various practical implementations and different degrees of preparedness1. Some practitioners were already familiar with telemedicine, as in the case of the Rheumatology Unit of ASST Niguarda Hospital in Milan (Italy), where telemedicine projects have been implemented for more than a decade with structured design and organized processes. Moreover, patients in Niguarda have experimented telemedicine with personalized mixes of channels, including e-mails and phone calls, Patient Reported Outcomes questionnaires, and home delivery of drugs. This represents a paradigmatic case study that enables us to deepen essential questions on the success of telemedicine.

Objectives: Given that the last decision on joining telemedicine rests with patients[2], we decided to adopt their perspective. We deepened three main aspects: i) the benefits perceived, ii) the willingness to enrol in future projects, iii) the preference on the service-mix, i.e., on-distance contacts rather than in-person visits. Most importantly, we investigated differences in the three areas among all patients based on the type of personalized experience had.

Methods: We conducted a survey from November 2021 to January 2022, enrolling randomly outpatients who attended the rheumatology unit for any reason. The survey originated from well-known surveys, such as the Tele-Health Usability Questionnaire[3] and the Intention to use telehealth services[4]. However, we decided to overcome the usual separation that makes surveys addressed either to users or no users of telemedicine. Our survey comprised an introductory set of questions related to personal, social, clinical and ICT skills information, followed by the central part on telemedicine, which explored the three areas mentioned: benefits, adherence, preferences on service-mix. For this part, questions were the same for all patients apart from the tense used, being conditional tense for no-users and past tense for users. All the answers were analysed with descriptive statistics and regression models.

Results: A complete response was given by 400 patients: 71% were female, 59% were 40-64 years old, 53% of them declared to work, and the diseases most represented were Rheumatoid Arthritis (36%) and Osteoporosis/arthrosis (21%).

The descriptive statistics revealed interesting differences between users and no users, e.g., the desire to participate in future projects was stated by 95% of users, 81% of no users. These results were confirmed by multivariate logistic regression models that controlled for the influencing patients' characteristics (such as being old or a frequent hospital attender).

It emerged that no-users imagined wide-ranging benefits. As for the willingness to participate to future telehealth projects, even if personal characteristics showed an impact (e.g., being a worker increased the probability to adhere), other things being equal, having had a more intense experience of telemedicine increased the odds of accepting by 3.1 times (95% C.I. 1.04-9.25), compared to no users. Furthermore, the more telemedicine was experienced, the higher the willingness to substitute in-person with online contacts.

Conclusion: Our study contributes to enlighten the crucial role played by the telemedicine experience in determining patients' preferences. On one side, users appeared more aware of the realistic benefits to be expected from telemedicine. On the other side, it seemed that the more telemedicine was experienced, the higher the willingness to adhere to future projects and to increase on-distance contacts.

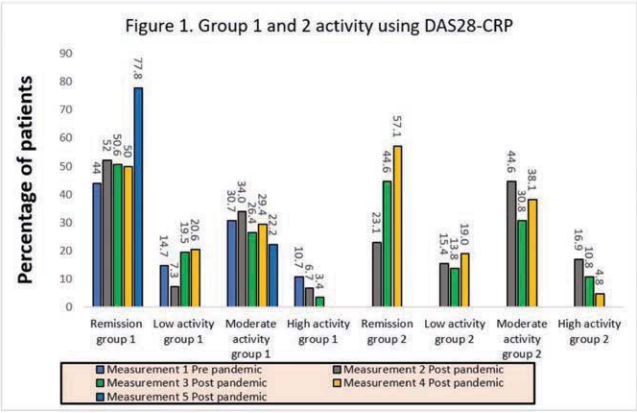
POS1544-HPR RHEUMATOID ARTHRITIS CONTROL USING SYNCHRONOUS TELEMEDICINE MODALITY IN THE PANDEMIC PERIOD

L. J. Cajas Santana[1], D. Cajas[2]. [1]*Universidad Nacional de Colombia-Clínica Universitaria Colombia, Rheumatology-Telemedicine, Bogota, Colombia;* [2]*Universidad del Cauca, Medicina, Popayan, Colombia*

Background: Telemedicine is a useful tool in the control of patients with rheumatological conditions, even more so in the pandemic period. The evolution of patients with rheumatoid arthritis (RA) treated exclusively under this modality has been scarcely described.
Objectives: Evolution of clinical activity in RA patients controlled exclusively by the synchronous telemedicine (ST) modality in the COVID-19 pandemic period.
Methods: An observational study was carried out.Two group of patients were analyzed separately, first group who had been treated using ST before the declaration of a health emergency in Colombia in march 2020 and second who were admitted to ST after this date. ST consists of a real-time video call with a trained general physician help on the referral site to performed physical examination. Assessments of disease activity was measured by DAS28 using C-reactive protein.
Results: Data was obtained from 150 and 65 patients in the first and second group. For the first group, more than a half of the patients had 2 controls with DAS28 assessment after march 2020, only 33% obtained 3 assessments, and very few with 4 or more. We found that the number of patients with high activity decreased significantly from 10% to 3%, remission increased from 44% to 50% and low activity from 14% to 19%, without major changes in the moderate activity group that remained close to a third. Same tendencies happened in group 2, with a difference in reduction of the moderate activity group from 44% to 38% (Figure 1)



Conclusion: When in person attention with rheumatologist is not possible, telemedicine is a useful and efficient way to control patients with RA, mainly finding a reduction in high activity and an increase patients in remission.

POS1545-HPR PATIENT SELF-SAMPLING IN RHEUMATOID ARTHRITIS: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

J. Knitza[1,2,3], K. Tascilar[1,2], N. Vuillerme[3], E. Vogt[4], P. Matusewicz[4], G. Corte[1,2], L. Schuster[1,2], T. Aubourg[3], G. Bendzuck[5], M. Korinth[5], C. Elling-Audersch[5], A. Kleyer[1,2], S. Boeltz[1,2], A. Hueber[1,6], G. Krönke[1,2], G. Schett[1,2], D. Simon[1,2]. [1]*Friedrich-Alexander University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 – Rheumatology and Immunology, Erlangen, Germany;* [2]*Friedrich-Alexander University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Deutsches Zentrum für Immuntherapie, Erlangen, Germany;* [3]*University Grenoble Alpes, AGEIS, Grenoble, France;* [4]*Thermo Fisher Scientific, R&D, Freiburg, Germany;* [5]*Deutsche Rheuma-Liga Bundesverband, e.V, Bonn, Germany;* [6]*Nürnberg Hospital, Paracelsus Medical University, Division of Rheumatology, Nürnberg, Germany*

Background: Rheumatoid arthritis (RA) requires early diagnosis and tight surveillance of disease activity. Patient self-sampling of blood for the analysis of autoantibodies and inflammation markers could facilitate the identification of patients at-risk for RA and improve tight disease monitoring [1].
Objectives: A randomized, controlled trial to evaluate the feasibility, acceptability and accuracy of an upper arm self-sampling device (UA) and finger prick-test (FP) to measure capillary blood from RA patients for C-reactive protein (CRP) levels and the presence of IgM rheumatoid factor (RF IgM) and anti-cyclic citrullinated protein antibodies (anti-CCP IgG).
Methods: 50 RA patients were randomly assigned in a 1:1 ratio to self-collection of capillary blood via UA or FP. Venous blood sampling (VBS) was performed as gold standard in both groups to assess the concordance of CRP levels as well as RF IgM and CCP IgG. General acceptability and pain during sampling were measured and compared between UA, FP and VBS. The number of attempts for successful sampling, requests for assistance, volume and duration of sample collection were also assessed.
Results: 49/50 (98%) patients were able to successfully collect capillary blood. Overall agreement between capillary and venous analyses for CRP (0.992), CCP IgG (0.984) and RF IgM (0.994) were good. In both groups 4/25 (16%) needed a second attempt and 8/25 (32%) in the UA and 7/25 (28%) in the FP group requested assistance. Mean pain scores for capillary self-sampling (1.7/10 ± 1.1 (UA) and 1.9/10 ± 1.9 (FP)) were lower on a numeric rating scale compared to venous blood collection (UA: 2.8/10 ± 1.7; FP: 2.1 ± 2.0). UA patients were more likely to promote the use of capillary blood sampling (net promoter score: +28% vs. -20% for FP) and were more willing to perform blood collection at home (60%) vs. 32% for FP).
Conclusion: This study shows that self-sampling is accurate, feasible and well accepted among patients. The implementation could allow tight remote monitoring of disease activity as well as identifying patients at-risk for RA and potentially other rheumatic diseases.

POS1546-HPR DISEASE ACTIVITY BURDEN FOR LONG TERM RHEUMATOLOGY FOLLOW-UP PATIENTS

G. Ansari[1], K. Manik[2], A. Nandagudi[2], A. Bharadwaj[2]. [1]*Southend UniversityHospital Mid and SouthEssex NHS Foundation Trust, Rheumatology, Souhend, United Kingdom;* [2]*Basildon University Hospital Mid and South Essex NHS Foundation Trust, Rheumatology, Basildon, United Kingdom*

Background: There has been a lot of emphasis for early diagnosis and treatment for immune mediated rheumatology conditions such as Treat to target (T2T) for inflammatory arthritis, Fast track pathway for Giant cell arteritis. However, the data regarding burden of disease activity, nature and proportion of long term rheumatology follow up patients in rheumatology clinics have not been explored. There are conditions which are refractory to treatment or affected by recurrent flare-ups requiring long term follow-ups and constant monitoring. With increasing life expectancy and better treatment of the long term conditions, emphasis on long term disease activity monitoring is under strain. It is important to understand the nature of illnesses and treatment of long term follow-up patients to decide management strategies.
Objectives: The aim of this quality improvement project was to understand profile of disease and management of patient being seen as long term follow-up (defined as >2 years follow-up after their first presentation in specialist clinic).
Methods: This was a single point, retrospective cohort analysis of patients seen in rheumatology clinics in a district general hospital, UK in March 2021. We reviewed consecutive 120 follow-up patients and recruited 80 patients who

had >2yrs follow-up. We have a community rheumatology service arm where all patients with stable inflammatory arthritis on non-biologic treatments are reviewed while patients with multisystem complicated illness and biologics are seen in secondary care. The stable patients from community clinics have not been included in this analysis. The data was reviewed using clinic letters, date of first appointment & last appointment. We looked at gender, age, diagnosis, number of follow ups in the first and last year, disease activity scores of the respective diagnosis and treatment given.

Results: Sixty six percent of follow-up patients are long term with complicated illness or treatment. Of these 52 patients (65%) were female with median age 64 years (range 23-94 years). Median duration of follow up for this group of patients was 6 years (range 2-11 years). Inflammatory arthritis was the most common diagnosis in 75% of patients (11 patients were Psoriatic arthritis, 30- Rheumatoid arthritis, 7- undifferentiated inflammatory arthritis and 7- Axial spondyloarthritis), 17.5% connective tissue disease, 11.2% vasculitis and others (Still's disease) 3.7%. Some patients had more than one diagnoses. The number of follow ups in the first year ranged from 1-13 (median 4). In final year of analysis, patients were seen median of 3 times (range1-8). Amongst them, 25% of patients were seen 4 or more times. The commonly prescribed drugs were methotrexate (41.2%), sulfasalazine(17.5%), hydroxychloroquine(15%), leflunomide (7.5%),biologics (8.7%), mycophenolate mofetil and azathioprine (6.5%).The activity scores such as DAS28, BVAS, PsARC and BASDAI were documented in 46 patients (57.5%).

Conclusion: This study shows that 66.6% of follow-up patients in rheumatology clinics are complicated long term conditions on immunomodulatory treatment. Despite T2T approach, use of combination DMARDs and early use of biologics, majority are inflammatory arthritis. It also shows that even after median follow-up of 6 years, these patients require an average review 3 or more times per year. The reasons for this may be poor disease control, disease complications, comorbidities and medication side effects. Further analysis is ongoing to look into these aspects for better disease control and long term outcome.

POS1547-HPR CREATION OF A MULTI-DISCIPLINARY TEAM (MDT) RHEUMATOLOGY CLINIC AT UNIVERSITY COLLEGE LONDON HOSPITAL (UCLH) TO TACKLE THE BACKLOG OF PATIENTS WAITING FOR TREATMENT AS A RESULT OF THE COVID-19 PANDEMIC.

D. Ludwig[1], F. Higgs[2], N. Allotey[1], S. Begum[1], J. Burton[3]. *[1]University College London, Rheumatology, London, United Kingdom; [2]University College London, Therapies & Rehabilitation Department, London, United Kingdom; [3]University College London Hospitals, Innovation Directorate, London, United Kingdom*

Background: Covid-19 has consumed hospital resources since January 2020. In the UK, routine care has been disrupted with an estimated 30 million fewer outpatient attendances (2020/21) and over 6 million patients waiting for consultant led care (1). The British Society for Rheumatology 'Rheumatology Workforce: a crisis in numbers (2021)' highlights the challenges facing National Health Service rheumatology departments in managing rising caseloads (2). In 2021, UCLH wait time for follow up rheumatology appointments was 9 months. We were inundated with patients requiring urgent treatment. Innovative ways of running outpatients were required which led to the formation of an MDT clinic.

Objectives: Create a Rheumatology MDT clinic to:

Reduce follow up time

Increase clinic capacity

Reduce number of hospital attendances

Add value to each clinic encounter

Methods: The consultant lead identified an existing clinical nurse specialist (CNS) interested in supporting the MDT. With a UCLH Outpatient Transformation grant of £15,000 we recruited an advanced physiotherapy practitioner (APP) and administrator for a 6 month trial period. Managerial support was provided by the board. We met weekly to agree aims and allocate responsibilities. We did the following:

- Reviewed clinic lists for 6 months to identify duplicate appointments.
- Identified patients with CNS and consultant follow up scheduled in a short time frame and cancelled unnecessary appointments.
- Reviewed the clinic list weekly to identify patients suitable for APP management. This allowed overbooking of urgent cases.
- Embedded hand ultrasound appointments in the clinic template.
- Created CNS 'Zoom' virtual drop-ins for routine enquiries to reduce the administrative burden of patient emails/phone calls occurring outside the clinic.
- Organised patient participation sessions to help shape the service and collected patient feedback questionnaires.

Results: We reduced our waiting time for follow up appointments from 9 months to 2 months. Pre-MDT the average wait from consultant referral to physiotherapist appointment was 55 days. The MDT allows for same day assessment (reducing 2-3 patient journeys a clinic) and where suitable, facilitates discharge or onwards referral to the appropriate service i.e. pain management, hand therapy, APP-led hypermobility programme. A dedicated MDT CNS has shortened treatment times, reduced email traffic between CNS and consultant and allows for same day, joint decision making resulting in fewer appointments. Patients welcomed the Zoom sessions as an efficient, reliable method of raising concerns/queries. Our administrator helps to facilitate communication between patients and clinicians and streamline MDT processes. Embedding point of care ultrasound reduces hospital visits and enhances treatment decision making thereby reducing follow up attendances.

Conclusion: Our MDT model has reduced waiting lists, decreased treatment delays and cut the number of hospital visits. Performing ultrasound in clinic helped prevent patients being sent for scans at private providers. This cost saving likely covers the APP, ensuring the project is close to cost neutral. Shared decision making added value to outpatient attendances, reflected in patients positive feedback. The MDT enhances the role of APP and CNS, utilising their unique skill set. Administrative support is crucial, enhances team working and places added value on this often underappreciated role. We encourage other Rheumatology departments to adopt an MDT approach to tackle the backlog of patients awaiting treatment, add value to clinic encounters and maximise the skill set of clinicians involved in patient care.

POS1548-HPR USEFULNESS OF AN ELECTRONIC CONSULTATION SYSTEM BETWEEN PRIMARY CARE HEALTH CENTERS AND RHEUMATOLOGY DEPARTMENT OF A TERTIARY HOSPITAL

N. De la Torre Rubio[1], J. Campos Esteban[1], M. Pavía Pascual[1], P. Navarro Palomo[1], M. Machattou[1], O. Rusinovich[1], M. Fernandez Castro[1], H. Godoy[1], C. Merino Argumánez[1], B. Garcia-Magallon[1], C. Barbadillo Mateos[1], J. Sanz[1], L. F. De Villa[1], J. L. Andréu Sánchez[1]. *[1]Puerta de Hierro Majadahonda University Hospital, Rheumatology, Majadahonda, Spain*

Background: The EPISER study is the first Spanish epidemiological study that has confirmed the great burden of rheumatic diseases in the general population: they consume a large quantity of health resources (doctor visits, medical products) and imply a high social impact in terms of work absenteeism. Rheumatic diseases represent almost 30% of Primary Care medical consultations in Spain[1,2]. Electronic consultation could be an alternative response to the increase of this demand, both to make an early diagnosis and derivation and to improve communication with Primary Care physicians[3,4].

Objectives: To analyze the demand of Primary Care and its resolution through the electronic consultation system of the Rheumatology Department of a tertiary hospital.

Methods: Retrospective descriptive study of the data collected in the request and information system (Sistema de Peticiones Electrónicas, SIPE) that supports electronic consultation between primary care physicians of the health area and the Rheumatology Department of a tertiary hospital, between July 2020 and May 2021.The following variables were collected: age, sex, reason for consultation, response time in days and destination (primary care/outpatient follow-up). Descriptive statistics were used to present the results.

Results: The last 500 consecutive electronic consultations registered in the system, referring to 496 patients, were collected. Mean age was 59.5±17.7 years; 74.2% women. Mean response time was 2 days, median response time 1 day and range 0-45. The reasons for consultation (see Graph 1) were: osteoporosis assessment 55 (11%), treatment adjustment 50 (10%), appointment request 49 (9.8%), loss to follow-up 43 (8.6%), local-regional pathology assessment 39 (7.8%), infiltration request 28 (5, 6%), suspected rheumatoid arthritis 19 (3.8%), flare 18 (3.6%), suspected polymyalgia rheumatica or giant cell arteritis 16 (3.2%), COVID vaccine consultation 14 (2.8%), Raynaud's phenomenon 13 (2.6%), monoarthritis assessment 12 (2.4%), assessment of polyarthritis 11 (2.2%), adverse effects of treatment 11 (2.2%), suspected spondyloarthritis 11 (2.2%), suspected psoriatic arthritis 8 (1, 6%), generalized pain 7 (1.4%), suspected Sjögren's syndrome 5 (1%), suspected systemic lupus erythematosus 1 (0.2%), suspected other systemic autoimmune diseases 9 (1.8%), others 81 (16.2%). Fifty-seven and four % (287) of the patients required an appointment at the Rheumatology outpatient clinic and in 42.6% of the patients (213) the electronic consultation was successful, so it was not necessary to refer the patient to the hospital.

Conclusion: Forty-two and six percent of the queries were resolved thanks to the electronic consultation system in an average of two days, otherwise that patients would have been referred to specialized care. The main reasons for consultation were osteoporosis assessment and clarification of doubts about the treatment of patients who were already being followed up by the Rheumatology Department.

POS1549-HPR IMPROVING EFFICACY AND SAFETY OF BLOOD MONITORING IN RHEUMATOLOGY PATIENTS ON DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (DMARDS) USING A NEW AUTOMATED ALGORITHM

M. Mirza[1], A. Escudero Siosi[1], D. Lang[1], K. Paddon[1], B. Shine[1], A. Soni[1], R. Luqmani[1]. [1]*University of Oxford, Rheumatology, Oxford, United Kingdom*

Background: Most patients in Rheumatology require early management with DMARDs to control their disease. In our department, around two hundred patients start a DMARD therapy every month and monitoring their blood test results whilst on DMARDs play an essential role to detect toxicity and the need for further action. This process has been done manually, which has been prone to error. Over the past six months, a minimum of three patients have had abnormalities which were missed, consequently identifying the need to improve the quality of the blood monitoring.

Objectives: The aim of the project was to develop, test and implement an automated algorithm to review multiple blood test results and highlight any changes, trends or abnormalities in patients starting DMARD therapy efficiently.

Methods: We designed a system to automatically review blood tests from patients newly started on DMARD therapy, following the recommended British Society for Rheumatology (BSR) schedule for blood monitoring. Results are processed in our local laboratory, subsequently uploaded to our unique database and analysed automatically using an algorithm against BSR guided threshold values for each blood test. According to the value, each blood result is identified as normal, mildly abnormal, missing, trending, or abnormal. A trained clinician or pharmacist will review the data and endorse the results after taking any appropriate action. Based on the results, if any actions are needed, patients are contacted either by phone or via a letter automatically generated by this software, recommending them to have a repeat test or temporarily stop the medication as required.

Results: The system was tested on two cohorts, comprised of 100 and 227 blood tests. It was faster and more efficient than the manual alternative. Following this test, each record was compared manually, based on the data stored on a spreadsheet.

This new system led to the identification of more abnormalities versus the manual inspection (29% vs 10%, Chi square P<0.001). Additionally, it took less than a minute compared to the manual method, which took three hours to complete. Follow up manual inspection confirmed that the new system had correctly identified every abnormality, based on test records.

