Methods: This was a retrospective, single-center study. The patients with CTD-ILD and IPAF were included. The PF-ILD was identified at two years after the ILD diagnosis, as according to the INBUILD study [2]. The ILD patterns on the HRCT and the pulmonary function tests at diagnosis and one year after ILD diagnosis were reviewed by three pulmonologists independently. The baseline demographics, autoimmune manifestations, and serology at diagnosis, three months, and one year after ILD diagnosis were collected. The data were analyzed using the R version 4.1.2.
Results: From 2010 to 2020, we enrolled 34 patients into the analysis. These included 11 patients with Sjogren's syndrome, 7 patients with idiopathic inflammatory myopathy, 3 patients with mixed connective tissue diseases, 1 patient with systemic sclerosis, and 14 patients with IPAF. The HRCT patterns were usual interstitial pneumonia in 13, non-specific interstitial pneumonia (NSIP) in 8, organizing pneumonia (OP) in 6, and lymphocytic interstitial pneumonia (LIP) in 1.
At 2 years, 15 patients developed PF-ILD. The CTD diagnoses and the radiographic patterns at diagnosis were not associated with the development of PF-ILD. The predicted functional vital capacity (FVC) at diagnosis (80% vs. 69%, p=0.047), diffusion capacity of the lung for carbon monoxide (DLCO) at diagnosis (76% vs. 44%, p = 0.021), FVC at one year (94% vs. 68%, p = 0.047), and DLCO at one year (68% vs. 36%, p = 0.018) were associated with the PF-ILD progression. Immunologically, the PF-ILD patients had a borderline higher 1-hour erythrocyte sediment rate (ESR) at baseline (36 vs. 22 mm/h, p = 0.051), but the difference became prominent after 3 months (38 vs. 10 mm/h, p = 0.023), and 12 months (28 vs. 8 mm/h, p = 0.005) after the ILD diagnosis. (Figure 1)

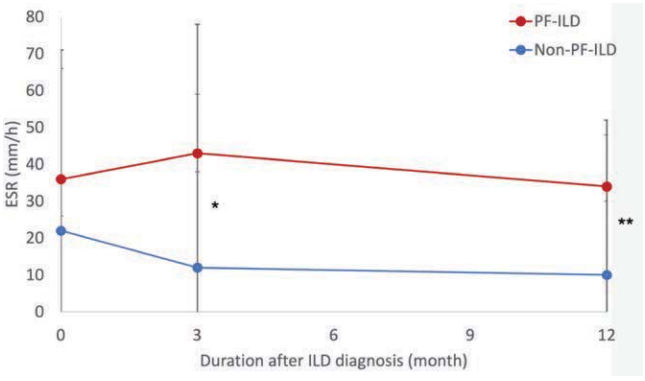

Figure 1. Change of erythrocyte sediment rate at 1 hour over time. ESR, erythrocyte sediment rate at 1 hour. ILD, interstitial lung disease. PF-ILD, progressive fibrosing interstitial lung disease. * $p < 0.05$, ** $p < 0.01$

Conclusion: The higher ESR during the first one year after ILD diagnosis was associated with the progression to PF-ILD. In serial pulmonary function tests, both the FVC and DLCO at baseline were associated with PF-ILD, and the between-group differences were more prominent at 1 year of follow up. The findings suggest that the persistent inflammation might contribute to the progressive worsening of pulmonary fibrosis and subsequent lung function decline. The immunology and pulmonary function parameters at one year predict the development of PF-ILD.

AB1430 COMPARISON OF COGNITIVE ABILITY ACROSS THE IMMUNE MEDIATED INFLAMMATORY DISEASES: SYSTEMATIC REVIEW AND META-REGRESSION

J. Gwinnutt[1], T. Toyoda[2], M. Barraclough[1,3,4], S. Verstappen[1,3], D. Montaldi[5], M. Hornberger[2], A. Macgregor[2,6]. [1]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Division of Musculoskeletal and Dermatological Sciences, Faculty of Biology, Medicine and Health, Manchester, United Kingdom*; [2]*University of East Anglia, Norwich Medical School, Norwich, United Kingdom*; [3]*Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom*; [4]*University Health Network, Schroeder Arthritis Institute, Toronto, Canada*; [5]*The University of Manchester, Division of Neuroscience and Experimental Psychology, Manchester, United Kingdom*; [6]*Norfolk and Norwich University Hospitals NHS Trust, Rheumatology Department, Norwich, United Kingdom*

Background: Age strongly influences cognitive ability. Previous studies have tried to compare the cognitive ability of people with different immune mediated inflammatory diseases (IMIDS: systemic lupus erythematosus [SLE], rheumatoid arthritis [RA], axial spondyloarthritis [axSpA], psoriatic arthritis [PsA], psoriasis [PsO]) in age-matched analyses. However, given the varying age of onset of these conditions, within direct age-matched comparisons one of the disease groups is necessarily older/younger than typical.
Objectives: (i) To perform a systematic review of the cognitive ability of people with IMIDs compared with age-matched controls, and (ii) use meta-regression to indirectly compare the cognitive ability of people with different IMIDs.
Methods: A search strategy was implemented in the Medline, Embase and PsychInfo databases on 29.5.2021. Identified studies were screened by two reviewers, selecting observational studies comparing the cognitive ability of people with an IMID against healthy controls. This abstract only includes studies reporting overall cognition scores, memory scores and attention scores. The standardised mean differences (SMDs) of the cognitive assessments between people with IMIDs and controls were pooled using random-effects meta-analysis, stratified by IMID. The IMIDs were compared using meta-regression, to identify the IMID with the greatest impairment in cognitive ability compared with healthy people of a similar age (inclusion cut-off: ≥5 studies).
Results: In total, 62 studies (SLE: 37, RA: 18, axSpA: 1, PsA: 2, PsO: 4) were included in the meta-analyses. People with IMIDs had moderate impairments in overall cognition, memory and attention compared with controls (Table 1), with similar results seen when limiting analyses to studies which included age-matched controls (N=48 studies). People with SLE and RA had similar levels of impairment compared with controls of comparable age in terms of overall cognition (coef: -0.12 (95% CI -0.42, 0.19) and attention (coef: -0.35 (95% CI -0.73, 0.04)). Other IMIDs and cognition dimensions were not included in the meta-regression analysis due to lack of studies.
Conclusion: People with IMIDs have significant impairments in terms of overall cognition, memory and attention. Whilst this indirect analysis shows that people with SLE and RA have a similar magnitude of impairment compared with healthy controls of a similar age, a number of factors could be influencing this finding (e.g. selection bias, demographic differences).

AB1431 EPIDEMIOLOGICAL AND GENETIC FEATURES OF ANTI-3-HYDROXY-3-METHYLGLUTARYL-COA REDUCTASE NECROTIZING MYOPATHY IN NORTHERN SPAIN: SINGLE-CENTER EXPERIENCE

D. Prieto-Peña[1,2], J. G. Ocejo-Vinyals[3], J. A. Mazariegos-Cano[4], A. L. Pelayo[5], S. Remuzgo Martinez[2], F. Genre[2], A. García Dorta[6], M. Renuncio-Garcia[3], V. Martinez-Taboada[1], C. Garcia-Ibarbia[4], J. Sanchez-Martin[1], B. Atienza-Mateo[1,2], M. Lopez-Hoyos[3], R. Blanco[1,2], M. A. González-Gay[1,2], J. L. Hernández[2,4]. [1]*Hospital Universitario Marqués de Valdecilla, Department of Rheumatology, Santander, Spain*; [2]*IDIVAL, Research Group on Genetic Epidemiology and Atherosclerosis in Systemic Diseases and Metabolic Bone Diseases of the Musculoskeletal System, IDIVAL, Santander, Spain*; [3]*Hospital Universitario Marqués de Valdecilla, Santander, Spain, Department of Immunology, Santander, Spain*; [4]*Hospital Universitario Marqués de Valdecilla, Department of Internal Medicine, Santander, Spain*; [5]*Hospital Universitario Marqués de Valdecilla, Department of Neurology, Santander, Spain*; [6]*Hospital Universitario de Canarias, Department of Rheumatology, Tenerife, Spain*

Background: Anti-3-hydroxy-3-methylglutaryl-CoA reductase (HMGCR) immune-mediated necrotizing myopathy (IMNM) is an entity of growing interest. However, data on epidemiology and clinical spectrum are still scarce and there is a need for the identification of its potential risk factors.
Objectives: To characterize the demographic, genetic, clinical, and serological features of patients with anti-HMGCR IMNM in a region of northern Spain.
Methods: Study of all patients diagnosed with anti-HMGCR IMNM during a 5-year period at a reference hospital in Northern Spain. Besides clinical and laboratory data, we analyzed the genetic influence of HLA genes and the rs4149056 (c.521T>C) single nucleotide polymorphism (SNP) in the *SLCO1B1* gene.
Results: 8 patients (5 women, 3 men) with a mean ± SD age of 64.9±7.3 years, fulfilled the criteria for anti-HMGCR IMNM. The incidence rate was 0.6 per 100.000 person-years and the prevalence 3 per 100.000 population. All patients had dyslipidemia and had been exposed to statins. Seven of the 8 of cases complained of myalgia. All of them had predominant lower limb proximal and symmetric muscle weakness that was severe in 2 of them. None of the patients had extra-muscular involvement. No evidence of malignancy was found. All patients had elevated serum CK levels with a median [IQR] of 4488 [2538-9194] IU/L. Serum 25-hydroxy vitamin D levels were decreased in all patients in whom it was determined. The 3 patients with a previous diagnosis of hypothyroidism had abnormal levels of TSH at the time of diagnosis. All patients experienced improvement with different schemes of immunosuppressive therapy. Noteworthy, 7 of 8 patients carried the HLA-DRB1*11 allele. The frequency of the rs4149056 C allele in the *SLCO1B1* gene (12.5%) was similar to that of the general population.
Conclusion: In northern Spain, the IMNM anti-HMGCR preferentially affects people over 50 years of age who are carriers of the HLA-DRB1*11 allele and take statins. Both low vitamin D levels and hypothyroidism may play a potential predisposing role in the development of this disease

AB1432 THE ASSOCIATION OF PAINFUL AND NON-PAINFUL COMORBIDITIES WITH CENTRAL MECHANISMS OF KNEE PAIN

H. R. Lewis[1,2,3], W. J. Chaplin[1,2,3], D. F. Mcwilliams[1,2,4], B. S. Millar[2,3,5], S. Shahtaheri[2,3,5], J. F. R. Gladman[6], D. Walsh[2,3,5,7]. *[1]Pain Centre Versus Arthritis, Academic Rheumatology, Nottingham, United Kingdom*; *[2]NIHR Biomedical Research Centre, Academic Rheumatology, Nottingham, United Kingdom*; *[3]University of Nottingham, School of Medicine, Nottingham City Hospital, United Kingdom*; *[3]University of Nottingham, School of Medicine, Nottingham City Hospital, United Kingdom*; *[1]Pain Centre Versus Arthritis, Academic Rheumatology, Nottingham, United Kingdom*; *[6]University of Nottingham, Centre for Rehabilitation & Ageing Research, Nottingham, United Kingdom*; *[7]Sherwood Forest Hospitals NHS Foundation Trust, Rheumatology, Nottingham, United Kingdom*

Background: Central mechanisms of knee pain occur in the central nervous system and may intensify and prolong pain. Central pain mechanisms might be facilitated by ongoing nociceptive input. A link between multimorbidity and central mechanisms of knee pain is proposed; ongoing sensory inputs due to comorbidities may trigger changes in pain processing by the CNS. This might be particularly expected with painful comorbidities.

Objectives: To investigate potential relationships of painful and non-painful multimorbidity with central mechanisms of knee pain.

Methods: Cross-sectional analysis of self-report data from participants of the Investigating Musculoskeletal Health and Wellbeing cohort, who reported knee as their most bothersome site of joint pain over the previous month, with pain rated ≥1/10, and who had completed FRAIL and CAP-Knee (1) questionnaires. Two indirect measures suggesting central mechanisms involvement in knee pain were used as dependent variables; pain intensity (0-10 numerical rating scale) and CAP-Knee score (0-16 scale). Comorbidities were assigned either "painful comorbidity" or "non-painful comorbidity" status based on IASP classification of chronic pain criteria (2). Multivariable linear regression models, adjusted for age and sex, were employed to explore associations of comorbidity counts with pain intensity and CAP-Knee score.

Results: 736 participants satisfied inclusion criteria. 55% were female, mean age 71 (range 40 to 95). Painful comorbidity count and non-painful comorbidity count each had positive associations with pain intensity (β=0.42, 95% CI=0.29 to 0.54, p<0.001; and β=0.31, 95%CI=0.16 to 0.45, p<0.001, respectively). Painful and non-painful comorbidity counts each also were associated with CAP-Knee score (β=0.80, 95% CI=0.59 to 1.01, p<0.001; and β=0.52, 95% CI=0.27 to 0.77, p<0.001, respectively). Painful and non-painful comorbidity counts each remained significantly associated both with pain intensity and with CAP-Knee scores when both types of comorbidity count were included in the same multivariable model.

Conclusion: Both painful and non-painful comorbidities were positively associated with central mechanisms of knee pain, providing further insight into the interconnectedness of pain processing systems and the rest of the body. The explanation behind these relationships may depend on more than just ongoing nociceptive input. Future work should address possible contributions from genetic, pathophysiological, psychological, and pharmacological factors associated with comorbid diagnosis.

AB1433 ASSESSING THE CARDIOVASCULAR RISK IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: QRISK AND GAPSS SCORES HEAD TO HEAD

A. Barinotti[1], M. Radin[1], I. Cecchi[1], S. G. Foddai[1], E. Rubini[1], D. Roccatello[1], E. Menegatti[1], S. Sciascia[1]. *[1]University of Turin, Department of Clinical and Biological Sciences, Turin, Italy*

Background: Cardiovascular diseases (CVDs) represent one of the most life-threatening conditions that can affect SLE patients. Assessing the potential CVD risk of these patients is still a challenge and an important aspect in the clinical practice. Recently the QRISK3 score has attempted to encompass for SLE augmented thrombotic risk by adding items (such as corticosteroid use) that are missing in traditional CVD risk scores.

Objectives: To apply and compare the QRISK3 and the adjusted Global AntiPhospholipid Syndrome Score (aGAPSS), a validated score to assess CVD and overall thrombotic risk in aPL positive patients, in a cohort of SLE patients with and without a concomitant diagnosis of APS.

Methods: 25-85 years old patients attending San Giovanni Bosco Hospital (Turin) during a period of 6 months (Sep 2019 – Feb 2020) with a confirmed diagnosis of SLE (2019 ACR/EULAR classification criteria) and/or a diagnosis of SAPS (Sidney criteria) were included in the study. QRISK3 has been calculated using the official online calculator (https://qrisk.org/). aGAPSS has been calculated using the validated point values based on aPL profile and independent risk factors: aCL=5, aβ2GPI=4, LA=4, aPS/PT=3, hyperlipidemia=3, hypertension=1.

Results: The analysis included a cohort of 142 SLE patients: 34 SAPS (23.9%) and 108 SLE patients without APS (76.1%), with a mean age of 48±12.9 (SAPS=51.6±12.8/SLE without APS=46.9±12.8). Table 1 summarizes patients characteristics. When focusing on cerebrovascular/coronary events, we found a statistical significance with respect to aGAPSS (pt with event =10.1±6.2 vs pt without event=5.8±6.1; p=0.007), but not QRISK3. Also, a significant association was observed between the occurrence of these events and high risk aGAPSS: p=0.03 for aGAPSS≥8, p=0.01 for aGAPSS ≥9, p=0.008 for aGAPSS ≥10. Moreover, the aGAPSS but not the QRISK3 resulted to strongly correlate with the occurrence of any thrombotic event, both at the uni- and multivariate analysis (univariate: pt with event =8.17±7.1 vs pt without event= 5.41±5.6; p=0.012 / multivariate: p=0.009). The same was observed for gender: male gender resulted to correlate with the occurrence of any thrombotic event at both uni- and multivariate analysis (p=0.017 and p=0.03, respectively). Finally, when focusing on aPL profile, regardless

the diagnosis, we found a statistical significance only with respect to aGAPSS (aPL+ =9.6±6.3 vs aPL- = 4.1±5.1; p<0.001).

Table 1. Demographic and clinical features of the patients included in the study.

PATIENTS CHARACTERISTICS	
Age (m±sd)	Tot=48±12.87
	SAPS=51.61±12.82
	SLE w/o APS=46.87±12.83
Females, n (%)	Tot=120/142 (84.5%)
	SAPS=22/34 (64.7%)
	SLE w/o APS=98/198 (90.74%)
THROMBOTIC EVENTS	
Thrombotic event, n (%)	Tot=48/142 (33.8%)
	SAPS=33/48 (68.75%)
	SLE w/o APS=15/48 (31.25%)
Arterial thrombosis, n (%)	Tot=22/142 (15.49%)
	SAPS=19/22 (86.36%)
	SLE w/o APS=3/22 (13.64%)
Venous thrombosis, n (%)	Tot=32/142 (22.53%)
	SAPS=18/32 (56.25%)
	SLE w/o APS=14/32 (43.75%)
Stroke, n (%)	Tot=13/142 (9.15%)
	SAPS=13/13 (100%)
	SLE w/o APS=0/13 (0%)
TIA, n (%)	Tot=6/142 (4.22%)
	SAPS=6/6 (100%)
	SLE w/o APS=0/6 (0%)

Conclusion: By encompassing factors that can contribute to CVD development in complex/autoimmune diseases, QRISK3 has been shown to be more accurate than traditional risk score in predicting SLE patients CVD risk. Nonetheless, the results of this analysis showed how the aGAPSS still seems to be the most valuable tool for this purpose when facing SLE patients. Moreover, the significance observed when focusing on patients' aPL profile, suggests that adding this item to the QRISK3 could be a useful strategy to improve the management.

AB1434 PREGNANCY AND RHEUMATIC DISEASES – COMBINING BIOLOGICAL MATERIAL AND CLINICAL DATA FOR FUTURE RESEARCH

I. R. Nilssen[1], B. Jakobsen[1], T. T. Pedersen[1], M. Wallenius[1,2]. [1]*Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, Department of Rheumatology, St.Olavs Hospital, Trondheim, Norway*; [2]*Norwegian University of Science and Technology, Department of Neuromedicine and Movement Science, Trondheim, Norway*

Background: Rheumatic diseases affect women in fertile age. There is an increased risk for disease flares and pregnancy complications, especially for patients with systemic rheumatic diseases. Improving knowledge of immunological changes that happen during and after pregnancy in women with rheumatic diseases is of great importance. The Norwegian National Advisory Unit for Pregnancy and Rheumatic Diseases (NKSR) therefore established a biobank in 2012 with material from this patient group. NKSR also administers RevNatus, a nationwide pregnancy quality register including women with inflammatory rheumatic diseases, with comprehensive clinical data.

Objectives: To facilitate high quality research by developing a possibility to combine biobank material and comprehensive clinical data. We aim to increase current knowledge in this field, with the ultimate goal of making pregnancies safer for women with rheumatic diseases.

Methods: The RevNatus biobank is part of the Regional Biobank of Central Norway (Biobank[1]). Biobank[1] is a research facility established to provide an organizational framework for all research, which involves biological material from patients in any of the public hospitals of the region. The collection of biologic material is approved by the regional committees for medical and health research ethics. Patients are included after having signed a consent form. Blood samples are collected before pregnancy, in each trimester, 6 weeks, 6 months and 12 months postpartum. So far, serum, plasma, buffy-coat and Tempus Blood RNA tubes have been collected. At the same time points when blood samples are collected, clinical data is registered in RevNatus. Serum, plasma, buffy-coat and Tempus Blood RNA tubes from 32 healthy pregnant women have also been collected as control group material.

Results: 310 donors are so far included in the RevNatus biobank. These include systemic lupus erythematosus (36), rheumatoid arthritis (61), juvenile idiopathic arthritis (40), spondyloarthritis (96), Sjögren's syndrome (8), granulomatosis with polyangiitis (5), MCTD (5), healthy controls (32) and others (27).

Table 1. Number of donors in the biobank at each time point

Time point	Number of donors
Before pregnancy	135 donors
1st trimester	123 donors
2nd trimester	124 donors
3rd trimester	117 donors
6 weeks postpartum	175 donors
6 months postpartum	166 donors
12 months postpartum	129 donors

Conclusion: Collections of biological samples from pregnant women with rheumatic diseases are hard to come by, and therefore research is scarce. RevNatus with its biobank has the potential to make a substantial impact combining clinical and biological material, and take an important role in further molecular research in the field of rheumatic disease and pregnancy.

AB1435 CLINICAL PREDICTION MODELS FOR METHOTREXATE OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS: SYSTEMATIC REVIEW AND CRITICAL APPRAISAL

C. Gehringer[1], G. Martin[2], K. Hyrich[1,3], S. Verstappen[1], J. Sergeant[1,4]. [1]*University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*University of Manchester, Centre for Health Informatics, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom*; [3]*Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom*; [4]*University of Manchester, Centre for Biostatistics, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: Methotrexate (MTX) is the preferred first line therapy for rheumatoid arthritis (RA). MTX has several advantages over other treatments including effectiveness and low cost; however, around 40% of patients are classed as non-responders after 6 months (1). Therefore, there is a clinical need to identify patients at high-risk of poor outcomes, such that patients could potentially be fast tracked onto alternative therapies to improve their clinical outcomes and quality of life. Such risk stratification is possible through prognostic prediction models, although models which have previously been developed appear to have had little impact on practice. This may be in part due to methodological features of their development and validation but, to date, no review has collated the evidence in this field.

Objectives: This systematic review aimed to (i) identify and summarise multivariable prediction models of MTX treatment outcomes in biologic-naïve adult RA patients, and (ii) critically appraise their methodological properties.

Methods: The electronic databases Medline and Embase were searched to identify studies developing or validating prediction models of MTX outcomes in the population of interest, including demographic, disease-specific or treatment-related covariates, published after 2005. Models were stratified by outcome definition, and information on participants, predictors, model performance, handling of missing data and model validation were extracted. A risk of bias (ROB) assessment using PROBAST (prediction model risk of bias assessment tool) was carried out. Two reviewers were independently involved in screening, data extraction, and ROB stages.

Results: The included studies used three main outcome definitions: a state of disease activity, such as low disease activity or remission; the EULAR response criteria; or discontinuation due to adverse events (AEs). Some studies incorporated AEs into a composite outcome with disease activity and few accounted for potential competing risks, which are events that preclude the occurrence of the primary outcome of interest. Not handling competing risks may result in under-prediction, leading to potentially compromised risk stratification. There was a lack of internal validation using cross sampling techniques, which is critical for reducing overfitting, as well as external validation in new data, a process necessary to ensure reproducibility and generalisability of a prediction model to the larger patient population. Missing data was mostly handled using complete case analysis, leading to potentially biased risk estimates. The ROB assessment showed overall high ROB of the included studies.

Conclusion: This systematic review summarises current prediction models of MTX treatment outcomes in RA. It highlights several methodological shortcomings, such as poor handling of missing data and competing risks to the primary outcome, and a lack of internal and external validation. These should be addressed in future model development and validation to improve accuracy of predictions. Without tackling these issues, prediction of MTX treatment outcomes will remain at high risk of bias and should not be recommended for informing risk stratification for RA treatment decisions.

AB1436 INFECTIONS IN PATIENTS WITH RHEUMATIC DISEASES IN TREATMENT WITH BIOLOGIC THERAPY

V. Rivera Teran[1], D. Vega-Morales[1], S. Sicsik[1], F. Irazoque-Palazuelos[1], M. A. Saavedra[1], J. C. Casasola[1], S. Carrilo[1], A. Peña[1], A. Castillo Ortiz[1], O. E. Muñoz-Monroy[1], S. Duran Barragan[1], A. Ramos[1], L. F. Valdés Corona[1], E. Torres Valdéz[1], A. Paz[1], E. A. Zamora-Tehozol[1], A. Torres[1], S. Mendieta[1], D. X. Xibille Friedmann[1], F. Guerrero[1], N. Santana[1], M. Vazquez[1], C. Zepeda[1], M. Rivera[1], K. Alvarado[1], D. Alpizar-Rodriguez[1]on behalf of the Mexican Adverse Events Registry (BIOBADAMEX). [1]*Colegio Mexicano de Reumatología, Unidad de Investigación, Mexico City, Mexico*

Background: Patients with rheumatic diseases (RD) have a higher risk of developing infections due to disease and immunosupressor treatment factors[1]. Biologic disease -modifying antirheumatic drugs (bDMARD) have been associated with the development of opportunistic infections, nevertheless their impact on severe infections has not been consistent[2].

Objectives: To describe the sociodemographic and clinical characteristics of patients with RD on bDMARD treatment with and without infections, using data from the Mexican Adverse Events Registry (BIOBADAMEX), as well as to identify factors associated with the presence of infections.

Methods: BIOBADAMEX is a Mexican ongoing cohort of patients using bDMARDs. In this analysis we included all patients registered in Biobadamex from 2016 to 2021. We compared sociodemographic, clinical and treatment characteristics between patients who developed infections with to those who did not. We used descriptive statistics, Chi square and Kruskal Wallis tests to analyze differences between the groups.

Results: A total of 780 patients registered in Biobadamex were included in this study, among them 42 (5%) patients presented infections and 738 (95%) did not. At baseline, patients had a median (IQR) age of 50 (40-58) years and median disease duration of 7 (3-15) years. The most common diagnosis was rheumatoid arthritis with 512 (66%) patients, followed by ankylosing spondylitis in 115 (15%), psoriatic arthritis in 44 (6%), systemic lupus erythematosus in 30 (4%) and idiopathic juvenile arthritis in 27 (3%) patients. Comorbidities were present in 351 (45%) of the patients. Conventional DMARD (cDMARD) were used by 626 (80%) patients, and 290 (37%) used steroids. The most frequently used bDMARDs were adalimumab in 166 (21%) patients, certolizumab in 129 (16%), tocilizumab in 103 (13%) and abatacept 94 (12%). Table 1 shows baseline characteristics in the groups with and without infections. Patients with infections presented more severe adverse events 3 (7%) compared to those who did not 11 (2%), p=0.007, with a complete recovery without sequels. Most common infection site was skin (21%) followed by superior airways (12%). Most common infectious agents were gram negative bacteria. Only 2 patients presented bacteremia.

Table 1. Patients baseline characteristics

	Infection n=42	Without infection n=738	p
Female, n(%)	33 (79)	595 (80)	0.74
Age, median(IQR)	50.9 (43-59)	49.8 (40-58)	0.58
Disease duration (years), median (RIC)	7.5 (2-16)	7.0 (3-15)	0.9
Diagnostic, n(%):			
Rheumatoid arthritis	25 (59)	487 (66)	0.42
Idiopathic Juvenile Arthritis	0 (0)	27 (4)	
Ankylosing Spondylitis	6 (14)	109 (15)	
Others	11 (26)	115 (15)	
Comorbidities, n(%):	22 (52)	329 (44.6)	0.32
Previous bDMARD, n(%):	15 (36)	271 (37)	0.89
Use of steroids, n(%):	16 (38)	274 (37)	0.9
cDMARD, n(%)	33 (79)	593 (80)	0.77
Severe Adverse Events, n(%)	**3 (7)**	11 (2)	0.007
Outcome, n(%)			
Recovered without sequels	3 (100)	6 (55)	p=0.34*
Not recovered	0	3 (27)	
Unknown	0	2 (18)	
Infection site, n(%)			
Skin	9 (21)		
Superior airways	5 (12)		
Urinary tract	4 (10)		
Agent, n(%)			
Gram- bacteria	9 (21)		
Gram+ bacteria	0 (0)		
Virus	4 (14)		

*Chi2

Conclusion: The frequency of infections in patients using bDMARD in Biobadamex is low compared to the frequency reported in similar studies in other countries[3]. The presence of infections was associated with more severe adverse events in general, which recovered completely without sequels.

AB1437 RHEUMATOLOGICAL IMMUNE-MEDIATED ADVERSE EVENTS OF IMMUNE CHECKPOINT INHIBITORS BASED ON THE FDA ADVERSE EVENTS REPORTING SYSTEM

A. Rodriguez-Pla[1]. [1]*Mayo Clinic, Rheumatology, Scottsdale, United States of America*

Background: Immune checkpoint inhibitors (ICIs) provide effective treatment for many cancers but, presumably due to persistent activation of the immune system, they cause a variety of immune-related adverse events (irAEs) in almost every organ. Rheumatological manifestations have been reported in ~5-10% of patients treated with ICIs.

Objectives: We aimed to analyze the rheumatological irAEs (rh-irAEs) reported to the FDA Adverse Event Reporting System (FAERS) from October 2012 through March 2021.

Methods: From October 1st, 2012, to March 31st, 2021, we studied all case reports found on the FAERS database when any of the following seven FDA-approved ICIs, nivolumab, pembrolizumab, ipilimumab, atezolizumab, durvalumab, avelumab, or cemiplimab, was the primary suspect of the reported adverse events (AEs). Of the 6,090 different AEs reported for the ICIs, we selected 186 irAEs, which were rheumatological manifestations, or were associated with rheumatological conditions. We calculated the frequencies of rh-irAEs for each ICI. RStudio v1.4.1106 was used for general data analysis and the R package

openEBGM v0.8.3 was used for the calculation of disproportionality scores such as the Empirical Bayes Geometric Mean (EBGM) with its 90% two-sided credibility interval, frequently used in safety signal detection models. Drug-event combinations with an EBGM 5% lower limit credibility interval ≥ 1 were considered significant.

Results: During the study period, 90,974 individual case safety reports (ICSR) included 236,239 AEs with one ICI as the primary suspect of the AE. The highest frequency of AEs was reported for nivolumab (49.6%), followed by pembrolizumab (23.4%), ipilimumab (12.6%), atezolizumab (8.6%), durvalumab (4.6%), avelumab (0.9%), and cemiplimab (0.3%). The AEs were more frequent in males (62.7%) than in females (37.3%). Of the total ICSRs, 84.2% were expedited because they reported serious, unexpected irAEs. Rh-irAEs were 11,203 (4.7%) out of the 236,239 AEs reported. These rh-irAEs were reported in 3,898 (4.3%) out of the 90,974 ICSRs. For the ICSRs containing rh-irAEs, 78.5% were expedited. Unspecific complains, such as arthralgia, myalgia or muscle weakness were among the most frequent rh-irAEs. Avelumab and atezolizumab were associated with Sjogren's syndrome and sarcoidosis. Durvalumab, avelumab, atezolimumab and cemiplimab were all associated with myositis. Twenty-one drug-event combinations were significant for EBGM. Of those, nivolumab and pembrolizumab were the two most frequent ICI, with 7 and 6 significant drug-event combinations, respectively.

Conclusion: Approximately 5% of the reported ICIs-associated AEs were rh-irAEs. The most frequent complaints were unspecific, such as arthralgia, myalgia, or muscle weakness. Arthritis, myositis, Sjogren's syndrome, and sarcoidosis were also relatively frequent. The improved understanding of the mechanism of action of the ICIs and the characteristics of the rh-irAEs may help to elucidate the pathogenesis of the rheumatological autoimmune diseases that they trigger.

AB1438 CARDIOVASCULAR RISK STRATIFICATION FOR TOFACITINIB PATIENTS IN A LARGE TEACHING HOSPITAL

A. Khatri[1], K. Tsoi[2], A. Rutherford[2]. [1]*King's College Hospital, Haematology, London, United Kingdom*; [2]*King's College Hospital, Rheumatology, London, United Kingdom*

Background: Tofacitinib is an oral JAK-Inhibitor often reserved for patients with treatment-resistant Rheumatoid Arthritis and Psoriatic Arthritis. Tofacitinib modulates cytokines crucial to the inflammatory response which characterises the above conditions, and inhibits certain pathways in the inflammatory response cascade. Rheumatoid and Psoriatic Arthritis are linked with an inherent increased risk for major cardiovascular events. Recent emerging data has evidenced increased cardiovascular risk associated with long-term use of tofacitinib.

Objectives: To identify all patients currently undergoing Tofacitinib treatment across all sites at King's College Hospital NHS Foundation Trust. To risk-stratify all patients into three categories; low risk of developing major cardiovascular events, moderate risk of developing MACE (patients with modifiable risk factors, eg. high cholesterol or a borderline blood pressure), and high risk of developing MACE (unmodifiable risk factors). To switch patients at high risk onto another treatment or alternative JAK-inhibitor.

Methods: Patient data was obtained through electronic patient records including age, blood pressure reading, full lipid profile, smoking status, and comorbidities (hypertension, diabetes, chronic kidney disease, previous cardiovascular history and history of malignancy). A QRISK3 score was calculated.