To date, we have analysed 3568 blood results using this technique. 1564 (44%) results have been normal and endorsed within seconds. 374 (10%) were mildly abnormal, 17 (0.5%) results have been abnormal requiring action and 311 (9%) were abnormal requiring no action. 265 (7%) results showed a trend within the blood results. Trending results were defined as being out of range and worsening on two consecutive occasions but not reaching the limits for stoppig a drug. 1032 (29%) results contained missing results, a consequence of the different timings of results uploaded by various laboratory sections.

Conclusion: We have developed an efficient and safe blood monitoring system for Rheumatology patients starting on a DMARD, proven to be more accurate compared to previous manual alternatives and able to process up to 10,000 results at a time.

POS1550-HPR DRIVE-THROUGH PHLEBOTOMY – DOES IT WORK FOR CDMARDS MONITORING?

J. Begum[1], M. Nisar[1]. [1]*Luton and Dunstable University Hospital, Rheumatology, Luton, United Kingdom*

Background: Centralised phlebotomy services have been an integral part of providing blood monitoring facility for people with chronic diseases prescribed vital therapies. However the patient experience is not always optimal due to the issues of congestion, parking, long waiting times and have been accentuated during COVID-19 pandemic with the need for minimising physical contact. Expert panels have advocated for the creation of innovative approaches to provide safe patient care while maintaining precautions against COVID-19 spread. Several groups have published the concept and experience of using a drive-through clinic for anticoagulation monitoring and management. There is limited data on how this model of care can impact other clinical services such as rheumatology where patient groups are more vulnerable.

Objectives: In response to the growing pressure on phlebotomy service at our institution enhanced by COVID-19 pandemic, our rheumatology service implemented a drive-through phlebotomy clinic to provide the option for patients and families to stay in their vehicles whilst having venepuncture. The objectives were to evaluate the feasibility and patient experience of the service.

Methods: At our large university teaching hospital, we set up a drive-through phlebotomy service provided by a senior health care assistant supervised by the lead nurse. It was located near the hospital entrance where vehicles could park for a few minutes without disrupting traffic flow. Patients were identified from the departmental database and were offered the facility via telephone. Eligibility was assessed using a standardised proforma focusing on logistics such as ability to drive and access to a mobile phone. Appointments were scheduled in advance with patients choosing this care option. On the day, patients were screened for COVID-19–related symptoms before their appointment and were encouraged to stay in their vehicles wearing a mask before being approached by the HCA. At the end of clinic, all samples were submitted to the central laboratory.

All the data was prospectively collated with patients' consent and anonymised for analysis. In addition to demographics, diagnosis and drug record, duration of visit and patient feedback was collected.

Results: 112 patients were offered the service during a 12-week pilot. Mean age of the participants was 49.5 yrs (19-91) with 73 (65%) women. 74 (65%) were of Caucasian and 28 (25%) of Asian origin. 94 (84%) had inflammatory arthritides and all were prescribed DMARDs and/or bone active agents.

69 (61%) had blood samples taken using this service. Most common reason to decline was an already arranged appointment with standard phlebotomy (n=14, 12.5%). Six (5%) could not be bled due to difficult venepuncture. Mean duration of appointment was 12.5 mins (5-60). 68 (60%) provided feedback with 61 (90%) rating 5/5 and 60 (89%) rating it better than standard phlebotomy. All would like to have the option for future and 67 (98%) were highly likely or likely to recommend the service to family and relatives.

Conclusion: To our knowledge, this is the first study to demonstrate the utility of drive-through phlebotomy for people with rheumatic diseases prescribed DMARDs. Excellent feedback of the participants confirms the need and desire for such innovation in health care. Prior publications have shown the benefits of such clinics in anticoagulation services. Arguably, it's more prudent to have this facility for those where there is no alternative such as point-of-care or home INR monitoring. In post COVID-19 services reconfiguration with telemedicine and innovative models of care, this allowed flexibility for our department to develop

and establish an alternative process. The availability of drive-through appointments and the close physical proximity to the clinic made it an appealing option for a vulnerable group of patients evidenced by their outstanding experience and feedback. Overall, an HCA-delivered, nurse-supervised drive-through pathway is highly effective, safe and provides an innovative solution to strained phlebotomy services.

POS1551-HPR MEDICAL EXPERT KNOWLEDGE MEETS AI: HOW EXPERT KNOWLEDGE CAN IMPROVE SYMPTOM ASSESSMENT APPS - A NEW APPROACH IN RARE DISEASES

A. Pankow[1,2], N. Meißner[3], L. Fouquette[3], E. Türk[3], S. Gilbert[3,4], T. Tübler[3], A. Das[5], C. Terkamp[2], J. Kaufeld[2], G. R. Burmester[1], A. D. Wagner[2]on behalf of Rheumatology 4.0. *[1]Charité - Universitätsmedizin Berlin, Medizinische Klinik mit Schwerpunkt Rheumatologie und klinische Immunologie Charité, Berlin, Germany; [2]Medizinische Hochschule Hannover, Ambulanz für seltene entzündliche Systemerkrankungen mit Nierenbeteiligung, Hannover, Germany; [3]Ada Health GmbH, Ada, Berlin, Germany; [4]University Hospital Carl Gustav Carus, Technische Universität Dresden, Else Kröner Fresenius Center for Digital Health, Dresden, Germany; [5]Medizinische Hochschule Hannover, Pädiatrische Nieren-, Leber- und Stoffwechselerkrankungen, Hannover, Germany*

Background: By definition, rare diseases occur in fewer than 5 in 10,000 people. However, in Germany alone, there are approximately 4 million people affected (1). Due to their rarity, rare diseases are often overlooked by general practitioners with limited knowledge about them. There are often only a handful of specialized experts for each condition. Yet, those experts are frequently not evenly distributed across the healthcare system, and often, patients lack access. Therefore, the time to diagnosis is often long and poses many challenges. Artificial intelligence (AI) approaches, such as those used in symptom assessment apps can potentially help to detect disease and thus, shorten the time to diagnosis (2).

The general approach underlying the AI of symptom assessment apps is to gather medical knowledge from data (e.g. electronic health record or literature searches). However, for rare diseases, there is only limited research available. In this study we used a new approach: to abstract medical expert knowledge by conducting guided interviews and transforming them into clinical vignettes.

Objectives: There are two objectives. First, we aimed to integrate expert knowledge on the lysosomal storage diseases (LSDs) Fabry, Gaucher and Pompe into the Ada symptom assessment application and use this expert knowledge to optimize Ada's LSD condition models. LSDs are of particular importance as they represent import differential diagnoses to rheumatic diseases.

Second, we will conduct questionnaires with patients and LSD experts, comparing the optimized to the previous condition models' performance. We will investigate whether the novel approach of guided interviews, in combination with literature research, results in a better performance than literature research alone.

Methods: Our novel approach is to curate expert medical knowledge from guided interviews with medical experts. The interviews aim to gather knowledge on the symptom constellations with which patients typically present to their physicians. This knowledge is subsequently used to create prototype clinical cases and transform them into structured case vignettes. The rare disease structured case vignettes can be readily transcribed into Ada's knowledge base.

Results: We conducted guided interviews with clinical experts from the Medizinische Hochschule Hannover (MHH) to create clinical vignettes for the LSDs Fabry, Gaucher and Pompe disease. We conducted interviews with four medical experts and created a total of 11 clinical vignettes: five vignettes for Fabry disease, four for Gaucher disease and two for Pompe disease. Figure 1 demonstrates the vignette creation process. Then, in combination with systematic literature searches, the vignettes were used to update Ada's existing condition models for Fabry and Gaucher disease and to add Pompe disease.

Figure 1. The novel medical model creation approach uses guided expert interviews to create prototypic clinical vignettes, which can be readily transcribed in a medical modeling language to create individual disease models

Conclusion: Participants will complete two assessments: an Ada version with the old knowledge base and an Ada version with the updated models. The study plans to enroll 15 LSD patients - five per condition - and nine LSD experts. For the conditions Fabry and Gaucher disease, we will ask the participants to rate both Ada versions. For Pompe disease, we will ask participants to rate the latest Ada version with the updated knowledge base. This novel approach has various clinical implications, including potentially shortening the 'time to diagnosis' for rare diseases, thus giving patients faster access to the treatments they need.

Background: Qualitative research is crucial to understand key stakeholders experiences and perspectives of care and health services. However, there is a lack of explicit frameworks and guidelines about how best to use qualitative evidence to formulate clinical recommendations. Part of the problem includes uncertainties about the contributions of qualitative research to the evidence, and the empirical and theoretical basis for appraising and synthesizing qualitative evidence in a standardized manner. In addition, most existing grading systems of qualitative research originates from quantitative research, and there is no clear guidance about how to incorporate qualitative research into the evidence hierarchy.

Objectives: To conduct a systematic literature review (SLR) to answer two research questions (RQ):

RQ1) *What guidance (e.g., tools, checklists, frameworks) exists to assess the methodological quality of qualitative research employed to inform clinical recommendations?;*

RQ2) *What methods exist specifically to grade levels of evidence for qualitative research?*

Methods: The protocol for this review was registered on www.researchregistry.com (reviewregistry1240). Electronic databases (PubMed/Medline, EMBASE, Web of Science, COCHRANE, Emcare, PsycINFO, ERIC, Academic Search

Premier, Sociological Abstracts, ProQuest Dissertations and Thesis Global) were searched for published and unpublished studies. Searches were completed from inception to 23rd October 2020. No restrictions were applied to clinical population. Eligible studies for both questions included primary articles and guideline documents available in English, describing the: i) development; ii) application of validated tools (e.g., checklists); iii) guidance on how to assess methodological quality of qualitive research and iv) guidance on how to grade levels of qualitative evidence. Opinion pieces and conference abstracts were excluded. Manual searches of the reference lists of full text articles were conducted. Two reviewers independently screened the titles, abstracts, and full text. A narrative synthesis was conducted to identify key aspects between the included studies.

Results: 9071 records were retrieved (Figure 1). After de-duplication and title/abstract screening, 51 full-articles articles were assessed for eligibility yielding 15 included articles. For RQ1, six articles were included that described six tools *(1) The society for Critical Care Medicine Family – Cantered Care Guidelines; 2) Nursing Management of the Second Stage of Labour evidence based clinical practice guidelines; 3) Jonna Briggs Institute Critical Appraisal of Qualitative Studies; 4) Critical Skill's Appraisal Programme (CASP) and 6) the Modified CASP checklist).* All tools ranged from 10 to 30 items, and evaluated research design, recruitment, ethical rigour, data collection and data analysis. Seven articles described one approach *(GRADE CER-Qual)* to assess methodological quality of qualitative research. This approach advised on the importance for assessing methodological limitations. For RQ2, two articles were included, one described a qualitative hierarchy of evidence, and another described a research pyramid that included a section on qualitative research.

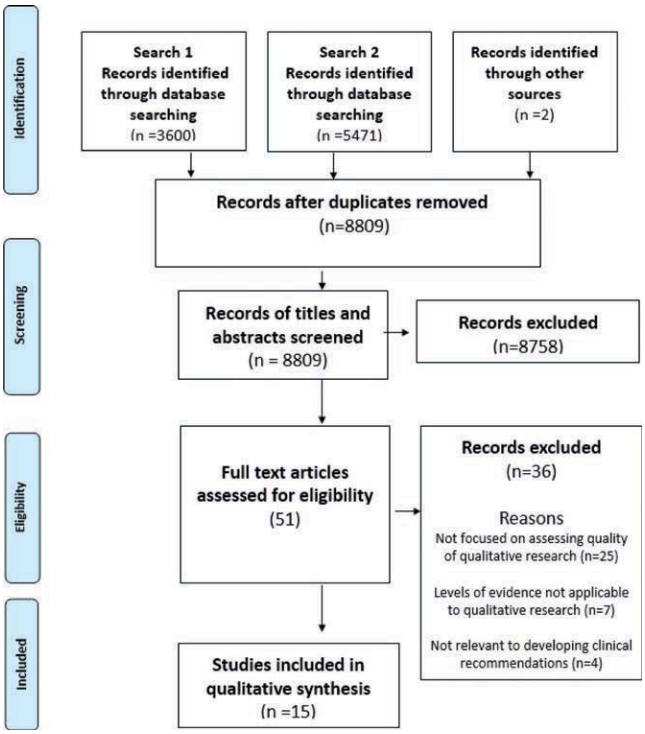

Figure 1. PRISMA diagram of included papers

Conclusion: This review highlights lack of consensus and limited availability of tools, checklists, and approaches to 1) appraise the methodological quality of qualitative research used to inform clinical recommendations and 2) grade levels of evidence for qualitative research. Current research agendas will need to determine the most relevant and appropriate method for the quality appraisal of qualitative research. This way, qualitative research could be more consistently and appropriately applied to the development of clinical recommendations.

A VIRTUOUS IMPLEMENTATION OF TELEMEDICINE SERVICES IN RHEUMATOLOGY: DESCRIPTION OF CHANGE MANAGEMENT PRACTICES ADOPTED BY THE NIGUARDA HOSPITAL

L. Ferrara[1], E. Listorti[1], A. Adinolfi[2], M. C. Gerardi[2], N. Ughi[2], O. M. Epis[2], V. Tozzi[1]. [1]*Cergas SDA Bocconi, Bocconi University, Government, Health & Not For Profit Division, Milan, Italy;* [2]*ASST Grande Ospedale Metropolitano Niguarda, Rheumatology Unit, Milan, Italy*

Background: Over the past few decades there have been an increasing debate around the use of telemedicine. Despite this, there is still a slow rate of adoption of telemedicine services. According to a recent scoping review this may be due to a piecemeal approach to the change process, and a lack of understanding of how to plan, manage and reinforce change when implementing telemedicine service[1]. A virtuous example of implementation of telemedicine services can be found within the rheumatology unit of Niguarda Hospital in Milan (Italy), where the whole staff has been involved in experimenting with new multichannel interactions to communicate with patients for more than a decade. Developed in 2011 with the introduction of the iAr Plus app for the collection of Patient Reported Outcomes (PROs), the project was first targeted to patients with Rheumatoid arthritis, Psoriatic arthritis and Spondylarthritis. In 2019 the project consolidated and added the home delivery of biological drugs for the stable patients. During spring 2020, this experience was further enhanced and extended to all patients treated with biological drugs to facilitate patient interaction during Covid-19 and was characterized by three elements: remote monitoring, triage through phone calls and home delivery of medication. What contextual factors and mechanisms adopted to plan, manage, and reinforce change where more successful?

Objectives: This study aimed to highlight what were the distinctive and successful elements of this implementation experience, what we could learn from it, and which managerial implications we could derive for future implementations.

Methods: We adopted a realist evaluation approach[2] to identify the underlying generative mechanisms that explain 'how' the outcomes were caused and the influence of context. Thus, we deepened how the change management process has been managed by conducting semi-structured interviews with the unit director, and the staff members involved in the phases of the project (i.e., clinicians, nurses, and administrative staff). The interviews were recorded and analyzed through an ad-hoc framework[1] for the analysis of change management practices. This framework identifies 10 change steps divided into 13 strategic practices and 6 operational practices that are important during the preparatory phase of the change process, for managing the change, and to sustain and reinforce long-term change.

Results: Our study identified the most relevant actions put in place by the rheumatology unit during the three major steps of preparing for change (e.g., developed telemedicine App, assigned coordinating role, identified champions), managing change (e.g., developed and articulated a clear vision, provided training, developed ownership), and reinforcing change (e.g., continued to engage partners). The analysis highlighted four main lessons learned: first the characteristics of the context and a strong managerial structure were a prerequisite for success. The generative mechanisms that explain how these successful outcomes were caused are: a leadership role able to define a clear vision and a clear specialization of tasks and roles; the involvement of all team members; regular meetings and interactions. Second, patients should be involved as central actors in the definition of the care pathway. The final decision on the kind of services to be used was made by the patient. Third, the relevant stakeholders should be involved since the co-design of the app. Finally, change should be incremental. The Rheumatic unit introduced one change at a time, and this brought to constant improvements.

Conclusion: The framework adopted can be used either to retrospectively analyze the experiences developed but may also act as a tool to guide future telemedicine service implementation and research. As well as the lessons learned can guide the implementation of future telemedicine experiences

POS1554-HPR

HEALTH PROFESSIONALS' PERSPECTIVES ON THE USE OF JANUS KINASE INHIBITORS TO TREAT PATIENTS WITH INFLAMMATORY ARTHRITIS

S. De Souza[1], A. Bassett[1], R. Williams[1], E. Nikiphorou[1,2]. [1]*King's College London, Centre for Rheumatic Diseases, London, United Kingdom;* [2]*King's College Hospital, Rheumatology, London, United Kingdom*

Background: Janus kinase inhibitors (JAKi) are relatively new to the field of rheumatology and provide health professionals in rheumatology (HPRs) with more therapeutic options for treating inflammatory arthritis (IA), specifically rheumatoid arthritis (RA) and psoriatic arthritis (PsA) [1]. Aside from a different target, JAKi differ from often currently prescribed biologics by being administered orally. To date, there is a lack of evidence on what HPRs think about their real-world use and how the COVID-19 pandemic affects JAKi prescription.
Objectives: To explore UK-based HPRs' perspectives towards JAKi use in IA patients, and in the context also of the COVID-19 pandemic.
Methods: A 15-item anonymous online survey, with both closed and open-ended questions, was designed and piloted on 5 HPRs with amendments made based on their feedback. The survey was advertised on Twitter and shared by email in September 2021. Data were exported from the online survey platform and analysed descriptively with the assistance of statistical software.
Results: Fifty-one HPRs responded to the survey: 37 Consultants, 7 Registrars, 5 Clinical Nurse Specialists, 1 Clinical Fellow and 1 'other rheumatology role' (not stated). Responses were received from 11/12 UK regions. Most represented was Greater London (18%) and North-West England (16%). 69% of respondents worked in secondary care, with the remaining 31% in tertiary care. The majority (40%) spent 1-25% of their job role doing research, followed by 27% who were not research active. 60% of HPRs indicated that 1-5% of their RA and/or PsA patients take a JAKi (no HPRs had more than 15% of their RA/PsA patients on a JAKi). 96% of HPRs indicated that they prescribe JAKi in their clinical practice, with 91% of those who prescribe following their local guidelines. 72% of respondents who prescribe JAKi, prescribed them 'frequently' as a monotherapy. Figure 1 shows responses chosen for when JAKi therapy is usually started and for feeling less confident with JAKi prescription. Of those HPRs who prescribe, 17% have continued JAKi in their patients. When discontinuation occurred, the most common reasons chosen (multiple responses allowed) were 'due to inefficacy' (60%), 'due to other adverse events' i.e., non-major adverse cardiovascular events (32%) and 'due to herpes zoster infection' (28%). 55% of HPRs would consider switching patients to another JAKi after initial failure. Across prescribers, 49% indicated no impact of the COVID-19 pandemic on their prescribing of JAKi. Common reasons chosen for a change in prescribing patterns for JAKi as a result of the pandemic (multiple responses allowed) included: prescribing them more as 'an alternative to infusions, in order to reduce hospital visits' (23%) and as 'an alternative to injections, in order to reduce at-home training visits' (21%). This was followed by 'other reason' (15%) with the free text from all 7 respondents highlighting the benefits of the shorter half-life of JAKi e.g., "Prescribed more as quick on and quick off so can be discontinued quickly in event of severe infection" (Registrar, Greater London). Safety concerns around the use of JAKi were raised in 13/14 free text comments left at the end of the survey e.g., "I am concerned about recent reports of increased VTE [venous thromboembolism] and malignancies" (Consultant, Yorkshire and the Humber) and "Concerns about cardiovascular safety" (Clinical Fellow, Scotland).
Conclusion: A large proportion of HPRs indicate confidence in prescribing JAKi to their patients with IA, adhering to local guidelines. JAKi are largely prescribed as monotherapy, with the most frequent reason for discontinuation being inefficacy. The COVID-19 pandemic seems to have positively impacted JAKi prescription, however, safety concerns over JAKi use remain for some HPRs.

EVALUATION OF CONVERSATIONS IN MOTION: A PROGRAM DESIGNED TO IMPROVE PATIENT-PROVIDER COMMUNICATION IN THE CARE OF RHEUMATOID ARTHRITIS

E. Nikiphorou[1], S. Péloquin[2], M. Augustyniak[2], A. Negoescu[3], D. Walker[4], F. Haq[5], P. Lazure[2], S. Murray[2]. [1]*King's College, Centre for Rheumatic Diseases, London, United Kingdom;* [2]*AXDEV Group Inc., Performance Improvement Division, Brossard, Canada;* [3]*Addenbrooke's Hospital, Cambridge University Hospitals NHS Trust, Rheumatology Department, Cambridge, United Kingdom;* [4]*Northumbria Healthcare NHS Foundation Trust, Rheumatology Department, Northumbria, United Kingdom;* [5]*Eli Lilly and Company, Global Medical Education, Toronto, Canada*

Background: Previous studies have found a need for improvement in communications between healthcare professionals (HCPs) and patients with rheumatoid arthritis (RA), especially in relation to shared-decision making (SDM), management of expectations, and goal-setting.[1-2] *Conversations in Motion* (CIM) is an educational program, consisting of four modules, that teaches HCPs how to use validated communication techniques to improve the quality and efficiency of their consultations with RA patients.
Objectives: This pilot study assessed the impact of CIM deployed in the United Kingdom (UK) on HCPs' knowledge, skills, confidence, beliefs, and performance using validated communication techniques in interactions with RA patients.
Methods: A longitudinal mixed-methods study, consisting of three surveys (pre/before the program, 2-3 weeks post, and 5-6 months follow-up) and semi-structured interviews (4-6 weeks post) was used to evaluate CIM based on the outcome model by Moore et al.[3] Surveys assessed outcomes via multiple choice or 11-point rating scale questions (0-none, 10-extreme). Participants included UK rheumatology physicians, nurses, and allied HCPs, all of whom had a minimum yearly caseload of 10 RA patients and participated in CIM between September and October 2020. Survey data was descriptively analysed in SPSS by comparing pre with post and pre with follow-up (matched samples). Interviews were thematically analysed using NVivo.
Results: Almost half (15/34) of registrants completed all four CIM modules. Of those, 53% (n=8) completed pre and post surveys; 33% (n=5) pre and follow-up surveys; and 27% (n=4) completed interviews. Post surveys showed greater knowledge for strategies to build trust and empathy with RA patients and practice efficiency than at pre (Figure 1). A decrease in helplessness was noted for dealing with a patient who is nonadherent (pre=3.9/10; post=1.6/10). Interviewees described CIM as "thought provoking" and reported improvement in their ability and confidence to use patient's own stories and words as a strategy to build trust and empathy (n=4). Post and follow-up surveys showed changes in skills and confidence were more pronounced for practice efficiency and discussing nonadherence (Table 1). At follow-up, most participants reported practicing at least one

technique to build trust and empathy with patients (80%, 4/5), save time (100%, 5/5), engage in SDM, or discuss nonadherence (60%, 3/5).

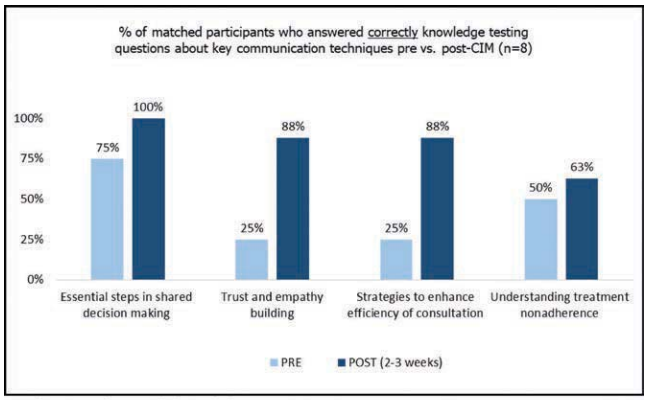

Figure 1 – Changes in knowledge post-CIM

Table 1. Changes in skill and confidence post-CIM

		Matched respondents (n=8)			Matched respondents (n=5)		
	Survey item	Pre	Post	Δ	Pre	Follow-up	Δ
Skill	Assisting patients in the conceptualization of treatment pros and cons	5.6	7.1	+15%	5.4	6.4	+10%
	Listening to and understanding patients' emotions, expectations, and personal needs	6.6	8.1	+15%	7.0	8.2	+18%
	Simplifying complex terminology related to RA	5.4	7.8	+24%	5.4	7.2	+16%
	Discussing reasons for nonadherence	5.4	7.8	+24%	4.2	6.4	+22%
Confidence	Engaging in shared decision making	6.1	7.9	+18%	5.0	6.2	+12%
	Building trust and empathy via telemedicine	5.9	6.9	+10%	5.0	6.0	+10%
	Addressing patient concerns in limited consultation	5.2	6.6	+14%	4.0	5.6	+16%
	Support patients through treatment adherence	6.0	7.5	+15%	4.0	6.2	+22%

Table description: All items were rated on an 11-point scale (0-none, 10-extreme). The matched sample of participants who completed the pre and 2-3 weeks post-CIM survey was not the same as the one who completed the pre and 5-6 months follow-up survey. Change (Δ) was measured as the percent difference between means.

Conclusion: This pilot evaluation suggests that CIM has a measurable impact on HCPs' learning and use of techniques that can enhance communication and collaboration with RA patients. Future studies should validate CIM impact in a larger sample size and/or by evaluating patients' perspective on observed changes in their communication and collaboration with HCPs.

POS1556-HPR RECOMMENDATIONS FOR NURSES ON THE MANAGEMENT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUS: A DELPHI CONSENSUS

L. Cano Garcia[1], C. Dominguez[2], A. I. Rodriguez Vargas[3], E. Trujillo Martin[3], J. M. Martín Martín[4]. *[1]Regional University Hospital of Malaga, Rheumatology Service, Málaga, Spain; [2]Virgen Macarena University Hospital, Rheumatology Service, Seville, Spain; [3]Canarias University Hospital, Tenerife, Rheumatology Service, Tenerife, Spain; [4]Nuestra Señora de la Candelaria University Hospital, Rheumatology Service, Tenerife, Spain*

Background: Nurses play a key role in the management of Systemic Lupus Erythematosus (SLE) due to their close contact with the patient. Well-structured resources and specialized training are necessary to ensure comprehensive and quality care. However, no complete clinical practice guidelines for nurses have been developed for the management of SLE in Spain or Europe [1].

Objectives: In this context, the OpenReuma scientific society decided to promote the RECOMIENDAles project, the aim of which is to create consensus-based recommendations for the management of SLE patients by nurses in Spain.

Methods: Following a bibliographic review, the Delphi method [2] was followed to reach the consensus and a structured survey was sent to nurses with expertise in SLE. Two successive rounds were conducted. Consensus was established when at least 70% of the panelists agreed or disagreed on a topic.

The final questionnaire contained 90 items divided into 3 sections (Figure 1).

Figure 1. Structure of the RECOMIENDAles project questionnaire.

Results: In Spain, few nurses could be considered experts in SLE, hence the number of panelists was small: 25 nurses from different specialties (Rheumatology: 80%, Autoimmune Disease Units: 4%, Internal Medicine: 4%, and Day Hospital Services: 12%) with sufficient experience to ensure validated recommendations that could translate into practice. All the participants worked in public hospitals and had more than 2 years of experience treating SLE patients.

A high consensus was reached on the role and responsibilities that nurses should have in relation to SLE patient management. The main results are summarized in Table 1.

Table 1. Summary of the main recommendations reached in the RECOMIENDAles Project.

RECOMMENDATIONS	% of agreement (7 – 9 score)
General recommendations	
• Multidisciplinary teams with at least one nurse trained in SLE	100%
• Participate throughout the SLE patient care process and have their own agenda of visits and content	92%
• Psychological and social worker support	96%
• Access to continuous training (SLE management, individual and group counselling and communication techniques)	100%
• Access to research projects	96%
Specific recommendations	
Diagnosis:	
• Inform the patient about the diagnosis (manage expectations and resolve doubts and fears)	100%
• Provide contact channels with the service and reliable sources of information	100%
• Collaborate in the physical examination	92%
• Collaborate performing diagnostic tests	76%
Education:	
• Have a structured plan for patient education, engaging family and friends	100%
• Inform about the pathology (disease course, symptoms indicating aggravation, comorbidities)	96%
• Inform about healthy lifestyle habits (diet, hydration, exercise, rest patterns, photoprotection measures), avoiding toxic habits such as alcohol or smoking	100%
Treatment:	
• Play an active role in treatment training, including self-administration and adherence monitoring	100%
• Take part in the decision to introduce injectable therapy at home	76%
• Prepare a youth-adult therapeutic transition plan	100%
Follow-up:	
• Supervise patient condition to prevent comorbidities (diabetes, obesity, osteoporosis, cardiovascular problems)	96%
• Promote family planning measures	100%
• Monitor patient needs during the youth-adult transition	96%

Conclusion: Despite the high consensus achieved, to bring these recommendations to fruition it is necessary to: 1) Reinforce the role and presence of the specialized nurse in multidisciplinary teams treating SLE patients; 2) Establish a specific training plan for nurses: accredited, subsidized and supported by the Scientific Societies; and 3) Create detailed clinical practice guidelines for the SLE nurse specialist.

POS1557-HPR PATIENT-CENTRIC INTERPROFESSIONAL EDUCATION AS A MEANS TO INCREASE HEALTH PROFESSIONAL STUDENTS' AWARENESS AND UNDERSTANDING OF SCLERODERMA

H. Bowen[1,2], M. Morgan[3,4], L. Shapiro[5,6]. *[1]Steffens Scleroderma Foundation, Research, Albany, United States of America; [2]Hartwick College, Translational Biomedical Research Management, Oneonta, United States of America; [3]Russell Sage College, Nutrition Science Department, Troy, United States of America; [4]Steffens Scleroderma Foundation, Educational Awareness, Albany, United States of America; [5]Albany Medical Center, Rheumatology, Albany, United States of America; [6]Steffens Scleroderma Foundation, Chief Medical Officer, Albany, United States of America*

Background: Incorporating a complex chronic disease into an interprofessional education (IPE) event is an appropriate method to increase knowledge and awareness of diseases that require multiple disciplines to manage. Scleroderma is one example of a rheumatic condition that requires an interprofessional (IP) team management approach. In practice, the rheumatologist must rely heavily on other healthcare professionals to provide optimal care to a scleroderma patient. Core competencies such as teamwork, leadership, and accomplishing common patient care aims are promoted by IPE[1]. The foundation of the patient-centric approach is seldom learned in a classroom setting while IPE can promote the observation of the patient-lived experience, the value of patients as a knowledge resource, and the emphasis of patient diversity[2].

Objectives: At each event we aim to increase awareness and understanding of scleroderma among health care professional students and enable patients to draw on their health histories to act as lead educators. Based on the success to date, we hope to promote replication of this model at other scleroderma centers.

Methods: Over four years, approximately 800 students from Russell Sage College, Albany College of Pharmacy and Health Sciences, and most recently The State University of New York at Albany, have participated in an IPE event which included individuals living with scleroderma and/or caregivers. For the first three years the event was held in person and the most recent was hosted virtually following the same structure as years prior. The event includes introductions of the moderators and words from a patient advocate followed by guidance on active listening and patient interview techniques. Eight to ten students enrolled in health-related programs including nutrition, psychology, occupational therapy, physical therapy, pharmacy, nursing and public health are assigned into small IP teams. Each team joins a round table or breakout room with one patient and/or caregiver. Students ask discipline specific questions which allows the patient and/or caregiver to share their narrative(s), enabling students to cultivate active listening skills and elicit the perspective of the patient. As the disease presentation and symptoms vary, the student IP teams will then interview another patient and/or caregiver. During the event students also hear best practices through a facilitated patient interview. An expert panel reflective of the disciplines represented on the student IP teams who have experience working with those diagnosed with scleroderma and other chronic conditions answer student questions. All attendees are asked to complete an anonymous pre and post event survey.

Figure 1.

Results: Including patients with scleroderma as educators is effective in increasing student awareness and knowledge of the disease. The implementation of this model into IPE also allows students to practice IP collaboration specific to the needs of an individual living with scleroderma, as it would occur in the health care setting.

Conclusion: This patient-centric IPE enables patients to share their medical journey as lead educators in increasing future health care professionals' awareness and knowledge of scleroderma. Replication of this pilot model at other scleroderma centers worldwide could promote the collaboration needed from healthcare professionals to assure the best quality of care for those living with scleroderma.

POS1558-HPR INFLUENCING FACTORS ON WORK BURNOUT OF PRE-EXAMINATION AND TRIAGE NURSES UNDER THE NORMAL EPIDEMIC PREVENTION AND CONTROL

B. L. Zhang[1,2], S. X. Zhang[1,2,3], T. Cheng[1,2,3], F. P. Lian[1,2], X. Si[1,2], C. H. Wei[1,2]. *[1]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China; [2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China; [3]Shanxi Medical University, Key laboratory of Cellular Physiology, Taiyuan, China*

Background: Nurse is a high-risk groups work fatigue feeling, which seriously affects the quality of conventional work efficiency and bureden pressures for contradiction between nurses and patients especially during the COVID-19 pandemic.Normalized epidemic prevention and control during the preview triage nurse need to all patients to the hospital and the accompanying personnel carries on the preliminary screening.COVID-19 fixed point hospital preview triage

nurse with an infected person contact, more prone to anxiety,depression, results in the decrease of efficiency, to treat the service object formulation work sense of fatigue performance, etc.

Objectives: To explore the influencing factors of work burnout of pre-test and triage nurses under normal epidemic prevention and control.

Methods: A total of 110 pre-test and triage nurses from 4 Grade-A hospitals in Shanxi Province were enrolled in this study. The general data questionnaire, Nurse Job Burnout Scale, Pittsburgh Sleep Quality Index Scale, Self-Rating Anxiety Scale and Self-Rating Depression Scale were investigated towork burnout of pre-examination and triage nurses. Comparison between groups using two Independent sample t-test and single factor variance analysis. Multiple regression were applied to analysis factors affecting nurse fatigue feeling dimensions by SPSS22.0. P values<0.05 were considered significant.

Results: As shown in Table 1, different professional title, department, and the sleep quality of preview triage nurses emotional exhaustion dimension comparison(P<0.001), different department nurses to personalized level dimension comparison(P<0.05), nurse personal accomplishment dimension comparison of different cultural levels(P<0.05). Professional title, working department, sleep quality and educational level were the influencing factors of job burnout of pre-test and triage nurses.

Conclusion: In the COVID-19 epidemic, managers should pay more attention to the main factors that affect the sense of exhaustion of pre-test and triage nurses, and take targeted intervention measures to alleviate the sense of exhaustion of nurses, so as to ensure the safety of nursing.

POS1559-HPR

PHYSIOTHERAPISTS MAKE LIMITED USE OF BEHAVIOUR CHANGE TECHNIQUES DURING PHYSICAL ACTIVITY COUNSELLING FOR PEOPLE WITH AXIAL SPONDYLOARTHRITIS

K. Niedermann Schneider[1], U. Vogt[2], A. K. Rausch Osthoff[1]. *[1]Institute of Physiotherapy, School of Health Sciences, Winterthur, Switzerland; [2]Startpunkt Physio&Training, physiotherapy practice, Zurich, Switzerland*

Background: The 2018 EULAR recommendations for physical activity (PA) in people with inflammatory arthritis and osteoarthritis state that PA in generally recommended dose is effective, safe and feasible (1). Based on the recommendations, the Ankylosing Spondylitis Association of Switzerland (SVMB) developed a concept for their exercise groups, consisting of guidance on exercising, regular fitness assessments and individual PA counselling by the group-leading physical therapist (PT). The use of behaviour change techniques (BCTs) during PA counselling ought to support counselees' adherence to individual, unsupervised exercising.

Objectives: To assess the BCTs used by the PTs during their PA counselling sessions with the members of their axSpA exercise groups.

Methods: An observational cross-sectional study was performed with the first cohort of PTs (n=16) who applied the new concept and provided PA counselling, and their group members who agreed to participate. All first counselling sessions with an individual with axSpA were audiotaped, transcribed and analysed using a coding manual for BCTs (2). The manual includes 38 BCTs across the determinants 'knowledge' (2 BCTs), 'awareness' (8 BCTs), 'social influence' (3 BCTs), 'attitude' (4 BCTs)', 'self-efficacy' (6 BCTs), 'intention (6 BCTs)', 'action control' (2 BCTs), 'facilitation' (2 BCTs), 'maintenance' (5 BCTs). Two raters familiar with BCTs identified the BCTs used by the PTs. They repeatedly discussed and agreed about their classifications of PTs' phrasings to BCTs in an iterative process to achieve consistency over all counselling sessions. A BCT could be used several times within one counselling session.

Results: A total of 12 PTs (75%) who counselled 41 people with axSpA participated. All 41 PA counselling sessions, lasting between 30-55 minutes were analysed. Overall, 15 out of the 38 BCTs were identified. Across each determinant (with its number of BCTs), the most and least frequently used BCTs were as follows: 1) determinant 'knowledge' (1 of 2 BCTs used): 'provide general information' (469 times by 12 PTs); 2) 'awareness' (3 of 8 BCTs used): reflective listening and 'self-monitoring of behaviour' (328x by 12 PTs and 39x by 9 PTs respectively); 3) 'social influence': none of 3 BCTs used; 4) 'attitude' (1 of 4 BCTs used): persuasive communication (184x by 11 PTs); 5) 'self-efficacy' (3 of 6 BCTs used): verbal persuasion and guided practice (77x by 11 PTs and 3x by 3 PTs respectively); 6) 'intention' (4 of 6 BCTs used): general intention formation and develop training schedule (250x by 12 PTs and 18x by 5 PTs respectively); 7) 'action control' (1 of 2 BCTs used): use of cues (199x by 12 PTs), 8) 'facilitation': none (of 2) BCTs used; 9) 'maintenance' (2 of 5 BCTs used): continuous professional support and individualize regimen (137x by 12 PTs and 70x by 10 PTs respectively).

Conclusion: The study identified that PTs used only a limited number of BCTs. BCTs considered less effective such as providing information were widely used, whereas BCTs that are considered effective, such as specific aims or coping with barriers were much less or not at all used. This study provides an insight in real clinical practice and may help to develop counselling training for PTs. There is a need to translate theoretical BCTs into effective measures that are easy to use in clinical practice.

HPR Interdisciplinary research

POS1560-HPR "MY GUT FEELING IS…": IDENTIFYING HOW HEALTHCARE PROFESSIONALS COMMUNICATE ABOUT PAIN IN PAEDIATRIC RHEUMATOLOGY MULTIDISCIPLINARY TEAM MEETINGS

R. Lee[1,2], J. Mcdonagh[1,2,3], T. Rapley[4], A. Farre[5], M. Connelly[6], T. Palermo[7], K. Toupin-April[8,9,10], S. Peters[11], L. Cordingley[1,2]. *[1]University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom; [2]Manchester University Hospital NHS Trust, National Institute for Health Research Biomedical Research Centre, Manchester, United Kingdom; [3]Manchester University Hospitals Trust, Royal Manchester Children's Hospital, Manchester, United Kingdom; [4]Northumbria University, Department of Social Work, Education and Community Wellbeing, Northumbria, United Kingdom; [5]University of Dundee, School of Health Sciences, Dundee, United Kingdom; [6]Division of Developmental and Behavioral Health, Children's Mercy Kansas City, Kansas City, United States of America; [7]Seattle Children's Research Institute, Center for Child Health, Behavior and Development, Seattle, United States of America; [8]University of Ottawa, School of Rehabilitation Sciences, Faculty of Health Sciences, Ottawa, Canada; [9]University of Ottawa, Department of Pediatrics, Faculty of Medicine, Ottawa, Canada; [10]Children's Hospital of Eastern Ontario, Research Institute, Ottawa, Canada; [11]University of Manchester, Manchester Centre for Health Psychology, Division of Psychology and Mental Health, Manchester, Canada*

Background: Multi-disciplinary teams (MDTs) are common in paediatric rheumatology where UK standards of care state that all children/young people should have access to a paediatric rheumatologist, nurse, physiotherapist, occupational therapist and a psychologist. MDTs in paediatric rheumatology regularly meet for the broader purpose of discussing the assessment of and future management plans for children/young people with a range of complex conditions in which chronic pain may feature. The content of these discussions has not been previously researched. Little is known about healthcare professional to healthcare professional communication and how this may influence the care of children/young people with chronic pain.

Objectives: The objective of the current study was to investigate healthcare professionals communication about children and young people with chronic musculoskeletal pain during MDT meetings in paediatric rheumatology.

Methods: This study was a non-participant ethnographic observation of virtual and face-to-face MDT meetings in three paediatric rheumatology centres in the UK. A structured observation checklist was used to capture and organise field notes which were analysed using an inductive thematic approach amongst research team members. Interpretation of field notes was guided by discussions with healthcare professionals from each of the teams involved.

Results: Forty-two healthcare professionals from across the three teams participated. Ten meetings from each team (n=30) were observed, with meetings ranging from 1-2 hours. Analysis was organised into three themes;

1)*Describing the child/young person with pain*: Healthcare professionals' perceptions about personality characteristics (e.g. "He is mature", "She is sensitive") were frequently used to introduce a child/young person to the team. A child/young person description was always accompanied by a description of parents and perceptions about their behaviour (e.g. "Dad is very disengaged", "Mum can shout").

2)*Interpreting the pain of the child/young person*: A core component of interpretations was professional's familiarity with the child/young person and parents (e.g., "I haven't got a handle on them yet"). Professionals also discussed how their interpretations of pain were influenced by "gut feelings" or "vibes that something else is going on at home".

3)*Managing the child/young person with pain*: Healthcare professionals discussed the need for acceptance of pain and treatment from children/young people (e.g., "She wasn't buying into that"; "He needs to get used to it"). Setting boundaries for children/young people and parents for accessing the team also featured in discussions (e.g., "We need to re-assure them but not always be available").

Conclusion: This study highlights a range of healthcare professional approaches and processes to communicating about and discussing children/young people with pain at paediatric rheumatology MDT meetings. Findings suggest that healthcare professionals in paediatric rheumatology describe, interpret and manage the child/young person presenting with pain alongside the broader psychosocial (and less frequently the biological) context. These findings will inform the content and methods of a behaviour change intervention to improve pain communication in consultations with children/young people, parents and amongst the paediatric rheumatology team of healthcare professionals in the UK.