Modifiable risk factors with a lower QRISK3 score were categorised as moderate risk. Patients were considered at high risk if they had a previous cardiovascular event, or a QRISK3 score of more than 10%.

Results: A total of 40 patients were on tofacitinib; 64% with RA, 31% with PsA, and 5% for other reasons (interstitial lung disease and colitis). Of the rheumatoid arthritis cohort: 36% of patients were at high risk, 40% at moderate risk, and 24% low risk. Of the psoriatic arthritis cohort: 67% at high risk, 25% at moderate risk, 8% at low risk.

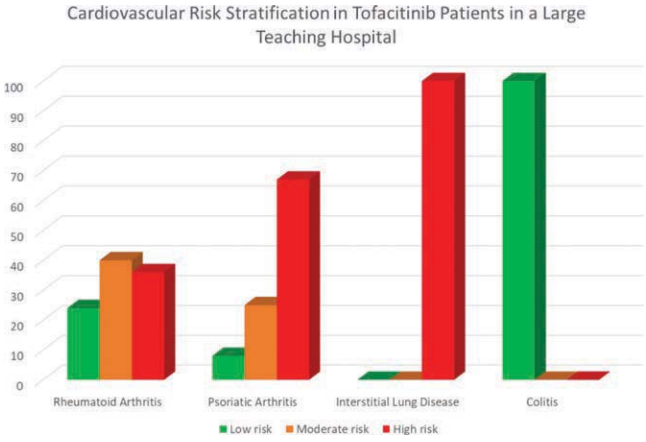

Figure 1.

Conclusion: A significant number of patients were deemed at moderate and high risk. Patients with moderate risk were advised to undergo lifestyle changes, like exercise and diet modification and smoking cessation.

Patients at high risk were discussed at the trust-wide Rheumatology local clinical governance meeting, and advised to switch onto an alternative treatment or alternative JAK-inhibitor.

A repeat audit will be made in a few months' time to assess the impact of lifestyle changes and alteration of drugs on cardiovascular risk.

AB1439 IS THERE AN INCREASED PREVALENCE OF DIABETES MELLITUS IN THE AXIAL SPONDYLOARTHROPATHY PATIENT GROUP: A REVIEW FROM A UK TEACHING HOSPITAL SPONDYLOARTHROPATHY SERVICE

S. Jothimurugan[1,2], S. Byravan[1], A. Moorthy[1,2]. [1]*University Hospitals of Leicester NHS Trust, Rheumatology, Leicester, United Kingdom*; [2]*University of Leicester, College of Life Sciences, Leicester, United Kingdom*

Background: The prevalence of diabetes mellitus (DM) has often been found to be increased in patients with axial spondyloarthropathy (axSpA) compared to the general population. However, studies conducted in the United Kingdom (UK) have found varying results with regards to prevalence. One study[1] found that 5% of patients with axSpA had DM, compared to 4% of patients without axSpA and another UK study[2] reported that although findings showed a 1.8% increase in DM in patients with axSpA compared to controls, this result was not significant. There is also the influence of ethnicity to consider as DM is more prevalent in the Asian and Afro-Caribbean population. Therefore, it is evident that more research is required into the relationship between DM and axSpA.

Objectives: This study aims to investigate the correlation between DM and axSpA, and also explore the influence of ethnicity on DM and axSpA.

Methods: Retrospective analysis was carried out for axSpA patients attending University Hospitals of Leicester axSpA services. Inclusion criteria entailed an axSpA diagnosis and a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) within a year of MRI spine and sacroiliac joints before starting biological therapy. Patients were excluded if they had an active infection or malignancy, BASDAI was not documented before starting biological therapy or within a year of MRI, or if clinical information was not able to be obtained. Data was obtained from electronic medical records, including age, gender, ethnicity, date of diagnosis of axSpA and DM, and cardiovascular comorbidities.

Results: Of the 149 patients, 8 (5.37%) had a diagnosis of DM. 4 (50%) of these patients were diagnosed with DM prior to diagnosis of axSpA, and 4 (50%) were diagnosed with DM post diagnosis of axSpA. Differences in ethnicity were analysed. Of the 149 axSpA patients, 102 (68.46%) were Caucasian, 45 (30.20%) were Asian, and 2 (1.34%) were Afro-Caribbean. Of the 102 Caucasian patients, 3 (2.94%) had DM, of whom 1 was diagnosed with axSpA prior to diagnosis of DM. Of the 45 Asian patients, 5 (11.11%) had DM, of whom 3 were diagnosed with axSpA prior to diagnosis of DM. Looking at cardiovascular comorbidities, of the 8 patients with axSpA and DM, 2 (25%)

had hypertension, and were both diagnosed with axSpA prior to diagnosis of DM.

Conclusion: This small study has found a similar prevalence of DM in patients with axSpA (5.37%) compared to the general UK population (6%), which contrasts with published international studies which have found a higher prevalence of DM in the axSpA group. However, the study did find a higher prevalence in the Asian population (11.11%) which is in keeping with ethnic variation for DM. Larger epidemiological studies are needed to understand the reason for reported higher prevalence of DM in patients with axSpA in other countries compared to the UK.

AB1440 ASSOCIATION BETWEEN GAMMA-GLUTAMYL TRANSFERASE (GGT) AND SERUM URATE: CROSS-SECTIONAL FINDINGS FROM THE 1993 PELOTAS (BRAZIL) BIRTH COHORT

T. Loyola Correa[1], D. Farias Freitas[2], C. Brinck Brum[2], I. Oliveira de Oliveira[2,3]. [1]*Universidade Federal de Pelotas, Faculty of Medicine, Pelotas, Brazil*; [2]*Universidade Federal de Pelotas, Centre for Epidemiological Research, Pelotas, Brazil*; [3]*Universidade Federal de Pelotas, Postgraduate Program in Epidemiology, Pelotas, Brazil*

Background: Gout attack is associated with an abrupt increase or decrease on serum urate concentrations, which can precipitate urate crystals in tissues in and around the joints. Serum urate (SU) has been positively associated with cardiometabolic risk factors and subclinical inflammation in observational studies, but causal roles remain unclear. [1] Additionally, gamma-glutamyl transferase (GGT) has been linked to oxidative stress, metabolic syndrome, and nonalcoholic fatty liver disease (NAFLD).

Objectives: The aim of this study was to assess the association between GGT and SU in Brazilian young adults.

Methods: During 1993, all live born babies in the city of Pelotas (Brazil) were invited to take part in a prospective study. At the 22-year follow-up of this birth cohort, SU was evaluated by enzymatic-colorimetric assay. GGT was evaluated by kinetic assay and converted into logarithm for regression analysis. The co-variables taken into consideration were waist circumference (WC), systolic and diastolic blood pressures (SBP, DBP), glucose (G), high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c), creatinine (Scr), fasting period, smoking status, excessive alcohol consumption (>8 points in the Alcohol Use Disorders Identification Test-AUDIT), and physical activity (PA). For association analyses, serum concentration of urate was categorized into tertiles. Sex-stratified linear regressions have been performed due to the significant interaction between GGT, SU and sex (p<0.001). A p-value less than 0.05 was considered statistically significant.

Results: The sample comprised 1660 (47.7%) men and 1822 (52.3%) women aged 22.6 (±0.34) years old. Median (IQR) GGT (U/L) was 26 (20-35) in men and 21 (16-30) in women (p<0.001). Mean (±SD) SU (mg/dL) was also higher in men (5.2±1.2 *vs.* 3.9±1.1; p<0.001). No significant association between GGT and tertiles of SU was observed in men (between the 1st and 2nd tertiles, the p-value was 0.713; and between the 1st and 3rd, p = 0.185). In women, between the 1st and 2nd tertiles, the linear p-value was 0.251; and between the 1st and 3rd; p = 0.001. The corresponding exponential mean of GGT for each SU tertile is described in (Table 1).

Table 1. Exponential means (95%CI) of GGT (U/L) according to the SU tertiles in 22-year-old individuals from the 1993 Pelotas (Brazil) birth cohort

	Men (n=1638)		Women (n=1801)	
SU Tertile	**Mean**	**95%CI**	**Mean**	**95%CI**
	*p=0.231**		***p=0.005****	
1	26.8	(25.3; 28.5)	22.6	(21.8; 23.3)
2	27.1	(26.3; 28.2)	23.3	(22.4; 24.3)
3	28.2	(27.4; 29.1)	26	(24.1; 28)

Linear regression adjusted for WC, SBP, DBP, Glu, HDL-c, LDL-c, Scr, fasting, smoking status, alcohol consumption (>8 points AUDIT), and PA. ***heterogeneity p-value**

Conclusion: GGT was positively associated with SU in women, even after adjusting for potential confounders. This finding reinforces that uric acid is associated with cardiometabolic risk factors since early adult age. Nonetheless, further prospective studies are needed to understand the causality of this association especially observed in women.

AB1441 LEARNING NEEDS ASSESSMENT FOR PATIENTS WITH CANCER AND A PRE-EXISTING AUTOIMMUNE DISEASE WHO ARE CANDIDATES TO RECEIVE IMMUNE CHECKPOINT INHIBITORS

M. A. Lopez-Olivo[1], J. I. Ruiz[1], G. F. Duhon[1], M. Altan[2], H. Tawbi[3], A. Diab[4], C. Bingham[5], C. Calabrese[6], R. Volk[1], M. Suarez-Almazor[2,7]. [1]*The University of Texas MD Anderson Cancer Center, Health Services Research, Houston, United States of America*; [2]*The University of Texas, MD Anderson Cancer Center, Thoracic-Head & Neck Medical Oncology, Houston, United States of America*; [3]*The University of Texas, MD Anderson Cancer Center, Melanoma Medical Oncology, Houston, United States of America*; [4]*The University of Texas MD Anderson Cancer Center, Melanoma Medical Oncology, Houston, United States of America*; [5]*Johns Hopkins University, Division of Rheumatology, Department of Medicine, Baltimore, United States of America*; [6]*Cleveland Clinic, Rheumatologic and Immunologic Disease, Cleveland, United States of America*; [7]*The University of Texas, MD Anderson Cancer Center, Internal Medicine, Houston, United States of America*

Background: Patients with autoimmune disorders and cancer are at risk of developing immune-related adverse events (irAEs) and increasing flares of their underlying disease with immune checkpoint inhibitors (ICI) and harms and benefits must be weighed.

Objectives: We conducted an assessment of learning needs.

Methods: We interviewed 19 patients who had received an ICI and 20 physicians who provide care for these patients. We asked what do cancer patients with pre-existing autoimmune diseases need to know in order to make an informed decision about whether to receive an ICI.

Results: Fifty-three percent of the patients were female, median age was 62.9 (±10.9). They had rheumatoid arthritis (47.4%), psoriasis (26.3%), Crohn's disease (10.5%), ankylosing spondylitis (5.3%), systemic lupus erythematosus (5.3%), or ulcerative colitis (5.3%). Half of the patients (52.6%) had a demonstrable disease activity of the autoimmune disease at the time of making the decision on whether to start ICI. Most (84%) of the patients had melanoma, and at the time of the interview 68.4% had completed or discontinued the ICI. Physicians were melanoma oncologists (30%), thoracic-head & neck medical oncologists (25%), rheumatologists (20%), gastroenterologists (10%), and dermatologists (15%) who treat patients with irAEs. Sixty percent were female. Key points mentioned by patients and physicians included information on probability of irAEs and flares of the autoimmune condition with discussion about severity, benefits of ICI, ICI mechanism of action in the context of the autoimmune disease, and management for flare-ups. Key topics raised only by patients included possible reasons for stopping or modifying treatment (for cancer or autoimmune disease), when to contact the provider, possibility of autoimmune disease progression or organ damage, sharing information with other providers, and lifestyle changes that can be done to help.

Conclusion: Although patients and physicians listed common learning points, patients also considered specific needs to increase their self-care. The information derived from this study will be used to develop a decision support tool.

diagnosis and treatment. A predictive model could help identify CAPS patients earlier and initiate early intervention.

Objectives: To develop a predictive model of CAPS in APS patients in a single-center prospective APS cohort.

Methods: Data of consecutive APS patients referred into Peking Union Medical College Hospital from May 2013 to October 2021 was collected. A binary logistic regression method was used to identify predictors of CAPS, coefficient B was assigned with score value in the development of prediction model, and risk-stratification was based on the calculated score using the predictive model. The performance of the model was assessed by Nagelkerke's R^2, Hosmer-Lemeshow test, Omnibus test, and area under the receiver operating characteristic curve (AUC).

Results: A total of 27 CAPS (11.9%) occurred in 226 APS patients. CAPS were more likely to occur in male secondary APS patients with history of arterial thrombosis. Precipitating factors (OR 108.961, 95% CI 23.299 to 509.572), thrombocytopenia (OR 14.765, 95% CI 3.088 to 70.612) and elevated serum creatine (OR 5.339, 95% CI 1.301 to 21.907) were selected by the binary logistic regression. The scores of precipitating factors, thrombocytopenia and elevated serum creatine were 5, 3 and 2. The risk scores were divided into high-risk (7-10) and low-risk (0-6), the risk for CAPS were 73.3% and 2.6%, with sensitivity of 81.5% and specificity of 96%. The Nagelkerke's R^2 (0.696), the Hosmer-Lemeshow test ($\chi2$ =2.192, df=4, p=0.701) and the Omnibus test ($\chi2$ =101.307, df=3, p=0.000) indicated the logistic regression model has a good fit. The AUC was 0.969 (95% CI 0.947 to 0.991, SE=0.011, p=0.000) indicated the model has good discrimination.

Conclusion: A predictive model of CAPS was developed with precipitating factors, thrombocytopenia, and elevated serum creatine. This model helps physicians identify CAPS in high-risk patients, could achieve early intervention and improve prognosis.

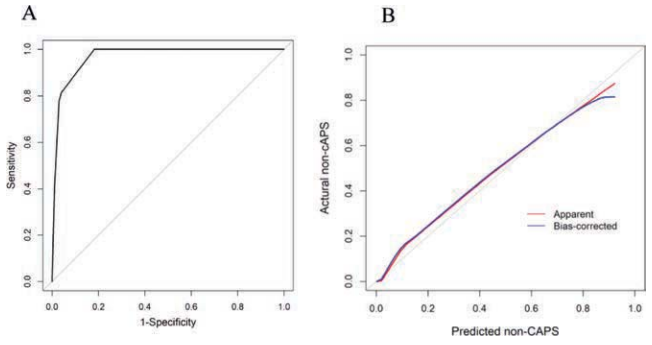

Figure 1. (A). Receiver Operating Characteristic (ROC) curve of the predictive model. Area under the receiver operating characteristic curve (AUC) was 0.969, the cut-off value of 7 were with sensitivity of 81.5% and specificity of 96%. (B). Calibration curve in internal validation.

INCIDENCE OF RHEUMATIC DISEASES DURING THE COVID-19 PANDEMIC IN KOREA: A NATIONWIDE CLAIMS STUDY

S. M. Ahn[1], S. Hong[1], C. K. Lee[1], B. Yoo[1], J. S. Oh[2], Y. G. Kim[1]. *[1]Asan Medical Center, Department of Rheumatology, Seoul, Korea, Republic of (South Korea)*; *[2]Asan Medical Center, Department of Information Medicine, Big Data Research Center, Seoul, Korea, Republic of (South Korea)*

Background: In Korea, it has been reported that the incidence of some respiratory diseases and Kawasaki diseases has decreased compared to the previous year along with active non-pharmaceutical interventions in the early stages of the COVID-19 pandemic. Autoimmune inflammatory rheumatic disease (AIIRD) is mainly affected musculoskeletal organs and connective tissues due to impaired immune regulation. Although gout and osteoarthritis are rheumatic diseases, they are not a disease of the immune system, and are not included in the AIIRD.

Objectives: In this study, we investigated the change and difference in the incidence rate of various rheumatic diseases during the COVID-19 pandemic after 2020.

Methods: The number of patients for each disease from January 2016 to December 2020 was obtained from the Korea Health Insurance Review and Assessment Service database. We compared the incidence of 9 rheumatic diseases [systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), ankylosing spondylitis (AS), Sjogren syndrome (SJS), Behcet's disease (BD), inflammatory myositis (IIM), scleroderma, polymyalgia rheumatica (PMR), and gout] and hypertension before and after the COVID-19 outbreak. The incidence rates of patients before and after the COVID-19 outbreak were compared using the Poisson test.

Results: From 2016 to 2019, the prevalence of rheumatic diseases showed gradually increased. In 2020, the incidence of SLE, AS, SJS, BD, and IIM were significantly decreased compared to the previous 4 years. In contrast, the incidences of gout and hypertension during the COVID-19 pandemic period were significantly increased from the predicted values.

Conclusion: In conclusion, we found that the incidence of many AIIRDs, including SLE, AS, SJS, BD, and IIM decreased despite the increased incidence of hypertension and gout during the COVID-19 pandemic.

AB1444 ASSOCIATION BETWEEN THIOPURINE S-METHYLTRANSFERASE POLYMORPHISMS AND HEPATOTOXICITY IN AZATHIOPRINE-TREATED PATIENTS WITH AUTOIMMUNE DISEASES

S. Heh-Shiang[1], W. T. Hung[1,2], W. Chia-Yi[3], W. N. Huang[1], Y. H. Chen[1], Y. M. Chen[1,3]. *[1]Taichung Veterans General Hospital, Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taichung, Taiwan, Republic of China*; *[2]Taichung Veterans General Hospital, Department of Medical Education, Taichung, Taiwan, Republic of China*; *[3]Taichung Veterans General Hospital, Department of Medical Research, Taichung, Taiwan, Republic of China*

Background: Azathioprine(AZA) is widely used in patients with autoimmun diseases. Thiopurine methyltransferase (TPMT) is the rate-limiting enzyme in AZA metabolization. Although several studies have investigated the association between TPMT polymorphisms and AZA-induced bone marrow suppression, the relationship of TPMT genotypes and hepatoxicity in patients taking AZA remained unclear.
Objectives: This study aimed to investigate the correlation between TPMT polymorphisms and adverse reactions of AZA.
Methods: This retrospective case-control study enrolled patients with prior exposure to AZA at the Taichung Veterans General Hospital (TCVGH) using data extracted from the Taiwan Precision Medicine Initiative (TPMI) cohort. Drug-prescription profile, comorbidities, the occurence of leukopenia and hepatotoxicity following AZA treatment were extracted from hospital health records. Genetic variatns affecting TPMT activity were determined using SNP array. Participants were categorized into normal metabolizer (NM) and non-normal metabolizer (Non-NM) groups accordingly.
Results: From the 43,035 patients in the TCVGH-TPMI cohort, we identified 2,128 azathioprine users; 2.6% (57 out of 2,128) were classified as TPMT Non-NM group. After matching by age and sex, we included 50 TPMT Non-NM, including 1 poor metabolizers (PMs), 49 intermediate metabolizers (IMs), and 1,000 NM patients for further analysis. The Non-NM genotype was associated with hepatotoxicity compared with NM genotype (HR: 3.85, 95% CI: 1.83–8.10) after adjustment for gender, AZA dosage, and comorbidities(Table 1). In the Non-NM group, the 3-year cumulative incidence of hepatotoxicity was 6.6% for one year, 16.9% for two and three years, respectively, which was significantly higher than the NM group (p=0.003)(Figure 1).

Table 1. Cox regression analysis of risk factors for hepatotoxicity following AZA treatment

	Hepatotoxicity*			
	HR	95% CI		*p* value
Age	0.99	0.98	1.01	0.60
Male gender	1.77	1.07	2.91	0.03
TPMT non-NM genotype	3.85	1.83	8.10	0.0004
AZA dose (mg)	1.00	1.00	1.01	0.31
Medication				
MTX	1.62	1.03	2.57	0.04
Comorbidity				
Hepatitis B carrier	1.18	0.40	3.48	0.76

By Cox regression model with adjustment of all listed variables. *Development of GPT ≥ 150 U/L after AZA treatment; GPT, glutamic pyruvic Transaminase; TPMT, thiopurine S-methyltransferase; NM, normal metabolizer; AZA, azathioprine; MTX, Methotrexate; CI: confidence interval

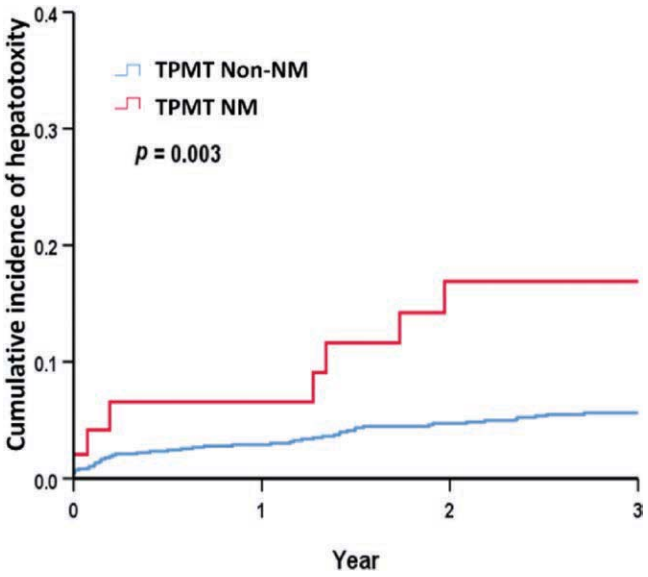

Figure 1. Cumulative incidence of hepatotoxicity

Conclusion: TPMT Non-NM genotype were associated with the developement of hepatotoxicity following AZA therapy. Prospective studies are needed to varify our results.

AB1445 SYNOVIAL FLUID ANALYSIS IN HOT SWOLLEN JOINTS – A QUALITY IMPROVEMENT PROJECT

F. Rabbani[1], Z. Jaffer[1], L. Sammut[2]. *[1]Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom*; *[1]Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom*

Background: Previous studies have reported delays in the investigation and suboptimal management of hot swollen joints, particularly crystal arthritis. In our hospital, it was noted that synovial fluid was inconsistently analysed for crystals which may lead to patients receiving delayed treatment.
Objectives: The aim of this quality improvement project was to 1) identify the number of synovial fluid samples that were not checked for crystals 2) implement changes to improve this process 3) re-audit and commitment to a continuous evaluation.
Methods: Retrospective review of synovial fluid analysis requested for adult patients presenting with hot swollen joints over a six month period. Following, the implementation of changes in the hospital, another comparison of pre-post intervention was performed.
Results: A total of 106 synovial fluid samples were sent for analysis between March and August 2021, of which only 69 (65%) of the samples were analysed for crystals. All samples were analysed for microscopy and culture. Following involvement with IT and laboratory departments we have introduced an intervention to make requesting crystal analysis easier. The request for synovial fluid analysis was grouped in a bundle (reflex test) so whenever a synovial fluid is collected, two forms are generated, one for microbiology (microscopy and culture), and the other for cytology (crystal analysis). Additional interventions included education and raising awareness. Post-interventions, another three month analysis of synovial fluid showed that compliance improved to 78%.
Conclusion: There was an improvement in the synovial fluid analysis requests of patients with hot, swollen joints. By implementing these changes and raising awareness, patients with acute crystal arthritis can be treated in a timely manner. We plan to continue our work with synovial fluid analysis following re-review and will continue to generate improvements.

AB1446

TRANSLATION AND CROSS-CULTURAL ADAPTATION OF COPING WITH RHEUMATIC STRESSORS (CORS) INTO TURKISH LANGUAGE

G. Ayan[1], S. Ramiro[2,3], F. M. Pimentel-Santos[4], W. Van Lankveld[5], L. Kılıç[1]. *[1]Hacettepe University Medical Faculty, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey*; *[2]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[3]Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands*; *[4]NOVA Medical School, Universidade Nova De Lisboa, Department of Rheumatology, Lisboa, Portugal*; *[5]HAN University of Applied Sciences, Research Group Musculoskeletal Rehabilitation, Nijmegen, Netherlands*

Background: Coping with Rheumatic Stressors (CORS) is a valid and reliable instrument that measures eight coping strategies directed at pain, limitations and dependency as the most prominent chronic stressors of Rheumatoid Arthritis (RA) (1). This questionnaire has also been used in axial Spondyloarthritis (ax-SpA) previously (2).
Objectives: To describe the translation and cross-cultural adaptation process of the CORS into Turkish as well as its cognitive debriefing to test the conceptual equivalence of the translated version among patients with RA, radiographic (r) and non-radiographic (nr) axSpA.
Methods: The CORS was firstly translated into Turkish (by 2 bilingual translators who are native speaker for Turkish) and then back-translated into Dutch (by 2 bilingual translators who are native speaker for Dutch) following the Beaton's method (Figure 1) (3). Back-translation procedure was done totally blinded to the original version. After the review of the Turkish version by an expert committee that included translators, two patients and the research team, a consensus was reached on the pre-final version. Using the pre-final version, the field test with cognitive debriefing involved a sample of 10 RA and 10 axSpA patients with different gender, age, disease duration, and educational background. After some small changes resulting from the feedback from patients the final version was obtained.
Results: The CORS was translated into Turkish following the forward-backward procedure. Minor incompatibilities arose from the translation process of CORS which have been easily resolved by the expert committee meetings. For example, `Ik concentreer me op iets anders` was translated as `Başka seylere odaklanırım` which is in English `I concentrate on something else`. The discrepancy was raised whether to use a word equivalent `to concentrate` or `to focus` and decision was made to use `to focus` while there was no exact Turkish word of `to concentrate`. A total of 10 patients with RA [9 females, mean (SD) age of 49 (13)] and 10 patients with axSpA [7 females, mean (SD) age of 38 (10), r-AxSpA, n=7, nr-AxSpA, n= 3] participated in the field test. Mean (SD) time to complete the CORS was 8.3 (3.4) minutes. Cognitive debriefing showed that items of the CORS are clear, relevant, understandable, and easy to complete. Cognitive debriefing revealed that the wording of one item had to be changed to provide better understanding (Section B, item 22 the word `stop` in Dutch and `stop` in English which was translated as `durdurmak` in Turkish changed to `sonlandırmak`.
Conclusion: The final Turkish version of the CORS showed acceptable linguistic validity and can be used in both clinical practice and for research purposes, in patients with RA and in patients with axSpA. However, to implement Turkish-CORS, further assessment is ongoing to test its psychometric properties (validity and reliability).

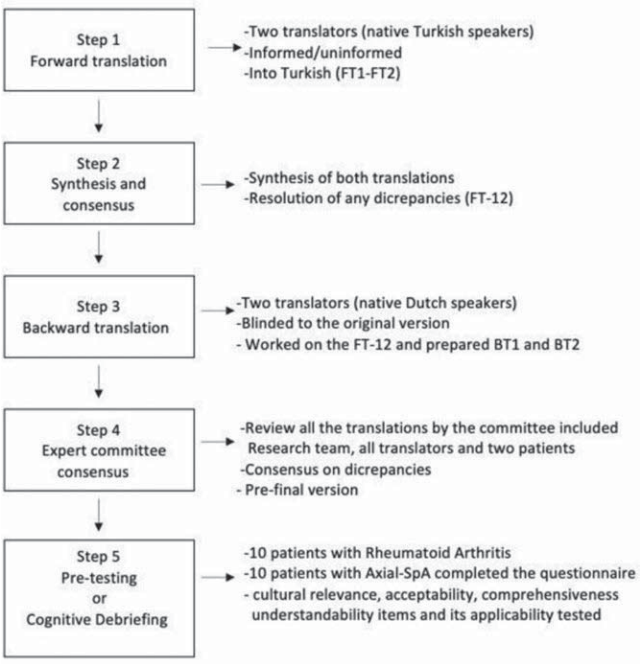

Figure 1. Flow-chart of the translation and cross-cultural adaptation process

AB1447

CATASTROPHISM IN MOROCCAN PATIENTS WITH CHRONIC RHEUMATIC DISEASES UNDER BIOLOGICS

H. Boutaibi[1], H. Azzouzi[1], I. Linda[1]. *[1]Mohamed I University, Rheumatology Department, Oujda, Morocco*

Background: Catastrophizing is a distortion of the perception of pain, both cognitively and emotionally, which leads patients to consider only the worst. There is a lack of knowledge about catastrophism in Moroccan patients with chronic rheumatic diseases under biologic DMARDs (disease-modifying anti-rheumatic drugs).
Objectives: To assess catastrophism and its associated factors in rheumatic patients under bDMARDs.
Methods: This is a cross-sectional study of patients admitted to a day hospital for biologic treatment evaluation. Patients included were all adults with SpA or RA diagnosed according to ASAS 2009 and ACR/EULAR 2010 classifications, respectively. The Pain Catastrophizing Scale (PCS) [1] was used to assess catastrophism. This scale is a self-report measure, consisting of 13 items scored from 0 to 4, resulting in a total possible score of 52. It is divided into three subscales: magnification, rumination and helplessness. A total score above 30 indicates a clinically relevant level of catastrophizing. Sociodemographic and treatment data were collected. Disease activity scores (DAS28, ASDAS) using C-reactive protein (CRP) dosage of the same day were calculated for each disease. Questionnaires were obtained for all patients for functional assessment (HAQ, BASFI), insomnia by the insomnia severity index (ISI), and depression by hospital anxiety and depression scale (HADS). Anxiety was evaluated by the generalized anxiety disorder-7 (GAD-7). Statistical analysis was done using regressions by SPSS.20.
Results: We included 75 patients with a mean age of 42.20 ± 16.206 years and a mean disease duration of 17.47 ± 8.758 years. Almost all patients (90.7%) had a disease lasting for more than 05 years. Twenty-nine patients (38.7%) had inactive disease. The average duration of bDMARDs use was 24.29 ± 18.96 months (27.83 ± 18.5 months in SpA patients and 19.53 ± 18.81 months in RA patients). Seventy-nine percent of these patients have received only one bDMARD, and 66.7% were currently taking a TNF inhibitor. The mean catastrophizing scores were 21.91 ± 11.38 for all patients, 22.05 ± 12.163 for SpA patients, and 21.72 ± 10.24 for RA patients. The prevalence of catastrophism was 25.3%, and the highest sub-score was helplessness (17.53 ± 3.95, p= 0). These scores were similar in RA and SpA patients. Catastrophizing was significantly associated with anxiety degree (p = 0.021, OR = 2.362, [1.211-4.607]), and swollen joints (p = 0.042, OR= 1.197, 95%IC [1.006-1.423]) using logistic regression analysis. Catastrophism scores were positively associated with the number of bDMARDs used (p = 0.044, ß = 0.233, 95%IC [0.095-7.211]). This association remained significant with anxiety (p<0.0001) and the number of bDMARDs received (p=0.04) at multivariate regression adjusted on swollen joints, ISI and HADS.
Conclusion: Catastrophizing scores were high despite biotherapy use. They were related to anxiety disorder, swollen joints, and bDMARDs rotation. It would therefore be interesting to detect catastrophism in clinical routine to ensure good patients care.

AB1448 DEEP VENOUS THROMBOSIS IN YOUNG ADULTS: INCIDENCE AND RISK FACTORS

F. Nabli[1], S. Daadaa[1], Y. Boussoukaya[1], I. Chaabene[1], M. Kechida[1], R. Klii[1], S. Hammami[1]. [1]*Hopital Fattouma Bourguiba Monastir, Internal Medecine Departement, Monastir, Tunisia*

Background: After a first venous thromboembolic (VTE) episode, recurrence is frequent and associated with significant morbidity and mortality.
Objectives: Our aim is to identify the risk factors for recurrent VTE in young subjects and to assess the risk-benefit ratio of continuing long-term anticoagulant treatment.
Methods: We carried out a retrospective study including 100 patients with deep vein thrombosis (DVT) admitted to the Internal Medicine Department at Fattouma Bourguiba University Hospital in Monastir between 2011 and 2020.
Results: In our study, the gender ratio was 1.17. The mean age was 34.49 years ± 9.19. Lower extremity deep venous thrombosis (LEDVT) was the most common location (90%). Pulmonary embolism (PE) was found in 8% of cases. The most frequent risk factors were obesity: BMI>30 (40%), bed rest (20%), personal history of DVT (18%), smoking (16%), recent surgery dating less than one month (14%), and recent trauma (12%). The etiological assessment had concluded to inherited thrombophilia in 41 cases: protein S deficiency (23%), protein C deficiency (8%), activated protein C resistance (8%), and antithrombin III deficiency (2%); acquired thrombophilia in 28 cases: hyperhomocysteinemia (HH) in 19 cases and antiphospholipid syndrome (APLS) in 9 cases; Behçet's disease in 10 cases and systemic lupus erythematosus in 5 cases. No cases of neoplasia were detected. The treatment was based on low molecular weight heparin (LMWH), relayed by vitamin k antagonists (VKAs), and physical therapy (graduated compression stockings and early mobilization). Duration of the treatment of DVT in the young adult depends on the nature and extent of the thrombosis, the underlying risk factors, and etiologies. Among the 100 hospitalized patients, recurrent DVT was detected in 20% of cases: 17% of patients reported a history of DVT with a mean number of previous episodes of 2, and only 3% developed DVT during their follow-up. The mean time to recurrence was three years. Recurrence was located on the same side in most cases (70%). In our study, only Behçet's disease was associated with an increased risk of DVT recurrence (p: 0.015, OR: 5.46, CI [1.38-21.56]). Gender, age, venous insufficiency, and bed rest had no significant influence on the risk of recurrence (p>0.05).
Conclusion: Young adults should be assessed for acquired and also genetic factors, which would suggest extending the duration of anticoagulant therapy in high-risk patients, reducing the incidence of post-thrombotic syndrome and VTE recurrence. Further studies are needed to evaluate the association of Behçet's disease with DVT recurrence.

AB1449 ADHERENCE TO MTX AT INITIATION OF FIRST TARGETED THERAPY (PREVALENCE AND ASSOCIATED FACTORS): RESULTS OF THE STRATEGE2 STUDY.

C. Gaujoux-Viala[1], E. Dernis[2], E. Senbel[3], H. Herman-Demars[4], J. Becker[4], R. M. Flipo[5]. [1]*IDESP, Université Montpellier, INSERM, Department of Rheumatology, CHU Nîmes, Nîmes, France*; [2]*Le Mans Central Hospital, Rheumatology Department, Le Mans, France*; [3]*Cabinet de Rhumatologie, NA, Marseille, France*; [4]*Nordic Pharma France, Medical Department, Paris, France*; [5]*Centre Hospitalier Universitaire de France, Université de Lille, Lille, France*

Background: Treatment adherence is a major challenge in chronic inflammatory rheumatic disease (CIRD). Mainly studied in rheumatoid arthritis (RA), this ranges from 30 to 80% [1]. Given the impact of non-adherence to disease-modifying therapy among RA patients, guidelines aiming to facilitate management of adherence were published in 2019 [2]. These guidelines highlight the multifactorial characteristics and importance of clarifying the factors determining non-adherence. In addition, treatment adherence was also listed as a point to consider for the management of difficult-to-treat RA by an EULAR task force [3].
Objectives: Based on inclusion results of STRATEGE 2 we explore the adherence to methotrexate (MTX) and its associated factors prior to initiation of a first targeted therapy.
Methods: The objective of STRATEGE2 is to describe the therapeutic strategy in RA patients treated with MTX for at least 3 months, naive of targeted biological (bDMARD) or synthetic (tsDMARD) therapy and who are candidates for initiation of first b/tsDMARD therapy due to RA activity. Patients were included prospectively in 2019-2020 and completed the Compliance Questionnaire for Rheumatology (CQR) [4], a self-administered questionnaire specific to rheumatology, measuring treatment adherence. They were then divided into 2 groups: adherence (Ad) (CQR19>80) *vs.* non-adherence (NAd) to investigate factors liable to be associated with adherence. Then, univariate and multivariate analysis was applied to identify potential predictors for adherence.
Results: Between Feb. 2019 and Dec. 2020, 230 patients were included, with 124 RA patients having an analysable CQR19: 73.4% females, mean age 56.6 years (±13.2), diagnosed 5.6 years (±7.4) previously, treatment with MTX for 4.4 years (±5.3) and a mean DAS of 4.3 (±1.2). The mean CQR score was 75.8. Patient distribution: 45.2% in the Ad group and 54.8% in the NAd group.

Table 1.

At baseline (before b/tsDMARD initiation)	Ad - N=56	NAd - N=68	*p*
Sex: female	73.2%	73.5%	-
Age (mean)	59.3 (±13.6)	54.4 (±12.4)	p < 0.05
BMI (mean)	27.2 (±7.0)	25.0 (±4.7)	p < 0.15
Still in work	39.3%	55.9%	p < 0.15
At least 1 comorbidity	60.7%	47.1%	p < 0.15
Positive anti-CCP	67.9%	80.6%	p < 0.15
Positive rheumatoid factor	69.8%	84.8%	p < 0.05
Radiological signs	57.1%	41.8%	p < 0.15
RA duration (years)	4.9 ±6.7	6.3 ±8.0	-
Average MTX initiation (years)	4.0 ±4.7	4.8 ±5.7	-
Per os MTX	28.6%	29.4%	-
→ mean dosage (mg/week)	16.4 ±4.5	15.6 ±4.6	
Subcutaneous MTX	69.6%	70.6%	-
→ mean dosage (mg/week)	20.1 ±4.6	19.4 ±3.3	-
Intramuscular MTX	1.8%	0%	-
Patients self-administration	30.0%	12.5%	P < 0.05
Corticosteroid therapy	53%	50.6%	-
→ mean dosage (mg/day)	8.1 ±4.1	9.5 ±5.8	
Mean DAS28	4.5 ± 1.3	4.2 ±1.2	-
Mean HAQ	1.1 ± 0.7	0.9 ±0.7	p < 0.15

In the multivariate analysis, no formal predictive factors to MTX adherence was identified except BMI>30kg/m^2 (odds ratio, OR (95% confidence interval, CI)=4.00, 1.08-14.86, p=0,038) and adherents who estimate having completely participate to the decision-making for the targeted therapy (OR (95% CI)=6.41, 2.32-17.65, p<0.001).
Conclusion: In this cohort, beyond the recently published guidelines, nearly half of patients do not show adherence to MTX (CQR19-based evaluation) before initiation of b/tsDMARD. As physicians tend to overestimate adherence to medication, clarification of the factors associated with non-adherence would help improve patient assessment and, therefore, management. Supplementary data on patients' adherence evolution and adherence predictors, might be observed on the follow-up data at 12 and 24 months of this cohort.

CHARACTERISTICS, OUTCOME AND FACTORS ASSOCIATED WITH EVOLUTION TO MULTIPLE MYELOMA AND SURVIVAL IN PATIENTS WITH SOLITARY BONE PLASMACYTOMA.

S. Ascione[1], S. Harel[2], F. Besson[3], R. Belkhir[4], B. Royer[2], B. Arnulf[2], X. Mariette[4], R. Seror[4]. *[1]Hôpital Lariboisière AP-HP, Rheumatology, Paris, France*; *[2]Hôpital Saint-Louis, APHP, Immunohematology, Paris, France*; *[3]AP-HP, Hôpital Bicêtre, Biophysics and Nuclear Medicine, Le Kremlin Bicêtre, France*; *[4]AP-HP, Hôpital Bicêtre, Rheumatology, Paris, France*

Background: Solitary bone plasmacytoma (SPB) is a rare malignancy whose main risk is progression to multiple myeloma (MM).

Objectives: To describe the characteristics and outcome of patients treated for SBP and to identify factors associated with progression to MM and death.

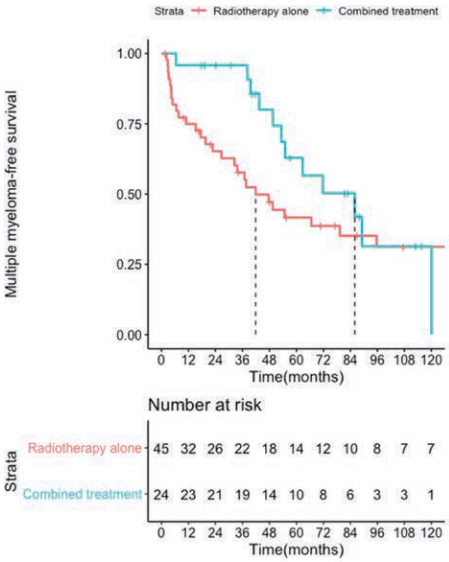

Figure 1. Myeloma-free survival in patients treated by radiotherapy alone compared to patients treated by radiotherapy followed by adjuvant chemotherapy (Combined treatment)

Methods: This retrospective study was conducted between 1992 and 2020. Patients were included if they met the International Myeloma Working Group (IMWG) criteria for the diagnosis of SBP (1). Treatment response was assessed according to the IMWG criteria (2) for patients with detectable monoclonal protein and according to radiological response only for non-secretory SBP. Hazard ratios (HR) and their 95% confidence intervals (CI) were estimated by Cox proportional hazards models, adjusted for potential confounders. When available, ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT) were reviewed by two experienced nuclear physicians.

Results: A total of 77 patients diagnosed with SBP were included. The median age was 59 years [range: 27-89]. Median follow-up duration was 87.1 months [range: 1.6-306.8]. At the end of the follow-up, 45 (58.4%) patients had developed a MM and 13 (16.9%) deaths occurred, including 10 patients with progression to MM. Five-year myeloma-free survival and overall survival were 47.9% and 86.8% respectively. All patients received radiotherapy with a median dose of 45 Grays [range: 30-55]. Chemotherapy was prescribed in 32 (41.6%) patients, concomitant to radiotherapy in 8, because of high risk of local extension, or adjuvant in 24 because of persistent disease after radiotherapy. Chemotherapy included mainly immunomodulatory drugs (28/32 (87.5%)) and/or proteasome inhibitors (11/32 (34.4%)) based combinations. Adjuvant chemotherapy after radiotherapy was associated with a reduced risk of MM compared to patients treated by radiotherapy alone, in a multivariate model adjusted for potential confounding factors, including response after radiotherapy alone (adjuvant chemotherapy *versus* no chemotherapy, HR 0.30, 95%CI [0.14-0.64]). Response to the first line of treatment (radiotherapy +/- chemotherapy) was the main factor associated with progression to MM (complete response *versus* partial response or progressive disease, HR 0.25, 95%CI [0.11-0.59]) and death (HR 0.22, 95%CI [0.05-0.99]). A non-significant trend between bone marrow plasmacytosis ≥ 5% at diagnosis and higher risk of MM was observed (≥ 5% *versus* <5%, HR 2.40, 95%CI [1.00-5.74]). ^{18}F-FDG PET/CT images were available for review in only 36/77 patients. A significant decrease of ^{18}F-FDG uptake after treatment was observed whereas the lesion size was unchanged. No association was observed with the risk of MM but the limited available images may have resulted in underpowered analyses.

Conclusion: In this large study of patients with SBP, we observed that even though mostly prescribed for insufficient response to radiotherapy alone, treatment with adjuvant chemotherapy was associated with a decreased risk of evolution to MM, suggesting that this treatment might be systematically prescribed in addition to radiotherapy alone. These observations need to be confirmed and justify conduction of a prospective trial evaluating adjuvant chemotherapy in patients with SBP.

MACHINE LEARNING MODEL OF THE ULTRASOUND INDEX OF MASEI ENTHESIS AND OTHER VARIABLES OF DISEASE ACTIVITY IN PATIENTS WITH SPONDYLOARTHRITIS.

D. Castro-Corredor[1], L. Á. Calvo Pascual[2], M. A. Ramírez Huaranga[1], E. C. Garrido Merchán[2], M. Paulino Huertas[1]. [1]*Hospital General Universitario Ciudad Real, Rheumatology Department, Ciudad Real, Spain*; [2]*Universidad Pontificia de Comillas, Quantitative Methods Department, Madrid, Spain*

Background: Spondyloarthritis (SpA) are a group of chronic inflammatory diseases with affectation, mainly of the axial skeleton, and also of peripheral joints. The enthesis is one of the target organs, and its inflammation known as enthesitis could be unnoticed. Machine Learning is a branch of artificial intelligence that studies the construction of a function y=f(x), from a finite set of observations D={x,y}, where y is an endogenous variable and x are explanatory variables. The objective of this method is to obtain a model that best fit to the data without overfitting, that could be useful to make predictions.
Objectives: We try to find Machine Learning models that relate the MASEI index (Madrid Sonographic Enthesitis Index) in entheses depending on the activity of the disease (ASDAS, BASDAI and DAPSA) and other variables in patients with spondyloarthritis.
Methods: Observational, descriptive and cross-sectional study. We have analyzed 24 patients with SpA who underwent musculoskeletal ultrasound using the MASEI index and who were treated in our clinics from May 2021 to September 2021 and under the approval of the CEICm of our center. First, we have done a feature selection of the variables most related to MASEI. To do so, we compute mutual information and chi-square test, using the scikit-learn (python) library and Matlab, respectively. Using Matlab Regression Learner package, we obtain the best Machine Learning model with the lowest RMSE for 5 fold cross-validation, which turned out to be a linear regression.
Results: To obtain regressive models that explain TOTAL MASEI, the following variables have been chosen: Type of SpA, BASDAI-DAPSA-ASDAS activity, Arthritis, Enthesophytes, Corticosteroids and CRP because they present a high degree of mutual information with MASEI and a high chi-square index. (See Figures 1 and 2). With these variables we have obtained the model that presents a lower RSME error for validated data, which has turned out to be a linear regression, given by the formula:
MASEI = -9.29-2,29* **type of SpA** + 10,42***ASDAS**+4,08***Corticoids** + 8,2***Arthritis/sinov**. + 4,46***Enthesithis**-8,6***CRP**
The basic statistical characteristics of the coefficients of this equation can be consulted in Figure 3. The characteristics of the model are specified in Figure 3. In Figure 4, we observe how the data fit the diagonal and in Figures 5 and 6, we have compute a prediction and confidence intervals of our model using ASDAS and MASEI as coordinate axes.
Conclusion: We have obtained a linear model, which explains the MASEI variable as an explicit linear combination of the variables: type of SpA, ASDAS, Corticoids, Arthritis/sinov, Enthesithis and CRP. Our model, not only is simple, but it is also optimal, in the sense that for 5-fold cross validation, it obtains the lowest RSME error, compared to other Machine Learning methods, such as: neural networks, SVM, Gaussian regression processes, etc. Our model is useful to build confidence intervals, make predictions and to understand the relation between the variables mentioned above.

EVALUATION OF HEPATITIS E VIRUS INFECTION DURING JAK INHIBITOR THERAPY IN AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES

I. Andreica[1], K. Volker[2,3], C. Elsner[4], R. Broering[5], F. Vondran[6], P. Behrendt[7,8], U. Dittmer[4], E. Steinmann[3], X. Baraliakos[1]. [1]*Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Rheumatology, Herne, Germany*; [2]*Carl von Ossietzky University Oldenburg, Department of Medical Microbiology and Virology Oldenburg, Oldenburg, Germany*; [3]*Faculty of Medicine, Ruhr University Bochum, Department for Molecular and Medical Virology, Bochum, Germany*; [4]*Institute for Virology, University Hospital Essen, University Duisburg-Essen, Virology, Essen, Germany*; [5]*University Hospital Essen, University Duisburg-Essen, Department of Gastroenterology and Hepatology, Essen, Germany*; [6]*ReMediES, Department of General, Visceral and Transplantation Surgery, Hannover Medical School, Surgery, Hannover, Germany*; [7]*Institute of Experimental Virology, TWINCORE Centre for Experimental and Clinical Infection Research, Virology, Hannover, Germany*; [8]*Hepatology and Endocrinology, Hannover Medical School, Department of Gastroenterology, Hannover, Germany*

Background: Although impacting hundreds of thousands of people in Western nations each year, hepatitis E virus (HEV) is an under-reported health problem (1). HEV usually is a self-limiting disease, but especially immunocompromised individuals are at risk to develop a chronic course of infection, with rapid progression to fibrosis, cirrhosis or even the development of liver failure. Janus kinase (JAK) inhibitors are a novel drug class for the treatment of autoimmune inflammatory rheumatic disease (AIRD). As JAKs play a key role in innate immunity, viral infections and reactivation are frequently reported during JAK inhibitor treatment in AIRD patients (2).
Objectives: To characterize the influence of JAK inhibitors on HEV replication *ex vivo* and assess the risk for the development of symptomatic HEV infection during JAK Inhibitor therapy *in vivo*.
Methods: To determine the effect of JAK inhibitors on HEV replication we performed infection experiments with primary human hepatocytes (PHH) followed by immunofluorescence analysis and RNAseq. To evaluate the risk of HEV infection during JAK Inhibitor therapy, we monitored HEV RNA and HEV IgG/IgM of 111 AIRD patients, receiving JAK inhibitors. Moreover, we conducted a retrospective analysis of liver enzymes of patients which were anti-HEV IgG/IgM positive.
Results: Transcriptomic analysis of PHH revealed an upregulation of innate immunity components during HEV infection. This induction was perturbed in the presence of a JAK inhibitor, concomitant with strong elevation of HEV RNA levels. In line, infection experiments displayed an up to 50-fold increase of progeny virus production during JAK inhibitor treatment indicating that JAK signaling is critical to control HEV infection. Monitoring of seroprevalence identified 17 patients which were anti-HEV IgG and/or IgM positive, while no patient hat detectable HEV RNA levels. Five patients had detectable anti-HEV IgM levels suggesting a recent HEV infection. Three of 17 had a period with elevated liver enzymes (f.e. GGT> 200 U/L) during time of retrospective analysis (ranging from 10 to 23 months).
Conclusion: Obtained *ex vivo* data suggest that JAK inhibition facilitates HEV life cycle progression. Considering that JAK inhibitors are routinely applied for the treatment of AIRD, these patients may be at higher risk for a symptomatic course and outcome of HEV infection. In addition to established protocols, screening for HEV seroprevalence and HEV RNA should be considered prior starting JAK inhibitor treatment and in case of elevated liver enzymes during JAK inhibitor therapy.

TRADITIONAL AND NON-TRADITIONAL CARDIOVASCULAR RISK FACTORS IN THE DEVELOPMENT OF EARLY ATHEROSCLEROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

N. Bashlakova[1], T. Tyabut[2], A. Trushyna[3]. [1]*Belmapo, Ultrasound Diagnostic, Minsk, Belarus*; [2]*Belmapo, Cardiology and Rheumatology, Minsk, Belarus*; [3]*Belarusian State Medical University, Polyclinic Therapy, Minsk, Belarus*

Background: It is known that patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are characterized with a variability of traditional and non-traditional cardiovascular risk factors for the early development of arthrosclerosis. The results of numerous studies, examining the significance of these factors for the development of atherosclerosis in patients with autoimmune rheumatic disease (ARD), are contradictory. Additionally the prevalence of these factors was compared between ARD patients and healthy persons. There are few data about comparison cardiovascular risk factors between patient with SLE, RA and ischemic heart disease (IHD).

Objectives: The aim of our study was to determine the frequency of occurrence of traditional and non-traditional cardiovascular risk factors in patients with SLE and RA in comparison to patients with IHD and to assess their role for the development of early atherosclerosis.
Methods: The study included 85 female patients with ARD (SLE (n=40), mean age 33,5 (27,5; 44,5) years old, disease duration 8,0 (5,0; 14,5) years, disease activity SLEDAI-2K 7,0 (4,0; 11,5) points and RA (n=45), mean age 43,0 (33,0; 52,0) years old, disease duration 9,0 (5,0; 13,0) years, disease activity (DAS28=5,37 (4,69;5,89) points. Fifty four healthy women of the same age formed the first control group (CG1), 22 women with IHD (mean age 50,0 (48,0; 51,0) years old) made the second control group (CG2). The presence of traditional (age, arterial hypertension (AH), smoking, obesity, dyslipidemia, low physical activity, family history of cardiovascular disease (CVD)) and non-traditional (menopause, hyperhomocysteinemia (HHC)) risk factors was assessed. The early development of atherosclerosis was confirmed with the help of common carotid artery sonography according to standard procedures.
Results: It was found that only AH and HHC were more in patients with SLE and RA in comparison to CG1 (AH: 65% vs. 0% (p<0,0001), HHC: 45% vs. 9% (p<0,0001), respectively for SLE patients and 27% vs. 0% (p<0,0001), 36% vs. 9% (p=0,001), respectively for RA patients). Age, smoking, obesity, dyslipidemia, low physical activity, family history of CVD, menopause were similar in both groups of patients and CG1. It was revealed that patients with SLE were 14 years younger (p<0,0001) than female patients with IHD. They had less often family history of CVD (18% vs. 41%, p=0,044), but HHC was revealed 2 times more often (45% vs. 22%, p=0,031) than in CG2. Patients with RA were 8 years younger than patients with IHD (p=0,007). Moreover the frequency of occurrence of AH, obesity, dyslipidemia, family history of CVD was less than in CG2 (27% vs. 73% (p=0,0003), 40% vs. 68% (p=0,030), 71% vs. 95% (p=0,025), 11% vs. 41% (p=0,005), respectively). HHC was detected 1,5 times more often in RA patients in comparison to patients with IHD, but without statistically difference (36% vs. 22%, p=0,288). Other risk factors were similar in both groups of patients with ARD and IHD. The presence of subclinical atherosclerosis was observed in 54% patients with ARD. Comparative analysis of the frequency of occurrence of investigated cardiovascular risk factors between these patients and those with IHD has shown the highest prevalence of HHC in patients with ARD (54% vs. 22%, p=0,014), what could be as a result of autoimmune inflammation in this group of patients.
Conclusion: Thus, we revealed a high prevalence of AH (as traditional risk factor) and HHC (as non-traditional risk factor) in patients with SLE and RA. More than half of patients with ARD had subclinical atherosclerosis. The presence of HHC in patients with SLE and RA may be associated with the development of early atherosclerosis.

AB1454 CLINICAL AND BIOLOGICAL FACTORS CORRELATED WITH MAGNETIC RESONANCE IMAGING RESULTS IN TUBERCULOUS SPONDYLODISCITIS

M. Mrabet[1], S. Boussaid[1], S. B. Troudi[1], S. Rekik[1], S. Rahmouni[1], S. Jemmali[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. *[1]Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: Tuberculosis is still endemic in Tunisia. Although pulmonary localization is the most common, other localizations, including osteo-articular involvement, are increasingly diagnosed. Tuberculous spondylodiscitis (SPDT) or Pott's disease is an infectious involvement of the disc-vertebrate couple, caused by the tubercular bacillus (Mycobacterium tuberculosis). Magnetic resonance imaging (MRI) is the most sensitive (95-100%) and the most early abnormal exam.
Objectives: Our aim was to study the correlation of contributing factors, epidemiological, clinical, biological, radiological and therapeutic data with positive signs of spinal MRI.
Methods: We conduct a retrospective and descriptive study in a single rheumatology department. Data were collected from observations of patients hospitalized in the past 20 years (2000-2020) who have been diagnosed with SPDT. Epidemiological, clinical, biological, radiological, and therapeutic data were analyzed. Each patient had spinal MRI. Positive signs have been individualized, represented by intervertebral disc involvement, vertebral body involvement and visualization of a paravertebral abscess.
Results: Fifty-two cases of SPDT were collected (37F/15M). The mean age of the population was 55.21±17.79 years [19-91]. Thirty-three patients (69.2%) were classified as young versus 16 elderly patients (30.8%), with female predominance in both groups (69.4% and 75% respectively, p = 0.57). The positive diagnosis of tuberculous spondylodiscitis was facilitated by the spinal MRI. Positive signs were sought in our patients which are represented by: the achievement of the intervertebral disc with diffuse T2 hypersignal (56.5%) and diffuse or circumferential increase of the signal in sp T1 Gadolinium (50.9%), Involvement of the vertebral body with moderate and extensive condensation (60.4%), macrogeodes (60.4%) and heterogeneous increase in spT1 Gado signal (52.8%) and visualization of a paravertebral abscess (51.9%). Correlations made between the favouring factors, epidemiological, clinical, biological, radiological and therapeutic data and the positive signs of spinal MRI, objecting that six parameters had a statistically significant correlation with MRI signs strongly suggestive of the diagnosis of SPDT: Hospitalization duration was correlated with the diffuse T2 disk hypersignal (p= 0.02; r= - 0.38), Hemoglobin rate was correlated with the diffuse or circumferential increase in T1 disk sp signal (p= 0.03; r= - 0.34), the initial rate of lymphocytes was correlated with the paravertebral abscess (p= 0.04; r= - 0.47). The extra-vertebral tuberculosis location was correlated with the diffuse T2 disc hypersignal (p= 0.03; r= -0.96), the moderate condensation and the extent of vertebral body (p < 0.001) and vertebral body macrogeodes (p < 0.001). The neurological clinical signs were correlated with the heterogeneous increase in vertebral body T1 sp signal (p= 0.04; r= -0.33) and the surgical treatment (p < 0.001).
Conclusion: Tuberculous spondylodiscitis is a frequent condition that needs to be diagnosed and treated rapidly. Spinal MRI is the first-line exam in case of suspicion. Clinical, biological and therapeutic parameters were correlated with the MRI images highly suggestive of positive diagnosis.

AB1455 VERY LOW FREQUENCY ANAS/DFS70 PATTERN POSITIVITY IN A LARGE COHORT OF AUTOIMMUNE/ AUTOINFLAMMATORY AND CONTROLS IN A SINGLE HOSPITAL FROM COLOMBIA

C. Romero-Sánchez[1,2,3], O. J. Calixto[1,3], V. S. Romero Alvarez[1], A. Vargas[4], L. Castro[5], J. Amador[5], P. Lopez-Mojica[5], D. Marin[5], D. Acero-M.[3,6], M. Acevedo-Godoy[3,6], D. Rincon-Riaño[1], W. Bautista-Molano[3], J. M. Bello-Gualtero[1,3]. *[1]Hospital Militar Central, Rheumatology and Immunology Department, Bogota, Colombia*; *[2]Universidad El Bosque, Cellular and Immunology Group /InmuBo, Bogota, Colombia*; *[3]School of Medicine, Universidad Militar Nueva Granada, Clinical Immunology Group-Hospital Militar, Bogota, Colombia*; *[4]Universidad Colegio Mayor de Cundinamarca, Bacteriology School, Faculty of Basic Sciences, Bogota, Colombia*; *[5]Hospital Militar Central, Universidad Militar Nueva Granada, Dermatology Department, Bogota, Colombia*; *[6]Hospital Militar Central, Immunology Laboratory, Bogota, Colombia*

Background: Antinuclear antibodies (ANA) have diagnostic significance in rheumatology. Anti-DFS70 (Dense Fine Speckle-70 kd) antibodies may be an exclusionary marker for systemic autoimmune rheumatic disease (SARD). Low frequency of this pattern has previously been described in healthy populations.
Objectives: To evaluate ANAS/DFS70 positivity and autoantibody profile in a large Colombian population with rheumatoid arthritis (RA), psoriasis (PsO), as well as, undifferentiated connective tissue diseases (UCTD), first degree relatives (FDR), and healthy controls (HC).
Methods: A cross-sectional study was conducted. We analyzed 531 individuals between 18-65 years, 101 RA patients (ACR/EULAR 2010 classification criteria), 137 relatives from RA, 60 PsO patients (Colombian classification consensus), 47 UCTD patients, and 186 HC matched by age and sex. The determination of ANAS-HEp2 antibodies, was carried out. The ANAS/DFS70 positive results used as a confirmatory test the determination by Knocked out, for the psip gen and CytoBead by indirect immunofluorescence-IFI technique. Absolute and relative frequencies were established and associations with chi square test.
Results: The distribution by diagnostic group was RA: 19%, PsO: 11,3%, UCTD: 8,9%, 25,8% RA relatives, and 35% healthy controls. RA was ANA test (+) in 42%, PsO 41,7%, UCTD 78,7%, FDR 26,3%, and HC 26,9%. The positive frequency of ANA/DFS70 in the total group was 2.3% and 1,4% in SARD (n=12; 2 FDR, 6 HC, 3 UCTD, and PsO 1), no RA patients were positive. These 12 participants were negative for rheumatoid factor (RF) and anti-citrullinated protein antibody (ACPA), one patient with UCTD were positive for Anti SSB/La, Anti Sm, Anti RNP, and anti DNAds, another was positive for anti Sm IgG and IgM B2GP, and IgG ACA. Most participants had negative acute phase reactants (erythrosedimentation rate ESR[-] 83,3% and C-reactive protein CRP[-] 66,6%). ANAS/DFS70 was associated with positivity for ANAS independently of ANAS titers, (p <0,001). None of the patients' positives ANAS DFS70 in the UCTD group in 5 years developed definitive autoimmune disease.
Conclusion: Despite the low frequency in the group in general, it has been shown that anti-DFS70 is more prevalent in healthy individuals than in patients with SARD, which was found in this group of individuals. ANAS/DFS70 autoantibodies were present in very low frequency in Colombian patients with SARD. Thus, patients with a positive result tend to have a mild or non-progressing phenotype of autoimmune or autoinflammatory diseases. This analysis reinforce evidence of ANA/DFS70 positivity as well as autoantibody negativity described abroad as a negative predictive marker of SARD.

AB1456 CLINICAL IMPACT OF THE INTERSTITIAL LUNG DISEASE MULTIDISCIPLINARY SERVICE

S. Eisa[1], B. Osei-Boadu[1], G. Singh-Rathore[2], M. Rabbani[3], K. Suthar[4], S. Ansari[3], G. M. Koduri[1]. *[1]Southend University Hospital, Rheumatology, Essex, United Kingdom*; *[2]Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom*; *[3]Southend University Hospital, Respiratory, Essex, United Kingdom*; *[4]Southend University Hospital, Radiology, Essex, United Kingdom*

Background: Interstitial lung diseases (ILD) are a diverse group of pulmonary diseases for which accurate diagnosis is critical for optimal management and outcomes. Diagnosing ILD, both idiopathic pulmonary fibrosis (IPF) and connective-tissue-disease-associated interstitial lung disease (CTD-ILD), has become critically important, as the disease has a devastating prognosis with poor survival. There are also management implications, as patients with ILD can now potentially be treated with new antifibrotic therapies such as pirfenidone and nintedanib, both of which have been approved. Certain types of CTD – ILD may benefit from systemic immunomodulatory therapies. Diagnosis of ILD can be challenging and a multidisciplinary team (MDT) approach is recommended in current guidelines. Several studies have reported that MDT diagnosis is associated with higher levels of diagnostic confidence and better interobserver agreement (1-3).

Objectives: We describe the benefits of an ILD multidisciplinary service on the diagnosis and management of patients with suspected ILD.

Methods: We performed a single-centre retrospective review of consecutive patients referred to the ILD clinic with subsequent discussions in ILD MDTs over a 36-month period from 2016 to 2019. We compared changes in ILD diagnosis and management at referral to those following the ILD-MDT. We collected data on the demographics, occupation, age at ILD onset, smoking status, imaging, blood tests including autoimmune serology, MDT recommendations, change in diagnosis after MDT, tertiary referral, serial PFTs, medications and outcomes. Cases of suspected ILD that were not fully characterised and those with complex management issues were presented at our monthly ILD MDT.

Results: A total of 208 patients were referred to the ILD clinic over a 36-month period. Of these, 106 cases were discussed at the ILD MDT and the remaining 102 cases did not require discussion at the MDT as these deemed to be clear cut, which included RA and CTD ILD. The mean age of the total cohort was 74 (min age 32, max age 97) and 120 (58 %) were males. Overall, evaluation by the ILD service (i.e. ILD clinic and MDT) resulted in a change in diagnosis in 106(51%) patients. Of those, 49(46%) didn't have ILD. In the remaining 57 patients with suspected ILD, the majority of the diagnoses were ILD with an uncertain classification (24, 23%). The other diagnoses included CTD-ILD (4, 3.7%), ILD with autoimmune serology 11(10.4%), IPF 10(9.4%), Drug-induced-ILD 3(2.8%), Hypersensitivity Pneumonitis 5(4.7%), Eosinophilic pneumonitis 1 (0.94%), Cryptogenic Pneumonitis 1(0.94%), PPFE with IPF 1 (0.94%), PPFE 1 (0.94%), CPFE 4 (0.94%), EAA 2 (0.94%), RB-ILD 2 (1.88%), Langerhans Histiocytosis 2 (1.88%).16/57(28%) were referred to a tertiary centre for further management. Serology was positive in 11 patients (ANA 6, CCP 3, and ANCA 2). Of the 57 patients with other diagnoses, the main recommendations included steroids (28), anti-fibrotic therapy (4), immunomodulatory therapy (6) and ambulatory Oxygen (1). Further analysis will be carried out on survival and treatment outcomes of the cohort.

Conclusion: Dedicated ILD-MDT service has an important clinical impact on the care of the ILD patient, with frequent changes in ILD diagnosis and subsequent management and outcomes. Multidisciplinary approach to the management of these patients should be standard of care for these patients.

AB1457 OPALE: A PROSPECTIVE OBSERVATIONAL STUDY OF THE REAL-WORLD USE OF AN ADALIMUMAB BIOSIMILAR AND EVALUATION OF NUTRITIONAL STATUS ON THE THERAPEUTIC RESPONSE. PATIENTS NUTRITIONAL STATUS AT BASELINE

M. Soubrier[1], M. Viguier[2], L. Peyrin-Biroulet[3], S. Czernichow[4]. *[1]University Hospital Gabriel Montpied, Department of Rheumatology, Clermont-Ferrand, France*; *[2]Robert Debre Hospital, Department of Dermatology, Reims, France*; *[3]University Hospital of Nancy-Brabois, Department of Gastroenterology, Vandoeuvre les Nancy, France*; *[4]Georges Pompidou European Hospital, Department of Nutrition, Paris, France*

Background: Chronic inflammatory diseases treatment has been greatly improved since the introduction of TNF inhibitors and later, of their biosimilars. In addition, epidemiological and interventional studies suggest a pathophysiological or therapeutic role, respectively, of nutrition in Inflammatory Rheumatic Diseases (IRDs).