POS1561-HPR HEALTH CARE PROVIDERS' PERSPECTIVE ON CONTINUATION VERSUS TEMPORARY INTERRUPTION OF IMMUNOMODULATORY AGENTS IN CASE OF AN INFECTION: AN INTERVIEW STUDY

M. Opdam[1], J. E. Vriezekolk[2], A. Den Broeder[1,3], L. M. Verhoef[1]. *[1]Sint Maartenskliniek, Rheumatology, Ubbergen, Netherlands; [2]Sint Maartenskliniek, Research, Ubbergen, Netherlands; [3]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands*

Background: Immunomodulatory agents (IA) are often used in the treatment of immune mediated inflammatory diseases (IMIDs). The use of some of these IA is associated with a slightly increased infection risk (1), which raises concerns especially during the current COVID-19 pandemic. It is however unknown whether it is best to continue or temporary interrupt IA in case of an infection, and what the views of health care providers are on this subject.

Objectives: To obtain insight in the health care providers' perspective regarding continuation and temporary interruption in case of an infection and to assess barriers and facilitators for both treatment strategies.

Methods: Health care providers, involved in the pharmacological treatment of different IMID patients, were interviewed by phone or face-to-face using semi-structured interviews. Recruitment was done using purposive sampling based on age, gender, function, specialty and affinity with the topic. Interviews were conducted until data saturation and analyzed by two researchers using inductive thematic analysis.

Results: Thirteen health care providers with three different functions (medical specialist, physician assistant, resident in training) from three different medical specialties (rheumatology, gastroenterology and dermatology) were interviewed. Mean age was 49 years (range 34 to 66) and the majority was female (69%). Ten main themes were constructed, yielding 77 barriers and facilitators across the two treatment strategies (see Table 1 for themes and a selection of barriers/facilitators). Health care providers mentioned that the choice between continuation and temporary interruption is often about balancing infection severity, IMID severity (e.g. risk of flare) and patient characteristics (comorbidities/vulnerability). They struggled with the lack of evidence on these two treatment strategies, which leads to choices being made based on previous experiences or intuition.

Table 1. Identified themes

Theme	Example of barrier/facilitator
1. IMID characteristics	Low disease activity (facilitator for interruption)
2. IA characteristics	Large administration intervals: interruption not possible (barrier for interruption)
3. Effects of IA on infection / immune system	Belief on positive effect (facilitator for continuation)
4. Patient characteristics	Patients with comorbidities / history of previous infections (facilitator for interruption)
5. Infection characteristics	Mild infection (facilitator for continuation)
6. Guidelines / current practice	Current practice = interruption of IA during infection (barrier for continuation)
7. Health care provider characteristics	Peer influence (facilitator for interruption; health care providers state that they would interrupt IA if for example an infectious diseases specialist would recommend so)
8. Financial	Higher costs (barrier for continuation)
9. Stopping IA in general	Chance to stop/taper IA (facilitator for interruption)
10. Interruption characteristics	Short duration: no impact on disease activity (facilitator for interruption)

Conclusion: A wide variety of barriers and facilitators for temporary interruption and continuation of IA during infection were identified. These perceived barriers and facilitators –together with emerging evidence on the risk and benefits of IA use during infections (2)– will aid implementation of the most optimal strategy regarding IMIDs, IA and infections.

Patient information and education

POS1562-PARE CAN EDUCATION PROGRAMS REDUCE ANXIETY IN PATIENTS WITH RHEUMATOID ARTHRITIS?

S. Lezhenina[1], N. Shuvalova[2], E. Guryanova[3], N. Igoshina[2]. *[1]Chuvash State University by I. N. Ulianov, Departament of Healthcare Management and Economics, Cheboksary, Russian Federation; [2]I.Ya. Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation; [3]Chuvash State University by I. N. Ulianov, Department Internal Diseases, Cheboksary, Russian Federation*

Background: Persistence of pain syndrome is accompanied by emotional changes and contributes to the formation of anxiety disorders in patients with rheumatoid arthritis (RA). Models of training patients with RA are aimed at developing the correct behavioral stereotype and improving the psychological status. To evaluate the effectiveness of these educational programs, it is required to study the impact of these programs on the level of anxiety in patients with RA.

Objectives: To assess the impact of education in an educational program in patients with RA on the level of anxiety.

Methods: The study was conducted in the Chuvash Republic, the city of Alatyr, from December to January 2020. 90 patients with RA of varying severity were examined. The inclusion criterion was a diagnosis of RA in accordance with the criteria of the European Antirheumatic League (EULAR) / ACR 2010. All patients were randomized into two groups: the main group (n=45), which, on the background of drug therapy (methotrexate at a dose of 7.5 to 15 mg/week and nimesulide 200 mg/week) was trained in the educational program: lectures and practical exercises. In the practical part, most of the time was devoted to the skills of self-control of the disease (taught how to self-assess swollen and painful joints). The training was carried out in two stages. The first stage (lecture-practical course) - twice a week for 1.5 hours, for two weeks, full-time education. The second stage (lecture course) - twice a week for 1.5 hours for two weeks, distance learning. In the control group (n=45), patients received the same treatment but were not trained in the educational program. Patients in these groups were representative by sex and age. All patients before and after completing the training program (after 1 month) were determined the level of situational and personal anxiety according to the Spielberger questionnaire modified by Yu.L. Khanina. The results obtained were interpreted: up to 30 points - a low level of anxiety, 31-45 corresponded to an average level, over 45 - a high level of anxiety. Statistical processing was carried out in the MS Office Excel package with the determination of average values (M), standard deviation. In each group, anxiety levels before and after training were compared using Student's t-test for normally distributed data, otherwise Wilcoxon's test. Differences were considered statistically significant at $p<0.05$.

Results: Before training in the main group, the structure of personal anxiety was represented by a high level of 62.14 ± 4.46 points (83.0% of patients), while reactive anxiety was represented by average values of 39.24 ± 3.29 (62% of patients). 2% of respondents had a low level of personal anxiety, 5.2% of patients had low levels of reactive anxiety. Anxiety scores were about the same in the two groups. After training in the main group, the level of personal anxiety decreased in 41% of respondents (53.22±6.87 points), reactive anxiety decreased by more than 2 times in 27% of patients. The number of patients with low levels of both personal and reactive anxiety increased to 40% and 40.2%, respectively. The differences were statistically significant ($p<0.05$). In the control group, the level of anxiety did not change statistically significantly.

Conclusion: Patients with RA who were trained in an educational program had a two-fold decrease in the level of personal anxiety and more than a two-fold decrease in the level of reactive anxiety, compared with patients who did not receive training. It is possible that the decrease in the level of anxiety in patients with RA occurred both due to a higher level of awareness of patients about this disease, and due to changes in the psycho-emotional state.

POS1563-PARE SELF-MANAGEMENT STRATEGIES FOR ADVERSE DRUG REACTIONS AS REPORTED BY TNF-ALPHA INHIBITOR USERS: AN OBSERVATIONAL STUDY

M. Ophoff[1], J. Van Lint[1], S. Tas[2], B. Van den Bemt[3], H. Vonkeman[4], F. Hoentjen[5], M. Nurmohamed[6], N. Jessurun[1]. *[1]Netherlands Pharmacovigilance Centre Lareb, Dutch Biologic Monitor, 's-Hertogenbosch, Netherlands; [2]Amsterdam UMC, Locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands; [3]Sint Maartenskliniek, Pharmacy, Research and Innovation, Ubbergen, Netherlands; [4]Medisch Spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands; [5]University of Alberta Hospital, Division of Gastroenterology, Edmonton, Canada; [6]Stichting Reade, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*

Background: Self-management strategies of adverse drug reactions (ADRs) are outside the vision of healthcare professionals (HCPs). Nevertheless, patients consider this information as one of the most important domains regarding ADR information (1). Therefore, identifying these strategies is important for both HCPs and patients.

Objectives: To identify which self-management strategies are applied by patients with immune-mediated inflammatory diseases (IMIDs) who encountered injection site reactions, local/systemic infections, or skin reactions during the use of adalimumab or etanercept.

Methods: Data of the Dutch Biologic Monitor (DBM), a prospective cohort event monitoring system, was used. Patients using biologics for IMIDs were asked to fill out bimonthly questionnaires on biologic use and experienced ADRs including questions on applied self-management strategies in an open-ended text field. For this study we included patients who used adalimumab or etanercept and reported injection site reactions, infections or skin reactions with self-management strategies. Self-management strategies were identified with thematic-analysis of the open-ended text fields.

Results: We included 160 patients and the characteristics are presented in Table 1. Most patients experienced injection site reactions (n=149), followed by infections (n=133), and skin reactions (n=101). Of these patients, the lowest number of applied self-management strategies was reported for injection site reactions (n=42, 28%), followed by skin reactions (n=62, 61%), and infections (n=88, 66%). The self-management strategies included themes such as 'Changing methods of administration' for injection site reactions, 'Change of personal care' for skin reactions, and 'Additional treatment for the ADR' for infections. Figure 1 shows which items are covered by these themes.

Table 1. Patient characteristics.

Patient characteristics, n=160	**n (%)**

POS1564-PARE EDUCATION TOPICS AND SMARTPHONE APP FUNCTIONS PRIORITIZED BY PEOPLE WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES

W. B. Nowell[1], K. Gavigan[1], K. Garza[2], A. Ogdie[3], M. George[3], J. A. Walsh[4,5], M. Danila[6], S. Venkatachalam[1], L. Stradford[1], J. Curtis[6]. *[1]Global Healthy Living Foundation, Patient-Centered Research, Upper Nyack, United States of America; [2]Auburn University, Harrison School of Pharmacy, Auburn, United States of America; [3]University of Pennsylvania, School of Medicine, Philadelphia, United States of America; [4]University of Utah, School of Medicine, Salt Lake City, United States of America; [5]George E. Wahlen Veterans Affairs Medical Center, Rheumatology, Salt Lake City, United States of America; [6]University of Alabama at Birmingham, School of Medicine, Birmingham, United States of America*

Background: Generating information that people living with a rheumatic and musculoskeletal disease (RMD) find useful while making decisions about their treatment requires identifying and understanding educational needs and interests directly expressed from people living with RMD.

Objectives: To identify what types of information US adults with RMD perceive as important to know about their disease and how they express and prioritize such information.

Methods: Using nominal group technique, focus groups of participants (pts) with RMD generated sets of rank-order educational items which were then aggregated across groups into themes. Based on nominal group results, a survey with the final 28 items was administered online, along with a question about desired functions of a smartphone app for RMD, to members of the ArthritisPower registry in January 2022.

Results: Six nominal groups (n=47) yielded 28 unique items for the online survey of educational priorities. To date, a total of 570 pts completed the survey, of whom 85.4% were female, 89.5% white, mean age of 59.6 (SD 11.2) years. Rheumatoid arthritis (52.5%), osteoarthritis (16.0%), psoriatic arthritis (12.5%), and axial spondyloarthritis (7.5%) were the most common RMDs. Knowing how to tell when a medication is not working, how RMD affects other medical conditions, understanding the results of tests used to monitor their RMD, available treatment options and possible side effects, and how life will change as an RMD progresses were each items that > 75% of pts considered extremely important (Table 1). Top functions pts listed as useful for a smartphone app included being able to participate in research, view lab results, record symptoms or flares, share how they are doing with their provider, and get educational information about their disease (Table 2).

Table 1. Top Education Topics Adults with Rheumatic and Musculoskeletal Disease Consider Extremely Important (N=570).

Item	n (%)
Knowing when the medication is not working	505 (88.6)
Knowing how a rheumatologic condition can affect your other health conditions or medical issues	481 (84.4)
Understanding the results of tests used to monitor your condition	471 (82.6)
Knowing the side effects of available drugs, and how the drugs interact with each other	461 (80.9)
Finding the right rheumatologist	453 (79.5)
Having realistic expectations of the effectiveness of the medications	445 (78.1)
Knowing how the disease will progress, even if the news is bad	439 (77.0)
Knowing the available medications and treatments for your rheumatologic condition	437 (76.7)
Knowing how long it takes drugs to work	436 (76.5)
Understanding how your life will change as your disease progresses	434 (76.1)

Table 2. Desired Smartphone App Functions Rated By Adults with Rheumatic and Musculoskeletal Disease (N=570).

App Function	n (%)
Participate in patient-centered research	299 (52.5)
View my lab results	283 (49.7)
Record my symptoms (e.g. pain, fatigue) or disease flares to track my health over time	278 (48.8)
Record my symptoms and share how I am doing with my rheumatology provider to know if I am meeting my treatment goals	230 (40.4)
Get educational information about my disease	225 (39.5)
Keep track of the medications prescribed by doctor	200 (35.1)
Schedule and keep track of my medical appointments, rheumatology and other	199 (34.9)
Track the vaccines I get (i.e. vaccination record)	188 (33.0)
Help me improve some of my health habits (e.g. sleep, diet, exercise)	187 (32.8)
Keep track of my use of over-the-counter, complementary or alternative therapies (herbs, tinctures, acupuncture, massage, stretching, etc.)	174 (30.5)
Get support for my disease from trained patients with my same health condition (i.e. 'peer coaching')	144 (25.3)

Conclusion: People with RMD prioritized information about medications and prognosis in educational materials, providing guidance for the development of educational tools. A sizeable minority felt educational materials were an important component of a smartphone app, but also identified other important features such as participation in research.

POS1565-PARE ASSESSMENT OF QUALITY AND RELIABILITY OF YOUTUBE VIDEOS FOR PATIENT AND PHYSICIAN EDUCATION ON INFLAMMATORY MYOSITIS

M. Joshi[1], N. R[2], R. Gupta[1], V. Agarwal[2], R. Aggarwal[3], L. Gupta[2]. *[1]Byramjee Jeejeebhoy Government Medical College and Sassoon General Hospitals, Department of Medicine, Pune, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India; [3]University of Pittsburgh, Department of Medicine, Rheumatology and Clinical Immunology, Pittsburgh, United States of America*

Background: Nowadays 80% of internet users access health information online, with YouTube being the second most popular search website worldwide. This study was undertaken to assess the reliability and quality of videos pertaining to myositis on YouTube and identify lacunae in information material on the platform.
Objectives: This study aims to assess the quality and profile of myositis information videos on YouTube, and to compare and delineate attributes of useful and not useful videos using standard metrics.
Methods: A thorough search was carried out on YouTube using 9 search terms related to myositis. The inclusion criteria were primary English content related to myositis, acceptable audio-video quality, and multi-part videos to be considered as one, while duplicates and advertisements were excluded. The videos were classified as useful, not useful or misleading, and patient experiences (Figure 1).

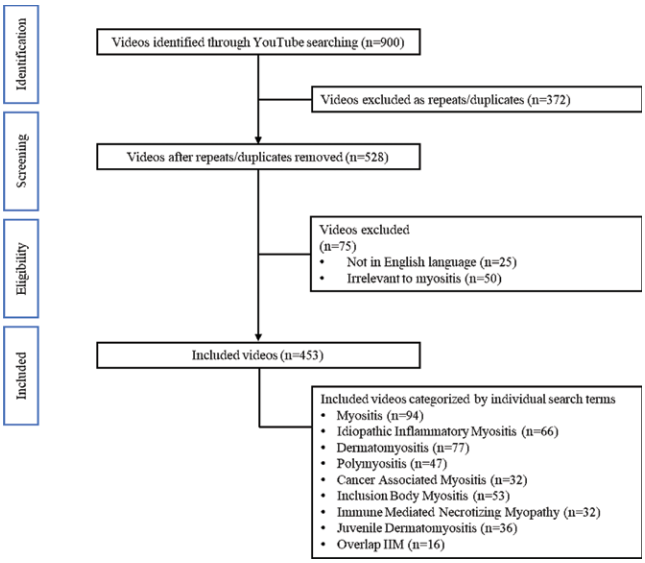

Figure 1. Flowchart of selection of YouTube videos for the study

Reliability of the videos was determined using the 5-point modified DISCERN (mDISCERN) criteria and quality by the 5-point Global Quality Scale (GQS) and 4-point JAMA scoring system. Score-based usefulness was defined as mDISCERN >4 or GQS >4 or JAMA >3. All values are in median and IQR.
Results: Of 453 analyzed videos 74% and 2% provided useful and not useful information respectively. 24% were patient experiences, and 324 (71%) were intended specifically for patients while 313 (69%) were for healthcare providers and students. Nearly one-thirds (n=143) reported information related to treatment of myositis.
Noteworthily, useful and not useful videos had similar views count. However, number of likes and daily viewership were higher for useful videos (p=0.024, p=0.046). Nearly half (47%) of useful videos were by professional medical societies/patient support groups while not useful ones were often by nonmedical media (38%).
Useful videos had higher mDISCERN reliability scores [4(3-4) vs 2(1-3), p<0.001] and better quality on GQS [4.5 (3.5-5) vs 1 (1-2.8), p<0.001] and JAMA [3 (3-4) vs 2.25 (2-3), p=0.004]. Physician predicted usefulness was discordant with score-based usefulness(κ=0.129). However, GQS score emerged significant (p=0.008) for predicting video usefulness in multivariate analysis (Table 1).

Table 1. Factors predicting usefulness of video in binary logistic regression.

Variable	B coefficient	S.E.	Exp (B) and 95% CI	p value
Intended audience	-5.45	2.586	0.004 (0.0-0.68)	0.035
Anyone/General public Average GQS	-2.86	1.076	0.05 (0.007-0.47)	0.008

GQS Global Quality Scale. Exp (B) is odd's ratio, p<0.05 is significant

Conclusion: Majority of English YouTube videos on myositis provide useful information for patients, largely related to treatment of myositis. However, the dynamic nature of YouTube could potentially change this equation in the future and physicians should correct any misinformation identified in face-to-face meetings or teleconsultations. High quality useful videos, often predicted by validated scores and produced by professional medical societies should be promoted as the first line of content consumed.

POS1566-PARE BEYOND MEDICATION – SELF MANAGEMENT AS A COMPLEMENTARY APPROACH FOR TREATING RMDS

S. David[1]. *[1]Cyprus League of People With Rheumatism., Self-Management Education Workshop, Nicosia, Cyprus*

Background: Upon diagnosis Rheumatoid Patients declare that the feeling that prevails is fear. Fear over the unknown over their health condition, their professional future, and their personal and social life. The person experiences a vicious cycle. Loss of control leads to anxiety which triggers pain which enhances psychological distress, thus the person feels completely helpless.
Objectives: The Self-Management education workshop is offered as a complementary aid, next to the arranged medical plan and the medications prescribed. The primary goal of the Workshop is for patients to accept their new reality which is, living with RMD. Further on, grounds for change are set. Patients within the program are taught in great detail how to engage new healthy, daily activities, such as appropriate exercise, appropriate use of medications, healthier nutrition, communicating effectively their fatigue, anxiety and psychological distress to family and friends. Patients are also taught, how to communicate to health professionals their condition, seek for information so as to evaluate new treatments, and demand the right for shared decision over their treatment. Moreover they receive information about the Cyprus League of people with Rheumatism, the social and psychological help provided, practicalities that concerns them, availability of Doctors, and new medications. Information, provides a strong Know-how, to deal with everyday problems. Such achievement enhances the confidence that a new well-being could be within the persons reach.
Methods: Participants meet for two hours once a week, for five weeks. Two trained leaders conduct the workshop, one being a health professional and one patient. Participants are to the maximum 15. Major rules of a therapeutic group apply, such as empathy, confidentiality, respect in every sharing, time keeping, simple language. All activities are Interactive. Discussions, questions and answers, brain storming, action-planning exercises and feedback, role playing, problem-solving techniques, and decision making. Moreover, symptom management activities are included, such as exercise, relaxation, communication, healthy eating, medication management, and managing sleep and fatigue. During the workshop, participants experience rapport, and trust thus they are motivated to manage the challenges associated with their condition.
Results: Participants demonstrated significant improvements in exercise, ability to do social and household activities, less depression, less fear and frustration about their health, reduction in symptoms like pain, improve mobility, increase energy, and boost confidence in their ability to manage their condition. Results of every workshop are scientifically documented.
Conclusion: Self-Management workshops are often described by new coming participants as "render of last hope". The structure and the facilitators create a safe environment for the patient to release the pain, seek knowledge, express the despair, set all the nightmares free. Acceptance, Respect, Rapport, Trust, knowledge aid the participants to experience the rebirth of hope. Self-Management workshops, are designed to complement clinical treatment and when delivered with empathy, lead RMD patients to physical and psychological well-being.

POS1567-PARE **ASSESSMENT OF ADHERENCE AMONG GREEK PATIENTS WITH RHEUMATIC DISEASES DURING THE COVID-19 ERA**

K. Koutsogianni[1], E. Repa[2], K. Spanidou[2], I. Papadakis[3], I. Chatzikrystallis4, P. Pratsidou-Gertsi[5], F. Asimakopoulou[6]on behalf of ReuMAzein's Team. *[1]PanHellenic Federation ReuMAZein, PanHellenic Federation ReuMAzein, Thessaloniki, Greece; [2]PanHellenic Federation ReuMAZein, Parents' and Caregivers' Association of Children With Chronic Rheumatic Diseases, Thessaloniki, Greece; [3]PanHellenic Federation ReuMAZein,The arthritis Foundation of Crete, Crete, Greece; [1]PanHellenic Federation ReuMAZein, PanHellenic Federation ReuMAzein,Thessaloniki, Greece; [5]PanHellenic Federation ReuMAZein, Friends Association of Children With Chronic Rheumatic Diseases,Thessaloniki, Greece; [6]PanHellenic Federation ReuMAZein, Patients' Association with Rheumatic Diseases of Patra, Patra, Greece*

Background: Patient's (pts) adherence is a EULAR important recommendation for an optimal disease course and outcome. COVID-19 pandemic has globally challenged the issue of adherence. As relevant Greek data are lacking, the Pan-Hellenic Federation "Rheumazein" (i.e., co-living with a Rheumatic Disease) conducted a survey among their members to assess adherence and a possible COVID-related negative impact.
Objectives: The main endpoint of the study aimed to capture the degree of pt adherence to treatment, either with conventional synthetic or/and biologic DMARDS (csDMARDS, bDMARDS). The secondary endpoints were: a. To record pts'–physicians' interactive communication to assess the level of shared disease making (SDM). b. The emerged barriers to medication access during the pandemic and consequent restrictive measures. c. To record pt perceptions on the usefulness of mobile reminder applications towards an uninterrupted regimen.
Methods: A 29-item quantitative questionnaire was uploaded in the social media of the Federation and its associations, in order to register pts' responses on the aforementioned sections. The questionnaire was accessible for a 58-day period (21/09/2021-17/11/2021).
Results: Participants' characteristics: The responses of 303 adults with RD (M:F 63:240), aged (in yrs) 18-44: 35%, 45-54: 26%, >55: 38% respectively, were available for analysis. The RD types were RA 33%, AS 18%, PsA 13%, SLE 18%, Juvenile Arthritis 5% and Other RD 13%, respectively. The education level was low/moderate 39%, high 30%, post-graduate 31%, respectively. Receivers of a monotherapy with either cs- or bDMARDS were 93(31%) and 83(27%), of a combined regimen cs+bDMARDs 114(38%) and off treatment 13 (4%). BDMARD receivers were mostly AS pts (93%) while the least, SLE pts (48%). The route of bDMARD administration (sc vs iv did not significantly differ (57% vs. 43%). Since diagnosis, the mean disease trajectory was 7.6 yrs, the mean time on medication 6.9 yrs, while the mean duration on the current regimen 3 yrs, respectively. Adherence: At least one skipped dose during the last trimester was reported, significantly more often by pts under csDMARDs than by those under bDMARDs, (60% vs. 40%, p<0.001) with a mean number of 2.7 vs. 1.8 skipped doses, respectively. Additionally, the main reasons of non-adherence under csDMARDs and bDMARDs significantly differed only in respect to pt responsibility (56% vs.19% p<0.001), but not for COVID-related reasons, namely fear either of getting infected, or due to a performed COVID vaccination (35% vs 42%), or due to physician recommendations (22% vs. 32%). Regarding the pt-physician interactive discussions on emerging new treatments, 90% of the pts reported this policy, but only 40% of them in a rather frequent to more frequent rate. In respect to satisfaction, 67% expressed a moderate to high satisfaction regarding the level of provided information, while the degree of their satisfaction was positively related with the frequency of these discussions. The main topics focused on the route and frequency of the medication, especially with bDMARD receivers. Of note, 80% of the bDMARD group participated in the SDM before commencing this therapy, but just 20% in the selection of the brand name. Only a minority of pts (17%) were aware of the existence of mobile applications, reminding the scheduled drug administration; however, they rated these programs as very useful (4.3 according to a 0-5 scale). Despite the difference source of supply of cs and bDMARDs on pt access to treatment, the impact of COVID-19 and consequent restrictive measures had not impaired it (1.5/5 and 1.7/5 by the above scale, respectively).
Conclusion: A significant percentage of pts skip scheduled DMARD administrations, especially those (60%) under csDMARDs. The relationship with the physician was considered relatively satisfactory. Most of the pts did not have any mobile phone reminder application regarding their dose. Finally, the COVID-19 pandemic appeared to have had little effect on pts' access to both cs- and bDMARDs and consequently, adherence to their treatments.

DOI: 10.1136/annrheumdis-2022-eular.4336

POS1568-PARE **THE BRIEF-ILLNESS PERCEPTION QUESTIONNAIRE: A METHOD FOR ASSESSING THE COGNITIVE REPRESENTATION OF RHEUMATIC DISEASE**

Z. Zeineb[1], S. Jemmali[1], S. Rekik[1], S. Boussaid[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. *[1]Rabta University Hospital, Rheumatology,Tunis,Tunisia*

Background: The common-sense model proposes that illness perception (IP), is how patients make sense of their illness and respond emotionally to it, influencing the way they cope with the illness and subsequently illness outcomes. This proposition has gained considerable empirical support, and the relevance of IP in understanding illness-related behaviors or outcomes has also been supported in patients with rheumatic diseases (RD). The Brief Illness Perception Questionnaire (B-IPQ) was designed to provide a simple and rapid assessment of IP. This questionnaire has been widely used in diverse ages, illness types, countries, and languages.
Objectives: This study aimed to examine the construct of IP as measured by the B-IPQ in patients with RD.
Methods: A cross-sectional study was conducted at a Tunisian rheumatology department on 80 patients with RD. Sociodemographic, disease-related variables were reported. Participants completed a questionnaire on illness beliefs (B-IPQ).
Results: Subjects were aged 22-74 years (mean 51 years), 61.6 % were female. Diagnoses included Rheumatoid arthritis (RA) (63%), axial spondylarthritis (AS) (37%). The mean disease duration was 11 years and 7 years for RA and AS respectively. The proportion of physical comorbidities was higher in RA patients (36%) versus AS patients (11%). Disease activity was low in 28.8% of patients. All patients were on medications for their rheumatic disease, and 34,6 % were on biological therapy.
In both diseases, the participants perceived their rheumatic illness as a chronic condition (9.4) that could be controlled by treatment (6.6) but not strongly influenced by personal actions (4.3). Overall, Rheumatic disease was seen as having an important impact on their life (7.9) without significant difference between patients with low or high activity disease (p=0.23). The majority believe that they have a moderate understanding of their illness (6.6). The frequency of symptoms was highly evaluated in RA patients than AS patients (7.3 vs 5.6) (p=0.01). In RA patients, 76% were extremely affected emotionally by their disease, however, the majority of AS patients were moderately affected emotionally with a significant difference (p=0.02). In addition, RA patients considered their disease mainly a result of psychological factors (66.8%). On the other hand, AS patients (73%) attributed their illness to various risk factors (especially physical overexertion).
Conclusion: High scores of B-IPQ shown in our studies, encourage the design of psychotherapeutic trials targeting disease-related cognitions in AS and RA in an attempt to improve patients' reported outcomes and disease outcomes.
Disclosure of Interests: None declared

Building patient led organisations

POS1569-PARE **TESTING A NEW APPROACH TO IDENTIFY AND ASSESS PATIENT-VALUED TREATMENT GOALS IN RHEUMATOID ARTHRITIS (RA): A PATIENT-ENGAGED HEALTHCARE VALUATION STRATEGY**

S. J. Bartlett[1], C. Bingham[2], Z. Predmore[3], T. Concannon[3], E. Chen[4], S. Schrandt[5], R. Xie[6], R. Chapman[6], L. Frank[4]. *[1]McGill University, Divisions of Clinical Epidemiology, Rheumatology and Respiratory Epidemiology and Clinical Trials Unit, Montreal, Canada; [2]Johns Hopkins University, Division of Rheumatology, Baltimore, United States of America; [3]RAND Corporation, RAND Health Care, Boston, United States of America; [4]RAND Corporation, RAND Health Care, Arlington, United States of America; [5]ExPPect, n/a, Arlington, United States of America; [6]IVI - Innovation & Value Initiative, n/a, Bethesda, United States of America*

Background: Common approaches to valuing health technologies often fail to capture outcomes that matter to patients and families. The treatment goals of people living with rheumatoid arthritis (RA) include common trial endpoints but also include other facets of disease impact. Identifying a feasible and rigorous approach to inclusion of the patient perspective is needed as trialists increasingly seek to incorporate patient-important outcomes in trial design and as varied patient-centered value assessment frameworks emerge. No standard approach is available to systemically identify and quantify patient-important outcomes, nor to include those outcomes in deliberative decision-making. We developed the Patient-Engaged Healthcare Valuation strategy, using principles of goal attainment scaling to frame survey-based goal collection directly from adults.

Table 1. Top Goals based on rating as "Very Important" by >70% of subjects, from set of 36. "My goals for living with RA are to…"

Goals	Not Important	Somewhat Important	Important	Very Important
Symptom Management				
improve the quality of my life with RA	0% (0)	0% (0)	23% (11)	77% (36)
manage my RA pain	0% (0)	2% (1)	11% (5)	87% (41)
reduce how my RA pain interferes with my life	0% (0)	9% (4)	17% (8)	74% (35)
Life Impact				
reduce the ways in which RA interferes with my life	0% (0)	2% (1)	21% (10)	77% (36)
be independent in my daily functioning	0% (0)	4% (1)	15% (4)	81% (22)
Managing my RA				
feel like I can manage my RA	0% (0)	2% (1)	26% (12)	72% (34)
Treatment Features				
understand my RA treatment options	0% (0)	4% (2)	21% (10)	74% (35)
have the information I need to make treatment decisions	0% (0)	0% (0)	19% (9)	81% (38)
know what to expect with my RA treatment	0% (0)	2% (1)	23% (11)	74% (35)
find treatments that are effective	0% (0)	0% (0)	6% (3)	94% (44)

Objectives: To develop and test a goal-based method for collecting RA patient input for use in clinical trials and value assessment and evaluating the feasibility of this approach in people with RA.

Methods: Patient goals and domains were identified from (1) a literature review (2010-2020) of patient outcomes, goals, and preferences in RA, and (2) discussions with patients and clinicians during two meetings with a steering committee (SC) consisting of clinicians, outcomes researchers, patients/advocates, and health economists. These goals informed the development of a draft survey. Adults with RA were recruited from online patient networks to rate goal importance and suggest additional goals. SC members reviewed the survey findings and assessed feasibility of scaling up goal collection for HTA.

Results: Of 135 articles identified, 17 were retained. An inductive and iterative approach was used to identify and thematically group the final set of 36 goals into 4 domains. The draft survey was cognitively debriefed with 4 adults with RA. The first survey was administered to 20 participants; results informed item revisions and additions for the second round of data collection (n=27).

The 47 respondents were mostly White (87%), college-educated (72%) women (93%) living with RA for an average of 15 years; 75% rated their RA as moderate to severe. Free-text goals added in round 1 include: 1) finding specialists who listen to patient input on symptoms; 2) addressing loneliness or isolation; and 3) finding support from or helping others with RA. All Symptom and Life Impact goals were rated as *Important* or *Very Important* by ≥85% of participants; endorsement for Management and Treatment goals was somewhat more variable, with ≥85% endorsing these as *Somewhat* to *Very Important*. Results suggested that domains match key goals. Steering committee ratings supported the feasibility of this method.

Conclusion: Goals relevant for RA treatment evaluation can be efficiently identified and rated for importance by patients. Patient-important goals can be incorporated into deliberative healthcare valuation using this method to permit "crowd-sourced" input from people living with RA and to capture heterogeneous patient perspectives in healthcare valuation.

Arthritis research

POS1570-PARE

A PATIENT-LED SURVEY INTO THE BENEFITS AND LIMITATIONS OF TELEMEDICINE APPOINTMENTS FOR ASSESSING CHILDREN AND YOUNG PEOPLE WITH RHEUMATIC CONDITIONS: COMPARING EUROPEAN AND CANADIAN COHORTS

R. Beesley[1,2], S. Angevare[2,3,4], J. Wilson[5], W. Costello[2,6]. *[1]Juvenile Arthritis Research, JAR Project, Tonbridge, United Kingdom; [2]European Network for Children With Arthritis, ENCA, Geneva, Switzerland; [3]KAISZ, KAISZ, Amsterdam, Netherlands; [4]Autoinflammatory Alliance, Autoinflammatory Alliance, San Francisco, United States of America; [5]Cassie And Friends Society, CAF Society, Vancouver, Canada; [6]Irish Children's Arthritis Network, iCAN, Bansha, Ireland*

Background: During the COVID-19 (coronavirus) pandemic, some provision of healthcare shifted to remote, technology-assisted appointments (telemedicine). Whilst parents/carers of children and young people with rheumatic conditions have reported benefits of telemedicine, concerns remain.

Objectives: This patient and parent-led project sought to understand the views of parents/carers about telemedicine, identifying the benefits and limitations of remote technology-assisted appointments, and comparing views between Canadian and European cohorts.

Methods: An online survey was developed, translated into multiple languages and shared via social media and patient organisations, targeted at parents of children and young people with rheumatic, autoimmune and autoinflammatory conditions. Fieldwork took place in April 2021 in Europe and May 2021 in Canada. Consent was provided during enrollment.

Results: A total of 290 responses were received (133 Europe; 157 Canada). Of these, 73% were female, median age 12.

Over half of respondents (53%) in Europe reported travelling over an hour to in-person appointments with their paediatric rheumatologist, compared to a significantly higher proportion of respondents in Canada (87%). Consequently, in-person appointments represent a greater time burden amongst Canadian caregivers, though both groups report appointments taking over three hours in total (51% Europe, 69% Canada).

Prior to COVID-19, most had never had a telemedicine appointment (92% Europe, 95% Canada). Since March 2020, the majority (71% Europe, 82% Canada) had at least one telemedicine appointment.

Table 1. Shows the scores (1 worst, 5 best) given by parents about their telemedicine experience. Overall, most aspects scored positively (p<.05). However, parents felt telemedicine was not as good as in-person appointments.

Easy to schedule	3.50 (3.18, 3.82) *	4.33 (4.14, 4.52) *	†
On time	3.22 (2.89, 3.55)	4.07 (3.85, 4.28) *	†
Enough time with doctor	3.51 (3.19, 3.83) *	4.24 (4.02, 4.45) *	†
As good as in-person visit	2.21 (1.96, 2.46) **	2.66 (2.42, 2.90) **	†
Easier to see doctor	2.84 (2.55, 3.13)	3.51 (3.25, 3.77) *	†
Easy to sign-in	3.52 (3.22, 3.82) *	4.25 (4.06, 4.43) *	†
Quality of video	3.23 (2.93, 3.53)	3.87 (3.66, 4.07) *	†
Quality of sound	3.54 (3.26, 3.81) *	3.94 (3.75, 4.14) *	†
Able to speak freely	3.61 (3.34, 3.88) *	4.05 (3.85, 4.24) *	†
Able to understand doctor	3.61 (3.32, 3.90) *	4.09 (3.90, 4.28) *	†
Quality of care provided	3.43 (3.12, 3.73) *	3.78 (3.56, 4.00) *	†
Overall telemedicine experience	3.23 (2.91, 3.55)	3.78 (3.57, 3.99) *	†

Table 1. Mean scores for a range of aspects of telemedicine (1-worst; 5-best). * Positive score (p<.05) ** Negative score (p<.05) † Difference between Canadian and European cohorts is statistically significant (p<.05), chi-square.

When asked about aspects of telemedicine, a greater proportion of respondents from Canada answered favourably compared to those from Europe with the majority reporting telemedicine appointments had saved them time, enabled them to have an appointment and that it made the appointment safer. However, most felt that their consultant could not properly assess their child (72% Europe, 78% Canada, P<.05).

Overall respondents said they would prefer the next appointment to be in-person (82% Europe, 62% Canada, p<.05), although 31% from Canada were amenable to a combination of in-person and telemedicine-based care.

Conclusion: There are advantages to telemedicine, notably saving time and making appointments accessible. Families from Canada tended to view telemedicine more favourably than those from Europe, although the majority from both cohorts reported concerns about the ability to assess their child. There may be value in providing training to parents to enhance the accuracy of home-based assessments, particularly when the disease is stable. However, parents continue to report the value of in-person appointments.

Innovations in arthritis health care

POS1571-PARE ONLINE COUNSELLING FOR PATIENTS WITH ARTHRITIS

S. Dordevic[1], M. Lapčević[2]. [1]"Association Of Patients With Rheumatic Diseases of the Republic of Serbia" (ORS), Association of Patients, Belgrade, Serbia; [2]"Association of Patients With Rheumatic Diseases of the Republic of Serbia" (ORS), Association of Patients, Belgrade, Serbia

Background: The Covid-19 pandemic has changed many aspects of our lives. Perhaps the biggest changes have been in medical services. Institutes specializing in RMD in Serbia were part of the covid system and patients only had access in emergency cases, there was no regular examinations.
Objectives: The paper will show how the "Online Counselling for Arthritis Patients (OCAP)" worked during the pandemic, how many rheumatologists and patients were involved and were patients satisfied with the service provided.
Methods: Through the platform "Lekarinfo" ORS,[1] in cooperation with pharmaceutical companies, organized an OCAP. Patients were informed about the possibility of using online consultations with rheumatologists via social networks, viber groups. email ... and they were given instructions how to use it, they were advised to send medical documentation before, so the doctor has time to look at it, which gives more time for conversation. Consultations were held by phone or online, depending of patient's wishes and abilities. The time set aside with a rheumatologist was 20 minutes and with a psychologist 30 minutes. One psychologist and 23 rheumatologists were available. The ORS distributed cards to rheumatogists with all necessary data about OCAP to inform their patients.
Results: ORS conducted a Survey about OCAP. It was completed by 100 respondents, aged 20 to 75 of whom 75% were women. The 44% of respondents were from Belgrade, but it also included respondents from all over the country. RA have 61% of respondents, but patients with other types of arthritis were also included. 4/5 of patients are non-smokers and half of them are on biological therapy. All but one respondents are ORS's members.
The results of Survey are the following: OCAP was used by 27% of respondents and all of them were satisfied except one. Everyone would use it again and would advise others to do so. Online consultation can replace live examination, when the disease is in remission, thinks 62% of respondents. The majority (90%) found it technically easy to use it, but also the majority of respondents felt that there is a space for improvement (70%). One third prefers to have online consultations with their rheumatologist, Half of them understand the importance of telemedicine, 61% think that C-19 pandemic has increased the need for it and 64% think that digital solutions are our perspectives and it should be further developed.
Conclusion: It is desirable to continue with this kind of telemedicine. Patients and their families should be encouraged and educated about using digital platforms, aim is to explain them the benefits of telemedicine and that consultations do not necessarily have to be with their rheumatologists. Regardless of the pandemic, digitalization is in every aspect of our life, it is inevitable, but also it is a great advantage that should not be missed. Investments in the development of online platforms, that will facilitate patients access to doctors are an investment in self-control of chronic diseases in extraordinary circumstances, but also in normal conditions when because of the overscheduled doctors, lack of time for employed patients or other reasons, it is not possible for frequent examinations. Telemedicine is an investment not only in physical health but also in mental health of patients, having a doctor "just a step from you" has calming and positively affects for patients. And without positive attitude it's hard to keep a chronic disease under control.

POS1572-PARE HELPER'S WAY OF WORKING IN ORS BRANCH – NIS DURING THE COVID-19 PANDEMIC IN 2021

D. Jankovic[1], V. Filipovic[1]. [1]Association of Patients With Rheumatic Diseases of the Republic of Serbia - ORS, Nis Branch, Belgrade, Serbia

Background: Helper is a person with RMD educated to help other patients. Based on the clearly defined authorizations this person helps in advising and information sharing among the ORS members.[1] Association of patients with rheumatic diseases of the Republic of Serbia (ORS) operates across the country through the reference centers/ branches, but in pandemic the functioning of helper in an regular way was significantly impacted.
Objectives: In order to continue with the functioning in Association and with Helper during the Covid-19 pandemic, new communication and info-sharing methods has been applied. In this work will be shown how the strategy of communication was shifted from physical to digital, methods used for information sharing and communication tools of the modern world has been used for this purposes. Also, functioning of the branch in Niš and its Helper will be shown through statistical comparison of data prior and during the Covid19.
Methods: In the definition phase of Association's response on the new circumstances, it has been concluded that most of the members are using some of IM platform or e-mail. Based on this fact, out of 247 members of branch in Niš, 168 members have been joined through the most popular IM platform in Serbia – Viber. Through the group the patients has been sharing the information, notifications and other news important for the patients. Group administrators supported discussions, but also identified patients who did note use IM platforms and those members were notified by phone or e-mail. This method of communication was symbiotic with other projects of the Association because we used the same communication channels to increase the awareness of members about the activities of the Association.
Results: During 2019, Helper's work took place under normal conditions. At the Niska Banja Institute, Helper used the office where patients with rheumatic diseases used to come. Four lectures by eminent experts in the field of rheumatology and physiatry were organized, as well as socializing in the form of meetings and field trips. We marked the World Arthritis Day and the World Osteoporosis Day.[2]
During 2021, most activities took place online or outdoors, depending on the intensity of the Covid-19 wave. Helper's work took place from home in January and February 2021, and from March to the end of 2021, Helper worked in the office. The lectures that were organized were exclusively online. We have marked the World Arthritis Day with a small number of participants. The event was realized with media support. [3]
Analysis and participation of members in 2019 and 2021 are shown below:

- In 2021, 208 vs 260 live contacts in 2019;on average 17 vs 22 contacts per month
  - In 2021, 216 contacts through online meetings; on average 18 per month. IN 2019 no such exercise.
  - In 2021, 2.000 vs 239 contacts in Viber group in 2019; on average 167 vs 20 members
  - In 2019, alternative communication methods were not used. In 2021, 1,023 contacts were made with messages, calls and emails, or 85 per month.