Objectives: The objective of the OPALE observational study was to describe in real life the profile of patients treated with an adalimumab biosimilar and to assess the impact of nutrition on disease evolution and response to treatment.

Methods: The study planned a one-year follow-up of patients with at least three visits: inclusion, six months and one year. In this study, 754 patients treated with Fresenius-Kabi adalimumab were included: 54.4 % of patients with an IRD, 42.8 % with Inflammatory Bowel Disease (IBD) and 2.8 % patients with a psoriasis. Patients' condition was assessed using a Clinical Global Impression of disease scale (CGI, primary end point of the study). Nutritional status was assessed through clinical data (weight, BMI (Body Mass Index), abdominal circumference) and the available biological analyses results. Screening for sarcopenia was based on a SARC-F score ≥ 4. Nutritional behavior was assessed using a diet questionnaire with a list of 48 foods divided into 6 classes (Fruits & vegetables, meat, fish & eggs, dairy products & fats, starchy foods, sweet foods and drinks). Foods voluntarily withdrawn due to illness and those avoided at acute flare-ups were recommended to be reported. This analysis aims to describe IRD patients' nutritional status at baseline.

Results: From 754 included patients, 410 patients presented with an IRD (Psoriatic Arthritis (PsA), n= 80 / Rheumatoid Arthritis (RA), n=102 / SpondyloArthritis (SpA), n=228). Mean patients' age was 47.7± 14.1 years, 56% are female, mean BMI was 26.0 ± 5.4 kg/m^2. From this IRD population, 28.5% of patients have a family history of chronic inflammatory disease. Mean disease duration was of 6.4 ± 8.4 years. Concerning the previous IRD treatment, 47.4% of patients had previously been treated by methotrexate among them 58% were still receiving this treatment at inclusion. Among IRD patients recruited in OPALE study, 72.8% received Fresenius Kabi adalimumab as their first biotherapy. Most of patients were assessed on the CGI scale as markedly ill (50.7%) or moderately ill (29.9%) and 110 patients (37.3%) had a score ≥ 4 on the SARC-F questionnaire (mean age 48.9 ± 14.1 years and mean BMI 27.2 ±5.6 kg/m^2). Concerning the disease history at baseline, the descriptive analysis of self-administered questionnaire shows that 68.3% of patients may have changed their nutritional behavior because of their illness, by banishing several foods (mean number: 12.7 ± 10.1). These restrictions are increased during flare-ups: 32.7% of patients removed an average of 6.0 ± 5.8 additional foods number. These changes are in part based on the patients' own beliefs: 17% of them consider that certain foods can improve their illness, 35% of patients think they have identified the foods likely to make it worse (Table 1).

Table 1. Patient-reported influence of certain foods on disease

	PsA	RA	SpA	TOTAL IRD
	(n=60)	(n=72)	(n=177)	(n=309)
Patients identifying foods with negative influence	21 37.5% [24.9% - 51.5%]	22 32.4% [21.5% - 44.8%]	58 36.0% [28.6% - 44.0%]	101 35.4% [29.9% - 41.3%]
Patients identifying foods with positive influence	9 16.4% [7.8% - 28.8%]	12 17.6% [9.5% - 28.8%]	27 17.2% [11.7% - 24.0%]	48 17.1% [12.9% - 22.1%]

Conclusion: These preliminary baseline data from OPALE observational study confirm the risk of decreased muscle mass in IRD. Mean BMI of patients screened for sarcopenia is higher than that of non-sarcopenic patients (respectively 27.2 ± 5.6 kg/m^2 and 25.6 ± 4.8 kg/m^2; p=0.02). These results plead for a systematic screening for sarcopenia in IRD patients. The risk of sarcopenia could be further aggravated by inappropriate nutritional behaviors aimed at excluding food groups, which would justify dietary education of these IRD patients.

AB1458 JAK INHIBITORS AND VENOUS THROMBOEMBOLISM EVENTS - REASSURING DATA FROM A LARGE SINGLE CENTRE RETROSPECTIVE STUDY

C. Beevor[1], S. Bartosz-Bowden[1], M. Fletcher[1], L. Goh[1], G. Dulay[1]. [1]*Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom*

Background: In March 2021, the European Medicines Agency (EMA) sent out a Medicine Alert related Xeljanz (tofacitinib): The Initial clinical trial results suggested an increased risk of major adverse cardiovascular events and malignancies with use of tofacitinib relative to TNF-alpha inhibitors. In light of these safety alerts, March 2021, the Rheumatology department at Portsmouth Hospitals University NHS Trust updated the Biologics Screening documents to include a cardiovascular and venous thromboembolism (VTE) risk assessment. We conducted a retrospective observational study to document the incidence of VTE in patients on Janus kinase (JAK) inhibitors admitted to our Venous thromboembolism Service from 14th April 2018 to 30th November 2021 (43 months). This includes patients who were suspected of having both deep vein thrombosis (DVT) and/or Pulomonary Thromboembolisim (PE). We were particularly interested to assess whether any patients with VTE events had been receiving JAK inhibitors given the potential association of JAK inhibitor usage and VTE.

Objectives: To establish whether patients exposed to JAK inhibitors had any increased incidence of VTE. This was done through a retrospective analysis for all patients presenting to Portsmouth Hospitals University NHS Trust.

Methods: We utilised the International Classification of Diseases (ICD10) diagnosis code of I82 (182.0, 182.1,182.2,128.3,182.8,1782.9). This includes; Budd Chiari syndrome, thrombophlebitis migrans, embolism and thrombosis of vena cava, embolism and thrombosis renal vein, embolism and thrombosis of other specified view and embolism and thrombosis unspecified vein. From this data set, we reviewed how many case of VTE were noted in patients on JAK inhibitors. The Data was confined to patients who underwent diagnostic tests for VTE at Portsmouth Hospials University NHS Trust.

Results: A total of 417 patients had been admitted to the VTE Service for diagnostic assessment between 14th April 2018 to 30th November 2021. A total of 261 patients had been on a JAK inhibitor during the period of observation. This included patients on Tofacitinib, Baricitinib, Filgotinib and Upadacitinib. This was for treatment in Rheumatoid Arthritis and Psoriatic Arthritis where liscenced indications were appropriate. None of these had a VTE event. The age range of the patients on active treatment was 18 to 86 years old with the average of 60.7 years. The majority of patients were female (72.7%) with male patients comprising the remainder (27.3%). 8 patients under the care of the Rheumatology service were identified as having VTE events.

Conclusion: From a total of 261 patients on JAK inhibitors during a 43 month period; 0 patients had a confirmed VTE event. After March 2021, the Rheumatology department soutght to address the concerns raised by the EMA alert. There were two key areas in addressing the concerns highlighted. Firstly, clinicians had an heightened awareness of the potnetial risk of VTE and JAK inhibitor useage. Additionally, there was also the introduction of a new screening process which focussed on highlighting and assessing risk facotrs for VTE in patients being screened for JAK inhibitors. This was a new departmental service innovation introduced following the potential patient safety alert. We would postulate that some of the highly encouraging data obtained may partly be influenced by this service development. Conversely, much of the data was gathered before these assocations were established and before any service changes were made. We acknowedge that this data set is from a single centre analysis. However, given the sample size and duration of retrosepctive review we hope this serves to reassure clinicians that JAK inhibitor usage should remain a valid treatment option in Rheumatology patients, for licenced indications.

AB1459 IMPACT OF SOCIOECONOMIC FACTORS ON THE DISEASE ACTIVITY: DATA FROM THE TUNISIAN BINAR REGISTRY

R. Ben Aissa[1], S. Boussaid[1], S. Rekik[1], S. Jemmali[1], S. Rahmouni[1], H. Srairi Sahli[1], M. Elleuch[1]. [1]*Rabta Hospital, Department of Rheumatology, Tunis, Tunisia*

Background: Despite the considerable therapeutic progress of inflammatory rheumatic diseases, access to treatment still challenging in developing countries because of scarce health resources and low socioeconomic status.

Objectives: To determine the influence of socioeconomic factors on disease activity in a national registry cohort, the Biological National Registry (BINAR) in Tunisia.

Methods: We enrolled patients with inflammatory rheumatic diseases under the first received biological drug and included in the BINAR registry from 2016 to 2020. Data on the inflammatory rheumatic disease (rheumatoid arthritis (RA) and spondyloarthritis (SA)), disease activity of RA and SA (DAS28-CRP and ASDAS-CRP respectively) at baseline, gender, active smoking, marital and work status and educational attainment were collected. Two groups were identified: Groupe 1 (G1) for patients with remission or low disease activity and groupe 2 (G2) for moderate or high disease activity according to DAS28-CRP and ASDAS-CRP.

Results: The study included 298 patients with a mean age of 49.2 years [18-79]. The mean disease duration was 6.7 ± 3.5 years [1-14] in patients with RA and 6.5 ±3.6 years [1-12] in patients with SA. G1 was made of 13 patients and G2 of 285 patients. The were no significant difference between G1 and G2 for (49.5 ± 11.9 versus 49.5±14.2, p=0.93) gender (% of females, 46.2% versus 37.1%, p=0.51) and marital status (% of single patients, 30.8 % versus 33.7%,p=0.82). Patients of G1 had better employability than G2 (61.5% % versus 45.6%) but this difference was not significant (p=0.26). Smoker patients had better disease outcomes comparing to nonsmokers but this difference was not significant (23.1 % versus 13.7%, p=0.34). Illiterate patients had more active diseases, comparing to literate, but this difference was not significant (30.8% versus 40.4%, p=0.49).

Conclusion: Our results did not confirm any difference in disease activity according to the collected socioeconomic factors. Data on the personal income, health insurance type and geographic distribution of our population should be further studied.

DOI: 10.1136/annrheumdis-2022-eular.4776

AB1460 ACCUMULATED ADVANCED GLYCATION ENDPRODUCTS ARE SIGNIFICANTLY HIGHER IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES THAN IN HEALTHY POPULATION.

L. Triginer[1], I. Carrión Barberà[2], L. Tío[1], T. C. Salman Monte[2], C. Pérez[2], L. Polino[1], A. Ribes[1], J. Llorente Onaindia[1], J. Monfort[2]. [1]*IMIM (Hospital del Mar Medical Research Institute), Inflammation and Cartilage Cellular Research Group, Barcelona, Spain*; [2]*Hospital del Mar, Rheumatology, Barcelona, Spain*

Background: Advanced glycation endproducts (AGEs) are the result of non-enzymatic glycation of proteins, lipids or nucleic acids. In circumstances characterized by increased oxidative and carbonyl stress, such as chronic inflammation, AGEs can be formed more rapidly1, generating reactive oxygen species and activating inflammatory signaling cascades through their chief signaling receptor (commonly abbreviated as RAGE)[2]. This positive feedback of inflammation can play a role in the etiology of immune-mediated inflammatory diseases, more specifically in rheumatoid arthritis (RA), ankylosing spondylitis (AS) and systemic lupus erythematosus (SLE).

Objectives: To investigate whether the accumulated concentrations of AGEs in patients with SLE, RA or AS are significantly higher than in healthy patients.

Methods: One hundred thirteen consecutive patients fulfilling ACR/EULAR criteria for RA, 60 patients fulfilling ASAS/OMERACT MRI criteria for AS, 97 patients fulfilling ACR/SLICC criteria for SLE and 527 sex-matched healthy controls were recruited.in cross-sectional study. Exclusion criteria were pregnancy, diabetes mellitus, corticosteroid treatment ≥ 20mg/day and malignant neoplasm.

Table 1. Descriptive characteristics of the cohorts

		SLE		RA		AS	
		Patients	**Controls**	**Patients**	**Controls**	**Patients**	**Controls**
		N=96	*N=189*	*N=113*	*N=240*	*N=60*	*N=99*
AGEs		2.57 (0.65)	1.98 (0.45)	2.59 (0.58)	2.00 (0.42)	2.26 (0.46)	1.90 (0.46)
Age		51.0 [43.0;61.0]	56.0 [52.0;62.0]	58.0 [54.0;65.0]	61.0 [56.0;66.0]	47.5 [41.0;55.0]	53.0 [49.0;57.0]
Smoker	**No**	76 (79.2%)	133 (70.4%)	86 (76.1%)	196 (81.7%)	42 (70.0%)	58 (58.6%)
	Yes	20 (20.8%)	56 (29.6%)	27 (23.9%)	44 (18.3%)	18 (30.0%)	41 (41.4%)
Packs/year		0.00 [0.00;10.8]	2.50 [0.00;18.8]	2.50 [0.00;18.0]	0.00 [0.00;12.6]	0.00 [0.00;7.88]	14.9 [2.00;30.6]
Hypertension	**No**	74 (77.1%)	116 (61.4%)	77 (68.1%)	146 (60.8%)	53 (88.3%)	75 (75.8%)
	Yes	22 (22.9%)	73 (38.6%)	36 (31.9%)	94 (39.2%)	7 (11.7%)	24 (24.2%)
Obesity	**No**	80 (83.3%)	128 (67.7%)	86 (76.1%)	163 (67.9%)	51 (85.0%)	81 (81.8%)
	Yes	16 (16.7%)	61 (32.3%)	27 (23.9%)	77 (32.1%)	9 (15.0%)	18 (18.2%)
Dyslipidemia	**No**	85 (88.5%)	104 (55.0%)	79 (69.9%)	108 (45.0%)	51 (85.0%)	55 (55.6%)
	Yes	11 (11.5%)	85 (45.0%)	34 (30.1%)	132 (55.0%)	9 (15.0%)	44 (44.4%)

Continuous normal: mean (SD); Continuous non-normal: median [IQR]; Categorical: absolute (relative frequency)

Accumulated AGEs were non-invasively measured by skin autofluorescence (Age Reader Mu Connect, Diagnostics Technologies B.V) and demographic and clinical data were collected. AGEs comparisons between patients and controls were performed by multiple linear regression analysis adjusted by confunders, previously described in literature (age, smoking habit and cardiovascular risk-factors). Age was centered at 55 years.

Results: Table 1 shows some descriptive characteristics of our cohorts. AGEs adjusted mean was significantly increased in SLE patients compared with matched controls (95% CI [2.27, 2.76] vs [1.66, 1.89], p<0.0001), RA patients and controls (95% CI [2.41, 2.61] vs [1.68, 1.88], p<0.0001) and AS patients and controls (95% CI [2.03, 2.6] vs [1.66, 1.93], p<0.0001). In all 3 models, AGEs were also significantly positive correlated with smoking habit measured by packs per year (p<0.001) and age (p<0.0001).

Conclusion: Accumulated AGEs in all 3 pathologies are significantly higher than in the healthy controls. The different means of AGEs in each of the diseases, being higher in SLE and lower in AS, may suggest a different participation of AGEs in the immune-mediated mechanisms of each pathology.

AB1461

IMPACT OF BASELINE DISEASE ACTIVITY ON DISCONTINUATION OF BIOLOGICAL DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE MEXICAN ADVERSE EVENTS REGISTRY (BIOBADAMEX)

V. Rivera Teran[1], D. Vega-Morales[1], S. Sicsik[1], F. Irazoque-Palazuelos[1], M. A. Saavedra[1], J. C. Casasola[1], S. Carrilo[1], A. Peña[1], A. Castillo Ortiz[1], O. E. Muñoz-Monroy[1], S. Duran Barragan[1], A. Ramos[1], L. F. Valdés Corona[1], E. Torres Valdéz[1], A. Paz[1], E. A. Zamora-Tehozol[1], D. X. Xibille Friedmann[1], F. Guerrero[1], N. Santana[1], M. Vazquez[1], C. Zepeda[1], M. Rivera[1], K. Alvarado[1], D. Alpizar-Rodriguez[1]on behalf of the Mexican Adverse Events Registry (BIOBADAMEX). [1]*Colegio Mexicano de Reumatología, Unidad de Investigación, Mexico City, Mexico*

Background: Decrease treatment persistence in rheumatoid arthritis (RA) patients has been associated with several factors, including number of previous biological DMARDs (bDMARDs), female gender and higher disease activity or lower function at baseline [1].

Objectives: Determine if drug discontinuation of bDMARDs differs by disease activity level at baseline in patients with RA in the Mexican Adverse Events Registry (BIOBADAMEX).

Methods: BIOBADAMEX is a Mexican ongoing cohort of patients using bDMARDs. In this analysis we included all patients with RA registered from 2016 to 2021 with at least two assessments. Survival on bDMARDs was estimated using Kaplan-Meier analysis. Predictors of discontinuation, including high disease activity defined as DAS28-ESR>5.1, were investigated by Cox regression analyses.

Results: Among 528 RA patients in the registry, 302 had at least two assessments. Of patients analyzed, 276 (91%) were women. At baseline, patients had a median (IQR) age of 52.7 (44-60) years old, median disease duration of 9.3 (4-16) months. A total of 142 (47%) had comorbidities, 34 (11%) had more than 2 morbidities. At baseline DAS28-ESR was 4.8 (4-6), 59 (20%) patients had low (DAS28-ESR<=3.2) and 130 (43%) had high disease activity. The most common bDMARDs received at baseline were abatacept 68 (23%), tocilizumab 59 (20%), adalimumab 50 (17%) and certolizumab 41 (14%). At the time of analysis, the median bDMARDs treatment duration was 17.2 (12-27) months. Overall, 130 (43%) patients had discontinued treatment, the most common causes of discontinuation were inefficacy in 64 patients, 15 for remission, 12 for adverse events and 26 for others. Figure 1 shows discontinuation rate curves in patients by disease activity. Cox proportional hazards demonstrated significant difference in bDMARD discontinuation between patients with baseline high disease activity (HR 1.3, 95% CI 1.1-1.7, p=0.03), but not differences were found regarding baseline age (HR 1.0, 95% CI 0.9-1.0, p=0.16), sex (HR 0.9, 95%CI 0.6-1.4), disease duration (HR 1.0, 95%CI 0.9-1.0, p=0.92), smoking (HR 1.2, 95% CI 0.7-2.1, p=0.44), number of comorbidities (HR 1.0, 95%CI 0.9-1.2, p=0.51) or other factors. The significant association of baseline high disease activity remained after adjusting by baseline age, sex, smoking, disease duration and number of comorbidities (HR 1.3, 95% CI 1.1-1.7, p=0.02).

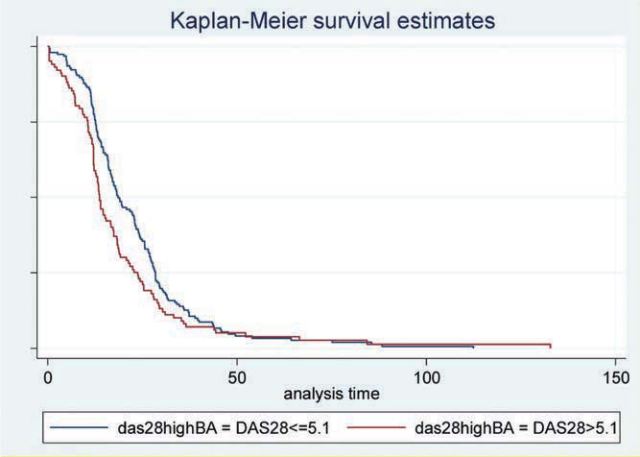

Figure 1. Discontinuation rate curves in RA patients with high disease activity (DAS28 >5.1) and DAS28<=5.1

Conclusion: In Mexican RA patients registered in BIOBADAMEX, we found that baseline high disease activity is associated with the discontinuation of bDMARDs. Further longitudinal analyses will be performed including more patients to assess retention rate of specific bDMARDs and identify predictive variables of discontinuation in Mexican population.

RHEUMATIC IMMUNE- AND NONIMMUNE-RELATED ADVERSE EVENTS IN PHASE 3 CLINICAL TRIALS ASSESSING PD-(L)1 CHECKPOINT INHIBITORS FOR LUNG CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Veccia[1], M. Kostine[2], A. Tison[3], M. Dipasquale[1], S. Kingspergher[1], G. Grandi[4], O. Caffo[1], S. Inchiostro[5], G. Paolazzi[5], R. Bortolotti[5], D. Cornec[3], A. Berti[5]. [1]*Hospital of Trento, University of Trento, Oncology, Trento, Italy*; [2]*CHU Bordeaux, Medicine, Bordeaux, France*; [3]*CHU de Brest, Rheumatology, Brest, France*; [4]*University of Trento, CIBIO, Trento, Italy*; [5]*Hospital of Trento, University of Trento, Rheumatology, Trento, Italy*

Background: Several adverse events (AEs) occurring during immune checkpoint inhibitors (ICIs) therapy are clearly related to their mechanisms of action, and in this case they are indicated as immune-related AEs (irAEs). Every organ may be affected, including the musculoskeletal system; myositis, polymyalgia rheumatica, arthritis or arthritis have been reported in several retrospective and prospective case series and cohorts, with an incidence between 1.5% and 22%. While arthritis, vasculitis, myositis, and polymyalgia rheumatica are usually defined as "irAE" in RCTs, other rheumatic musculoskeletal conditions such as arthralgia, myalgia, back pain and muscular pain are often reported under the umbrella of "general" AEs.
Objectives: We aimed to analyze rheumatic irAE and non-irAE due to immune-checkpoint inhibitors (ICIs) targeting programmed cell death-1 or its ligand PD-(L)1 in lung cancer patients from the available literature.
Methods: We performed a systematic review and meta-analysis of phase III randomized clinical trials (RCTs) assessing PD-(L)1 -ICIs in lung cancer patients, from inception until January 12th, 2021. We extracted data of each trial to estimate odds ratio (OR) for rheumatic ir or non-irAE as classified in RCTs safety data. Sensitivity analyses (by ICI, treatment group and histology) were performed.
Results: Eighteen RCTs met the inclusion criteria (n=12172 subjects). The OR [95%IC] for rheumatic irAE in ICIs versus controls (either placebo or chemotherapy) was 2.20 [0.85,5.72].
Among rheumatic non-irAEs, both overall (any grade, Figure 1A) and severe (grade≥3, Figure 1B) back pain were significantly more frequent in ICIs versus controls (2.01 [1.09;3.73] and 2.90 [1.18;7.08], respectively).

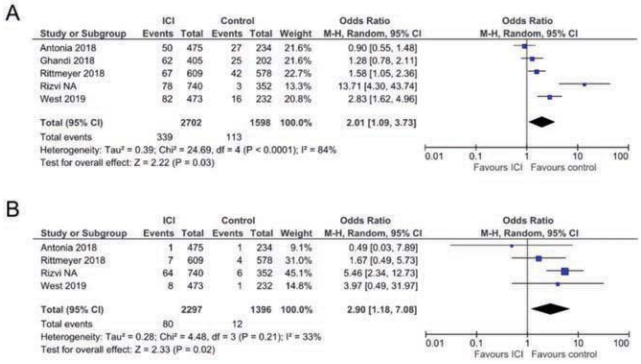

Figure 1. Forest plot showing pooled odds ratio (OR) for back pain (5 phase III trials) (A) and severe back pain (4 phase III trials) (B), respectively.

The overall frequency of arthralgia and severe arthralgia was similar between ICIs and controls (1.13 [0.86, 1.47] and 1.69 [0.68, 4.20], respectively). By sensitivity analysis RCTs assessing ICIs in combination with chemotherapy versus chemotherapy alone showed a significant association with arthralgia (1.55 [1.15;2.10]). Similarly, the frequency of myalgia did not differ between ICIs and controls, but was significantly lower in RCTs assessing ICIs alone versus chemotherapy (OR 0.32 [0.24;0.42]). Muscular pain was not significantly increased with ICI. **Conclusion:** Rheumatic irAEs are not increased in RCTs assessing PD-(L)1 inhibitors, not reflecting the real-life incidence, therefore likely underreported or misclassified. Back pain is significantly associated with PD-(L)1-ICIs regardless its severity, suggesting a possible implication of the PD-(L)1 axis in the development of inflammatory back pain in some patients. In addition, PD-(L)1-ICIs added on conventional chemotherapy are associated with a significantly higher frequency of arthralgia than ICI alone. This trend was seen in the other rheumatic AEs, suggesting that conventional chemotherapy might be a confounder in the interpretation of the occurrence of rheumatic AEs.

AB1463

CHARACTERISTICS AND MORTALITY OF PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES ADMITTED TO THE INTENSIVE CARE UNIT.

J. P. Baldivieso[1], E. Miguelez Tato[2], C. Valero[1], F. Gutiérrez-Rodríguez[1], C. Alvar González[3], D. Rodriguez Serrano[3], A. García-Vadillo[1]. [1]*Hospital de La Princesa, Rheumatology, Madrid, Spain*; [2]*Autonomous University of Madrid, School of Medicine, Madrid, Spain*; [3]*Hospital de La Princesa, Intensive Care Unit, Madrid, Spain*

Background: Autoimmune rheumatic diseases (ARD) are associated with multiple organ dysfunction, which may require admission to Intensive Care Units (ICU), constituting a challenge for rheumatologists and intensivists. The new immunomodulatory treatments may be changing the characteristics and mortality of these patients.
Objectives: The primary objective of the study is to know the mortality and the characteristics related to this event of our patients admitted to the ICU in the last 5 years. The secondary objective is to compare the characteristics of our series with the series of our patients admitted to the ICU in the previous decade.
Methods: We conducted a retrospective transversal observational study using computerized medical records. A database was created with patients with ARD admitted to the ICU of the Princess University Hospital between October 1, 2015 and September 30, 2020, excluding those with a stay of less than 24 hours. Information was collected about the characteristics and treatments of the disease prior to their admission to the ICU, as well as the clinical characteristics and therapeutic measures established in the ICU during their stay. Statistical analysis was performed using SPSS.
Results: After ruling out admissions of less than 24 hours, a population of 45 patients with a mean age of 65.3 ± 12.2 years and 69% women were included. Connectivopathies (40%) and rheumatoid arthritis (37.8%) were the most prevalent ARDs that required admission to the ICU. Cardiovascular events (51%) were the main reason for ICU admission, followed by infectious processes (27%). The median ICU stay was 5 days. It is striking that 77% of the patients had received glucocorticoids prior to admission throughout their disease. The median score on the severity scales was 34 in SAPS II and 17 in APACHE II. Mortality during the ICU stay was 30.4% and in the multivariate analysis it was associated with the previous administration of glucocorticoid boluses and the APACHE II scale score. This mortality is higher compared to historical series of patients admitted to Spanish ICUs with similar APACHE II severity scores. In the comparative study with the previous period, similar mortality rates were observed, an increase in the mean age of those admitted, a decrease in patients with vasculitis and an increase in patients with rheumatoid arthritis. Likewise, an increase in cardiovascular events is observed as a fundamental reason for admission to the ICU.
Conclusion: The mortality of our patients with ARD admitted to the ICU in the last five years is 30.4%, similar to the previous decade but higher than the observed in other pathologies with similar severity characteristics. It is related to the APACHE II score and to the prior administration of glucocorticoid boluses. Connectivopathies and rheumatoid arthritis are the diseases that are most frequently admitted to the ICU and the fundamental reasons are cardiovascular events and infections.

THE ROLE OF EPSTEIN-BARR VIRUS ACTIVITY IN RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS PATIENTS

A. Banko[1], D. Miljanovic[1], I. Jeremic[2], M. Basarić[3], M. Grk[4], I. Lazarevic[1], R. Miskovic[5], A. Cirkovic[6]. [1]*Institute of Microbiology and Immunology, Faculty of Medicine, University of Belgrade, Virology Department, Belgrade, Serbia*; [2]*Institute of Rheumatology, Faculty of Medicine, University of Belgrade, Department of Biochemistry, Belgrade, Serbia*; [3]*Institute of Rheumatology, Rheumatology Department, Belgrade, Serbia*; [4]*Institute of Human Genetics, Faculty of Medicine, University of Belgrade, Human Genetics, Belgrade, Serbia*; [5]*Clinic for Allergology and Immunology, University Clinical Center of Serbia, Faculty of Medicine, University of Belgrade, Allergology and Immunology, Belgrade, Serbia*; [6]*Institute for Medical Statistics and Informatics, Faculty of Medicine, University of Belgrade, Medical Statistics and Informatics, Belgrade, Serbia*

Background: Rheumatoid arthritis (RA) is one of the most common autoimmune diseases with a 1% worldwide prevalence (1) and still elusive etiology (2). Epstein-Barr virus (EBV) evidently plays an important role in the pathogenesis of autoimmune diseases by molecular mimicry, bystander activation effect or epitope-spreading (3). However, cause/effect relationship between EBV and RA is still missing.
Objectives: The aims of this study were to explore the association between EBV infection activity, findings of autoantibodies and markers of acute inflammation in patients with two most prevalent diseases of joints, autoimmune RA and degenerative osteoarthritis (OA).
Methods: A blood samples of 89 seropositive RA patients, 64 newly diagnosed (RAa) and 25 with poorly controlled disease (RAb) (unsuccessfully methotrexate treatment ≥ 6 months), and 50 OA were enrolled. The complete anti-EBV serological panel was detected by commercial ELISA kits. Nested-PCR was used for detection of EBV DNA. Clinical data, biochemical and immunological parameters were obtained from electronic medical records. Complete statistical analysis was performed in IBM SPSS ver. 21.

Results: The average age of all patients was 61.54±11.77 years (p=0.007) with predominant female gender in all groups, 81.3% (p=0.139). Anti-EBNA1 IgG antibodies were present in 95%, 92%, and 98% (p=0.474), anti-EBV-CA IgG antibodies in 98%, 60%, and 100% (p<0.001), anti-EBV-CA IgM antibodies in 25%, 40%, and 4% (p=0.008), anti-EBV-EA IgG antibodies in 14.1%, 20%, and 4% (p=0.084), and anti-EBV-EA IgM antibodies in 20%, 16%, and 6% (p=0.094) in RAa, RAb, and OA, respectively. There was statistically significant difference in the titer of anti-EBV-CA IgG and IgM antibodies between all three groups (p=0.001 and p=0.007, respectively). According to serology findings active EBV infection was present in 47.5%, 40%, and 12% in RAa, RAb, and OA, respectively (p<0.001). On the other hand, corresponding to PCR results only, active EBV infection was detected in 6.3%, 0%, and 20% in RAa, RAb, and OA, respectively (p=0.010). There was statistically significant difference in way of detecting active EBV infection based on serology or PCR only (p<0.001). Further analysis showed that over 80% of all RA patients (81% in RAa and 96% in RAb), whilst 48% of OA had elevated values of sedimentation (SE) (p<0.001). C-reactive protein (CRP) was raised in 83% RA (79% in RAa and 100% in RAb) and in 26.5% of OA patients (p<0.001). The majority of all RA patients had elevated rheumatoid factor (RF) and ACPA (84% and 92%) with no difference between RAa and RAb patients (p=0.361 and p=0.203, respectively). Among patients with active EBV infection (based on both serology and PCR results), there was a significantly higher level of anticardiolipin IgG (p=0.012) and anticardiolipin IgM (p=0.009) autoantibodies in RAa patients, while the level of SSA autoantibodies (p=0.024) was higher in RAb patients. On the other side, there was no significant difference in the level of any autoantibody or factors of acute inflammation (SE and CRP) in patients with past EBV infection.
Conclusion: This study demonstrated linkage between an active EBV infection and elevation of some autoantibodies in RA pathogenesis. As EBV DNA was not found only in a group of RA patients under immunosuppressive therapy, it's suggested that EBV clearing from blood could be direct consequence of methotrexate use. Collectively, these findings indicate that determining of EBV activity must be based on both serology and molecular methods in order not to oversee EBV reactivation during follow-up of these patients.