Conclusion: Based on the fact mentioned above, 2019 was richer and more fulfilling with lectures, socializing and direct contacts with members, while in 2021 communication was dominated by digital tools and methods (Viber groups, calls, emails) and consultation with doctors via e-consultations and by phone[4].
The pandemic disabled direct contact with members of the Association and live lectures, but the Association used digitalization as a complement to new ways of working that connected us more than ever before, enabled instant transmission of information and created a basis for support at times when it was necessary the most. With this process in place, we not only fulfilled the goal of the Association, but we went a step further - we became the first contact for patients with RMD.

POS1573-PARE PATIENT-REPORTED OUTCOME MEASURES OF PAIN ALLEVIATION WITH CANNABINOID USAGE IN RHEUMATOID AND PSORIATIC ARTHRITIS: A CROSS-SECTIONAL STUDY.

T. Jehu[1], N. Bhaskar[1], S. Beg[1,2], K. Camargo Macias[2], S. Chalise[3], N. Bhanusali[1,2]. [1]University of Central Florida College of Medicine, Medical Education, Orlando, United States of America; [2]University of Central Florida College of Medicine, Rheumatology, Orlando, United States of America; [3]University of Central Florida College of Medicine, Statistics, Orlando, United States of America

Background: Patient-Reported Outcome Measures (PROMs) give us direct, immediate evidence of patient experience. Pain is a chronic, debilitating, multifactorial, presenting symptom that remains a difficult target to treat in populations with Inflammatory Arthritides.[1] Increasingly, cannabis products are being utilized and investigated for their potential analgesic and immune-modulatory effects.[2] The legislation and form of cannabis products deployed as therapy varies around the world and across populations. More data on usage and patient reported outcomes is needed to guide better clinical practice and inform sound legislative policy.

Objectives: To describe PROMs of pain, stiffness with cannabis use in a population of patients with Rheumatoid Arthritis (RA) or Psoriatic Arthritis (PsA).
Methods: This investigation was a monocentric, cross-sectional study. Inclusion criteria were adults receiving care at a University Rheumatology practice in Central Florida, USA from December 2019 to March 2020 who provided informed, written consent. Those who consented were provided with a brief, voluntary, and anonymous Qualtrics survey which queried patient-reported prevalence and outcome measures of short and long-term pain relief. 236 RA and 43 PsA patients were enrolled in this study. All subjects met the criteria for Rheumatoid, Psoriatic, or Inflammatory Arthritis (seronegative RA). Subjects' scores before and after cannabinoid use were compared with a paired T-test after the parametric nature of the data was established. Ethical approval was obtained from the University of Central Florida Institutional Review Board (Study00001041).
Results: Cannabis product usage was reported in 16.95% of RA subjects (40/236) and 11.63% of PsA subjects (5/43). Of this group, 71% (RA) and 40% (PsA) endorsed current usage. Inhalation was the most prevalent form used in RA (27.50%). In PsA, the most commonly reported forms were liquid (30%) and topical/skin (30%). On the 10-point pain scale, RA patients reported a significant reduction in average pain by 1.83±1.91 points in the long-term and 2.28±2.10 points in the short-term. Those with PsA reported a significant reduction in average pain by 1.60±0.89 points in the long-term and 1.80±0.84 points in the short term. Stiffness was also reduced in the RA group (7.3%). 17.5% of patients with RA using cannabinoids reported side effects not leading to cessation.
Conclusion: In an academic rheumatology practice population, a substantial number of RA and PsA patients are choosing to self-treat with cannabis therapy to manage their pain and other symptoms. Subjects reported significant reductions in both short- and long-term pain; some patients reported total pain resolution with ongoing cannabinoid therapy. Stiffness was also reduced in a subset of RA patients. Subjects that reported adverse effects did not find these severe enough to warrant cessation. These study results may allow for a more open discussion to improve safety and optimize outcomes. Additionally, the significant prevalence of usage and pain reduction reported provide a compelling rationale for further interventional studies in populations with Inflammatory Arthritides.

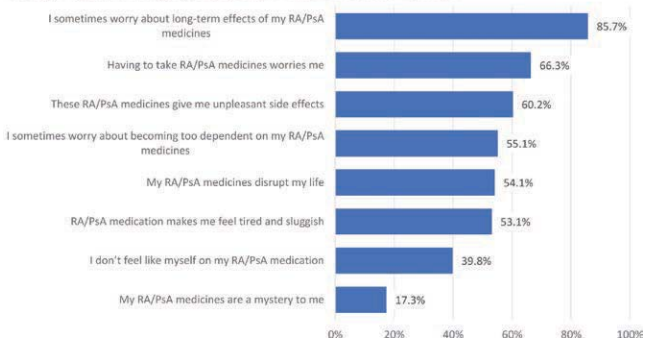
Psychosocial support

POS1574-PARE PATIENTS REPORT HIGH LEVELS OF CONCERNS ABOUT MEDICATION FOR PSORIATIC AND RHEUMATOID ARTHRITIS: UNMET NEEDS REVEALED BY A UK PILOT WEB SURVEY.

S. Chapman[1,2], A. Jordan[3], W. Tillett[2,4]. *[1]King's College London, Waterloo Bridge Wing, Franklin Wilkins Building, Institute of Pharmaceutical Sciences, London, United Kingdom; [2]University of Bath, Pharmacy & Pharmacology, Combe Down, United Kingdom; [3]University of Bath, Psychology, Bath, United Kingdom; [4]Royal United Hospital, Rheumatology, Bath, United Kingdom*

Background: Patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are often nonadherent to prescribed symptom-modifying drugs. [1] Concerns about the potential negative effects of medication have been implicated in medication nonadherence. Few evidence-based interventions to address concerns about medication and support medication-taking are available in the UK context.
Objectives: To inform the development of intervention to support people with RA and PsA to manage medication we conducted a survey of unmet needs relating to perceptions of arthritis and arthritis medication, medication-taking behaviour and experience of side effects.
Methods: We recruited people with arthritis via local and national patient groups for participation in an online survey. The survey included clinical and demographic questions, validated measures of treatment (Beliefs about Medication Questionnaire; BMQ) and illness perceptions (brief Illness Perception Questionnaire; bIPQ), medication adherence (Compliance Questionnaire Rheumatology; CQR), and patient-reported side effects. Participants were asked about consequences of taking and not taking their arthritis medication as free text to contextualize scores.
Results: Questionnaire responses from 98 participants (42 with PsA, 56 with RA, 89.8% female) indicated participants typically viewed arthritis negatively with ratings on the bIPQ indicating high emotional impacts, symptoms and affects on everyday life, and doubts about their ability to control their arthritis. Analysis of the BMQ indicated ambivalence about RA/PsA medications; while few people expressed doubts about their personal need for medication, concerns about RA/PsA medications were common, see Figure 1). Most, 85.7% (n=84), reported a side effect in the last month, with a mean of 10 'moderately severe' or 'very severe' side effects (m=10.02, sd = 5.98). Just over a quarter (26.0%, n=25) were classed as low adherers using the CQR with 54.6% reporting they had missed some of their arthritis medication over the last year. Free text responses indicated that some participants had additional concerns about medication (e.g. worries about impact on life expectancy) not addressed in the questionnaire measures.

Figure 1: Concerns about arthritis medication
Percentage of participants strongly agreeing/agreeing with statements about their medication



Conclusion: In this pilot survey, many participants reported concerns about medication, doubts about whether medication controls arthritis symptoms, severe side effects and medication nonadherence. Although our small sample is unlikely to be generalizable to all arthritis patients, these findings suggest potential targets for intervention and indicate that some patients have needs for support with medication that are not currently being addressed.

Work and rehabilitation

POS1575-PARE WORKING AND HEALTH STATUS IN NORWEGIAN PATIENTS WITH TAKAYASU ARTERITIS

T. Garen[1], A. Tollisen[2], H. Andersson[1], B. Gudbrandsson[3], Ø. Palm[3]. *[1]Oslo University Hospital, Rikshospitalet, Department of Rheumatology, Oslo, Norway; [2]Lovisenberg Diaconal Hospital, Oslo, Unger-Vetlesens Institute, OSLO, Norway; [1]Oslo University Hospital, Rikshospitalet, Department of Rheumatology, Oslo, Norway*

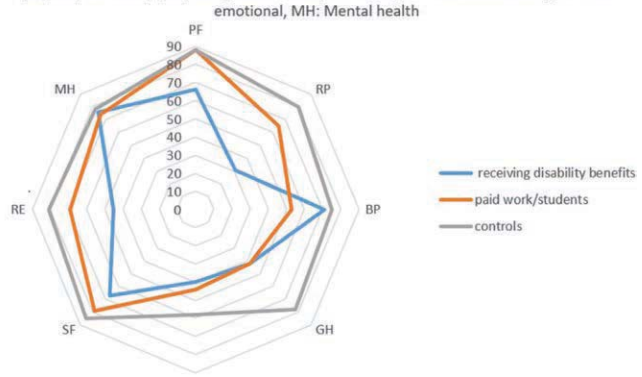
Background: Takayasu arteritis (TAK) is a rare vasculitis of large vessels, mainly in young women, with a point prevalence of 25.6/10^6 in a Norwegian population. TAK is most prevalently limited to the aortic arch and its branches (Type 1) among North Europeans (1). Early symptoms include fever, myalgia and loss of appetite. Later, irreversible vascular damage and ischemic symptoms with claudication of the extremities may occur. We have previously observed a reduced life expectancy, mainly due to cardiovascular complications and a median age among those deceased of only 58 years (2). These findings clearly indicate that TAK may have severe impact on the wellbeing of the patients and their physical capacity. Furthermore, being part of the working life is a major component of life but is affected in chronic autoimmune diseases (3,4)
Objectives: (i) To describe general health status and quality of life in patients with different working status.
(ii) To estimate the rates of patients having paid work or receiving disability benefits, compared to the general Norwegian population.
Methods: Patients with TAK registered in "The Norwegian Systemic Connective Tissue Disease and Vasculitis Registry" (NOSVAR) were included. All patients fulfilled the American College of Rheumatology classification criteria and/or the modified Ishikawa diagnostic criteria for TAK. (3). General health status was measured with 10-cm visual analogue scale (VAS) of pain and fatigue, ranging from 0 (best possible score) to 10 (worst possible score) and with Patients´ global assessment (PtGA) of health measured by a five-point Likert scale with scores ranging from 1 (very good health) to 5 (very bad health). The SF-36 was applied

to measure health related quality of life and included 8 scales with score ranging from 0 (worse) to 100 (best). Disease duration was defined as the time from diagnosis to date of registration. Working full- or part time was defined as paid work. We adjusted for age, gender and residence counties in southeast Norway using reference data from Norway Statistics. Indirect standardization with 95% confidence interval rates was calculated. Descriptive analyses were conducted.

Results: Patients with paid work were more educated compared with those receiving disability benefits (81% vs 19% p=0.031). Patients receiving disability benefits reported higher levels of pain (3,4 vs.1,4, p=0.024) and disease activity (3,8 vs. 0,8, p=0.025), more frequently claudication in legs (83% vs. 17%, p= 0.009) and impaired quality of life measured with SF- 36, physical functioning (66 vs 88, p=0.002) and role physical (32 vs 65, p=0.017) compared to patients with paid work/students (Figure 1).

Compared with the age and gender matched general population, the disability rate of female patients was 16 % higher, adjusted ratio (CI 95%) 2 (1,2-3,3), p=0.038. The paid work rate was 51% lower in women with TAK compared to the general population, adjusted ratio (CI 95%) 0,38 (0,23-0,64), p=0.001 .

Figure 1 Comparison between patients groups and controls. PF: physical functioning, RP: role physical, BP: bodily pain, GH: general health, VT: vitality, SF: social functioning, RE: role emotional, MH: Mental health



Conclusion: TAK-patients receiving disability benefits reported lower health status and lower quality of life by physical functioning and role physical in SF 36. Work disability in female TAK patients was 16 % higher and for paid work 51 % lower compared to the general population.

Best practice campaigning

POS1576-PARE IMPROVING METHOTREXATE PRESCRIBING AND DISPENSING SAFETY THROUGH A SIMPLE ADJUSTMENT TO ELECTRONIC PRESCRIBING.

C. Stovin[1], K. Lawan[2], C. Byrne[2], A. Choy[2], N. Purkayastha[1]. [1]*Kings College Hospital, Rheumatology, London, United Kingdom;* [2]*Kings College Hospital, Pharmacy, London, United Kingdom*

Background: Methotrexate (MTX) is the most commonly prescribed disease-modifying antirheumatic drug (DMARD) in rheumatoid arthritis, as well as being frequently used in other rheumatic conditions. Having been discovered in 1948 [1], its use is established and the toxicity profile is well recognised. In the rheumatology setting, it is prescribed as a once weekly dosing regimen. However, despite experience in the use of MTX, there still remains a concern for patient safety with regards to more frequent ingestion than the weekly dose. This can result in severe complications such as acute kidney injury, myelosuppression, mucositis and even death. According to Medicines and Healthcare products Regulatory Agency (MHRA), there were 11 adverse event reports between 2006 and 2020, and as a result, in 2020 the MHRA outlined guidance to reduce the potentially fatal dosing errors associated with the prescription of MTX [2].

Amongst this guidance, prescribers are instructed to discuss, document and include in the prescription, the specific day of the week MTX is to be taken. Dispensers are also advised to document the day of the week on the MTX drug dispensing label. At King's College Hospital (KCH) there is an existing mandatory field for day of the week when prescribing inpatient non-cancer MTX treatment. However, this does not exist currently for outpatient electronic prescribing.

Objectives: To update practice in the KCH Rheumatology department, in line with MHRA guidance on MTX prescription.

Methods: A retrospective audit of 30 MTX new and renewal prescriptions over 1 month was conducted to assess concordance with MHRA guidance. The safety-nets of documentation of day of the week on most recent clinic letter, drug prescription and drug dispensing label were reviewed. Following this the electronic prescription system was updated to make "day of the week" a mandatory field required to complete MTX prescriptions. A sample of 30 patients post intervention was then re-audited.

Results: The percentage of new prescriptions across the 2 groups were roughly equivalent (30% vs 33%).

Prior to intervention, 44% of new MTX prescriptions had no form of documentation of the day of the week across all 3 safety-nets, and only 33% had at least 2 of the 3 safety-nets completed. Post-intervention this has increased to 100%. Of those newly prescribed MTX, the inclusion of day of the week on clinic letters rose from 22% to 40%. There were similar improvements seen in safety-nets achieved for repeat prescriptions.

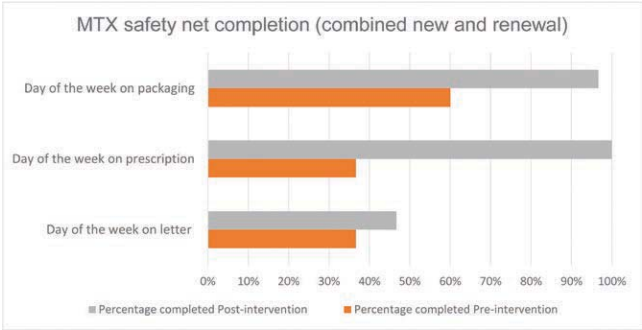

Figure 1.

Table 1.

	Percentage completed			
	Pre-intervention		Post-intervention	
	New	Renewal	New	Renewal
Day of the week on letter	22%	43%	50%	45%
Day of the week on prescription	33%	38%	100%	100%
Day of the week on packaging	33%	71%	90%	100%
None of the above	44%	14%	0%	0%
At least 2 of 3 of the above	33%	52%	100%	100%
All 3 completed	22%	14%	40%	45%

Conclusion: A significant improvement in concordance with MHRA guidance on MTX prescribing and dispensing can be easily achieved by making "the day of the week" a mandatory field to be included on all electronic MTX prescriptions. This change also produces a significant improvement in drug dispensing label safety and clinic letter documentation for patients newly initiated on MTX.

POS1577-PARE WHAT PATIENTS VALUE AND NEED FROM HEALTHCARE IN THE DIAGNOSIS AND MANAGEMENT OF AXIAL SPONDYLOARTHRITIS

A. Drury[1], D. Webb[2], J. Hamilton[2], A. Hardy[3], L. Brady[1]. [1]*Community Research, London, London, United Kingdom;* [2]*National Axial Spondyloarthritis Association, London, London, United Kingdom;* [3]*Headstrong Thinking Limited, London, London, United Kingdom*

Background: The clinician's understanding of what constitutes good quality care for axial spondyloarthritis (axial SpA) has been explored (1) and used to define quality standards (2,3). However, research into the patient perspective on what constitutes good quality care was lacking. The UK's National Axial Spondyloarthritis Society (NASS) commissioned Headstrong Thinking, and its research partner, Community Research, to investigate this issue.
Objectives: The objectives of the research included: to explore the lived experience of those with an axial SpA diagnosis, to identify all the stages (domains) and milestones they identify and describe in their journey; to identify tangible person-centred indicators of "quality" in each of those stages, covering clinical care, patient care (non-clinical) and support for their mental health needs; to capture the everyday language used to articulate their values and needs around "quality"; and to understand possible differences between individual/subgroup experiences.
Methods: The project will use both qualitative and quantitative methods sequentially.
This paper reports only on the qualitative stage of the project, which comprised twelve individual depth interviews, conducted online, across a broad spectrum of people living with axial SpA in the UK, allowing for variation in age, sex, socioeconomic status, presence of children, length of time since diagnosis, physical symptoms and comorbidities.
Findings from the qualitative stage will inform the questionnaire for the quantitative stage (target n=1,500), which will seek to validate and refine initial hypotheses and quantify differences between sub-groups.
Results: This paper presents a rich understanding of the impacts on mental, emotional, cognitive and practical aspects of life with axial SpA. A detailed picture of a wide range of clinical, psychological and practical adverse impacts around delayed diagnosis is described.
Further, the qualitative research found that, from the perspective of people with axial SpA, quality care consists of three elements, defined by patients as: to be seen, heard and believed; to experience a purposeful, consistent pathway of care, underpinned by effective administration and communication (rather than a series of care "snapshots"); and to be helped to know what they can do to help themselves, including making a care plan that evolves as needs change.
Individuals with multiple or complex comorbidities were less likely to report having experienced good quality care, as they defined it, in part due to the challenges of accessing a joined-up patient journey and their greater reliance on an effective cross- disciplinary (NHS) healthcare system.
Conclusion: Patients define quality care in the diagnosis and management of axial SpA differently to clinicians. Professionals involved in the diagnosis and care of people living with axial SpA (including rheumatologists, but also those involved in the wider care of people living with axial Spa, such as physiotherapists and even mental health professionals) would benefit from a greater understanding of the patient perspective.
The individual stories uncovered in this qualitative phase underline the importance of collecting and analysing quantitative data by demographics, life stage and by discrete phases in the diagnostic /ongoing patient (self) management journey.

POS1578-PARE TO OBTAIN GREATER AWARENESS OF ARTHRITIS AND THE DANISH ARTHRITIS ASSOCIATION BY MEDIA COVERAGE

J. Lüthcke[1]. [1]*Gigtforeningen, Communications Department, Gentofte, Denmark*

Background: Despite arthritis being among the most common diseases in Denmark, the overall personal consequences followed are generally unknown. You don't die of arthritis. This is reflected in the population's general knowledge of The Danish Arthritis Association of a mere 57 %, despite being Denmark's third largest patient organisation.
Objectives: To obtain greater awareness of arthritis and the Danish Arthritis Association by media coverage
Methods: We use case stories strategically in our offensive political agenda. By presenting a good case story with a personal, yet wide perspective, we quite often succeed in getting our agenda in the media – as personal and emotional case stories are more likely stories to be chosen by journalists than political solutions from organisations like ours.
On social media (especially Facebook and Instagram) we also use case stories to a great extent – 2 – 3 times a week. Our followers like to read stories about people who struggle with the same issues as themselves – and to reflect their own issues. Whether they are newly diagnosed or have lived with arthritis for a long time.
In general, we get good response on these personal case stories. Many likes, and often our followers share their own experience with each other and pass on good advice.
Helping out the media: The media and journalists are always in need of case stories to back up their articles and agendas. We have introduced the principle of always being willing to help the media with case stories. By providing cases with arthritis– even though the issues aren't exclusively about arthritis, we help solving a problem, as well as we manage to turn the agenda into a story about arthritis as well. Examples are corona, vaccination, deferred surgeries, lack of coherence in the health system.
What does it take to use cases?: As an organisation, you have a responsibility to take care of your cases by informing them of what it means to be in the media. They must be prepared and helped out – also along the way. It is also important to choose cases who are well spoken and not afraid to express themselves.
Debate group: Some of the topics such as coherence in health care, are immediately academic topics, and difficult to understand – and therefore more difficult to get covered in the media. We have successfully initiated a debate group consisting of a small group of young arthritis patients, whom we have taught how to write debate posts. By telling their own personal stories – often with an underlying political angle – these articles have been published in the major national newspapers.
Results: We have succeeded in getting media coverage in both women's magazines, tabloid newspapers, national newspapers as well as radio and television.
Conclusion: It is a fairly simple concept that easily can be copied by other patient organisations despite size.