AB1465 BLACK PATIENTS ARE LESS SATISFIED WITH THE PROCESS OF CARE FOLLOWING PRIMARY HIP AND KNEE ARTHROPLASTY: A RETROSPECTIVE STUDY

J. A. Gibbons[1], O. Burke Jr[2], H. Do[3], E. Y. Lai[3], B. Mehta[1,4], L. Bradford[5], M. Parks[6], L. Russell[1,4], A. Bass[1,4], M. Figgie[6], S. Goodman[1,4]. *[1]Hospital for Special Surgery Main Hospital, Medicine, New York, United States of America*; *[2]Rutgers Robert Wood Johnson Medical School, Medicine, New Brunswick, United States of America*; *[3]Hospital for Special Surgery Main Hospital, Clinical Data Core, New York, United States of America*; *[4]Weill Cornell Medicine, Medicine, New York, United States of America*; *[5]Nth Dimensions, Leadership, Chicago, United States of America*; *[6]Hospital for Special Surgery Main Hospital, Surgery, New York, United States of America*

Background: Patients' post-operative satisfaction with their hospital experience is important to patient care, hospital reimbursement, and comparison between hospitals. The Press Ganey (PG) inpatient survey is commonly administered to assess patient satisfaction with the process of care. However, whether patient PG survey scores following primary unilateral hip and knee arthroplasty are associated with a patient's race and socioeconomic status (SES) is unknown.
Objectives: We aimed to determine whether patient PG survey overall assessment scores differ by race and SES.
Methods: We linked data for patients in large institutional hip and knee arthroplasty registries consisting of surgeries from July 2010–February 2012 to their PG survey responses. Patients undergoing primary unilateral surgery of Black or White race who resided in New York, New Jersey, or Connecticut at the time of surgery were included in the analysis. The primary outcome variable was the PG overall assessment score, calculated as the mean of a patient's ratings for the three questions in the "Overall Assessment" section of the PG survey and dichotomized as either completely satisfied (score of 100) or not completely satisfied (score <100). Primary payor was used as a proxy for patient SES. Multivariable logistic regression was performed for the hip and knee cohorts separately to determine if patient race and primary payor were associated with not being completely satisfied, adjusting for age, sex, and American Society of Anesthesiology (ASA) score.
Results: There were 2,516 hip patients and 2,113 knee patients with PG overall assessment scores included in the analyses (Table 1). Black patients were more likely to be not completely satisfied compared to White patients in both cohorts [hip (odds ratio (OR)=1.64; 95% confidence interval (CI): 1.03, 2.61; p=0.04)]; [knee (OR=1.83; 95% CI: 1.16, 2.88; p=0.01). In the hip cohort, patients between 70-79 years old (OR=1.71; 95% CI: 1.09, 2.67; p=0.02) and older than 80 years (OR=2.00; 95% CI: 1.20, 3.32; p<0.01) were more likely to be not completely satisfied. In the knee cohort, patients 50-59 years old (OR=0.56; 95% CI: 0.33, 0.97; p=0.04) and 60-69 years old (OR=0.57; 95% CI: 0.33, 0.96; p=0.03) were less likely to be not completely satisfied compared to patients <50 years old.

Table 1. Likelihood of not being completely satisfied with the process of care (PG score <100)

			Hip Cohort (n = 2,516)			Knee Cohort (n = 2,113)		
Variable	Reference	Category	Odds Ratio	95% CI	p-value	Odds Ratio	95% CI	p-value
Age Group	<50	50-59	1.02	(0.69, 1.50)	0.939	0.56	(0.32, 0.97)	**0.039**
	<50	60-69	1.04	(0.70, 1.54)	0.858	0.57	(0.33, 0.96)	**0.034**
	<50	70-79	1.71	(1.09, 2.67)	**0.019**	0.63	(0.36, 1.11)	0.113
	<50	80+	2.00	(1.20, 3.32)	**0.008**	0.97	(0.53, 1.77)	0.912
Sex	Female	Male	0.84	(0.69, 1.02)	0.082	1.03	(0.83, 1.26)	0.816
Race	White	Black	1.64	(1.03, 2.61)	**0.038**	1.83	(1.16, 2.88)	**0.010**
ASA status	1	2	1.04	(0.70, 1.55)	0.832	1.23	(0.60, 2.51)	0.580
	1	3	1.45	(0.91, 2.29)	0.116	1.36	(0.64, 2.87)	0.419
	1	4	<0.01	(0.00, ***)	0.968	<0.01	(0.00, ***)	0.977
Primary Payor	Medicare	Medicaid	1.35	(0.26, 7.01)	0.718	<0.01	(0.00, ***)	0.983
	Medicare	Other/ Unknown	1.24	(0.94, 1.64)	0.126	0.87	(0.65, 1.17)	0.362
	Medicare	Private	1.13	(0.61, 2.10)	0.688	1.01	(0.57, 1.78)	0.983

ASA = American Society of Anesthesiologist (ASA) physical status classification. PG = Press Ganey. CI = Confidence Interval. *** indicates >999.99. **Bold** indicates p < 0.05

Conclusion: Black patients were less likely to be completely satisfied compared to White patients following total hip and knee arthroplasty. More research is needed to investigate other factors such as perceived staff courtesy and baseline pain and function to understand why these disparities exist.

AB1466 CORRELATION BETWEEN SALES OF CERTAIN BEVERAGES AND GOUT ATTACKS DURING THE COVID-19 CURFEW IN CAMEROON: A HOSPITAL-BASED STUDY

F. Kemta Lekpa[1,2], K. Frank Forex[1], H. Mbatchou[2], A. Jerome[1], H. Namme Luma[2], S. P. Choukem[1,2]. *[1]University of Dschang, Faculty of Medecine and Pharmaceutical Sciences, Dschang, Cameroon*; *[2]Douala General Hospital, Internal Medicine, Douala, Cameroon*

Background: An unusual increase in the number of gout cases was observed in Cameroon in 2020. Was there a link with lifestyle changes during confinement, especially the consumption of certain types of beverages (beer, liquor, water, sweetened drinks)?
Objectives: To determine if there was a correlation with the consumption of different beverages (water, beer, liquor, sweetened drinks).
Methods: Cross-sectional study in the rheumatology consultation of the Douala General Hospital, from January 1 to December 31, 2020, including all patients with a diagnosis of gout (ACR/EULAR criteria of 2015). Pearson's correlation (r) was used to determine the effect of the consumption of the different beverages on the increase in the number of gout cases. A p<0.05 was significant.
Results: We included 1952 patients, including 111 gout cases (107 men; median age: 51 years [36-81]). Compared with the same period in 2018 and 2019, a peak in gout cases was observed between May and November 2020 (Figure 1). In the same period, a positive correlation existed between the number of gout cases and the increase in sales of liquor (r=0.8434, p=0.034) and sweetened beverages (r=0.8436, p=0.034). This correlation was not significant for beer sales (r=0.7980, p=0.057) [Table 1].

Table 1. Correlation between the number of gout cases and sales of different types of drinks

Variables	Correlation coefficient (r)	*p*
Beer	0.7980	0.0571
Liquor	0.8434	0.0349*
Sweetened beverages	0.8436	0.0348*
Water	-0.7569	0.0815

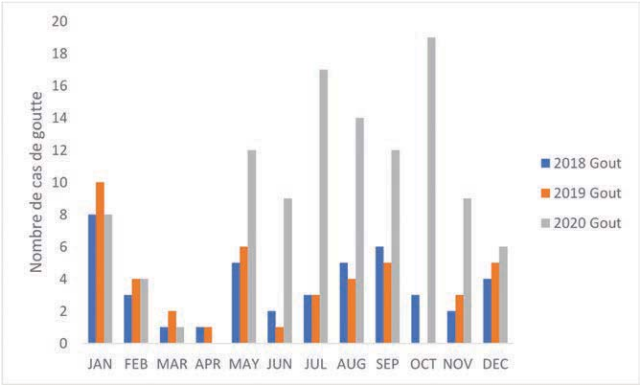

Figure 1. Evolution of Gout cases from 2018 to 2020

The COVID-19 PCR test was negative in all patients.
Conclusion: The real "outbreak" of gout observed during the curfew related to COVID-19 between May and November 2020 was favored by a punctual increase in the consumption of liquors and sweetened drinks.

AB1467 EPIDEMIOLOGICAL DESCRIPTION OF JUVENILE IDIOPATHIC ARTHRITIS FROM A COLOMBIAN POPULATION

M. D. Canola Escobar[1], D. Rodriguez-Ariza[1], L. Aaron-Infante[1], D. Cardona[1], Y. Hernandez-Arenas[1], D. Melo[1], J. Puentes[1], P. Rozo-Tellez[1], V. Usuga-Graciano[1], O. Ariza-Quintero[2]on behalf of Grupo de Autoinmunidad Artmedica-Universidad CES. [1]*Artmedica, Reumatología, Medellín, Colombia*; [2]*Novartis, Área Médica, Medellín, Colombia*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood and presents predominantly with peripheral arthritis; this pathology is divided into subgroups. In Colombia there are few descriptive studies.
Objectives: The objective was to describe the sociodemographic, immunological and clinical characteristics of a cohort of patients with Juvenile Idiopathic Arthritis.
Methods: An observational cross-sectional study was conducted that included 171 JIA patients treated at a specialized rheumatology institution between 2010 and 2021. Univariate analyzes were performed to describe the sociodemographic, immunological, and clinical profile of the population. The epidemiological characteristics were obtained from the review of medical reports.
Results: 171 patients were analyzed. 58.48% were women; with a median age at diagnosis of 12.25 years (IQR=6.55), and a median duration of the disease of 3.71 years (IQR=5.52). According to the classification criteria of the International League of Associations for Rheumatism (ILAR), the most frequent were enthesitis related to JIA present in 61 patients (35.67%), oligoarticular 27 (15.79%), negative polyarticular rheumatoid factor (14.62%) and positive polyarticular rheumatoid factor (14.04%). JIA-enthesitis related was 17,85% ANAs positive, 16,66% rheumatoid factor positive and HLA-B27 en 22,72%. In JIA oligoarticular the auto-antibodies ANAS, FR was present in 26,32% and 16,66%. The JIA-polyarticular rheumatoid factor positive was positive for ANA in 76.47% and AntiCCP in 88.88%. JIA-polyarticular rheumatoid factor negative was positive for ANAs (40%) and AntiCCP (10%).
Conclusion: The epidemiological description of JIA in the Colombian population is similar to the current one in other populations, but we found differences in the subtypes of juvenile idiopathic arthritis and in the presence of autoantibodies. This is the first step to discover the characteristics of this autoimmune disease in this population.

AB1468 ALL-CAUSE MORTALITY IN PATIENTS WITH PALINDROMIC RHEUMATISM: A POPULATION-BASED COHORT STUDY

H. H. Chen[1], D. Y. Chen[2]. [1]*Taichung Veterans General Hospital, Department of Internal Medicine, Taichung, Taiwan, Republic of China*; [2]*China Medical University Hospital, Center of Allergy, Immunology and Rheumatology, Taichung, Taiwan, Republic of China*

Background: Palindromic rheumatism (PR), is a clinical syndrome characterized by the intermittent acute arthritis or peri-arthritis involving one or several regions. It presents with pain with or without redness or swelling, lasting from a few hours to days with variable symptom-free periods. Different from rheumatoid arthritis (RA), PR does not lead to residual joint destruction. A recent study showed that RA patients had a mean loss of life expectancy of about 5 years [1]. However, whether all-cause mortality rate in PR patients differs from that in individuals without PR was still known.
Objectives: To compare the all-cause mortality rate between PR patients and non-PR individuals.
Methods: Usint a two-million representative cohort from the 2000-2018 Taiwan's National Health Insurance Research Database, we identified 2,791 incident adult (aged ≥ 20 years) PR patients. Matching for sex, age and year of index date at a 1:40 ratio, we selected 111,640 non-PR individuals for comparison. Then using the greedy algorithm, we further selected another comparison group of 5,582 non-PR individuals by propensity score (PS) matching for Charson comorbidity index (CCI) at a 1:2 ratio. Using the Cox proportional hazard model, we examined the risk of all-cause mortality in PR patients shown as adjusted hazard ratios (aHRs) with 95% confidence intervals (CIs). Potential confounders included age, sex, CCI, a history of immune mediated inflammatory disease (IMID) including systemic lupus erythematosus erythematosus (SLE), RA, idiopathic inflammatory myopathies (IIM, including dermatomyositis and polymyositis), Sjögren's syndrome (SS), inflammatory bowel disease (IBD), psoriasis, and medication use including corticosteroid (0, 1-5, >5 mg/day prednisolone equivalent dose), methotrexate, sulfasalazine, leflunomide, hydroxychloroquine and nonsteroidal anti-inflammatory drugs within one year before the index date.
Results: In the 1:2 PS-matched popultion, the mean age was 48.4 years and female to male ratio was 1.54 in the PR group and non-PR group. Amon 2,791 PR patients, 226 (8.10%) died during a mean follow-up period of 8.29 years; while 11,958 (10.71%) of 111,640 non-PR individuals expired during a mean follow-up period of 8.13 years. The all-cause mortality rates in PR patients and non-PR individuals were 976.83 per 10^5 years and 1,317.93 per 10^5 years, respectively (incidence rate ratio, 0.74; 95% CI, 0.65-0.85, $p < 0.001$). After adjusting for potential confounders, the risk of all-cause mortality was significantly lower in PR patients compared with non-PR individuals (aHR, 0.70; 95% CI, 0.59–0.82). In the subgroup of subjects without IMID, the relative risk of all-cause mortality in PR patients compared with non-PR individuals was 0.68 (0.58–0.80), $p < 0.001$. In the subgroup of subjects with a history of any IMID, the relative mortality risk in PR patients compared with the non-PR group was 0.64 (0.30–1.34), $p = 0.236$. The top 3 causes of mortality with their proportions in the PR group (n = 226) were neoplasms (28.3%), diseases of circulatory system (23.5%) and diseases of the respiratory system (11.5%). While the top 3 causes of mortality in the non-PR group (n = 11,958) was neoplasms (32.3%), diseases of circulatory system (21.5%) and disease of respiratory system (9.6%).

	1:40 age and sex-matched population		1:2 age, sex and CCI-matched population	
	HR (95% C.I.)	P value	HR (95% C.I.)	P value
PR (ref: non-PR)	0.61 (0.57–0.74)	<0.001	0.70 (0.59–0.82)	<0.001

Conclusion: This population-based cohort study showed that the all-cause mortaltiy rate in PR patients was lower than that in non-PR individuals, in particular in subjects without a history of IMIDs.

Validation of outcome measures and biomarkers___

AB1469 SPANISH TRANSLATION AND CROSS-CULTURAL ADAPTATION OF THE MSQUASH

D. Benavent[1], A. Jochems[2], D. Pascual-Salcedo[2], G. Jochems[3], C. Plasencia[1], S. Ramiro[4,5], S. Arends[6], A. Spoorenberg[6], A. Balsa[1], V. Navarro-Compán[1]. *[1]Hospital Universitario La Paz, IdiPaz, Department of Rheumatology, Madrid, Spain*; *[2]Hospital Universitario La Paz, IdiPaz, Immuno-Rheumatology Group, Madrid, Spain*; *[3]Promega Biotech Ibérica, -, Madrid, Spain*; *[4]Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; *[5]Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands*; *[6]University Medical Center Groningen, University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Regular physical activity is recommended for all patients in the ASAS/EULAR recommendations for the management of axial spondyloarthritis (axSpA). However, there is a lack of outcome measures that assess the amount and type of physical activity in patients with axSpA. For this matter, the modified Short QUestionnaire to Assess Health enhancing physical activity (mSQUASH) was developed and validated, originally in Dutch1.

Objectives: To translate and cross-culturally adapt the mSQUASH into Spanish and to test the equivalence of the translated version in patients with axSpA.

Methods: The mSQUASH was translated into Spanish and then back-translated into Dutch, following forward-backward procedure as described by Beaton[2] (Figure 1). Two bi-lingual translators (native speakers for European Spanish) produced independent forward translations of the item content, response options, and instructions of the mSQUASH into Spanish. Both versions were harmonized in a meeting among the Spanish translators, a methodologist and a rheumatologist into a consensual version. Another translator (native speaker for Dutch), blinded for the original version, back translated the synthesized version into Dutch. An expert committee, including all translators, one methodologist and a rheumatologist, reached consensus on discrepancies, ensuring equivalence between the Dutch and Spanish versions, and developed a pre-final version of the Spanish mSQUASH. The field test with cognitive debriefing involved a sample of 10 patients with axSpA covering the full spectrum of the disease -radiographic axSpA (r-axSpA) and non-radiographic axSpA (nr-axSpA)- with different gender, age, disease duration, and educational background. Each patient was interviewed to check understandability, interpretation and cultural relevance of the translation.

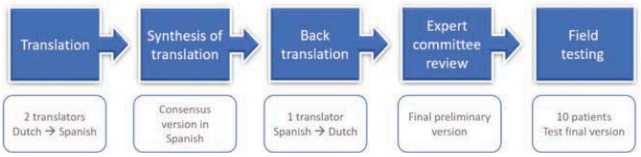

Figure 1. Cross-cultural adaptation of the mSQUASH

Results: The translation process of the mSQUASH was completed without major complications following the forward-backward procedure. The first translation needed several iterations due to small discrepancies in the wording. Back-translation was performed without difficulties, and the expert committee agreed upon a final version of the questionnaire. A total of 10 patients with axSpA participated in the field test (Table 1). Seven were male, mean age (SD) was 38.9 (14.4) years; 6 patients had r-axSpA, 9 were HLA-B27+. Cognitive debriefing showed the Spanish questionnaire to be, relevant, understandable and comprehensive. The preliminary version was accepted with minor modifications. As a result of the interviews, minor spelling errors were corrected, and the wording of the response categories was homogenized ("despacio/ligero"). Besides, the term "colegio"- translated literally from the Dutch "school"- was found not comprehensive enough to reflect possibilities on education (i.e. it does not include university), so it was adapted to "el lugar de estudio".

Conclusion: The resulting Spanish version of the mSQUASH showed good linguistic and face validity according to the field test, revealing potential for use in both clinical practice and research settings. In order to conclude the cross-cultural adaptation of the mSQUASH into Spanish, the next step is the assessment of psychometric properties of the Spanish version.

AB1470 DOES TESTING FOR SAA IS MORE BENEFICIAL THAN CRP FOR THE FOLLOW-UP OF PATIENTS WITH FMF?

M. Oztas[1], O. Selvi[1], B. Ergezen[1], H. Ozdogan[1], S. Ugurlu[1]. *[1]İstanbul University-Cerrahpasa, Department of Rheumatology, İstanbul, Turkey*

Background: In order to follow subclinical inflammation and adjust the therapy for an optimal disease control, clinicians seek for readily accessible, affordable and reproducible markers. C reactive protein (CRP) is widely used for this purpose. Some suggest that the Serum Amyloid A (SAA) is preferable to CRP as a biomarker of inflammation in FMF patients[1].

Objectives: To evaluate and to compare the sensitivity of the serum SAA and CRP levels in FMF patients.

Methods: Serum SAA and CRP levels were measured in 45 patients. 153 measurements from 28 patients with M694V homozygous mutation and 74 measurements from 17 patients with M694V heterozygous mutation were obtained during a mean follow-up of 1 year. For the analysis, the folds of normal CRP and SAA values were used for correlation. Serum levels of the given markers were measured with nephelometric kits (normal CRP levels < 5 mg/L and SAA levels < 6,8 mg/L). More than one and half fold increasement of CRP and SAA was defined as an active inflammation. The correlation coefficients and their significance were calculated using the Spearman test.

Results: Except a patient, all patients in whole cohort were on prophylactic colchicine. Among 28 patients with M694V homozygous mutation, a patient with adalimumab, 12 (42,8%) patients with anti-IL-1 regimens. Of the 17 patients with M694V heterozygous mutation, four (23,5%) were under anti-IL-1 treatment. There was a total of 227 measurements of CRP and SAA from 45 patients. Twenty-five (11%) measurements were obtained during the attack period in and the remaining 202 measurements were collected in attack free period. Figure 1 demonstrates the correlation between CRP and SAA levels (r=0.8, p< 0,001). Both acute phase reactants were increased in 72 (31,7%) measurements, while in 13 (5,7%) CRP level was high but SAA level was normal and in 31 (13,6%) SAA level was high however CRP level was within the normal limits. The vast majority (30:31) of high SAA with normal CRP levels were observed in patients with M694V homozgous mutation. The mean increase in CRP of the entire cohort was 2,06 ± 3,34-fold, whereas mean increase in SAA was 6,23 ± 15,04-fold of the normal levels.

Table 1. Patients' characteristics

#	Gender	Age	Working status	Education	axSpA subtype	Disease duration	HLA-B27	Drug	BASDAI
1	Male	63	Working	University	r-axSpA	35 y	+	NSAIDs	2.3
2	Male	24	Student	Secondary	r-axSpA	6 y	+	NSAIDs	0
3	Male	37	Working	University	r-axSpA	5 y	+	ADA	2.5
4	Male	66	Retired	University	r-axSpA	23 y	+	IFN	3.1
5	Male	29	Working	University	r-axSpA	11 y	+	ADA	0
6	Female	26	Working	University	nr-axSpA	2 y	+	NSAIDs	-
7	Male	24	Student	University	nr-axSpA	1 y	+	ETA	4.5
8	Male	35	Working	University	r-axSpA	12 y	+	GOL	0
9	Female	40	Working	Secondary	nr-axSpA	4 y	+	NSAIDs	-
10	Female	45	Unemployed	Primary	nr-axSpA	9 y	-	GOL	8.2

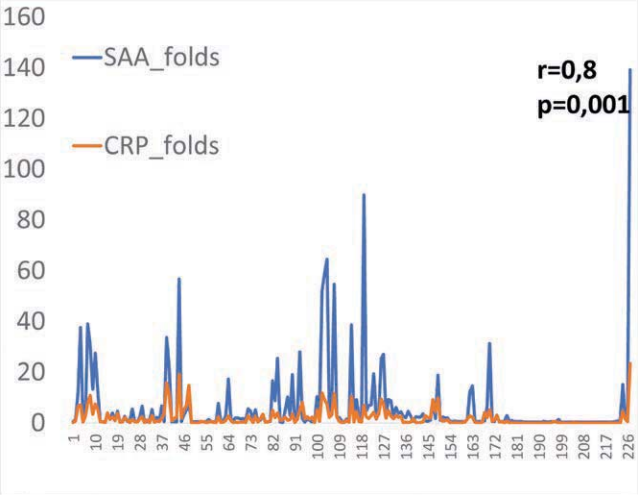

Figure 1. The folds of the serum CRP and SAA levels in the entire cohort.

Conclusion: According to our results, serial testing of SAA does not provide any additional advantages over CRP. Readily accessible and affordable bio-marker CRP seems to be sufficient for follow-up of patients with FMF.

AB1471 EVALUATION OF CXCL13 SERUM LEVELS IN A COHORT OF PATIENTS WITH PERIPHERAL PSORIATIC ARTHRITIS IN COMPARISON WITH RHEUMATOID ARTHRITIS.

S. Piantoni[1], F. Angeli[1], F. Regola[1], L. Valtellini[1], F. Franceschini[1], P. Airò[1]. [1]*Rheumatology and Clinical Immunology Unit, ASST Spedali Civili and University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy*

Background: The research of circulating biomarkers in the field of chronic arthritis is still an unmet need, especially for the subgroup of seronegative arthritis [e.g., negative for anti-citrullinated peptides autoantibodies (ACPA) and/or rheumatoid factors (RF)]. In fact, in this clinical subset, there is a lack of soluble molecules which could help for a diagnostic or prognostic purpose, and the differential diagnosis between psoriatic arthritis (PsA) and seronegative rheumatoid arthritis (RA) is still a challenge. C-X-C motif chemokine 13 (CXCL13) is one of the most promising biomarkers recently identified, because of its association with active synovitis (1) and with a poor prognosis in RA (2), although there are still inadequate results to justify its routine use. No data are available of the determination of CXCL13 serum levels in PsA.

Objectives: To analyze CXCL13 serum levels in a cohort of PsA patients with a history of peripheral involvement in comparison with RA.

Methods: Cross sectional analysis of consecutive patients with peripheral PsA [n:81; male/female=44/37; median age (25°-75° percentile)=54 (46-62) years; 28-joint Disease Activity Score-C Reactive Protein (CRP-DAS28)=1.9 (1.6-2.5); active psoriasis=43%; DAPSA (Disease Activity in PSoriatic Arthritis) score=8 (3-14)] and RA [n:143; male/female=30/113; age =62 (50-70) years; seropositive=67%; CRP-DAS28=2.1 (1.5-2.8)] was performed. 100 sex and age-matched healthy controls (HC) were enrolled. CXCL13 serum levels were assessed through commercial ELISA test (R&D).

Results: CXCL13 serum levels were higher in all the subgroups of patients [PsA: 50.9 (34.5-80.2) pg/mL, p<0.01; RA: 77.2 (52.9-107.7) pg/mL, p<0.01; RA ACPA+: 77.7 (55.9-110.7) pg/mL, p<0.01; RA ACPA-: 69.5 (49.3-104) pg/mL, p<0.01] than in HC (22.3 (17.7-33.8) pg/mL). No significant differences were found among RA patients according with their seropositivity (p=0.378). CXCL13 serum levels were lower in PsA patients than in RA patients, independently from their seropositivity [vs RA ACPA+, p<0.01; vs RA ACPA-, p=0.012]. CXCL13 serum levels were positively correlated with CRP in PsA patients (r=0.30; p=0.008), but not with DAPSA score.

Conclusion: These results confirm the value of CXCL13 as a biomarker in the field of chronic arthritis. Its higher levels in seronegative RA than in PsA suggests its possible value in the differential diagnosis of these two subsets of arthritis.

AB1472 TRANSLATION AND CROSS-CULTURAL ADAPTATION OF THE CORS INTO SPANISH

D. Benavent[1], A. Jochems[2], D. Pascual-Salcedo[2], G. Jochems[3], C. Plasencia[1], S. Ramiro[4,5], W. Van Lankveld[6], A. Balsa[1], V. Navarro-Compán[1]. [1]*Hospital Universitario La Paz, IdiPaz, Department of Rheumatology, Madrid, Spain*; [2]*Hospital Universitario La Paz, IdiPaz, Immuno-Rheumatology Group, Madrid, Spain*; [3]*Promega Biotech Ibérica, -, Madrid, Spain*; [4]*Leiden University Medical Center, Department of Rheumatology, Leiden, Netherlands*; [5]*Zuyderland Medical Center, Department of Rheumatology, Heerlen, Netherlands*; [6]*HAN Unitversity of Applied Sciences, Institute of Paramedic Studies, Nijmegen, Netherlands*

Background: Rheumatic diseases substantially affect the lives of patients, with complex associations between disease severity and self-perceived health status. In this regard, the Coping with Rheumatic Stressors (CORS) questionnaire was developed to measure how patients with rheumatoid arthritis cope with stressors such as pain or dependence. There is no validated instrument to measure coping in axial spondyloarthritis (axSpA) and therefore the adaptation of the CORS would be of great value.

Objectives: To cross-culturally adapt the CORS into Spanish and to test the conceptual equivalence of the translated version in patients with axSpA.

Methods: A translation of the CORS into Spanish was performed, followed by a back-translation into Dutch, following forward-backward procedure as described by Beaton[1](Figure 1). Two bi-lingual translators (native speakers for Spanish), one of them informed of the content of the questionnaire and the other not informed, produced independent forward translations of the item content, response options, and instructions of the CORS into Spanish. Both versions were harmonized in a consensual version. Another translator (native speaker for Dutch), not informed of the concepts used in the questionnaire, back translated the synthesized version into Dutch. An expert committee including all translators, one methodologist and a rheumatologist, held a meeting and reached consensus on discrepancies to develop a pre-final version of the Spanish CORS. The field test with cognitive debriefing involved a sample of 10 patients with axSpA covering the full spectrum of the disease and with different sociodemographic backgrounds.

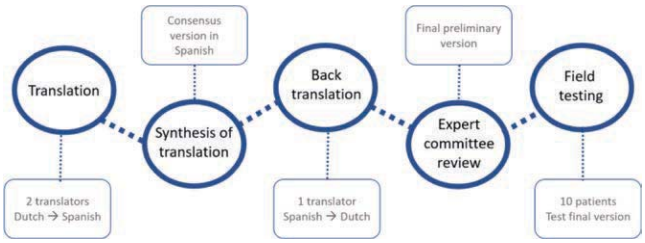

Figure 1. Cross-cultural adaptation of the CORS

Results: The translation process of the CORS was completed following the forward-backward procedure, after discussion of the discrepancies throughout the process. The first translation was done without major complications. However, several discrepancies appeared in the back-translation, in which there were minor modifications in the wording in one response option ("muchas veces" to "muy a menudo") and 15 questionnaire items. As an example, "Ik ga de deur uit", literally meaning "I go out by the door", was initially translated as such ("salgo por la puerta"); however, it conceptually represents "I go away", and it was adapted like this ("me voy a la calle"). Thus, a pre-final consensus version of the CORS was agreed by the expert committee. This pre-final version was field tested in 10 patients with axSpA: mean age (SD) was 38.9 (14.4) years, 7 patients were male, 6 had radiographic axSpA, and 9 were HLA-B27+. The Spanish questionnaire appeared clear and understandable to all patients. However, some minor modifications were proposed in some items (Table 1). As a result of the cognitive debriefing, two changes were implemented (one instruction and one item), whereas two other suggestions did not lead to any change due to minor wording discrepancies with similar conceptual equivalence. The final version of the Spanish CORS is shown at shorturl.at/cimC6.

Table 1. Cognitive debriefing queries and decisions from the expert committee

Original Dutch item	Spanish translation pre-final	# Patient queries	Queries	Final version
(….) aan te geven hoe vaak u het beschreven gedrag uitvoert.	*(…) indique cuán a menudo usted ha llevado a cabo dicho comportamiento.*	1	Literal discrepancies	*(…) indique la frecuencia con que usted ha tenido dicho comportamiento.*
Ik rust op tijd uit	*Me voy a tiempo a descansar*	1	Literal discrepancies	No changes
Ik probeer er het beste van te maken	*Intento aprovechar al máximo*	1	Literal discrepancies	No changes
Ik houd rekening met anderen	*Tengo en cuenta a los demás*	2	Meaning doubts	*Tengo en consideración a los que me ayudan/ cuidan*

Conclusion: The Spanish version of the CORS showed good cross-cultural validity and good face validity in patients with axSpA according to the field test. Before the Spanish CORS is implemented, further validation is in progress to test the psychometric properties of the instrument.

AB1473

EFFICACY RESPONSES ACROSS DISEASE SEVERITY AND TREATMENT HISTORY SUBGROUPS OF PATIENTS WITH MODERATE TO SEVERE PLAQUE PSORIASIS TREATED WITH GUSELKUMAB: POOLED RESULTS FROM VOYAGE-1 AND VOYAGE-2 THROUGH 5 YEARS

K. Gordon[1], J. F. Merola[2], P. Foley[3], O. Choi[4], D. Chan[4], M. Miller[5], Y. You[6], Y. K. Shen[6], Y. W. Yang[7], A. Blauvelt[8]. *[1]Medical College of Wisconsin, Department of Dermatology, Milwaukee, WI, United States of America*; *[2]Harvard Medical School, Brigham and Women's Hospital, Department of Dermatology, Boston, MA, United States of America*; *[3]The University of Melbourne, St. Vincent's Hospital Melbourne and Probity Medical Research, Skin Health Institute, Department of Dermatology, Carlton, VIC, Australia*; *[4]Janssen Scientific Affairs, LLC, Department of Dermatology, Horsham, PA, United States of America*; *[5]Janssen Research & Development, LLC, Department of Immunology, Spring House, PA, United States of America*; *[6]Janssen Research & Development, LLC, Department of Clinical Biostatistics, Spring House, PA, United States of America*; *[7]Immunology Global Medical Affairs, Janssen Pharmaceutical Companies of Johnson & Johnson, Department of Dermatology, Horsham, PA, United States of America*; *[8]Oregon Medical Research Center, Department of Dermatology, Portland, OR, United States of America*

Background: The VOYAGE-1 and VOYAGE-2 phase 3 studies evaluated efficacy and safety of guselkumab (GUS) in patients with moderate-to-severe plaque psoriasis.

Objectives: To assess the five-year efficacy of GUS by baseline disease characteristics and treatment history.

Methods: This study evaluated 1829 patients randomized to GUS, placebo (PBO)→GUS, and adalimumab (ADA) →GUS from the VOYAGE-1 and VOYAGE-2 trials. All patients received open-label GUS 100 mg every 8 weeks (Q8W) during Week (W) 52 to W252 in VOYAGE-1 and during W76 to W252 in VOYAGE-2. The proportions of combined GUS patients (including PBO→GUS and ADA→GUS) achieving Investigator's Global Assessment of cleared or minimal (IGA-0/1) and Psoriasis Area and Severity Index (PASI) 90 response were evaluated from W100 to W252 by baseline PASI (<20/≥20) and IGA (<4/=4) scores, body surface area (BSA; <20%/≥20%), and prior psoriasis treatments. Analysis was performed using observed data after applying treatment failure rules.

Results: At W252, proportions of combined GUS patients achieving IGA 0/1 or PASI 90, respectively, were comparable or numerically greater for patients with baseline PASI < 20 (85.4%; 81.1%) vs PASI ≥ 20 (81.4%; 83.8%); IGA < 4 (85.1%; 82.7%) vs IGA = 4 (78.9%; 81.1%); BSA < 20% (85.1%; 82.7%) vs BSA ≥ 20% (82.6%; 82.0%); no prior phototherapy (83.3%; 84.0%) vs prior phototherapy (83.8%; 81.1%); no prior non-biologic systemic therapy (84.5%; 83.0%) vs prior non-biologic systemic therapy (83.2%; 82.0%); and no prior biologics (85.3%; 83.8%) vs prior biologics (76.7%; 76.3%). This trend was consistent at each timepoint evaluated from W100 to W252.

Conclusion: This analysis demonstrated that the high degree of efficacy of GUS treatment is durable through 5 years among broad subpopulations of patients with varying disease severity characteristics and previous psoriasis treatments.

AB1474

LIPIDOMIC PROFILING IDENTIFIES SERUM LIPIDS ASSOCIATED WITH PERSISTENT MULTISITE MUSCULOSKELETAL PAIN

C. Ma[1], M. Liu[2], J. Tian[1], G. Zhai[2], F. Cicuttini[3], Y. Schooneveldt[4], P. Meikle[4], G. Jones[1], F. Pan[1]. *[1]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*; *[2]Memorial University of Newfoundland, Faculty of Medicine, St. John's, Canada*; *[3]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*; *[4]Baker Heart and Diabetes Institute, Metabolomics, Melbourne, Australia*

Background: Lipid mediators have been suggested to have a role in pain sensitivity and response; however, longitudinal data on lipid metabolites and persistent multisite musculoskeletal pain (MSMP) are lacking.

Objectives: This study was to identify lipid metabolic markers for persistent MSMP.

Methods: Lipidomic profiling of 807 lipid species was performed on serum samples of 536 participants from a cohort study. MSMP was measured by a questionnaire and defined as painful sites ≥4. Persistent MSMP was defined as having MSMP at every visit. Logistic regression was used with adjustment for potential confounders. The Benjamini Hochberg method was used to control for multiple testing.

Results: A total of 530 samples with 807 lipid metabolites passed quality control. Mean age at baseline was 61.54±6.57 years and 50% were females. One hundred and twelve (21%) of the participants had persistent MSMP. Persistent MSMP was significantly associated with lower levels of monohexosylceramide (HexCer)(d18:1/22:0 and d18:1/24:0), acylcarnitine (AC)(26:0) and lysophosphatidylcholine (LPC)(18:1 [sn1], 18:2 [sn1], 18:2 [sn2], and 15-MHDA[sn1]

[104_sn1]) after controlling for multiple testing. After adjustment for age, sex, body mass index, diabetes status, and physical activity, HexCer(d18:1/22:0 and d18:1/24:0) and LPC(18:1 [sn1] and 15-MHDA [sn1] [104_sn1]) were significantly associated with persistent MSMP [Odds Ratio (OR) ranging from 0.24 - 0.32]. Two lipid classes -- HexCer and LPC were negatively associated with persistent MSMP after adjustment for covariates (OR=0.19 and 0.21, respectively).

Conclusion: This study identified four novel lipid signatures of persistent MSMP, suggesting that lipid metabolism is involved in the pathogenesis of persistent pain.

Loginov Moscow Clinical Research and Practical Center, Moscow Healthcare Department, Moscow, Russian Federation, Laboratory of Clinical Immunology, Moscow, Russian Federation*; *[3]A.S. Loginov Moscow Clinical Research and Practical Center, Moscow Healthcare Department, Moscow, Russian Federation, Rheumatology, Moscow, Russian Federation*; *[4]A.S. Loginov Moscow Clinical Research and Practical Center, Moscow Healthcare Department, Moscow, Russian Federation, Rheumatology, Moscow, Russian Federation*

Background: Ankylosing spondylitis (AS) is an immune-mediated inflammatory disease of the musculoskeletal system, that is often accompanied with a subclinical intestinal inflammation. Inflammatory bowel diseases (IBD), including, Crohn's disease (CD) and ulcerative colitis (UC), are the most frequent extra-articular manifestation in patients (pts) with AS. Several autoantibodies and antimicrobial antibodies are used as additional non-invasive serological markers for the diagnosis of CD and UC [1]. The evaluation of IBD-associated antibodies in AS pts provided conflicting results [2, 3].

Objectives: The aim of the study was to determine the serum levels of IBD-specific antibodies in AS.

Methods: We studied 51 pts with AS fulfilled modified New York criteria (1984); (40M/11F); median and interquartile range (25th—75th percentile) of age 44.0; 34.0-49.0 years; disease duration 12.0; 5.0-20.0 years; BASDAI - 5.3; 4.5-6.4; ASDAS ESR - 3.6; 3.0-4.4; ASDAS CRP - 3.7; 2.8-4.5; 40% HLA-27 positive. In 22% of pts with AS, IBD (CD and UC) were diagnosed. The control group included 44 healthy donors (HC). Atypical perinuclear anti-neutrophil cytoplasmic antibodies (pANCA) were detected using indirect immunofluorescence. The serum levels of IgA/IgG antibodies to *Saccharomyces cerevisiae* (ASCA), IgA/IgG antibodies to glycoprotein 2 (GP2), IgG antibodies to cathepsin G, lactoferrin, elastase and bactericidal permeability-increasing protein (BPI) were detected by ELISA.

Results: AS pts without signs of IBD and AS with IBD (AS/IBD) pts had significantly higher serum levels of IgA ASCA, IgA anti-GP2, anti-elastase antibodies than HC (4.5; 2.6-6.4 U/ml and 4.9; 3.7-7.3 U/ml vs 1.9; 0.6-2.6 U/ml, p=0.0008, p=0.001; 1.2; 0.8-5.5 U/ml and 1.2; 0.9-11.8 U/ml vs 0.7; 0.6-1.3 U/ml, p=0.007, p=0.02; 8.2; 5.9-9.9 U/ml and 9.1; 8.5-10.5 U/ml vs 5.6; 4.7-8.3 U/ml, p=0.01, p=0.003). The median concentration of anti-cathepsin G antibodies was greater for AS/IBD pts than AS pts (0.8; 0.5-1.0 U/ml vs 0.4; 0.3-0.6 U/ml, p=0.02). In AS and AS/IBD, the occurrence of anti-elastase antibodies (23.0%, 33.0%) was higher than for HC (0%, p=0.05, p=0.01). The positivity rate of IgA anti-GP2 in AS/IBD exceeded that in HC (27.0% vs 0%, p=0.025). AS/IBD pts demonstrated a higher prevalence of pANCA (36.0%), and anti-BPI antibodies (36.0%), when compared to AS alone (4.8%, p=0.005, and 8.0%, p=0.02) and HC (0%, p=0.0001, and 0%, p=0.008).

Conclusion: Our findings indicate that elevated serum levels of IgA ASCA, IgA anti-GP2, anti-elastase antibodies in AS did not differ from those in AS/IBD and may serve as potential biomarkers for predicting intestinal inflammation at an early stage. For AS/IBD, the most useful diagnostic markers were atypical pANCA, IgA ASCA, IgA anti-GP2, anti-elastase and anti-BPI antibodies.

AB1477 MEDIAN 0-10 PATIENT GLOBAL ASSESSMENT WAS 2.5-5 POINTS HIGHER IN INFLAMMATORY ARTHRITIS PATIENTS POSITIVE VS NEGATIVE FOR FAST4 (FIBROMYALGIA ASSESSMENT SCREENING TOOL) AND/OR MSD2 (MDHAQ DEPRESSION SCREEN): 2 EASILY-SCORED MULTIDIMENSIONAL HEALTH ASSESSMENT QUESTIONNAIRE (MDHAQ) INDICES

T. Li[1], K. Gibson[2,3], T. Pincus[4], J. Schmukler[4,5], R. Morlà[6], G. Luta[1]. *[1]Georgetown University, Department of Biostatistics, Bioinformatics and Biomathematics, Washington, DC, United States of America*; *[2]UNSW Sydney, Department of Rheumatology, Liverpool Hospital, Ingham Research Institute, Sydney, Australia*; *[3]Eli Lilly Pty Ltd, Rheumatology, Sydney, Australia*; *[4]Rush University Medical Center, School of Medicine, Chicago, United States of America*; *[5]Mount Sinai Hospital, Department of Rheumatology, Chicago, United States of America*; *[6]August Pi i Sunyer Biomedical Research Institute, Department of Rheumatology, Hospital Clínic de Barcelona, Barcelona, Spain*

Background: Patient global assessment (PATGL) is included in DAS28, CDAI, ASDAS, DAPSA, and other indices to assess rheumatoid arthritis (RA) or spondyloarthropathy (SpA). PATGL reflects inflammatory activity in many patients, but may be elevated by comorbid fibromyalgia (FM) and/or depression (Dep), which are often unrecognized in others, complicating interpretation and use in treat-to-target. A 2-page multidimensional health assessment questionnaire (MDHAQ) includes PATGL and two easily scored cumulative indices, FAST4 (0-4 FM assessment screening tool) and MDS2 (0-2 MDHAQ Dep screen), which agree more than 80% with reference 2011 revised FM criteria, HADS-D and PHQ-9,[1-3] and may clarify interpretation of high PATGL and index scores, particularly in busy clinical settings.

Objectives: Analysis of PATGL in patients with RA or SpA according to MDHAQ FAST4 and/or MDS2 positivity (+) or negativity (-).

Methods: MDHAQ was completed at a routine care visit at 3 sites in Australia, Spain, and USA. Medians and interquartile ranges (IQRs) for PATGL were computed for RA and SpA, according to FAST4 + or – and/or MDS2 + or -. Differences between medians of PATGL with 95% confidence intervals (CIs) for FAST4 and/or MDS2 were estimated from median regression models that included FAST4 and MDS2 for each setting, and setting for pooled analyses.

Results: Among 393 RA and 175 SpA patients, 23.0%-32.7% were FAST4+ and 29.4%-36.7% MDS2+, with 41.1% positive for either FAST4 or MDS2 (data not shown). PATGL medians were 4.8-5.0 in all RA and 3.0-6.0 in SpA, 2.0-3.0 in FAST4-/MDS2-, 5.5-6.0 in FAST4-/MDS2+, 7.0-7.5 in FAST4+/MDS2-, and 7.0-8.0

Table 1. Median scores and interquartile ranges for PATGL according to positive or negative FAST4 and/or MDS2

Primary ICD10 diagnosis	Total	FAST4 NEG MDS2 NEG	FAST4 NEG MDS2 POS	FAST4 POS MDS2 NEG	FAST4 POS MDS2 POS	Adjusted median difference (95% CI) (FAST4 POS – FAST4 NEG)	Adjusted median difference (95% CI) (MDS2 POS – MDS2 NEG)

Spain	n=169	n=90 (53.3%)	n=27 (16.0%)	n=18 (10.7%)	n=34 (20.1%)		
RA	101	3.0 (1.0, 4.5)	5.5 (3.6, 6.8)	6.0 (5.5, 7.0)	8.5 (8.0, 8.5)	3.0 (2.1, 3.9)	2.5 (1.7, 3.3)
SpA	68	3.0 (0.8, 5.0)	6.5 (6.0, 7.0)	7.3 (6.5, 8.0)	7.5 (6.5, 10.0)	3.0 (1.1, 4.9)	2.5 (0.9, 4.1)
USA	n=92	n=60 (65.2%)	n=9 (9.8%)	n=10 (10.9%)	n=13 (14.1%)		
RA	72	3.0 (1.0, 6.0)	6.0 (3.5, 7.0)	8.5 (8.0, 9.5)	7.0 (7.0, 9.0)	5.0 (2.7, 7.3)	1.0 (-1.3, 3.3)
SpA	20	2.0 (1.0, 4.5)	2.0 (1.0, 3.0)	7.0 (7.0, 7.0)*	8.5 (5.5, 10.0)	5.0 (0.5,10.5)	0 (-3.3, 3.3)*

NEG = negative, POS = positive, NA=Not available (No patients or the adjusted median differences cannot be estimated due to the small number of patients), *=Only one patient in category.

in FAST4+/MDS2+ patients, similar in RA and SpA at 3 settings in 3 continents (Table 1). Adjusted median differences were 3.0–3.5 for FAST4 + vs - (twice the level for FAST4 -, MDS2 -) and 2.0–2.5 for MDS2 + vs - groups (Table 1).

Conclusion: Median 0-10 PATGL was 2-3-fold higher in 41.1% of RA or SpA patients with positive MDHAQ FM and/or DEP screening indices vs 59% with 2 negative indices. Differences were greater according to FM than Dep. MDHAQ may clarify interpretation of PATGL and indices, including in treat–to–target, using a single, brief, feasible questionnaire in research and busy clinical settings.

AB1478 RELIABILITY AND CONTENT VALIDITY OF THE PORTUGUESE VERSION OF THE COMMISSIONING FOR QUALITY IN RHEUMATOID ARTHRITIS PATIENT-REPORTED EXPERIENCE MEASURE (CQRA-PREM): PRELIMINARY RESULTS

D. Santos Oliveira[1,2,3], R. Rainho[3], M. Bernardes[1,3], C. Vaz[1,3], L. Costa[1], J. A. Fonseca[2,4,5,6], C. Jácome[2,4]. *[1]Centro Hospitalar Universitário de São João, Rheumatology Department, Porto, Portugal*; *[2]Faculty of Medicine, University of Porto, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*; *[3]Faculty of Medicine, University of Porto, Department of Medicine, Porto, Portugal*; *[4]Faculty of Medicine, University of Porto, Department of Community Medicine, Information and Health Decision Sciences (MEDCIDS), Porto, Portugal*; *[5]Instituto and Hospital CUF, Allergy Unit, Porto, Portugal*; *[6]MEDIDA, Medicina, Educação, Investigação, Desenvolvimento e Avaliação, Porto, Portugal*

Background: The CQRA-PREM has been developed in the United Kingdom to evaluate the perspective of patients with rheumatoid arthritis (RA) about the care provided in rheumatology units of the National Health Service (1). This PREM might also be feasible to be used in Portugal, yet an adaptation and validation process is needed.

Objectives: We aimed to translate and cross-cultural adapt CQRA-PREM to Portuguese and evaluate the reliability and content validity of this version.

Methods: A study combining qualitative and quantitative approaches was conducted with patients with RA from a single rheumatology center. The translation and cultural adaptation of Portuguese CQRA-PREM included initial translation and cultural adaptation by 2 native Portuguese researchers, evaluation of this initial translation by a panel of 5 experts during an online meeting and back translation by 1 bilingual researcher. Authors of the original version approved this initial translation. CQRA-PREM includes 7 domains for patient-centered care: Needs and preferences (5 items); Coordination of care and communication (4 items); Information, education, and self-care (4 items); Daily living and physical comfort (2 items); Emotional support (2 items); Family and friends (1 item); Access to care (5 items) and 1 question for the overall experience with the care provided. Answers are given on a 5-point Likert scale (strongly disagree-1 to strongly agree-5). A total of 21 patients were invited to participate in online focus groups and 14 accepted. Patients were then asked to fill in a consent form and the preliminary version of the CQRA-PREM. The focus groups were transcribed and analyzed using thematic analysis. Questionnaire responses were analyzed with descriptive statistics and reliability (internal consistency) with the Cronbach´s alpha (α).

Results: A total of 12 patients (53±9y; 92% female) with a mean disease duration of 14±9 years participated in 2 focus groups (duration 95±7min). The focus groups revealed that patients considered CQRA-PREM "simple" and "objective" and that all questions were easy to understand. Nevertheless, patients suggested the addition of synonyms for certain terms and of daily living examples to clarify some items. The "Needs and preferences" and "Access to care" were the domains with better experience (Table 1). The Cronbach's alpha was 0.94 for the total questionnaire and between 0.71 and 0.91 for the domains.

Table 1. Median's responses and quartile (Q) for each domain (1-Strongly disagree; 2-Disagree; 3-Neither agree nor disagree; 4-Agree; 5- Strongly agree).

CQRA-PREM domains	Median (Q1-Q3)
1.Needs and preferences	4.5(4.25-4.5)
2.Coordination of care and communication	4(3.25-4.5)
3.Information, Education and Self-care	3(2-4)
4.Daily living and physical comfort	3.25
5.Emotional support	3.25
6.Family and friends	4(3-4)
7.Access to care	4.5(2.5-5)

Conclusion: Our findings suggest that both content validity and internal consistency of the Portuguese version of CQRA-PREM are acceptable. In future, a field-testing study to assess other psychometric properties (e.g., test-reliability and validity) should be conducted. We believe this PREM will contribute to optimize patient-centered care in Portugal.

AB1479 VALIDATION OF RUSSIAN VERSION PSAID-12: ASSESSMENT OF THE RELIABILITY, CONSTRUCTIVE AND CONVERGENT VALIDITY OF THE QUESTIONNAIRE

L. Vorobyova[1], T. Korotaeva[1], E. Loginova[1], E. Gubar[1], Y. Korsakova[1]. *[1]V.A. Nasonova Research Institute of Rheumatology, Spondyloarthritis and Psoriatic Arthritis, Moscow, Russian Federation*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease of widely varying presentation, which determines functional and psychological impairment, with a high negative impact on patients' quality of life. Therefore, knowing the patient's perception of their health status is of fundamental importance for understanding the real impact of PsA. In recent years, a PsAID (Psoriatic Arthritis Impact of Disease) questionnaire has been developed for PsA EULAR, consisting of 9 or 12 questions related to the severity of pain, anxiety, fatigue, disability, sleep disorders, and social activity.

Objectives: To study, in a real-life setting, the construct and convergent validity, the reliability, and the interpretability of the Russian version PsAID-12 in patients with PsA.

Methods: 187 (M/F=97 (50.2%)/90(48.8%) PsA pts fulfilling the CASPAR criteria were included. Mean age 45.6±11.7 years (yrs), DAPSA 21.05±21.03, median (Me) PsA duration 88 [16;421] mo. All pts underwent standard clinical examinations and PROs (EQ-5D, PsAID12). Reliability was assessed by Cronbach's alpha coefficient and by the intraclass correlation coefficient (ICC) for each of the 12 scales. The construct validity was evaluated by exploratory factorial analysis and also by Spearman correlation with EQ-5D and measures of disease activity evaluation.

Results: The reliability of ICC (alpha-Cronbach = 0.8-0.9) and test-retest (ICC 95%CI 0.85-0.96) were good. Construct validity: Factor analysis revealed a 2-factor result defined as the PsAID-12: Phisical health score and Emotional health score. A strong correlation was also found for each of the 12 scales with the questionnaire EQ-5D was strong correlation (r= -0.52 to -0.78, p<0.001) In determining convergent validity, significant correlations were found between the PsAID-12 and TJC 68, SJC 66, DAPSA, VAS global assessments, VAS global pain, BASDAI. The high correlation was found between the BASDAI and the scale "Functional capacity" (r=0.8, p<0.001), as well as sufficiently high correlation coefficients with parameters were noted with the scales "Pain", "Fatigue", "Work and/or leisure activities", "Discomfort" and "Coping". The lowest was observed with scales "Skin problems" and "Depression" (Table 1).

Table 1. Convergent validity PsAID-12 with clinical parameters (r)

Scales	TJC 68	SJC 66	DAPSA	VAS global assess-ments	VAS global pain	BASDAI
Pain	**0,6**	**0,68**	**0,71**	**0,72**	**0,75**	**0,78**
Fatigue	**0,59**	**0,62**	**0,68**	**0,71**	**0,68**	**0,75**
Skin problems	0,35	0,36	0,41	0,47	0,37	0,46
Work and/or leisure activities	**0,57**	**0,62**	**0,68**	**0,75**	**0,71**	**0,67**
Functional capacity	**0,61**	**0,64**	**0,72**	**0,79**	**0,71**	**0,80**
Discomfort	**0,61**	**0,65**	**0,71**	**0,77**	**0,70**	**0,76**
Sleep disturbance	0,44	**0,50**	**0,54**	**0,55**	**0,60**	**0,61**
Coping	**0,59**	**0,63**	**0,67**	**0,66**	**0,65**	**0,76**
Anxiety, fear and uncertainty	0,46	0,48	**0,52**	**0,52**	**0,51**	**0,64**
Embarrasment	0,47	0,49	**0,51**	0,48	0,41	**0,52**
Social participant	**0,54**	**0,57**	**0,62**	**0,64**	**0,62**	**0,66**
Depression	0,43	0,43	0,49	**0,57**	**0,54**	0,47

Conclusion: The russian version of PsAID-12 has been shown to be a reliable and valid measure of the impact of the disease in patients with psoriatic arthritis.

Background: The Psoriatic Arthritis Impact of Disease 12-item questionnaire (PsAID-12) has been developed to measure impact of Psoriatic Arthritis (PsA) for purposes of monitoring and clinical management.
Objectives: Assessment the sensitivity of the russian version of PsAID-12 against the background of ongoing therapy at baseline and after 12 month (mo).
Methods: 172 (M/F=90 (52.3%)/ 82(47.7%) PsA pts fulfilling the CASPAR criteria were included. Mean age 45.1±11.8 years (yrs), DAPSA 28±22.2 median (Me). All pts underwent standard clinical examinations and PROs (EQ-5D, VAS global assessments, VAS global pain, BASDAI, PsAID-12). All pts at the time of inclusion in the study and 12mo received DMARDs: NSAIDs-158 (91.8%), methotrexate -134 (77.9%), leflunomide- 11 (6.3%), sulfasalazine - 12 (6.9%), TNFα inhibitors - 72 (44.04%), sekukinumab -14 (8.1%), ustekinumab -3 (1.74%), ixekizumab - 1 (0.58%), apremilast- 16 (9.3%), tofacitinib - 51 (29.1%). To determine the sensitivity of PsAID-12, its changes were analyzed depending on: I group of patients in whom MDA was achieved - 50, II - 43 REM / LDA patients, III - 79 patients with no effect on therapy.
Results: By 12 mo of therapy significant improvement in all PsA clinical examination (DAPSA - 28±22.2 vs 15±14.1, TJC 68 – 10.5±10.1 vs 6.68±5.77, SJC 66 – 8.31±7.4 vs 4.62±3.17, CRP – 13.6±8.06 vs 13.6±8.06) and PROs (BASDAI – 3.93±2.56 vs 2.49±1.93, VAS global pain – 40.1±25.1 vs 24.7±20.0, VAS global assesments – 43.4±27.1 vs 27.6±19.5, EQ-5D – 0.68±0.21 vs 0.72±0.18) were observed (p<0.0001 for all). The sensitivity assessment of the PsAID-12 showed that in groups I and II there were statistically significant differences on all scales of the questionnaires, in group III with no effect on therapy, there were no significant improvements on the scales “Pain” (p = 0.37), “Fatigue” (p=0.15), “Skin problems” (p=0.23), “ Work and/or leisure activities “ (p=0.056), “ Functional capacity “ (p=0.44) (Table 1).
Conclusion: The russian version of the PsAID-12 questionnaire reflects the dynamics depending on the activity of the disease during treatment, which proves its good sensitivity.

AB1481 REDOX HOMEOSTASIS AND ANTIOXIDANT RESPONSE DEFENSE IN SKELETAL MUSCLE PERFORMANCE IN THE ELDERLY

I. Ghzaiel[1], A. Zarrouk[2], S. Ben Hammouda[3], M. Hammami[4], G. Lizard[5], S. Hammami[6]. *[1]University Bourgogne Franche-Comté, Faculty of Medicine, University of Monastir, Monastir 5019, Tunisia, Team ‘Biochemistry of the Peroxisome, Inflammation and Lipid Metabolism’ EA 7270/Inserm, 21000 Dijon, France Laboratory, Dijon, France*; *[2]University of Monastir, Faculty of Medicine, LR12ES05, Lab-NAFS ‘Nutrition - Functional Food & Vascular Health’, 5000 Monastir, Tunisia*; *[3]University of Monastir, Faculty of Medicine, LR12ES05, Lab-NAFS ‘Nutrition - Functional Food & Vascular Health’, 5000 Monastir, Tunisia*; *[4]University of Monastir, Faculty of Medicine, LR12ES05, Lab-NAFS ‘Nutrition - Functional Food & Vascular Health’, 5000 Monastir, Tunisia*; *[5]University Bourgogne Franche-Comté, Faculty of Medicine, Team ‘Biochemistry of the Peroxisome, Inflammation and Lipid Metabolism’ EA 7270/Inserm, 21000 Dijon, France Laboratory, Dijon, France*; *[6]University of Monastir, Faculty of Medicine, CHU F Bourguiba, LR12ES05, Lab-NAFS ‘Nutrition - Functional Food & Vascular Health’, 5000 Monastir, Tunisia*

Background: Aging is accompanied by a progressive decline in physical activity due to a loss of skeletal muscle mass and strength considered as a geriatric characteristic defined as sarcopenia. This latter may be associated with joint damage, all of which may predispose older people to the risk of falls. Few evidences suggest that oxidative stress plays a key role in the pathophysiology of sarcopenia.
Objectives: The aim of this study was to clarify the relationship between sarcopenia and oxidative stress. To this end, measurements of antioxidant enzyme activities as well as levels of lipid oxidation products were performed on plasma and/or red blood cells.
Methods: All the participants (age ≥ 65) were classified into two groups according to the SARC-F score: non-sarcopenic patients (SARC-F <4; n=50) and sarcopenic (SARC-F ≥4; n=50). Redox biomarkers: antioxidant enzymes (erythrocyte superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GPx) activities) as well as, lipid peroxidation products (plasma malondialdehyde (MDA), and conjugated dienes (CD) levels), were measured using spectrophotometric methods.
Results: SOD levels were significantly higher in the group of sarcopenic patients than in non- sarcopenic subjects (3.20 ± 1.00 U/mg Hb vs. 2.41 ± 0.88 U/mg Hb, respectively, p= 0.007). Similarly, catalase levels were significantly higher in sarcopenic patients compared with non sarcopenicsubjects (0.13 ± 0.04 U/mg Hb vs. 0.11 ± 0.03 U/mg Hb, respectively, p= 0.008). However, no significant differences in GPx levels were detected (p= 0.254). An accumulation of lipid oxidation biomarkers MDA (17.14 ± 3.13 nmol/mg protein vs. 10.39 ± 2.60 nmol/mg protein) and CD (0.24 ± 0.09 nmol/mg protein vs. 0.17 ± 0.06 nmol/mg protein) was observed in the plasma of sarcopenic patients compared with non- sarcopenic subjects(p< 0. 001 and p= 0.003, respectively).
Conclusion: Sarcopenia is associated with oxidative stress as shown by increased levels of antioxidant enzyme activities (SOD, GPx) and lipid peroxidation products (MDA, CD).

AB1482 PROGNOSTIC FACTORS FOR TUBERCULOUS SPONDYLODISCITIS

M. Mrabet[1], S. Boussaid[1], S. B. Troudi[1], S. Rekik[1], S. Jemmali[1], S. Rahmouni[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. *[1]Rabta Hospital, Rheumatology, Tunis, Tunisia*

Background: Tuberculous spondylodiscitis (SPDT) or Pott’s disease is an infectious involvement of the disc-vertebrate couple, caused by the tubercular bacillus (Mycobacterium tuberculosis). It accounts for 46% to 64% of infectious spondylodiscitis and is the most common form of vertebral tuberculosis. Pott’s disease still poses a public health problem in Tunisia due to the endemicity of tuberculosis and the increase in extra-pulmonary forms.
Objectives: Our aim was to study factors impacting SPDT outcome.
Methods: We conduct a retrospective and descriptive study in a single rheumatology department. Data were collected from observations of patients hospitalized in the past 20 years (2000-2020) who have been diagnosed with SPDT. The diagnosis was based either on a range of highly evocative clinical, biological and radiological arguments or on the disco-vertebral biopsy puncture. The study included correlations of the promoting factors of SPDT (tuberculosis infection, history of tuberculosis, diabetes, corticosteroids and trauma), epidemiological, clinical, biological, radiological and therapeutic data with good clinical outcome in the fourth week of the anti-tuberculosis drugs treatment.
Results: Fifty-two cases of SPDT were collected (37F/15M). The mean age was 55.21±17.79 years [19-91]. Thirty-three patients (69.2%) were aged under 65 years versus 16 elderly patients (30.8%), with female predominance in both

groups (69.4% and 75% respectively, p = 0.57). The diagnosis of SPDT was based either on a range of highly evocative clinical, biological and radiological arguments (71.2%) or on the disco-vertebral biopsy puncture (28.8%). Among the clinical arguments suggestive of tuberculous SPD were: progressive onset of symptoms in 47 patients (90.4%), segmental spinal stiffness in 37 patients (71.2%), spinal pain with general signs of tuberculosis such as impaired general condition, fever, night sweats and weight loss in 32 patients (61.5%). Lumbar spine involvement was the most common in tuberculous SPD (57.7%). A biological inflammatory syndrome has been objectified in 38 patients (73.1%). Imaging was contibutive to positive diagnosis using standard X-rays, computed tomography and magnetic resonance imaging. Disc pinch, erosion of vertebral plateaus and vertebral collapse were the major signs. The treatment was based on anti-tuberculosis drugs for at least nine months. Only four factors had an unfavourable predictive value ($p \leq 0.05$): Normochromic normocytic anemia observed in 53.8% of our patients (p = 0.018; Odds Ratio = 6.66), initial lymphocytosis (p = 0.048), fever in 36.5% of our patients (p = 0.01; Odds Ratio = 9.6) and standard X-ray vertebral compression in 67.3% of our cases (p = 0.001; Odds Ratio = 13).
Conclusion: Tuberculous spondylodiscitis is a frequent condition that needs to be diagnosed and treated rapidly. Poor prognosis factors have been identified to provide insight into disease progression.

AB1483 ASSOCIATION BETWEEN THE DECREASE OF CAPILLAR DENSITY IN THE CAPILLAROSCOPY AND THE DIAGNOSIS OF SYSTEMIC SCLEROSIS PATIENTS WITH RAYNAUD

R. Rojas Tessel[1], E. Picco[1], E. Buschiazzo[1], M. Aciar[1], A. C. Ralle[1], N. Cucchiaro[1], V. Juarez[1], M. B. Lecumberri[1], D. Alonso[2], L. Ibañez Zurlo[3], J. Picchi[4], M. E. Crespo Espindola[1]. [1]*Hospital Sr del Milagro, Rheumatology, Salta, Argentina*; [2]*Punto Doc, Rheumatology, Salta, Argentina*; [3]*Instituto ALAS, Rheumatology, Salta, Argentina*; [4]*Cardiomed, Rheumatology, Salta, Argentina*

Background: Videocapillaroscopy (VC) has become a widely used tool due to its low cost, accessibility and no invasive nature. PANLAR study group proposes a semi-quantitative method to inform it, which includes four grades to categorize capillary density (methods). Previous studies found that capillary density is associated with microvascular damage, predicts disease progression and organ affection in systemic sclerosis (SSc) and can be useful as a follow-up tool (1-5).
Objectives: Describe the associations between the different patterns and grades of capillary density loss and the SSc diagnosis.
Methods: A cross sectional study was designed using clinical records, including outpatients attending to a VC consult between the March and October 2021. Descriptive data regarding patients demographics, presence of rheumatologic diagnosis and treatment was registered. The VC was performed by an experienced rheumatologist (RTR) (DinoLite), with a 200x amplification. Capillary density loss (CDL) was scored based on PANLAR recommendations: Grade 0 (no loss), Grade I (7-9 capillaries / lineal mm), Grade II (4-6 capillaries / lineal mm), Grade III (< 4 capillaries / lineal mm). Descriptive statistics were performed and data was compared using Student´s T test, Mann-Whitney, Chi2 or exact Fisher´s test depending on the type of data and its distribution. A p value < 0.05 was considered as significative.
Results: One hundred and one patients were included, 91 (91%) female, mean age 43 years (SD 13.9), 72 (71,3%) had raynaud phenomenon (RP), with a mean evolution of 1 year (IQR 0.5-3.5). Rheumatologic diagnosis was: 19 rheumatoid arthritis (RA), 16 SSc, 11 systemic lupus erythematosus (SLE) and 27 no diagnosis, including 2 with digital necrosis and one with endocarditis suspicion. VC was normal in 40 (39.6%) patients, 34 (33.7% had non-specific findings, and 26 (26%) SD pattern. In the latter, the pattern was 2 were early pattern, 11 active and 13 late. SD pattern was associated with SSc diagnosis, and the use RP medication (both p<0,001). Three patients with inflammatory idiopathic myopathy (IIM), 2 SLE, 2 primary sjögren syndrome (pSS) and 2 without diagnosis had also this pattern. LCD was found in 27% of the patients, and Grade III was associated with SSc diagnosis being 14 times more frequent compared with non-SSc. [Table 1]

Table 1. Capillary density loss presence and grades in SSc vs non-SSc

Variable	SSc	No-SSc	OR (95%CI)	p value
CDL – n (%)	12 (75)	15 (17.6)	14 (3.9-49.4)	0.0001
Grade I – n (%)	7 (8.2)	4 (25)	3.8 (0.9-14.6)	0.07
Grade II – n (%)	3 (18.8)	6 (7.1)	3 (0.6-13.8)	0.1
Grade III – n (%)	4 (25)	2 (2.4)	13.8 (2.2-83.8)	0.005

Ssc (systemic sclerosis), CDL (capillary density loss),

Conclusion: CDL was present in almost 1/3 of non selected patients attending to a VC study, and was strongly associated with SSc diagnosis. Future studies including this outcome can bring new data regarding microvascular damage and its implications.