POS1579-PARE LET'S TAKE AN HEALTHY WALK IN THE PARK

U. Viora[1], P. Guiso[2], M. T. Mascarino[3], G. Mascarino[4]. [1]*ANMAR Italia, Piemonte, Turin, Italy;* [2]*AMaR Piemonte, AAI, Moncalieri, Italy;* [3]*AMaR Piemonte, Presidency, Turin, Italy;* [4]*AMaR Piemonte, Young, Turin, Italy*

Background: Patients with RMDs are not yet used to live phisical activity such as an important part of their therapy;
Covid 19 pandemic, with the restrictions imposed on interpersonal approaches and the the fear of being infected and spreading the virus, has further slowed down the way towards these kind of empowerment.
During the pandemic, in Italy the number of pets (mainly dogs) had an exponencial increase.
Animal Assisted Interventions /Animal Assisted Therapies seems to be really successful.
Objectives: Our project aims:
to offer people with RMDs the opportunity to move playing fitwalking under control of WALKin trainers who can teach them the right way to practice this new discipline or simply walking properly with their dogs or playng rehabilitative exercises (specific for each one) with the help of animals specially trained.
a number of meetings (at least 12) in which experts will discuss about RMDs, comorbidities, nature, animals, man-animal relationship adn so on.
Methods: Thanks to an agreement with a natural park (UNESCO MAB Collina Po reserve), we could draw 4 different routes (3-4-5-7 Km) and a safe area in which all the participants can play different activities.
Based on the medical prescription, people will be assigned to different groups (no more than 7 people in each group) and to different activities (walking, rehabilitative exercises, alone or with animals).
Twice a week during an hour the groups will meet and practice their activity, not only working together, but also sharing experiences, sesations, feeling.
Each group will be lead by an expert (walking trainers, health pofessionals, teamsters).
Either each group leader or each participant will wright a diary at the end of the activity session, to let us have a number of encoded informations which drive us to verify all progresses in term of improvement of mobility and mood and reduction of drugs cosumption.
Results: The participation (face to face and virtual) in the first three meetings (October, November 2021 and January 2022 has been continuously increasing and we have a good core of "fans", but also every time a lot of new people who want to join us.
We are collecting the first inscriptions and we preview to start the activity on March 20 when the first goups will be leaded by Maurizio Damilano, twice world and Olympic running champion and inventor of fitwalking.
First preliminary results will be available in December 2022.
Conclusion: With this project we hope to help people with RMDs to live physical activity as an important part of their therapeutic pathway and to rediscover how nice it is to be together, finding new friends (either humans or animals)

ALLELIC POLYMORPHISM OF INFLAMMATORY CYTOKINES GENES FOR PREDICTION OF CARDIOVASCULAR DISORDERS IN CHILDREN WITH JIA

A. Artsymovych[1], O. Oshlianska[1]. [1]*Kyiv, pediatrics #1, Kyiv, Ukraine*

Background: It is known that defects in the synthesis and structure of cytokines or their receptors can lead to modification of many pathological processes in the organism: inflammation, coagulation, impaired cell regeneration, which makes it appropriate to further study the genetic preconditions for the violation of immunoregulatory mechanisms. Great attention is paid to the study of allelic polymorphism of genes in chronic inflammatory diseases as a potential marker of functional activity of proteins encoded by them and related features of the course of various disease.
Objectives: To assess the impact of allelic polymorphism of TNFα (G308A) & IL6 (G174C) genes on the development of cardiovascular disorders in children with JIA.
Methods: 102 children with JIA were examined. Allelic polymorphism of TNFα (G308A)& IL6 (G174C) genes was determined by PCR using specific oligonucleotide primers, subsequent analysis of polymorphism of restriction fragments was made. Activity of disease was calculated using JADAS27. Functional state of the myocardium was assessed using software-hardware complex "Cardioplus P", an ECG of 4th generation. Cluster analysis of obtained data was performed. K-means and EM algorithms were used. The number of children who finally entered this stage of the analysis was 25.
Results: According to the disease activity, the number of mutations and the complex indicator of the functional state of the myocardium (CI FS, %), two clusters were identified. In cluster 1 (10 children, group 1) the higher score of CI FS (median 78%) and lower disease activity degree (JADAS 27 median 9.5) was noted, and in cluster 2 (15 children, group 2) high disease activity (JADAS 27 median 14) was observed and a decrease in the CI FS (median 62%). The CI FS according to the ECG of 4th generation differed significantly (p = 0.00001) in clusters. It is noted that in the second group the disease debuted relatively earlier (p>0.01). Among these cluster groups of patients with JIA there were a number of significant differences in general clinical laboratory parameters: the activity of AST in the blood of patients with JIA was 29±3.1 IU/ l in the first group vs 24±2.2 IU/l in the second group (p = 0.07 Wald-Wolfowitz), serum creatinine was higher in the first group 68.8±11.0 μmol/l (against 57.0±9.3 μmol/l in the second group; t = -2.24, p = 0.044), also in the second group according to the results of the study according to the general analysis of blood there was leukocytosis (11.6±4.1 $x10^9$ vs. 6.69±0.8 $x10^9$, p = 0.075 Wald-Wolfowitz).
According to the obtained data of the cluster analysis, the total number of mutations in the genes IL6 and TNF-α was significant for the course of disease. In cases with a larger number of mutations, a more aggressive course of the disease, a more pronounced degree of inflammation, a higher frequency of extra-articular lesions, including changes in the CVS, was noted.
Conclusion: The overall number of mutations in TNFα (G308A) & IL6 (G174C) genes makes impact on the course of the disease; two and more mutations are associated with a more aggressive course of the disease and can lead to cardiovascular lesions more likely. Determination of allelic polymorphism should be recommended to patients who have changes on ECG performed by a 4th generation ECG.

ATTEMPTS TO LINK EXONIC GENE POLYMORPHISMS TO ANKYLOSING SPONDYLITIS (AS)- ASSOCIATED PROTEIN MODIFIED FUNCTIONALITY: A STRUCTURAL BIOLOGY APPROACH

E. Eliopoulos[1], G. Goulielmos[2], M. Zervou[2]. [1]*Agricultural University of Athens, Department of Biotechnology, Athens, Greece;* [2]*Medical School of Crete, Department of Internal Medicine, Heraklion, Greece*

Background: Genome wide association studies (GWAS) have played a primary role in depicting genetic contributions to ankylosing spondylitis (AS) development, while accommodating the exonic polymorphisms on the protein structure level, when available, enhances our understanding of protein function modification. AS is a polygenic disorder and it is the archetype of a group of inflammatory conditions known as spondyloarthropathies because of their tendency to involve the spine [1]. Linking human genetics with therapeutic targets requires understanding of the biological function and structure of the expressed protein by the causal gene variant to be known.
Objectives: We sought to investigate recently identified AS-associated functional gene polymorphisms, such as *ERAP1*, *PON1*, *CARD9* and *JARID1A* [2-5] by correlation to protein structure and function.
Methods: The experimental 3D model structures of the human ERAP1, PON1, CARD9 and JARID1A proteins were used for the localization of the polymorphisms under study. Molecular mechanics/dynamics studies were applied to determine the impact of the polymorphisms on the structural stability of the enzyme and the conformational changes caused were structurally analyzed. The mutants were constructed using molecular modeling with the program MOE (Molecular Operating Environment V.2019.01, Chemical Computing HPC), which was also used to analyze the conformational changes caused by the mutation. All figures depicting 3D models were created using the molecular graphics program PyMOL V.2.2 [6].
Results: ERAP1 plays a role in trimming peptides for optimal binding to MHC1 molecules by utilizing a complex catalytic mechanism. High resolution structures of ERAP1 have shown that K528 and Q730 are located distal from the active site of the enzyme (Figure 1a). Recent enzymatic and computational studies have demonstrated that the presence of Lys or Arg at position 528 and of glutamine or glutamic acid in position 730 affects differently the conformational distribution of the protein ensemble by altering the conformational plasticity of the enzyme and, therefore, indirectly affecting dissimilarly its activity [7]. The *PON1* rs662 (Gln192Arg) variant affects stability and recognition of the ligand recognition site and plays a functional role in inflammatory disorders (Figure 1b). The caspase recruitment domain (CARD) interaction of CARD9 with Bcl10 promotes downstream activation of factors including NF-κB and the mitogen activated protein kinase (MAPK) p38 [8]. The *CARD9* rs4077515 (Ser12Asn) variant affects the conformational flexibility of the interacting N-terminal [9] (Figure 1c). *JARID1A* gene codes for lysine demethylase 5A (KDM5A) a histone demethylase that specifically demethylates 'Lys-4' of histone H3. The *JARID1A* rs11062385 (Met865Thr) SNP that is strongly correlated with expression has been associated with a protective role for the disease but is located in a region of the KMD5A protein with an undefined yet function.
Conclusion: Based on several examples, we have tried to define a rational link from AS-associated gene polymorphisms to structure and to modified function, including metagenomic analysis of SNPs, protein crystallography, protein molecular modeling, molecular mechanics and dynamics. Locating, shaping and understanding the target protein interaction interface plays a decisive role in most cases and provides clues for further pharmacological or medical actions.

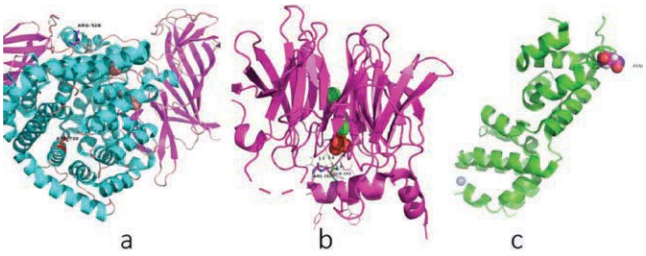

Figure 1. The structures of huERAP1 (a), huPON1 (b) and huCARD9 (c) with the mutations highlighted and labeled

PHENOTYPIC EFFECTS OF GENETIC LOSS OF FUNCTION IN TYROSINE KINASE 2 USING LARGE-SCALE BIOBANKS

N. Raghupathy[1], E. Kvikstad[1], E. Holzinger[1], I. Catlett[2], J. Maranville[1]. [1]*Bristol Myers Squibb, Informatics & Predictive Sciences, Princeton, United States of America;* [2]*Bristol Myers Squibb, Dermatology, Princeton, United States of America*

Background: We used a naturally occurring germ-line genetic variant in tyrosine kinase 2 (*TYK2* [P1104A, rs34536443]), which has been shown to cause partial loss of function and protect against autoimmune disease,[1] to survey the phenotypic consequences of reduced TYK2 function.

Objectives: Survey the phenotypic consequences of a naturally occurring partial loss of TYK2 function, and directly test for an effect of naturally occurring TYK2 partial loss of function on risk of cardiovascular disease, thromboembolism, and lymphoma.
Methods: We performed phenome-wide association studies (PheWAS) in 2 large biobanks (FinnGen and UK Biobank) and across public case-control genetic studies using Open Targets Genetics.
Results: This study found additional support for a protective effect (odds ratio [OR] ≤0.8, $P<1x10^{-4}$) of TYK2 partial loss of function in multiple autoimmune diseases, including rheumatoid arthritis, psoriasis, psoriatic arthritis, systemic lupus erythematosus, sarcoidosis, type 1 diabetes, inflammatory bowel disease, and hypothyroidism. We did not observe any novel phenotypic associations that could highlight safety concerns for TYK2 inhibition. Additionally, we used well-powered and focused analyses to demonstrate that TYK2 partial loss of function is not associated with nonselective Janus kinase inhibitor safety concerns in any of the genetic studies. Our meta-analysis across the included studies showed no association with increased risk of cardiovascular disease (OR=0.97; *P*=0.02; 258,279 cases / 549,387 controls), venous thromboembolism (OR=0.97; *P*=0.52; 11,966 cases / 260,704 controls), and lymphoma (OR=1.06; *P*=0.47; 2687 cases / 220,721 controls).
Conclusion: TYK2 P1104A, a partial loss-of-function polymorphism, enables assessment of TYK2 involvement in immune-mediated disease and other pathologies. Loss of function in TYK2 reduces risk of immune-mediated disease but does not significantly increase risk of cardiovascular disease, thromboembolism, or lymphoma.

AB0004 PTPN22 AND TNFAIP3, BUT NOT STAT4, ARE RISK FACTORS FOR IGG4-RELATED DISEASE

E. Martin-Nares[1], G. Hernandez-Molina[1], J. Ramírez Bello[2]. [1]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Department of Immunology and Rheumatology, Mexico City, Mexico;* [2]*Instituto Nacional de Cardiología Ignacio Chávez, Department of Endocrinology, Mexico City, Mexico*

Background: The etiology of IgG4-related disease (IgG4-RD) is not yet clear, but environmental and genetic factors are thought to be involved. Little is known about the genes that confer susceptibility to this disease, which is why various *loci* related to inflammation or autoimmunity have begun to be studied. Such studies are limited to Asian and European cohorts. To date, no study has searched susceptibility genes for the development of IgG4-RD in the Mexican Mestizo population.
Objectives: To determine whether three single nucleotide variants (SNVs) located in classic genes associated with systemic lupus erythematosus and rheumatoid arthritis, namely, *TNFAIP3* (rs2330926T/G), *STAT4* (rs7574865G/T), and *PTPN22* (rs2476601C/T), confer susceptibility for the development of IgG4-RD in the Mexican Mestizo population.
Methods: Patients who met the 2019 ACR/EULAR classification criteria for IgG4-RD were included. For each patient, two healthy controls were matched by sex who had no history of chronic, inflammatory, or autoimmune diseases. Both patients and controls were unrelated and self-reported with Mexican Mestizo ancestry by linage (at least three generations including their own). Genomic DNA was extracted from peripheral blood cells. SNVs were genotyped using TaqMan probes and the 5' exonuclease assay. The Chi-square test was used to determine odds ratios.
Results: We included 124 controls and 60 patients with IgG4-RD (31 (51.6%) female and 29 (48.4%) male). Patients with IgG4-RD had a mean age of 52.1 ±15 years. Ten (16.6%) had single organ involvement, 10 (16.7%) had two involved organs, and 40 (66.6%) had ≥ 3 involved organs. Thirteen (21.7%) belonged to the pancreato-hepato-biliary, 5 (8.3%) to the retroperitoneal/aortic, 19 (31.7%) to the head/neck-limited, 18 (30%) to the Mikulicz/systemic, and 5 (8.3) to the undetermined phenotype, while 43 (71.7%) belonged to the proliferative and 17 (28.3%) to the fibrotic phenotypes.
The allelic and genotypic frequencies of the SNV rs7574865G/T of *STAT4* did not show statistically significant differences between cases and controls ($p>0.05$); while the *PTPN22* variant rs2476601C/T showed association with IgG4-RD: allele C vs T, OR 10.6, CI 95% 1.22 - 91.37, $p=0.02$ and CC vs CT, OR 11.0, CI 95% 1.25 - 96.2, $p=0.008$; and the SNV rs2230296T/G of *TNFAIP3* showed the following association: T vs G, OR 2.8, 1.03 - 7.87, $p=0.04$ and TT vs TG, OR 3.0, 95% CI 1.07 -8.60, $p=0.03$.
Conclusion: This is the first study to suggest that the *STAT4* variant rs7574865G/G is not a risk factor for the development of IgG4-RD, while the variants rs2476601C/T of *PTPN22* and rs2230936T/G of *TNFAIP3* confer susceptibility to the development of this disease in the Mexican Mestizo population. Our study provides new information on the genetic basis of IgG4-RD.

AB0005 INTEGRATED ANALYSIS OF LNCRNAS AND MRNAS EXPRESSION PROFILING IN SYSTEMIC LUPUS ERYTHEMATOSUS

F. Zhang[1,2,3], S. X. Zhang[1,2,3], Y. Wang[1,2,3], J. An[1,2,3], R. Fan[1,2,3], Y. Q. Liu[1,2,3], X. R. Hu[1,2,3], J. Chen[1,2,3]. [1]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China;* [2]*Ministry of Education, Key laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China;* [3]*Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by over-activity of lymphocytes, production of autoantibodies and effects on multiple organs 1. Growing evidences suggest long noncoding RNAs (lncRNAs) and mRNAs widely participate in physiological and pathological processes. However, knowledge of related lncRNAs and mRNAs in SLE remains limited.
Objectives: The aim of our study is to investigate the levels of differential expression of lncRNAs and mRNAs in the peripheral blood mononuclear cells (PBMCs) of SLE patients and their correlation with disease activity, clinical features and cell differentiation.
Methods: Peripheral venous blood 4ml were collected from 11 patients with SLE before and after treatment and 11 sex-and age-matched healthy individuals and saved in EDTA tubes. PBMCs were isolated from peripheral blood samples by Ficoll-Histopaque density gradient centrifugation. Total RNA was extracted from PBMCs with TRIzol reagent. RNAs amount and quality were quantified by using a NanoDrop ND-1000. Peripheral blood samples were sent to Novogene Co. Ltd (Beijing, China) for sequencing. The DESeq package in R language was used to analyze the differential expression of lncRNAs and mRNAs in the two groups. GO and KEGG databases analyze the potential biological functions and signal transduction and disease pathways affected by abnormal expression of lncRNAs and mRNAs[2].
Results: According to the RNAs expression profiles, 338 lncRNAs (173 upregulated and 165 downregulated) and 2020 mRNAs (1292 upregulated and 728 downregulated) were differentially expressed between SLE patients and control groups. In addition, 17 lncRNAs were significantly downregulated and 66 mRNAs (47 upregulated and 19 downregulated) were differentially expressed between active and treated SLE patients. There were 1645 RNAs up-expression in active

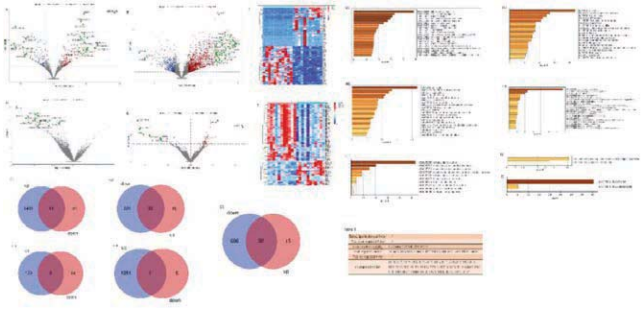

Figure 1. (A-C) Analysis of DElncRNAs and DEmRNAs of pre-treated SLE and cotrols. (A) The volcano plot with the DElncRNAs. (B) The volcano plot with the DEmRNAs. (C) The hierarchical clustering heatmap of DElncRNAs and DEmRNAs. (D-F) Analysis of DElncRNAs and DEmRNAs between pre-treated and treated SLE. (D) Volcano plot with the DElncRNAs. (E) Volcano plot with the DEmRNAs. (F) The hierarchical clustering heatmap of DElncRNAs and DEmRNAs. (G1-G5) Partial RNAs expression changed in active and treated SLE patients. Table 1 showed specific changed RNAs. (H1-H4) The top 20 GO and KEGG terms related to the up-regulated and down-regulated DEmRNAs. (I1-I3) GO and KEGG analyses of DEmRNAs between active and treated SLE patients.

Table 1: The relativity between aberrantly expressed mRNA and LncRNA and clinical characteristics of active and treated SLE patients.

SLE patients and 36 RNAs under-expression in treated SLE patients, and total 14 RNAs changed direction of expression. GO and KEGG pathway analysis showed most of mRNAs were related to transcription, inflammation and immunity. The relativity between aberrantly expressed RNAs and clinical characteristics of active and treated SLE patients were shown in Table 1.

Conclusion: Dysregulation of lncRNAs and mRNAs involves in molecular regulation of SLE, which may support for diagnosis or determination of the susceptibility of individuals of SLE.

Background: Systemic lupus erythematosus (SLE) has been associated with more than 100 genetic loci. This parallels positively to the clinical diversity that is reflected by the classification of SLE.

Objectives: We aimed to investigate associations between disease manifestations of SLE and risk gene variants relevant to Danish subjects of European ancestry.

Methods: We included 427 SLE patients of European ancestry similar to previous reports.[1] We also included 89,699 controls from the Danish Blood Donor Study Genomic Cohort. SLE risk loci in this population were identified by

Table 1. Associations between five SLE risk loci and specific disease manifestations in 427 Danish patients with SLE*.