AB1484 THE SIGNIFICANCE OF ANTI-DFS70 ANTIBODIES IN HEALTHY POPULATION AS A MARKER OF EXCLUSION OF SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES

Z. Verizhnikova[1], V. Rybakova[1], A. Avdeeva[1], T. Panafidina[2], A. Lila[3], E. Nasonov[4]. [1]*V.A. Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russian Federation*; [2]*V.A. Nasonova Research Institute of Rheumatology, Department of Systemic Rheumatic Diseases, Moscow, Russian Federation*; [3]*V.A. Nasonova Research Institute of Rheumatology, Medical Academy of Continuing Professional Education, Rheumatology, Moscow, Russian Federation*; [4]*V.A. Nasonova Research Institute of Rheumatology, Scientific Department, Moscow, Russian Federation*

Background: The prevalence of anti-DFS70 antibodies in healthy volunteers (HV) by various methods ranges from 0 to 22% [1]. This pattern, which is rare in patients with systemic autoimmune rheumatic diseases (SARDs), has been described as the second most common in serum HV [2].
Objectives: To study the frequency of detection of anti-DFS70 in HV, patients (pts) with undifferentiated SARDs and systemic lupus erythematosus (SLE).
Methods: A total of 45 HV, 17 undifferentiated SARDs pts and 81 SLE pts were included in the study. Groups were comparable in gender and age among themselves. The diagnosis of SLE was performed according to the ACR/EULAR 2019 classification criteria. Serum samples were tested for anti-DFS70 (ANA HEp-2 ELITE/DFS70 knock-out IFA, "Trinity Biotech", Ireland). Fluorescence titers ≥1:160 were considered as positive for ANA HEp-2 cell patterns.
Results: Positive results of the ANA study were found in 81 (100.0%) pts with SLE, in 16 (94.0%) pts with undifferentiated SARDs and 7 (15.6%) HV (Table 1). Abs to DFS70 were isolated, detected in 4 (57.1%) HV, in 9 (56.2%) undifferentiated SARDs, but were not detected in SLE pts. Classical HEp-2 cell patterns (homogeneous AC-1, speckled AC-4.5, homogeneous+speckled AC-1,4,5, cytoplasmic AC-19,20,21) without anti-DFS70 were deficient in 3 (42.9%) HV, in 7 (43.8%) patients with undifferentiated SARDs and in 81 (100%) patients with SLE (Table 2). Therefore, monospecific anti-DFS70 were detected in the HV and undifferentiated SARDs groups, but were not detected in patients with a reliable diagnosis of SLE.

Table 1.
ANA-HEp-2/DFS70 KO detection rate

Groups of pts	n	ANA-HEp-2/DFS70 KO ≥ 1:160, n (%)
HV	45	7 (15.6)
SLE	81	81 (100.0)
Undifferentiated SARDs	17	16 (94.0)

Table 2.
Detection rate of patterns in ANA-HEp-2-positive pts

HEp-2 cell patterns	HV, n=7	SLE, n=81	Undifferentiated SARDs, n=16
Nuclear dense fine speckled - DFS70 (AC-2), n (%)	4 (57.1)	0 (0.0)	9 (56.2)
Nuclear homogeneous (AC-1), n (%)	0 (0.0)	26 (32.1)	0 (0.0)
Speckled (AC-4,5), n (%)	1 (14.3)	14 (17.3)	1 (6.2)
Nuclear homogeneous+speckled (AC-1,4,5), n (%)	2 (28.6)	35 (43.2)	3 (18.8)
Cytoplasmic (AC-19,20,21), n (%)	0 (0.0)	6 (7.4)	3 (18.8)

Conclusion: Monospecific anti-DFS70 can potentially be considered as a possible marker for the exclusion of SARDs and a sign of benign autoimmunity.

AB1485 PATIENT-REPORTED OUTCOMES AND BIOMARKERS ASSOCIATED WITH THE CUTANEOUS DERMATOMYOSITIS AREA AND SEVERITY ACTIVITY (CDASI-A) SCORE IN A PHASE 2 CLINICAL TRIAL IN DERMATOMYOSITIS

J. Dan[1,2], J. Patel[1,2], G. Sprow[1,2], J. Concha[1,2], R. Feng[3], N. Kodali[1,2], T. Vazquez[1,2], D. Diaz[1,2], B. White[4], V. Werth[1,2]. *[1]Perelman School of Medicine at the University of Pennsylvania, Dermatology, Philadelphia, United States of America*; *[2]Corporal Michael J. Crescenz VA Medical Center, Dermatology, Philadelphia, United States of America*; *[3]Perelman School of Medicine at the University of Pennsylvania, Biostatistics and Epidemiology, Philadelphia, United States of America*; *[4]Corbus Pharmaceuticals, Inc., Corbus, Norwood, United States of America*

Background: Retrospective reviews of clinical databases from two sites have identified strong relationships between patient-reported outcomes and skin activity in dermatomyositis (DM), as measured by CDASI-A.[1,2] No studies validate these associations in a controlled setting. Additionally, the relationship between the PROMIS-29 Short Form and skin activity in DM has not been assessed. Previous investigations have demonstrated a correlation between IL-31 and itch in DM.[3] IFN-β and IFN-γ are known type I and II interferons, which are critical drivers of DM pathogenesis.[4]

Objectives: To assess correlations between CDASI-A, quality of life (QoL), and biomarkers of disease activity in a double-blind, randomized, placebo-controlled clinical trial.

Methods: Data were retrospectively collected from five visits of a Phase 2 trial evaluating Lenabasum, a cannabinoid receptor type 2 agonist. Quality of life assessments extracted from the trial included Patient Global Assessment (PtGA) scores, PROMIS domains, and Skindex domains. Skindex question 10, regarding itch, was included in the analysis as a separate domain. Physician Global Assessment scores were also evaluated. Additionally, biomarkers derived from skin samples via IHC/PCR collected at visits 1 and 6 were assessed for predictors of CDASI-A response and association with disease activity. Analysis used linear mixed effect models to account for within subject-variability and repeated measures, where applicable. Analysis was performed without regard to treatment arm, as our goal was to correlate CDASI, QoL, and biomarkers among all subjects.

Results: Data from 22 subjects with DM and a combined total of 110 visits were included. Biopsies were collected from 12 subjects. Improvement in CDASI-A significantly correlated with Skindex-S, Skindex-E, Skindex-F, Skindex-Itch, PtGA global skin, PtGA global skin, PtGA global skin, and PtGA global skin, with $p < 0.001$. Improvement in PROMIS social role ($p = 0.046$) correlated with improvement in CDASI-A. Worsening of PROMIS fatigue ($p = 0.019$) and pain ($p < 0.001$) correlated with improvement in CDASI-A. Decreases in PGA overall disease, PGA skin activity, and PGA global skin all correlated with improvement of CDASI-A ($p < 0.001$). Change in IL-31 protein area positively correlated with change in disease activity ($p = 0.047$). A positive relationship between changes in IFN-β and IFN-γ protein area and disease activity trended towards significance.

Conclusion: In accordance with previous investigations from our group, well-established measures of QoL correlated significantly with CDASI-A. These findings support that CDASI-A reflects both clinical and patient-reported aspects of skin disease and is an appropriate outcome in DM clinical trials. Additionally, Skindex and PtGA scores may better relate to skin activity as measured by the CDASI compared to PROMIS domains. IL-31, a cytokine previously associated with itch in DM,[3] correlated significantly with CDASI-A in our study. Trends for IFN-β and IFN-γ reduction with disease improvement support their role in the pathogenesis of DM. This study helps define patient-reported outcomes and biomarkers that may be informative in DM trials.

AB1486 ASSESSMENT OF GLUCOCORTICOID-RELATED ADVERSE EVENTS BY THE GLUCOCORTICOID TOXICITY INDEX (GTI) IN RHEUMATIC PATIENTS

M. Bahap[1], E. Duran[2,3], A. B. Ekincioğlu[1], O. Karadag[2,3]. *[1]Hacettepe University School of Pharmacy, Department of Clinical Pharmacy, Ankara, Turkey*; *[2]Hacettepe University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[3]Hacettepe University School of Medicine, Vasculitis Research Centre, Ankara, Turkey*

Background: Glucocorticoids (GCs) remain the mainstay treatment for several autoimmune and inflammatory diseases however, its long-term or high-dose usage also has many potential side effects. The glucocorticoid toxicity index (GTI) is a novel global monitoring tool (1) developed to systematically assess glucocorticoid-associated morbidity.

Objectives: To evaluate GC toxicity by using GTI in patients with rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and vasculitis receiving glucocorticoids.

Methods: This descriptive, cross-sectional study included patients who were admitted to the rheumatology clinic between January 2021 and December 2021, were diagnosed with RA, SLE or vasculitis and treated with GCs. A single measurement of GC toxicity was performed using the GTI for each patient. Baseline GTI consists of twelve domains that related to commonly recognized adverse events that result of cumulative GCs exposure: body mass index (BMI), glucose metabolism, blood pressure, lipids, GC-induced myopathy, bone mineral density, skin toxicity, neuropsychiatric effects, infection, ocular, gastrointestinal and endocrine toxicity. The total GTI score ranges from 0 to 538 depending on the increase in toxicity burden.

Results: The study included 85 patients (55.3% male) with a mean age of 47.5 (±16.0) years (Table 1). Twenty (23.5%) patients had BMI values ≥30 kg/m2 and 63% of the patients were either hypertensive or receiving medications for hypertension. While HbA1c was ≥5.7% in 30 (35.3%) patients, 17 (20.0%) patients had glycated hemoglobin (HbA1c) value of ≥5.7% despite antidiabetic medication. Low density lipoprotein cholesterol (LDL-C) value of 33 (39%) patients was not on target. The median (IQR) GTI score of the study patients was 73 (81.5). Only 10 patients had a score of 0 in the GTI assessment. GTI scores were not correlated with the cumulative steroid doses ($r=0.145$, $p=0.198$) however, age was strongly associated with GTI scores ($r=0.605$, $p<0.001$).

[¶] n (%), if otherwise specified; median (IQR) for numeric values other than ageGTI: Glucocorticoid toxicity index, RA: Rheumatoid arthritis, SLE: Systemic lupus erythematosus, BMI: Body mass index, HbA1c: Glycated hemoglobin, LDL-C: Low density lipoprotein cholesterol*Vasculitis patients include ANCA-associated vasculitis, Giant cell arteritis, Takayasu arteritis, Behcet's syndrome, Igg4-related disease, Polymyalgia rheumatica and Leukocytoplastic vasculitis patients.***BVAS value given only for ANCA-associated vasculitis (n=19)

Conclusion: Our study revealed the iceberg of glucocorticoid toxicities in patients with rheumatic disease. Usage of GTI would help management of these possible toxicities. Therefore, it is important to assess GC toxicity at regular intervals during ongoing treatment in order to detect potential differences in the GTI scores.

AB1487

VALIDATION AND CULTURAL ADAPTATION OF THE QUALISEX QUESTIONNAIRE IN WOMEN WITH SJÖGREN'S SYNDROME IN ITALY

F. Giardina[1], G. Curcio[2], C. Gioia[1], R. Izzo[1], E. Simoncelli[1], A. Gattamelata[1], S. Colafrancesco[1], L. Mastromanno[1], M. Villa[1], C. Iannuccelli[1], M. Di Franco[1], F. Conti[1], R. Priori[1]. [1]*Sapienza University of Rome, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rheumatology Unit, Rome, Italy*; [2]*University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy*

Background: The quality of sexual life (QSL) is a complex and multimodal experience influenced by endogenous and external factors, including age, gender, and cultural environment. Rheumatic diseases, with their burden of pain, fatigue, organ damage, and disability, can severely impair sexual life and this is true also for Sjögren's Syndrome, where simple tools to assess the QSL in everyday clinical practice are needed.
Objectives: To translate ad adapt into Italian the Qualisex, a new brief questionnaire originally created for Rheumatoid Arthritis patients, for women with primary Sjögren's Syndrome (pSS) and evaluate the impact of the disease on their sexuality.
Methods: Consecutive sexually active pSS (according to ACR/EULAR 2016 criteria) patients aged >18 were asked to participate in this study approved by the local bioethics committee. With the permission of the developer, the French original version of the Qualisex questionnaire (consisting of 10 items, the higher the score, the greater the negative impact of the disease on the QSL) was translated and adapted into Italian according to current guidelines. In the absence of a gold standard assessment for sexuality in pSS, face and content validity was assessed cross-sectionally by correlations with other disease aspects such as anxiety and depression measured by Hospital Anxiety and Depression Scale (HADS), EULAR SS patient-reported index (ESSPRI), and quality of the relationship. As a measure of reliability, internal consistency was assessed through Cronbach's Alpha coefficient. A Cronbach's value >0.7 is generally regarded as satisfactory. The feasibility of the scale was indirectly assessed through missing data. To assess the factorial structure of the Italian version of the questionnaire an Exploratory Factor Analysis (EFA) was carried out. Moreover we also assessed the level of redundancy by means of intra-item correlation of the Qualisex questionnaire. ESSDAI (EULAR Sjögren's Syndrome Disease Activity Index), and SSDDI (Sjogren's Syndrome Disease Damage Index) were assessed as well. Analyses were carried out with IBM SPSS Statistics for Macintosh, version 22.0 (IBM Corp., Armonk, NY, USA).
Results: 40 sexually active women with pSS and a median age of 53 (IQR 45.25-57.25) were enrolled. The EFA showed that the model with a single factor appeared to be highly significant (Chi235= 2943.10; p<0.05); the average inter-item correlation was found to be 0.392 (Min -0.479; Max 0.834) which is an acceptable value as for redundancy. There were no missing answers. Cronbach's alpha coefficient resulted to be 0.86 which indicates an adequate internal consistency. The median Qualisex score was 4.65 (IQR 2.13–6.2). As far as correlations, age (Rho=0.39; p<0.05), menopause (Rho=0.41; p<0.05), relationship quality (Rho=0.55; p<0.05), anxiety (HADS-A; Rho=0.38; p<0.05), and depression (HADS-D; Rho=0.47; p<0.05) appeared to be positively correlated with Qualisex score. Also, a positive correlation with ESSPRI (Rho=0.43; p<0.05), and drug use (Rho=0.37; p<0.05) was demonstrated. On the contrary no significant correlation was found with education (Rho=-0.07; p=0.64), systemic disease activity (Rho=0.14; p=0.39), and damage (Rho=0.06; p=0,74).
Conclusion: The Italian version of the Qualisex questionnaire is a valid, reliable and useful tool to assess the quality of sexual life in pSS. QSL in pSS women has an inverse relationship with age, menopause, drug use, ESSPRI, mood disorders, and dissatisfaction with the partner, while, as previously reported, no correlation was found with disease activity, damage, and educational status. This further highlights the impact of subjective symptoms such as dryness, pain, fatigue, and the overall psychological well-being on patients' life. Thus, it is critical for the physician to consider patients' perspective.

AB1488

GRAY INTENSITY RATIO INDICES AS A METHOD OF DISCRIMINATION BETWEEN CHANGES INDUCED BY SPORT AND BY SPONDYLOARTHRITIS IN LOAD-BEARING ENTHESES.

M. Tortosa-Cabañas[1], C. Guillén-Astete[1], Á. Andreu-Suárez[1]. [1]*Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: Computer analysis of radiological images has recently been introduced in the study of patients with musculoskeletal pathologies. In the field of ultrasound, baseline settings and differences between images obtained by different equipment pose a potential problem in the comparative study of patients. Our research group has shown that this type of ultrasound image analysis is sensitive to exercise-induced adaptive changes.
Objectives: The purpose of this study is to determine if the computer analysis of entheses ultrasound images can distinguish adaptive changes from those produced by spondyloarthritis.
Methods: A test validation study was carried out. Since the analysis of static ultrasound images strongly depends on the characteristics of the image and the ultrasound settings, three indices based on the findings in pathological territories and their counterpart in healthy entheses were defined. Gray Intensity Mean Index (iMIG): Mean gray intensity in the clinically affected enthesis/mean gray intensity in the same healthy enthesis. Gray intensity dispersion index (iDIG): Mean of the standard deviation of the gray intensity means in the clinically affected enthesis/mean of the standard deviation of the gray intensity means in the same healthy enthesis. Index of gray intensity modes (iMoG): Mean gray intensity modes in the affected enthesis/mean gray intensity in the same healthy enthesis. The same indices were used in the controls with the dominant side as the numerator and the non-dominant side as the denominator. All the studied entheses corresponded to the lower limb.
Results: Records of 49 patients (20 diagnosed with psoriatic arthritis, 19 with radiographic axial spondyloarthritis and 10 with non-radiographic axial spondyloarthritis) and 100 healthy controls were included. Of the 49 studies, 30 corresponded to the Achilles tendon, 10 to the distal patellar tendon and 9 to the proximal patellar tendon. In the patient group, iMIG was 0.917 SD 0.062, iDIG was 0.976 SD 0.042, and iMoIG was 0.962 SD 0.041. In the control group, iMIG 1 SD 0.020, iDIG was 1.001 SD 0.03, and iMoIG was 0.999 SD 0.03. The area under the curve (Figure 1) for the three indices was: iMIG 0.879 (95% CI 0.807 to 0.951), iDIG (95% CI 0.582 to 0.785), iMoIG 0.751 (95% CI 0.662 to 0.840). All areas demonstrated diagnostic validity with P<.0001. According to the matrix of coordinates of the receiver-operating-characteristic (ROC) curve, for an iMIG cut-off point less than or equal to 1.02, a sensitivity of 95.9% and a specificity of 71% would be achieved.

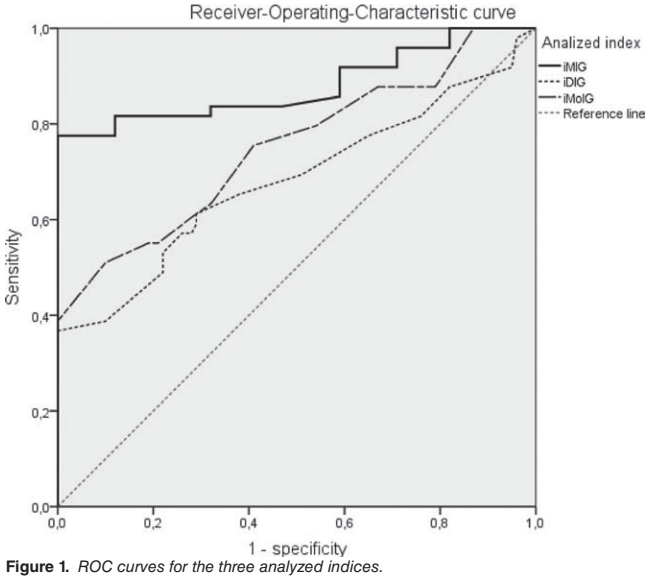

Figure 1. *ROC curves for the three analyzed indices.*

Conclusion: The indices that contrast the means, dispersion and mode of gray intensities are valid for discriminating between healthy subjects and patients with load-bearing enthesopathies related to spondyloarthritis. Of all of them, the iMIG seems the most reliable. A cut-off point of less than 1.02 is proposed to identify patients with inflammatory enthesopathies. In patients, the affected entheses have a lower mean gray than the healthy counterpart, so iMIG tends to be less than 1. In healthy subjects, the mean gray is slightly higher in the dominant enthesis, so iMIG tends to be greater than or equal to 1.

AB1489

VALIDATION OF QUANTITATIVE COMPUTER ANALYSIS OF ULTRASOUND IMAGES OF THE ACHILLES AND PATELLAR TENDONS IN HEALTHY SUBJECTS.

Á. Andreu-Suárez[1], C. Guillén-Astete[1], M. Tortosa-Cabañas[1]. [1]*University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: The ultrasound study of tendons is a component of the complementary evaluation of patients with different musculoskeletal pathologies, which include immune-mediated rheumatological diseases. Until now, the assessment

of the ultrasound status of the tendons largely depends on the subjectivity of the explorer, following specific guidelines such as the fibers structure, their global echogenicity and their thickness. This evaluation is of great interest for the diagnose, however its role for the follow-up is not so clear as the subjective evaluation may not perceive subtle changes. Computerized image analysis has recently been introduced to complement the echographic evaluation. Two of the most useful parameters in this analysis are the mean and mode of gray intensities. Both allow a global evaluation of the echostructure of an organ based on the distribution of shades of gray and the highest concentration of a particular shade, without evaluating the organization pattern of the image obtained.

Objectives: To determine if computer analysis of static images is valid and suitable for its use in the study of tendons.

Methods: The ultrasound images of healthy volunteers were analyzed. The analysed tendons were: the body of the patellar tendon in transverse approach and the longitudinal section of the Achilles tendon, both of them from the dominant side. Image processing was performed using the ImageJ 1.53e program (Wayne Rasband & contributors – NIH, USA). A gray spectrum analysis (0-255) was performed with the calculation of the mean, standard deviation (SD), range, median and mode. Two measurements of different cuts of the patellar tendon (at the point of emergence of the tibial plateau and 20 mm proximal to it) and three longitudinal cuts of 20 mm of the Achilles tendon (paramedial, central and paralateral) were used for the validation process of the analysis carried out by the software.

Results: Images from 44 healthy volunteers were analyzed: 20 men and 24 women. 44 Achilles tendon image trios and 44 patellar tendon image pairs were analyzed and their corresponding means and modes were compared as related variables. In the study of the Achilles tendon, according to the Shapiro-Wilk test, the distribution of the gray distribution means had a non-normal distribution while the modes had a normal distribution. The means ± standard deviation of gray intensity was: 80.15 ± 26.04, 80.05 ± 25.57 and 79.91 ± 25.83 for the medial, central and lateral slices, respectively (Friedman, P=.454; Bonferroni not applicable). The means of the modes of gray intensities for the same measures were 67.35 ± 31.60, 67.76 ± 32.18 and 68 ± 32.18, respectively (ANOVA paired data, P=.259; Bonferroni not applicable). In the patellar tendon study, all measurement distributions were non-normal. Mean gray intensity at the point of tendon emergence (P) was 81.35 ± 29.63 and at 20mm proximal to this point it was 80.97 ± 29.08 (Wilcoxon, P=.327). The means of the modes at the same locations were 82.71 ± 28.75 and at 20mm proximal to this point it was 64.44 ± 33.31 (Wilcoxon, P=.079).

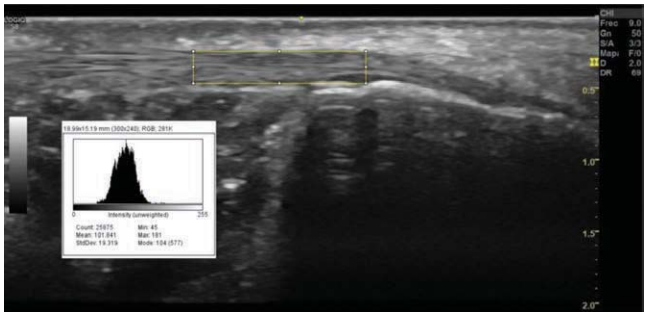

Figure 1. *Image analysis of an Achilles tendon in the central longitudinal plane.*

Conclusion: The quantitative analysis of static images of healthy tendons shows no differences between the same structures in longitudinal or transverse planes. Based on this validation test, the demonstration of sensitivity to change caused by any stimulus (sport, noxae or treatments) could allow its use as a complementary instrument for the assessment of tendinous structures over time.

AB1490 THE POLISH VALIDATION OF A DISEASE SPECIFIC PATIENT REPORTED OUTCOME MEASURE OF SYSTEMIC LUPUS ERYTHEMATOSUS

A. Saletra[1], J. Meenakshi[2], K. Fronczyk[3], Z. Czuszyńska[4], M. Sierakowska[5], M. Szmyrka[6], M. Olesińska[1]. *[1]National Institute of Geriatrics, Rheumatology and Rehabilitation, Connective Tissue Disease Department, Warsaw, Poland*; *[2]Rush University Medical Center, Department of Rheumatology, Chicago, United States of America*; *[3]University of Warsaw, Department of Psychology, Warsaw, Poland*; *[4]University of Gdańsk, Department of Intern Diseases, Connective Tissue Diseases and Geriatrics, Gdańsk, Poland*; *[5]Medical University in Białystok, Department of Integrated Medical Care, Białystok, Poland*; *[6]Wroclaw Medical University, Department of Rheumatology, Wrocław, Poland*

Background: Systemic Lupus Erythematosus (SLE) is a chronic multisystemic autoimmune disease with a very broad clinical picture. Due to its generalized nature, it affects all aspects of the patient's life, such as physical, psychological and social well-being. As a result, the quality of life in patients with SLE is substantially decreased. Therefore, it is recommended to introduce evaluation of quality of life in clinical trials and in the daily practice. LupusPRO is a disease-targeted, patient reported outcome measure developed for assessment of quality of life in patients with Systemic Lupus Erythematosus. Originally, the questionnaire was validated among US patients of varied ethnic background and both genders. What differs LupusPRO from previous disease-specific quality of life questionnaire used in SLE is its comprehensiveness. It comprises two constructs: health- related quality of life domains (HRQOL) and non- health - related quality of life domains.

Objectives: The aim of this study is to carry out a cross-cultural adaptation and validation of the Polish-translated version of LupusPRO.

Methods: The Polish version of LupusPRO was administrated along with the 36-Item Short Form Health Survey (SF-36) and EQ-5D-5L questionnaire and Hospital Anxiety and Depression Scale (HADS). At the same time, demographics and clinical characteristics were collected. Disease activity, damage and exacerbation were assessed using SELENA-SLEDAI, SLICC/ACR DI and LFA Flare. Internal consistency reliability, test-retest reliability, convergent validity (against corresponding domains of SF-36) and criterion validity (against disease activity and damage) and known group validity were tested.

Results: A total of 199 (91% females) patients with SLE with a mean age of 42.6 ⊥12.62 years participated in the study. The mean SELENA-SLEDAI reached 5.3(⊥ 5.9) points and SLICC/ACR DI was observed at 1.3(⊥ 2.0) points. The internal consistency reliability of LupusPRO domains ranged between 0.737-0.925 (except for Lupus Symptoms, Social Support, Coping and Satisfaction with care). For all domains, except Social Support, test-retest reliability exceeded 0.7. Convergent validity with corresponding domains of the SF-36 was good (r>0,5). All health-related quality of life domains performed well against disease activity and damage measure, establishing its criterion validity. Known group validity against disease activity was observed. Confirmatory factor analysis showed a good fit.

Conclusion: The Polish version of LupusPRO has proved to have fair psychometric properties among Polish patients with SLE. It is the first disease-specific quality of life questionnaire in Polish, validated among Polish patients with Systemic Lupus Erythematosus.

ACUTE EFFECTS OF AN INSTRUMENT ASSISTED SOFT TISSUE MOBILIZATION TECHNIQUE ON CHRONIC NECK PAIN: A DOUBLE-BLIND, RANDOMIZED CONTROLLED TRIAL

H. Gerçek[1], B. S. Unuvar[1], O. Umit Yemisci[2], A. Aytar[3]. [1]*Vocational School of Health Sevices, Physiotherapy, Karatay, Turkey*; [2]*Başkent University, Faculty of Medicine, Physical Medicine and Rehabilitation Department, Ankara, Turkey*; [3]*Başkent University, Physiotherapy and Rehabilitation, Ankara, Turkey*

Background: Individuals with chronic neck pain, proprioceptive afferent information from the cervical spine may be impaired due to the presence of pain. Instrument-assisted soft-tissue mobilization (IASTM) is used to reduce pain and improve range of motion (ROM) and function. Cervical sensorimotor control includes the central integration and processing of all afferent information and the execution of the motor program through the cervical muscles and contributes to the maintenance of head posture and balance(1). In individuals with chronic neck pain, proprioceptive afferent information from the cervical spine may be impaired due to the presence of this pain(2). Many treatment modalities such as instrument-assisted soft-tissue mobilization (IASTM) have been used to reduce pain and increase proprioception(3). IASTM is used to reduce pain, increase soft-tissue mobility, and improve range of motion (ROM) and function. These instruments cause microtrauma to restore normal elasticity and function in soft-tissue(4). Kivlan has shown that significant and rapid changes in muscle function can occur with only a single IASTM application and have suggested the following mechanisms of action: an increased fascial motility, a proliferation of extracellular matrix fibroblasts, and an increased blood flow to the area close to the injured tissue, with decreased cellular matrix adhesion and localized ischemia(5).
Objectives: Aim of this study, to determine the acute effects of single-session, IASTM on cervical joint position error (JPE) and pain in individuals with chronic neck pain.
Methods: A total of 39 individuals (mean age=40.18±11.10 years) with chronic neck pain were included in this study. We divided the participants into IASTM, sham, and control groups of 13 members each. In the IASTM group, intervention was applied to the sternocleidomastoid and trapezius muscles with an application time of 45 seconds and a frequency of 60 beats/min. In the sham group, IASTM was applied at a 90° angle without pressure. The control group received no intervention. The pain severity and joint position error were evaluated before and after the intervention, by using the visual analog scale (VAS) and a cervical range of motion device.
Results: The effects of time and treatment group on VAS score were statistically significant. The effect of time and treatment for VAS score was statistically significant (p=0.001). When the post-test was examined according to application, a statistically significant difference found in VAS scores (p=0.001), with the lowest pain score in the IASTM group and the highest pain score in the control group. The significant improvements found in JPE in all aspects of the cervical region in the IASTM group (p<0.05). In the sham group, significant improvements observed in cervical extension, left rotation, and left lateral flexion movements in JPE (p<0.05).
Conclusion: Single-session IASTM is effective for improving the acute pain and JPE in individuals with chronic neck pain.

COMPARISON OF TELEREHABILITATION METHODS FOR SYSTEMIC SCLEROSIS PATIENTS IN THE COVID-19 ERA: A RANDOMIZED CONTROLLED STUDY

T. Civi Karaaslan[1], E. Tarakcı[1], O. Keles[2,3], Y. Aslan Keles[4,5], S. Ugurlu[6]. [1]*Istanbul University-Cerrahpasa Health Sciences Faculty, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey*; [2]*İstanbul Medipol University, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey*; [3]*Biruni University, Vocational School, Occuptional Therapy Program, Istanbul, Turkey*; [4]*Istanbul University-Cerrahpasa, Institute of Graduate Studies, Department of Physiotherapy and Rehabilitation, Istanbul, Turkey*; [5]*Biruni University, Vocational School, Physiotherapy Program, Istanbul, Turkey*; [6]*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Scleroderma (SSc) is an autoimmune connective tissue disease progressing with fibrosis. SSc patients need to be protected from epidemic diseases as well as rehabilitation needs. For this reason, it is important for them to continue their exercises in an environment where they can be both rehabilitated and protected from infectious diseases.
Objectives: In this study, it was aimed to reveal the effects of exercises performed by telerehabilitation on individuals with Scleroderma with hand involvement and to compare the effects of real-time telerehabilitation (RTT) and asynchronous telerehabilitation (AT).
Methods: Forty-two participants with a mean age of 44.17±11.05 years were included in the study. The patients were divided into three groups and followed for 8 weeks. RTT was applied to the 1st group and AT was applied to the 2nd group, and the 3rd group was the control group. Participants' finger and wrist joint range of motion (ROM) were evaluated with a goniometer, upper extremity functions were evaluated with Scleroderma Hand Mobility Test (HAMIS), Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire and 9Hole Peg Test (9HPT), grip strength was evaluated with a dynamometer, superficial sense of touch was evaluated with the Semmes Weinstein Monofilament test, activities of daily living (ADL) were evaluated with the Michigan Hand Outcomes Questionnaire (MHQ), and general health status was evaluated with the Scleroderma Health Assessment Questionnaire (SHAQ).
Results: There were improvements in finger and wrist ROM, upper extremity functions and ADL parameters in the RTT group; and there were improvement in finger ROM and hand functions in the AT group (p<0.05). Wrist radial deviation ROM decreased in the control group (p<0.05). Significant differences were noted between the groups in finger ROM and upper extremity functions after treatment (p<0.05).
Conclusion: Our study shows that exercises performed via RTT and AT are effective in individuals with Scleroderma with hand involvement, and RTT has additional benefits.