* Logistic regression models for each manifestation included all five lead variants (multivariate) and were adjusted for age and sex

genome-wide association methodology and hereafter correlated to cumulative occurrence of SLE classification items.
Results: Fourteen variants mapped to the following genes: *NCF2, STAT4, TNPO3/TPI1P2, IRF5,* and *ITGAM,* were significantly associated (p<5E-8) with SLE.
The five lead variants were associated (p<0.05) with the following manifestations; *NCF2*: proteinuria and anti-phospholipid antibodies, *STAT4*: arthritis, serositis, neurologic disorder, lymphopenia, and anti-Smith antibodies, *IRF5*: seizures and proteinuria, *TNPO3*: proteinuria, and *ITGAM*: photosensitivity (Table 2).
Conclusion: Our findings support the future use of select, relevant genetic markers in predicting various SLE phenotypes.

AB0007 ASSOCIATION OF RS172378 VARIANT IN C1Q GENE CLUSTER WITH SOME CLINICAL AND IMMUNOLOGICAL ASPECTS OF SYSTEMIC LUPUS ERYTHEMATOSUS IN BULGARIAN PATIENTS

M. Kosturkova[1], T. Shivacheva[2], G. Mihaylova[3], V. Vasilev[4], M. Radanova[3]. *[1]Varna Medical University, Department of Propedeutics of Internal Diseases, Varna, Bulgaria; [2]Varna Medical University, First Department of Internal Diseases, Varna, Bulgaria; [3]Varna Medical University, Department of Biochemistry, Molecular Medicine and Nutrigenomics, Varna, Bulgaria; [4]Sofia Medical University, Department of Nephrology, Sofia, Bulgaria*

Background: Single nucleotide polymorphisms (SNPs) in complement C1q component are found to be linked with systemic lupus erythematosus (SLE), but less is known about their association with the clinical and immunological aspects of the disease.
Objectives: The aim of the study was to examine five SNPs – rs665691, rs682658, rs172378, rs294179, rs292001 in C1q gene cluster for association with some clinical (age at disease onset, organ involvement, BILAG score, SLICC/ACR DI) and immunological (ANA, anti-dsDNA, complement factors C3 and C4) aspects of SLE.
Methods: 53 SLE patients were enrolled in this cross-sectional study and relevant clinical information was collected. SNP genotyping was performed on extracted DNAs from patients using a TaqMan allelic discrimination assay. ANA, anti-dsDNA and complement proteins C3 and C4 were measured by IIF, ELISA and radial immunodiffusion resp.
Results: G-allele and GG-genotype of rs172378 were overrepresented among patients with LN compared to the other SLE patients – 64% vs 31% for G-allele and 48% vs 7.7% and were associated with renal involvement – OR=3.96 (95%CI: 1.53 – 10.23), p=0.005 for G-allele and OR=10.86 (95%CI: 1.29 – 91.58), p=0.028 for GG-genotype.
G-allele and GG-genotype were also associated with increased levels of anti-dsDNA antibodies – OR=2.95 (95%CI: 1.21 – 7.18), p=0.017 and OR=6.33 (95%CI: 1.41 – 28.39), p=0.016, resp.
G-allele showed weak correlation with earlier age at disease onset (point biserial r=-0.22, p=0.03) and patients, carrying it (GG- and AG-genotypes) were younger at disease onset then those with AA-genotype (p=0.05 and p=0.02 resp.).
Conclusion: rs172378 associates with some clinical and immunological parameters of SLE, traditionally linked to disease severity, therefore it may possibly play a role in disease pathogenesis.

AB0008 ACESO APPLICATION: AN INTEGRATED GENOTYPE ANALYSIS WEB SERVER FOR CLINICAL GENOMICS IN CROHN'S DISEASE AND IBD-RELATED ARTHRITIS

L. Papageorgiou[1], M. Zervou[2], I. Katsimpoula[1], D. Vlachakis[1], G. Bertsias[3], G. Goulielmos[2], E. Eliopoulos[1]. *[1]Agricultural University of Athens, Department of Biotechnology, Athens, Greece; [2]University of Crete, Section of Molecular Pathology and Human Genetics, School of Medicine, Heraklion, Greece; [3]University of Crete, Department of Rheumatology and Clinical Immunology, School of Medicine,, Heraklion, Greece*

Background: Genome Wide Association Studies (GWAS) observe the set of different variants throughout the genome of different individuals and study whether a particular trait is due to one variant. Many autoimmune diseases have been identified to have a linkage with specific loci and metabolic pathways, but the exact cause of disorders is still remaining unknown [1]. Aceso Application is an integrated bioinformatics web-tool designed for researchers and medical experts towards to estimating the clinical genomic profile of a candidate patient with Crohn's Disease (CD)[2-4].

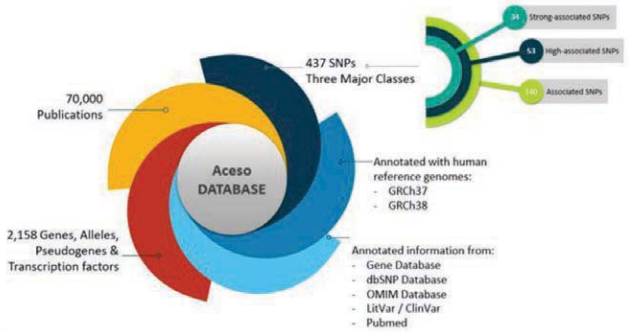

Figure 1. The Aceso app web-server Database. Left are shown the three identified SNPs classes of the genomic "grammar" of CD.

Objectives: To identify the most reliable gene variants, single nucleotide polymorphisms (SNPs) and epigenetic related SNPs that causing CD using the genomic data provided for the patient and aid the medical expert in CD diagnosis.
Methods: In the present study, we have analyzed more than 149.000 CD related publications using data mining and semantic techniques towards extracting the Crohn's Disease-related genes, non-coding regions and generally candidate SNPs. The extracted knowledge has been filtered, evaluated, annotated, classified, and stored in the Aceso Application Database (AAD). This was followed by the design and development of the Aceso application, in which the generated datasets and results were included. The application has been tested and presented here with whole-exome sequencing data from several related patients with CD.
Results: CD-related SNPs and variants identified in genome-wide association studies (GWAS), whole-genome (WGS), whole-exome (WES), or targeted sequencing information are classified, annotated, and analyzed in an integrated patient profile with clinical significance information. Probable genes associated with the patient's genomic profile are visualized with chromosome ideograms, statistic bars, and regulatory networks through data mining studies with relative publications. An evaluation study was performed on 2 patients from a three-generation family with CD [5].
Conclusion: The Aceso application was designed to assist early stage diagnosis by using the patients's genomic data. It provides the patient's genomic profile which is generated based on the list of the most predictable candidate gene variants related to CD and has implications also for IBD-related arthritis. This novel and accessible webserver tool of CD to assist medical experts in the clinical genomics and precision medicine procedure is available at http://geneticslab.aua.gr/aceso.

AB0009 DIFFERENTIALLY EXPRESSED GENES BETWEEN FLARE OF PALINDROMIC RHEUMATISM AND ACTIVE RHEUMATOID ARTHRITIS

H. H. Chen[1]. [1]*Taichung Veterans General Hospital, Internal Medicine, Taichung, Taiwan, Republic of China*

Background: Although the mechanisms of palindromic rheumatism (PR) is still unclear, an association between PR and rheumatoid arthritis (RA) has been well recognized in previous studies, with one to two-thirds of PR patients developing RA during a period of follow-up. RNA sequencing (RNA-Seq) is a next-generation sequencing (NGS) method that measures genome-wide RNA abundance. Using RNA-Seq to identify the DEGs between flare PR and active RA could help elucidate the pathogenic mechanisms of PR flare and find novel genes to predict RA progression.
Objectives: The aim of this study is to identify gene expression signatures between PR flare and active RA using whole blood RNA-seq.
Methods: We collected clinical data, and blood samples from 12 flare PR patients and 12 active RA (defined as DAS28-ESR≥3.2) patients from Taichung Veterans General hospital. We obtained high-quality RNA by using PAXGene tube for whole blood sampling and PAXGene blood RNA Kit to extract RNA. Cuffdiff (Cufflinks option) output was filtered for differentially expressed genes (DEGs) with p-value < 0.05. Gene set enrichment analysis (GSEA) were performed using the GSEA version 4.0.0 with immunologic gene sets (C7 sets containing 4872 gene sets) from The Molecular Signatures Database (MSigDB). According to GSEA web suggestion, a false discovery rate (FDR) < 0.25 with a p-value < 0.05 was considered statistically significant. We obtained rank ordered gene list from GSEA.
Results: We compared flare PR and active RA using GSEA. Five of the top 12 enrichment in phenotype with flare PR was related to lipopolysaccharide (LPS), which was found in the outer membrane of Gram-negative bacteria. And other pathways were also related to immune response, e.g., B cell, T cell and macrophage. In active RA, the characteristic gene expressions were associated with immune response, such as genes up-regulated in dendritic cells, genes down-regulated in B cell, and genes up-regulated in T cells.
We obtained top 3 differential gene expressions in flare PR patients and top 3 differential gene expressions in active RA patients. FCGBP, GLRX3 and RTN4R genes were significantly associated with immune response in flare PR patients. And we observed that 3 genes had statistically significant *t-test* result (FCGBP, p-value< 0.001; GLRX3, p-value< 0.001; RTN4R, p-value< 0.001) (Figure 1**a, 1b and 1c**). This result showed that FCGBP, GLRX3 and RTN4R may play an important role on immune response related to flare PR. In active RA patients, 3 genes had statistically significant *t-test* result (HK3, p-value< 0.001; HIST1H2AI, p-value= 0.002; BST1, p-value<0.001) (Figure 1**d, 1e and 1f**).

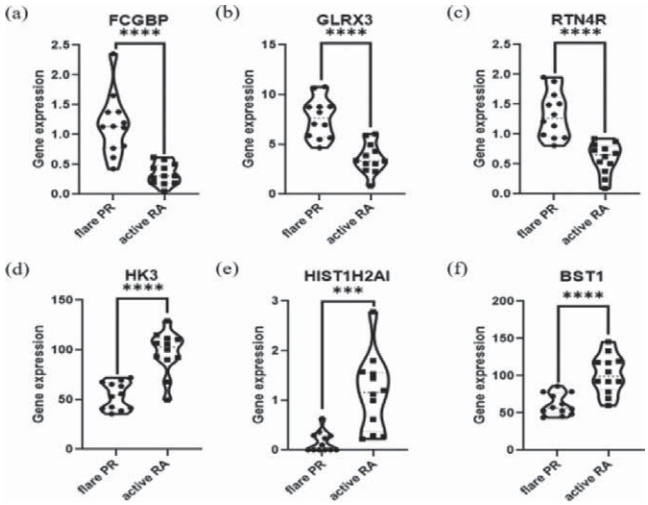

Figure 1. Differential gene expressions between flare PR and active RA. (a) FCGBP, (b) GLRX3, (c) RTN4R, (d) HK3, (e) HIST1H2AI, (f) BST1

Conclusion: GSEA analyses showed that five of the top 12 enrichment in flare PR was related to LPS and other pathways were related to immune responses of B cell, T cell and macrophage. However, in active RA, the characteristic gene expressions included genes up-regulated in dendritic cells, genes down-regulated in B cell, and genes up-regulated in T cells, suggeting different physiological pathways from flare of PR.

AB0010 ASSOCIATION OF SOME NON-HLA GENE POLYMORPHISMS WITH SUSCEPTIBILITY TO SYSTEMIC LUPUS ERYTHEMATOSUS IN WOMEN IN BELARUSIAN POPULATION

N. Dostanko[1], E. Siniauskaya[2], V. Yagur[1], R. Goncharova[2], H. Yatskiu[2]. [1]*Belarusian State Medical University, 2-nd Department of Internal Medicine, Minsk, Belarus;* [2]*National Academy of Sciences of Belarus, Institute of Genetics and Cytology, Minsk, Belarus*

Background: Despite the recent progress in our understanding of the genetic predisposition to systemic lupus erythematosus (SLE) its clinical and functional significance is not fully clarified yet and needs to be implemented in personalized care [1].
Objectives: To estimate the association between some single nucleotide polymorphisms (SNPs) of 9 non-HLA genes-candidates as STAT4 rs7574865, PTPN2 rs2542151, PTPN22 rs2476601, AGER rs1035798, TRAF1/C5 rs3761847, SLC7A11 rs13128867, RUNX1 rs9979383, IL6 rs1800795, IL6R rs2228145, IL6R rs4845618 and susceptibility to SLE in Belarusian women for the following predictive model development.
Methods: We examined 316 women: among them 59 SLE patients (mean age 39.84, CI95% 36.62-43.06) classified according to the 1997 American College of Rheumatology (ACR) revised classification criteria and 257 age-matched healthy controls (blood donors, mean age 38.12, 95% confidence interval (CI95%) 36.77-39.46). Deoxyribonucleic acid was extracted from peripheral blood samples by phenol-chloroform method. Genotyping was performed by real-time PCR with fluorescent probes. Descriptive analysis, test for Hardy–Weinberg equilibrium, multiple inheritance models (co-dominant, dominant, recessive, over-dominant and log-additive) for single SNPs, Akaike information criteria (AIC) and Bayesian information criteria (BIC) were analyzed using SNPStats web tool [2]. Pearson χ^2 (χ^2), two-way Fisher exact test (F, $p_{2\text{-t}}$), odds ratio (OR), likelihood ratio of positive (LR^+) and negative (LR^-) tests with corresponding $CI_{95\%}$ were also calculated.
Results: Exact test for all genotype frequencies distribution of all studied SNPs didn't reveal significant differences with Hardy-Weinberg equilibrium in all controls and SLE groups. We noted significant increase of minor TT genotype frequency of STAT4 rs7574865 in SLE vs healthy women with recessive inheritance model as the best-fitting one according to its less AIC and BIC values (OR=3.78 ($CI_{95\%}$ 1.35-10.62); p=0.016; LR^+=3.45 ($CI_{95\%}$ 1.37-8.60); LR^-=0.91 ($CI_{95\%}$ 0.84-0.98)). We revealed protection of minor A allele of AGER rs1035798 carriership with log-additive model of inheritance as the best-fitting one according to AIC and BIC values against SLE development in women (OR=0.52 ($CI_{95\%}$ 0.33-0.83); p=0.004; LR + =0.70 ($CI_{95\%}$ 0.50-0.93); LR – =1.47 ($CI_{95\%}$ 1.10-1.86)). We also noted significant increase of minor allele G frequency of TRAF1/C5 rs3761847 in SLE vs healthy women with dominant inheritance model (OR=3.61 ($CI_{95\%}$

1.05-12.38); p=0.019; LR $^{+}$ =1.30 ($CI_{95\%}$ 1.03-1.43); LR $^{-}$ =0.36 ($CI_{95\%}$ 0.12-0.92)) and increase of AA genotype frequency in healthy women (p_{2-t} =0.041). We revealed that minor allele G of PTPN2 rs2542151 is more frequent in SLE women vs healthy controls and has overdominant model of inheritance (OR=1.98 ($CI_{95\%}$ 1.09-3.59); p=0.026; LR $^{+}$ =1.57 ($CI_{95\%}$ 1.07-2.20); LR $^{-}$ =0.79 ($CI_{95\%}$ 0.62-0.97)). There were no significant differences in genotypes and alleles distribution for PTPN22 rs2476601, RUNX1 rs9979383, SLC7A11 rs13128867 and IL6 rs1800795 in studied population and we noted only non-significant tendency in minor SNP genotypes distribution of IL6R rs4845618 and IL6R rs2228145 between healthy controls and women with SLE.

Conclusion: Our data suggest the susceptibility to SLE in women with TT genotype of STAT4 rs7574865 polymorphism and allele G carriers of both TRAF1/C5 rs3761847 and PTPN2 rs2542151 as well as protective role of AGER rs1035798 A allele carriership againt SLE development in women of Belarusian population.

AB0011 DNA METHYLATION AS A BIOMARKER OF TOCILIZUMAB RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS

N. Nair[1], D. Plant[1], J. Isaacs[2], A. Morgan[3,4], K. Hyrich[5,6], A. Barton[1,5], A. G. Wilson[7]. *[1]The University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester Academic Health Sciences Centre, Manchester, United Kingdom; [2]Newcastle University and Musculoskeletal Directorate, Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom; [3]University of Leeds, Leeds Institute of Cardiovascular and Metabolic Medicine, Leeds, United Kingdom; [4]NIHR Leeds BRC, Leeds Teaching Hospitals Teaching Trust, Leeds, United Kingdom; [5]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester University NHS Foundation Trust, Manchester, United Kingdom; [6]The University of Manchester, Versus Arthritis Centre for Epidemiology, Manchester Academic Health Sciences Centre, Manchester, United Kingdom; [7]University College Dublin, School of Medicine and Medical Science, Dublin, Ireland*

Background: Tocilizumab (TCZ) is a disease-modifying antirheumatic biologic drug, which targets the IL-6 signalling pathway and is effective in ameliorating disease activity in rheumatoid arthritis (RA). However, approximately 50% of patients do not respond adequately to TCZ and some patients report adverse events. Considering there is growing evidence that DNA methylation is implicated in RA susceptibility and response to some biologics (1, 2), we investigated DNA methylation as a candidate biomarker for response to TCZ in RA.

Objectives: To identify differential DNA methylation signatures in whole blood associated with TCZ response in patients with RA.

Methods: Epigenome-wide DNA methylation patterns were measured using the Infinium EPIC 850k BeadChip (Illumina) in whole blood-derived DNA samples from patients with RA. DNA was extracted from blood samples taken pre-treatment and following 3 months on therapy, and response was determined at 6 months using the Clinical Disease Activity Index (CDAI). Patients who had good response (n=10) or poor response (n=10) to TCZ by 6 months were selected. Samples from secondary poor responders (n=10) (patients who had an improvement of CDAI and were in remission at 3 months, followed by a worsening of CDAI at 6 months) were also analysed. Differentially methylated positions (DMPs) were identified using linear regression, adjusting for gender, age, cell composition, smoking status, and glucocorticoid use.

Results: In the pre-treatment samples, 20 DMPs were significantly associated with response status at 6 months (unadjusted p-value $<10^{-6}$), whilst in the 3 month samples, 21 DMPs were associated with response. One DMP, cg03121467, was significantly less methylated in good responders compared to poor responders in the pre-treatment samples. This DMP is close to *EPB41L4A* and may play a role in β–catenin signalling. Interestingly, cg10136146 was significantly less methylated in secondary poor responders compared to both good and poor responders in the 3 month samples. This DMP maps close to *CD81*, which plays a role in mediating the development and activation of B and T lymphocytes.

Conclusion: These preliminary results provide evidence that DNA methylation patterns may predict response to TCZ. Further regional and pathway analyses is in progress and validation of these findings in other larger data sets is required.

AB0012 IDENTIFICATION OF NEW BIOMARKERS FOR SINOMENINE TREATMENT IN RHEUMATOID ARTHRITIS BASED ON BIOINFORMATICS ANALYSIS

X. Shen[1], L. Yanqun[1], X. Guo[1], W. Linfeng[1], J. Zhang[1], Z. Feng[1]. *[1]Third-Grade Pharmacological Laboratory on Chinese Medicine Approved by State Administration of Traditional Chinese Medicine, Medical College of China Three Gorges University, Medical College of China Three Gorges University, Yichang,Hubei, China*

Background: Sinomenine (SIN) were extracted from Caulis Sinomenii and achieved an remarkable therapeutic effect for Rheumatoid Arthritis (RA). However, the mechanism of SIN acting on RA is not clear yet.

Objectives: To excavate potential targets and mechanisms of SIN for RA through bioinformatics.

Methods: The microarray data were downloaded from the Gene Expression Omnibus (GEO) database. GEO2R was used to identify differentially expressed genes (DEGs) and the unique value was retained. The potential targets of active compounds from various databases were screened. Based on the overlapping genes, Cytoscape 3.7.2 software was used to construct a protein-protein interactions (PPI) network and to visualize the mechanisms of the treatment by Gene Ontology (GO) enrichment analysis Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis by DAVID database. Finally, we used AutoDockTools 1.5.6 for molecular docking.

Results: A total of 5053 DEGs and 1070 intersections were obtained, including 486 up-regulated and 584 down-regulated targets. 298 SIN targets were collected from various databases, 84 potential targets were obtained by intersecting with DEGs. There are 80 nodes and 305 edges were obtained in PPI network. Based on the degree, the top 10 target genes were AKT1, RGFR, MTOR, JAK2, NOS3, IL2, IL6, MMP9, MAPK8, HSP9OAA1. The core targets was most relevant to protein phosphorylation, signal transduction though GO analysis. The results of the KEGG enrichment analysis included PI3K-Akt signaling pathway and Neuroactive ligand-receptor interaction. Following analysis found that AKT1, EGFR, MTOR and JAK2 existed in the PI3K-Akt signaling pathway. Molecular docking was used to confirm that the binding energy of AKT1 was -7.68 kJ mol $^{-1}$, EGFR was -5.33kJ mol^{-1}, and MTOR was -4.77 kJ mol^{-1},JAK2 was -3.25 KJ mol^{-1}. AKT1 and EGFR was further identified as the core targets.

Conclusion: Present study show that AKT1 and EGFR may be the key targets of SIN acting on the PI3K-Akt signaling pathway, thereby inhibiting the progression of disease and improving RA.