REHABILITATION OF PATIENTS WITH OSTEOARTHRITIS OF THE KNEE USING MAGNETIC THERAPY

A. Arkhipova[1], N. Zhuravleva[2], E. Guryanova[2], V. Diomidova[2]. [1]*Republic Clinical Hospital, Department Rheumatology, Cheboksary, Russian Federation*; [2]*I. N. Ulianov Chuvash State University, Department Internal Diseases, Cheboksary, Russian Federation*

Background: Currently, along with the basic treatment at the outpatient stage of rehabilitation, methods using physical and balneological factors are successfully applied: magnetotherapy, electrotherapy, peloidtherapy.
Objectives: Evaluation of the effectiveness of rehabilitation using magnetotherapy for osteoarthritis of the knee joints at the second radiological stage.
Methods: The study included 75 patients with primary osteoarthritis of the knee joints of the II X-ray stage, who were on outpatient rehabilitation in the sanatorium "Chuvashiyakurort", including 45 women and 30 men aged 50 to 65 years with a disease duration of 15 to 20 years. Rehabilitation was carried out by a multiprofessional team led by a physical and rehabilitation doctor. All patients were divided into two groups by simple randomization. The main group (n = 50) received basic treatment (chondroprotectors) + non-steroidal anti-inflammatory drugs (NSAIDs on demand) and a course of apparatus magnetotherapy. Magnetic therapy was applied to the area of the knee joints using the «Polus-2» apparatus using solenoid inductors, mode - continuous, frequency - 50 Hz,

low-sinusoidal current, intensity 111-1V, procedure duration 20 minutes, daily, № = 10. The control group (n = 25) received basic treatment (chondroprotectors) and NSAIDs (on demand). When analyzing the results of treatment, the VAS and WOMAC scales were used, and the Bartel index was estimated.

Results: In both groups, from the 2nd week of treatment, there was a decrease in pain during movement and at rest according to the VAS data compared with the baseline level. In patients in the main group, there was a decrease in joint swelling, a decrease in the level of pain according to the VAS by 41.3% ($p < 0.05$). The range of motion in the joints increased by 19.5% ($p < 0.05$) in the study group. In the control group, a decrease in the level of pain by 20.1% ($p < 0.05$) was recorded, the range of motion in the joints did not change. The overall WOMAC index was also lower in the main group compared with the control group ($p = 0.03$). Patients in the main group differed from patients in the control group in a significantly higher degree of dependence in daily life (Bartel index) and a lower score on the battery of tests of physical functioning. According to the results of dynamic observation of patients, no side effects associated with the use of the device "Polyus-2" were registered.

Conclusion: Magnetic therapy relieves pain, improves motor and daily activity in patients with osteoarthritis of the knee joints and can be recommended for use in medical rehabilitation programs in addition to basic therapy.

AB1494 THE QUALITY OF REPORTING IN RANDOMIZED CONTROLLED TRIALS OF BALANCE EXERCISES IN TOTAL KNEE ARTHROPLASTY

D. Ozcan[1], T. Ünver[2], B. Unver[3]. *[1]Dokuz Eylul University, Health Sciences Institute, Izmir, Turkey*; *[1]Dokuz Eylul University, Health Sciences Institute, Izmir, Turkey*; *[3]Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, Izmir, Turkey*

Background: Total knee arthroplasty (TKA) is used to treat patients with end-stage osteoarthritis who experience pain and struggle to perform activities of daily living owing to having degenerative knee joints. Although TKA can improve the quality of life of patients, some may experience a decrease in their proprioception and the ability to balance after surgery (1). Decreased balance ability makes it difficult to undertake daily life activities in patients after TKA, impairs walking capacity and increases the risk of falling (2). Almost all studies which investigate the risk of falling conclude that physical activity(PA) are effective methods in order to maintain an intact balance control and prevent falls(4). Today, however, measures aimed at controlling COVID-19 include quarantines that lead to PA restrictions (5). In these days when PA cannot be increased due to quarantines, the most effective way to prevent falls in TKA patients may be to apply balance exercises (3). The "gold standard" in clinical trials are randomized controlled trials(RCTs) in which healthcare professionals make decisions about the safety and efficacy of treatments. However, poorly designed and reported RCTs can give misleading results. Methodological quality (MQ) assessment of clinical trials is important because it can prevent erroneous results in clinical practice and improve the quality of medical care. (6) Although RCTs provide the highest quality clinical evidence selection of balance exercises(BE) to be applied, there is no study in the literature investigating the MQ of RCTs of BE in TKA patients.

Objectives: The aim was to investigate assess the reporting MQ of RCTs of BE in patients with TKA.

Methods: We analyzed 17 published full-text reports of RCTs using BE in patients who underwent TKA. RCTs were sourced from PubMed, the Cochrane Reviews and PEDro Database. The PEDro scale and the 9-item CONSORT (7) were used to evaluate the MQ of the studies.

Results: The mean PEDro score was 6,64 ± 1,57. Classification of RCTs according to total PEDro score revealed that 1 study was classified as excellent, 13 studies as good, and 3 as fair. The least fulfilled criteria in the PEDro scale were: Blinding of all therapists who administered the therapy (1[5.88%]), allocation was concealed (5[29.4%]) and blinding of all subjects (7[41.17%]). The adherence of the reports to CONSORT items ranged from 41.17 % to 100%. The most underreported CONSORT items were: funding sources (7[41.17%]), statistical adjustment for multiple primary outcomes (8[47.05%]), and number of primary outcomes (8[47.05%]).

Conclusion: Our findings show that the quality of reporting for RCTs of BE in TKA patients is not high quality. Since it is not possible to improve balance with PA today, when there are quarantine due to COVID-19, patients should be encouraged to participate in BE programs with telerehabilitation, home-based or web-based exercises, and high quality RCTs should be planned in these programs.

AB1495 THE QUALITY OF REPORTING IN RANDOMIZED CONTROLLED TRIALS OF STRENGTHENING EXERCISES IN TOTAL KNEE ARTHROPLASTY

T. Ünver[1], D. Ozcan[1], B. Unver[2]. *[1]Dokuz Eylul University Health Sciences Institute, Pysical Therapy and Rehabilitation, İzmir, Turkey*; *[2]Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, İzmir, Turkey*

Background: End-stage knee osteoarthritis (KOA) is a significant health issue worldwide resulting in severe pain and disability. Total knee arthroplasty (TKA) leads to significant improvements in pain and the performance of functional activities such as walking for patients with end-stage KOA. Although TKA reduces pain and improves perceived function, patients continue to exhibit reduced muscle strength, voluntary muscle activation, and functional performance even years after surgery (1). In addition, quarantine, and related social restrictions due to the current Covid-19 pandemic may have affected the recovery of patients undergoing TKA due to limited access to exercise, physiotherapy, face-to-face follow-up, and medical services (2).Limited recovery after TKA will require intensive rehabilitation programs in the future. Strengthening exercises(SE) are the most effective intervention for improving muscle strength and functionality and have been recommended in the guidelines for KOA management and in clinical reviews for TKA rehabilitation (3). Randomized controlled trials (RCTs) are the gold standard for assessing the effects of health care interventions. However, RCTs may yield misleading results if they lack methodological rigors(4). RCTs provide the highest quality clinical evidence in the selection of the SE method to be applied (5). However, there are no studies examining the quality of RCTs related to SE in patients with TKA.

Objectives: The aim of this study was to assess the reporting quality of RCTs of SE in patients with TKA.

Methods: RCTs published between 2002 and 2021 were sourced from clinical trial registers, PubMed, and the Cochrane Reviews. RCTs were included if they involved SE in patients who underwent TKA. Analysis was carried out with two assessment tools: PEDro scale and 9-items from CONSORT(6). In addition, we have identified some key methodological elements and examined their relationship to their methodological quality.

Results: We found 35 RCTs that included SE in individuals with TKA. The mean PEDro score was 6.40 ± 1, 73. The most common deficient PEDro Items were: Blinding of all therapists who administered the therapy (14,2 %: 5/35 trials), allocation was concealed (31,4 %; 11/35 trials), blinding of all subjects (31,4 %: 11/35 trials). The most common deficient CONSORT Criteria were: Statistical adjustment for multiple primary outcomes (40 %; 14/35 trials), funding sources (40 %; 14/35 trials) and identification as a randomized trial in the title (62,85%; 22/35 trials). Of the key methodological factors we identified, only exercise duration (weeks) was associated with PEDro score ($R^2 = .169$, $p<0.01$).

Conclusion: Our results show that the quality of reporting in the literature on RCTs of SE in patients with TKA is insufficient. In order to increase muscle strength after TKA, the lack of face-to-face programs due to COVID-19 should be eliminated with telerehabilitation methods, video conferencing platforms and virtual reality applications, and high-quality RCTs should be planned where these programs are examined.

AB1496 THE EFFECTS OF TELEREHABILITATION BASED EXERCISE PROGRAM IN PATIENTS WITH SYSTEMIC SCLEROSIS

F. Sari[1], D. Oskay[1], A. Tufan[2]. *[1]Gazi University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Ankara, Turkey*; *[2]Gazi University, Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Ankara, Turkey*

Background: Systemic Sclerosis (SSc) is a rare, systemic autoimmune disease characterized by skin fibrosis and vasculopathy [1]. Patients may experience a

decrease in their daily activities, physical activity levels and quality of life, while psychological problems such as anxiety and depression may increase. In order to eliminate or reduce these symptoms and the consequences of symptoms, exercise programs for the patient, as well as medical treatment, are an important part of the treatment [2, 3]. Telerehabilitation increases overall health awareness, treatment adherence, and satisfaction by enabling patients to take an active role in decision-making and disease management [4]. Telerehabilitation replaces the traditional face-to-face treatment approach, allowing patients to access treatment remotely [5, 6]. In addition Telerehabilitation enabled patients with chronic diseases to access exercise during the COVID 19 pandemic [7].

Objectives: The aim of the study was to investigate the effect of telerehabilitation-based exercise program in patients with SSc.

Methods: Forty-six SSc patients were included in the study. The patients were randomly divided into two groups as telerehabilitation and control group. Youtube videos consisting of clinical pilates-based exercises were uploaded to the system so that only the patients in the telerehabilitation group could see it. In the telerehabilitation group; An exercise program was applied for eight weeks, twice a day. Video interviews were conducted with the patients once a week. To the control group; the same exercises were given to the telerehabilitation group. An eight-week exercise program was given in the form of a home program. Brochure introducing the exercises was given and exercises were taught. Pain, dyspnea, fatigue, physical activity, anxiety-depression, sleep and quality of life levels were evaluated in all patients at the beginning of the study and at the end of the eight weeks.

Results: Demographic and clinical features of the patient groups were similar (p>0.05). After the exercise program, pain, fatigue, anxiety-depression levels decreased in the telerehabilitation group compared to the control group, while sleep quality and quality of life increased (p<0.05). The results of the study induced that both exercise programs improve pain, fatigue, anxiety-depression, physical activity, sleep quality and quality of life in SSc patients. The telerehabilitation-based treatment program are more and more effective than the home program.

Conclusion: Our study shows that this innovative treatment program should be applied especially in SSc patients and it will be beneficial.

AB1497 THE EFFECT OF AQUATIC REHABILITATION ON QUALITY OF LIFE IN PATIENTS WITH KNEE OSTEOARTHRITIS

R. Maaoui[1], M. Hfaidh[1], Z. Mrizak[1], N. Mouhli[1], H. Rahali[1], I. Ksibi[1], M. Slouma[2], L. Ben Ammar[2], L. Metoui[2], R. Dhahri[2], I. Gharsallah[2]. *[1]The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia*; *[2]The Military Hospital of Tunis, Rheumatology Departement, Tunis, Tunisia*

Background: In addition to its multiple functional, social and economic consequences, knee osteoarthritis is responsible for a significant deterioration in the quality of life (QOL)[1]. Studies examining the impact of osteoarthritis on quality of life have been made possible through the development of validated measurement questionnaires. The SF-12 score with its aspects (physical, mental and social) is a valid and reliable instrument for the assessment of QOL.

Objectives: The main aim of our study was to make a comparison between the contribution of aquatic rehabilitation and classic rehabilitation in patients with knee osteoarthritis using the SF-12 score.

Methods: We carried out a prospective, comparative study carried out over a period of 15 months, (September 2016- December 2017), in 120 patients recruited from the outpatient department of the Physical Medicine and Functional Rehabilitation Department of HMPIT in whom the diagnosis of knee osteoarthritis was made according to the criteria of the ACR.

The patients were randomly divided into 2 groups of 60 patients each. The first group called G1 received a classic rehabilitation program. The second group called G2 benefited from aquatic gymnastics. The study was based on the SF-12 quality of life assessment. Two evaluations were made, the first (T1) before the start of rehabilitation and the second (T2) at the end of the eight weeks of care.

Results: The mean age of our patients was 57.2 ± 12.5 years in G1 vs 54.3 ± 7.1 years in G2 (p = 0.012). The sex ratio was 0.2 in G1 versus 0.37 in G2 (p = 0.011). The duration of knee osteoarthritis was 63.4 ± 4.5 months in G1 vs 56.2±7.5 months in G2 (p=0.172). Initially, the mean of SF12-P in G1 patients was 31.2 ± 6.5 compared to 35.4±6.2 in G2 patients. In our patients, the SF12-P score was less than 50 in 100% of cases in G1 and in 98% of cases in G2. There was a statistically significant difference between the 2 groups (p = 0.04). After classical rehabilitation, the SF12-P had increased on average by 2.3 against 6.1 after aquatic gymnastics with a statistically significant difference between the 2 groups (p = 0.012). Initially, the mean of SF12-M in G1 patients was 32.5 ± 10.2 and 35.3 ± 8.9 in G2 patients. In our patients, the SF12-M score was less than 50 in 94% of cases in G1 and in 98% of cases in G2. There was no statistically significant difference between the 2 groups (p = 0.652). After classical rehabilitation, the SF12-M increased on average by 6.9 and 12.1 after aquatic gymnastics with a statistically significant difference between the 2 groups (p = 0.005).

Conclusion: The effectiveness of functional rehabilitation, whether aquatic or dry, has been well demonstrated by the study of quality of life, with better results for balneotherapy. The physical properties of water and heat have a positive short-term impact on quality of life by acting on several parameters, including pain, contractures and anxiety. Further studies evaluating this long-term effectiveness will be required.

AB1498 THE BIOPSYCHOSOCIAL-BASED EXERCISE MODEL VIA TELEREHABILITATION IN PATIENTS WITH INFLAMMATORY AND NON-INFLAMMATORY RHEUMATIC DISEASES: A PROSPECTIVE COHORT STUDY DURING THE COVID-19 PANDEMIC

N. E. Nacar[1], N. B. Karaca[2], L. Kılıç[3], S. Kiraz[3], E. Ünal[2]. *[1]Hacettepe University, Graduate School of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey*; *[2]Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Department of Physiotherapy and Rehabilitation, Ankara, Turkey*; *[3]Hacettepe University, Faculty of Medicine, Department of Rheumatology, Ankara, Turkey*

Background: During the COVID-19 pandemic, the patients with rheumatic disease in the biopsychosocial perspective have been adversely affected by social isolation, uncertainty, and the thought that their chronic disease will worsen and increase in their symptoms. ACR/EULAR (American College of Rheumatology / European League Against Rheumatism) defines recommendations about continuing current pharmacotherapy and the significance of the biopsychosocial approach and exercise for patients with rheumatic diseases during a COVID-19 infection [1, 2].

Objectives: This study aims to investigate the effectiveness of the biopsychosocial exercise performed by telerehabilitation on biopsychosocial status, general health status, and anxiety-depression levels in the patients with inflammatory and non-inflammatory rheumatic diseases.

Methods: Fourteen patients with inflammatory rheumatic diseases (rheumatoid arthritis: 4; ankylosing spondylitis: 4; sjogren's syndrome: 3; polymyalgia rheumatica: 2; and vasculitis: 1) and eight patients with non-inflammatory rheumatic diseases (fibromyalgia: 6; and osteoarthritis: 2) performed a biopsychosocial-based exercise model (named as "Bilişsel Egzersiz Terapi Yaklaşımı"-(BETY) in original; "*Cognitive Exercise Therapy Approach*" in English) via telerehabilitation continued for three sessions per week for 12 months [3]. Outcome measures were Health Assessment Questionnaire (HAQ), Hospital Anxiety and Depression Scale (HADS), and BETY-Biopsychosocial Questionnaire (BETY-BQ) [4]. All outcomes were measured baseline and at the 12th month. The Wilcoxon's test was used for statistical analysis.

Results: All of the 22 patients were female. The mean age was 57.4 and 55.8 years in the inflammatory and non-inflammatory rheumatic diseases groups respectively, and they had a mean BMI of 25.9 and 25.3 kg/m^2. There was no significant difference by time for HAQ score (p = 0.125), HADS anxiety and depression (p = 0.916 and p = 0.663, respectively), and BETY-BQ score (p = 0.753) between the baseline and at the 12th month follow-up in the patients with inflammatory rheumatic diseases. Similarly, in the patients with non-inflammatory rheumatic diseases, there was no significant difference by time for HAQ score (p = 0.546), HADS anxiety and depression (p = 0.343 and p = 0.527, respectively), and BETY-BQ score (p = 0.068) between the baseline and at the 12th month follow-up.

Conclusion: This study showed that biopsychosocial-based exercise through real-time telerehabilitation was able to maintain their conditions before pandemic in biopsychosocial status, general health, and anxiety-depression levels on the patients with inflammatory and non-inflammatory rheumatic diseases during COVID-19 pandemic period in one-year follow-up.

AB1499 **PAIN MANAGEMENT IN KNEE OSTEOARTHRITIS: BALNEOTHERAPY VERSUS CLASSIC REHABILITATION**

R. Maaoui[1], M. Hfaidh[1], Z. Mrizak[2], N. Mouhli[1], H. Rahali[1], I. Ksibi[2], M. Slouma[3], L. Ben Ammar[3], L. Metoui[3], R. Dhahri[3], I. Gharsallah[3]. *[1]The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia*; *[1]The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia*; *[3]The Military Hospital of Tunis, Rheumatology Departement, Tunis, Tunisia*

Background: Knee osteoarthritis presents a heavy financial burden due to disability and supported care. Gonalgia is the main symptom leading patients to consult. For some clinicians, this is a warning signal that correlates with the extent of joint degradation [1]. The management of pain in knee osteoarthritis is multidisciplinary comprising pharmacological and non-pharmacological means including classical rehabilitation and aquatic gymnastics. The objective of our work was to study the contribution of aquatic gymnastics compared to conventional rehabilitation in the management of pain in patients with knee osteoarthritis.

Objectives: The objective of our work was to study the contribution of aquatic gymnastics compared to conventional rehabilitation in the management of pain in patients with knee osteoarthritis.

Methods: Prospective, evaluative and comparative study about 120 patients with knee osteoarthritis carried out over 15 months (September 2016- December 2017) in the Department of Physical Medicine and Functional Rehabilitation. The patients were divided into two groups of 60. The first group (G1) benefited from a classic rehabilitation program, the second group (G2) benefited from aquatic gymnastics. The 2 programs were carried out at the rate of three sessions per week for two months. The study was based on the assessment of pain by the following scales: VAS pain and the Western Ontario and McMaster Universities' Osteoarthritis Index (WOMAC) questionnaire for the lower limbs (pain section).

Results: The mean age of our patients was 57.2 ± 12.5 years in G1 vs 54.3 ± 7.1 years in G2 (p = 0.012). The sex ratio was 0.2 in G1 versus 0.37 in G2 (p = 0.011). The duration of knee osteoarthritis was 63.4 ± 4.5 months in G1 vs 56.2±7.5 months in G2 (p=0.172). The pain was mechanical in 89 % of cases. Positional nocturnal pain was noted in 72% of cases. Hydarthrosis was associated in 46% of cases. A daily intake of palliative I analgesics was noted in 56 % of patients. The mean pain VAS at rest of 33.4±18 in G1 vs 27.3±23.2 in G2 (p=0.13). On exertion, it was 72.3±19 in G1 vs 83.3±20 in G2 (p = 0.72). After the rehabilitation treatment, an improvement in the two groups was objectified, which was significantly more marked in G2: Resting VAS improved by 57 % for G1 and by 84% for G2 (p = 0.015). Exercise VAS improved 20% in G1 and 43% in G2 (p <0.001). The mean WOMAC pain score was 14.3 in G1 and 10.3 in G2 (p = 0.006). There was an improvement in the WOMAC pain score of 24% in G1 and 58% in G2 (p <0.001).

Conclusion: Functional rehabilitation in the water or in the dry has a marked effect on pain in gonarthrosis patients. The aquatic environment can also bring many benefits on pain by lightening the weight of the body and the analgesic effect of the heat.

AB1500 **ASSESSMENT OF CLINICAL PARAMETERS AFTER CLASSIC REHABILITATION VERSUS BALNEOTHERAPY IN GONARTHROSIS**

R. Maaoui[1], S. Karoui[1], M. Hfaidh[1], N. Mouhli[1], H. Rahali[1], I. Ksibi[1], M. Slouma[2], L. Ben Ammar[2], L. Metoui[2], R. Dhahri[2], I. Gharsallah[2]. *[1]The Military Hospital of Tunis, Physical Medicine and Rehabilitation Departement, Tunis, Tunisia*; *[2]The Military Hospital of Tunis, Rheumatology Departement, Tunis, Tunisia*

Background: Knee osteoarthritis (KOA) is the most common pathology of the lower limb. It is multifactorial and constitutes a real public health problem. Nowadays, in addition to the rehabilitation that is part of the multidisciplinary management of this affection, water gymnastics is increasingly finding its place [1].

Objectives: The main objective of our work was to compare the contribution of aquatic gymnastics compared to classical rehabilitation in patients with knee osteoarthritis through a clinical evaluation.

Methods: This is a prospective, comparative and evaluative study carried out in a department of Physical Medicine and Functional Rehabilitation over a period of 15 months between September 2016 and December 2017, including 60 patients with KOA. The patients were randomly divided into 2 groups of 60 patients each one. The first(G1) benefited from a classic rehabilitation program. The second(G2) benefited from water gymnastics. Two clinical evaluations were carried out: T1 before the start of rehabilitation and T2 at the end of the eight weeks of treatment.

Results: The mean age of our patients was 57.2 ± 12.5 years in G1 vs 54.3 ± 7.1 years in G2 (p = 0.012). The sex ratio was 0.2 in G1 versus 0.37 in G2 (p = 0.011). The duration of knee osteoarthritis was 63.4 ± 4.5 months in G1 vs 56.2±7.5 months in G2 (p=0.172). 55 patients presented with a misalignment of the lower limbs with a varus knee in 33% of cases (G1 25% and G2 42%). 5 patients in G1 and 7 patients in G2 had a valgus knee. In G1, one patient had recurvatum and two patient had knee flexum with no statistically significant difference between the two groups. After classic rehabilitation, Zohlen's sign had disappeared in 6 patients for the right knee and 3 patients for the left knee. However, after water gymnastics, this sign had disappeared in 12 patients for the right knee and in 16 patients for the left knee. A functional mobility sector (>90◦) was found in all patients with an average of 120◦ in G1 and 126◦ in G2. After rehabilitation, an improvement of 2% in G1 and 5% in G2 was noted with a statistically significant difference between the two groups (p<0.001). Thirty-sex percent of G1 patients had quadriceps amyotrophy versus 32 % of G2, which disappeared in 5 patients after classic rehabilitation and in 6 patients after hydrotherapy. 48 patients of G1 and 56 patients of G2 presented with quadriceps retraction which disappeared in 21 subjects of G1 after classic rehabilitation and in 45 subjects of G2 after hydrotherapy. A retraction of the hamstrings was noted in 13 and 18 patients respectively in G1 and G2 with a total improvement in the 2 groups.

Conclusion: Dry rehabilitation has its place in the management of knee osteoarthritis, but rehabilitation in water has better results. The aquatic environment makes it possible, by reducing the weight of the body, to reduce the stresses exerted on the knee joints, allowing better joint mobility with the added effect of heat on the reduction of pain and muscle relaxation.

Education

AB1501 **EFFECT OF SARS-COV-19 PANDEMIC ON RHEUMATOLOGY TRAINING IN INDIA**

K. Kunalchandwar@gmail.com[1], K. Kishor[1], P. Dogga[1], D. Ekbote[1], J. Dixit[1], P. Kumar[1], U. Dhakad[1]. *[1]King George's Medical University, Clinical Immunology and Rheumatology, Lucknow, India*

Background: The current study aims to gauge the magnitude of the effect the pandemic has had on Rheumatology training (including the effect on clinical,

academic and research training) in India, their physical, mental and social well-being during the pandemic and the perceived changes in Rheumatology training and care during the pandemic from the trainee's view

Objectives: 1.To asses the Impact of COVID-19 Pandemic on the training of Rheumatology Residents (DM, DNB and Fellows)

2.Understand the issues faced by trainees and the extent of affection.

Methods: Study design: We conducted an observational cross-sectional study using an online survey sent to rheumatology trainees in India.

Sample: Convenience sampling was used, so the sample size was not calculated.

Inclusion and exclusion criteria: Rheumatology trainees from India including DM/DNB residents and fellows with the ability and desire to complete the survey were included.

Data collection and instruments: The link to the survey was sent to the rheumatology trainees through social media platforms like WhatsApp, Telegram and email.

Statistical analysis: Descriptive statistics were performed by calculating measures of central tendency for quantitative variables and using counts and percentages for qualitative and nominal variables.

Results: A total of 78 trainees from 24 institutes in 12 states participated in the study. Mean age of the participants was 31 with 70% of trainees being male and 30 % females. 56 (70%) participants were DM students, 15 (19%) participants were DNB students, 5 fellowship students and 2 Non- academic Senior Residents. An overwhelming majority of residents (84%) felt COVID-19 Pandemic Negatively impacted their residency and their Physical (65%), Mental(74%) and Social wellbeing (80%). 79% of trainees felt burnt-out due to the pandemic. Majority of trainee felt the pandemic negatively impacted their training with clinical teaching(91%), Clinical examination skill (74%), current(80%) and future(70%) research opportunities suffered during the pandemic. Most residents felt diminution and significant reduction of the overall footfall(99% & 72%) of patients in rheumatology including OPD(100% & 77%) and indoor(99% & 67%) admissions along with academics(85% & 35%), procedures(97% & 66%) and exposure to musculoskeletal ultrasound(96% & 71%). Almost 60% and 40% of trainees had their OPDs and indoor admissions stopped during COVID-19 pandemic of these 20% had their OPDs and Admissions closed for more than 6 months. 85% of the participants had one or the other psychological symptoms with almost half experiencing anxiety(44%), low mood(47%) or lack of sleep(41%); 85% were concerned about their family members being infected and 40% lost a close relative to COVID. 91% of the trainee were posted in COVID-duties 2/3rd of them in ICUs, 50% being posted for 1-3 months and 20% more than 3 months, a quarter of trainees got infected during their duties (COVID and Non-COVID) and though most had asymptomatic to mild COVID, 15% still had moderate to severe COVID. Teleconsultation was started by more than half of the respondents after COVID related lockdowns with greater than half not being happy with teleconsultations.

Conclusion: The COVID-19 Pandemic has completely altered the status quo for rheumatology trainees and has affected their physical, social and mental wellbeing. Academic and clinical training has reduced, Current and future Research has become difficult, disruptions in OPDs and Admissions, recurrent COVID postings and reduction in patient footfall, Procedures and MSK-US have been detrimental to trainees.

AB1502 AWARENESS OF BIOLOGICAL AGENTS RELATED SIDE EFFECTS AMONG INTERNAL MEDICINE RESIDENTS IN A UNIVERSITY HOSPITAL

M. Oztas[1], S. Ugurlu[2]. *[1]İstanbul University-Cerrahpasa, Department of Rheumatology, İstanbul, Turkey*; *[2]Istanbul University-Cerrahpasa, Department of Rheumatology, İstanbul, Turkey*

Background: Biological agents have become a core component of therapeutic strategies in the last two decades. The number of patients treated with biological agents has been increasing with the expansion of these agents' indications among rheumatic disorders.

Objectives: Unfortunately, biological agents have varied side effect profiles, and rheumatic patients with possible side effects are commonly consulted with internal medicine physicians in emergency departments. We surveyed to assess the awareness of biological agents related side effects among internal medicine residents in our university hospital.

Methods: We conducted a web-based multiple-choice test with 10 questions in total. Monoclonal antibodies (anti-TNF, anti-CD20), anti-cytokines, and JAK inhibitors related side effects and management of these adverse events were assessed. Figure 1 depicted the topics and the correct answer rate of the related questions.

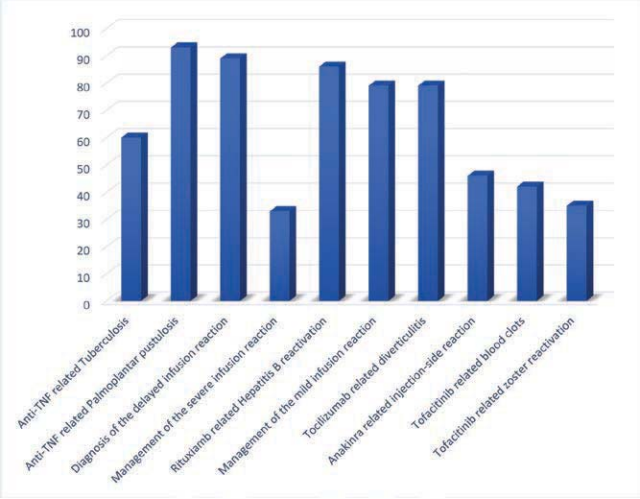

Figure 1. The topics and the correct answer rate of the related questions

Results: A total of 57 responses were collected and analyzed. The mean number of the correct answers was 6,4± 1,5. Fourteen (24,6%) out of the 57 participants scored below 5, whereas 58% of the participants scored ≥6 points. The majority of the participants have correctly answered the anti-TNF, rituximab and tocilizumab-related questions, however, less than half of the participants have accurately answered the anakinra and JAK inhibitors-related questions (Figure 1). Awareness of the JAK inhibitors related zoster reactivation and increased risk of serious cardiovascular events were 35% and 42%, respectively. The approach to the delayed and mild infusion reactions was adequate, however, 33% of the participants accurately approached the severe infusion reaction.

Conclusion: Our survey suggests that the awareness of biologic agents related side effects among the internal medicine residents is satisfactory. Poorer results were observed especially in JAK inhibitors related side effects and severe infusion reaction management which indicate the educational needs of the residents for these topics.

Disclosure of Interests: None declared

AB1503 MOST MEDICINE RESIDENTS WOULD LIKE TO LEARN JOINT ASPIRATION PROCEDURES BUT 2/3 HAVE NEVER DONE IT: SURVEY OF COMMUNITY HOSPITAL TRAINEES IN NORTHEASTERN USA

P. Gonzalez[1], R. Kaler[1], N. Sukumaran[1], A. Eldib[1], Y. Turkowski[1], Z. Y. Li[2], K. Gilek-Seibert[2]. *[1]Roger Williams Medical Center, Internal Medicine, Providence, United States of America*; *[2]Roger Williams Medical Center, Rheumatology, Providence, United States of America*

Background: Arthrocentesis is a procedure performed to aspirate synovial fluid from a joint cavity. It has both diagnostic and therapeutic utilization in outpatient and inpatient settings. While arthrocentesis is considered a minor surgical procedure, there is always potential to injure blood vessels, nerves, and tendons[1]. Although joint arthrocentesis is not an Accreditation Council for Graduate Medical Education procedural requirement for Internal Medicine (IM) residents in the United States, several studies have revealed that training on knee arthrocentesis and injection provided a solid foundation to medical residents toward increasing their confidence and refining motor skills[2].

Objectives: To evaluate the current Roger Williams Medical Center (RWMC) IM residents' confidence level in performing intra-articular injection. Results from this study will inform the design of resident-orientated quality improvement arthrocentesis teaching series in RWMC.

Methods: Project was incepted and designed by one rheumatology faculty, one fellow and five IM residents of RWMC. We selected the survey as a tool to elicit information from all current IM residents who filled out a 7-question survey regarding their residency experience and exposures to knee aspiration and injection. We used Survey Monkey as an anonymous survey tool (see Table 1). Data were collected between 1/14/22 until 1/27/22 and were verified by two members of the research team.

Results: A total of 47 IM residents within three classes in this community residency program were provided with the survey. The survey response rate was 82.9% (39 /47). 69.23% residents do not feel comfortable doing arthrocentesis. More than half of the resident population (51.28%) do not think they have adequate exposure to knee arthrocentesis. 73.68% respondents have never performed knee injections/arthrocentesis. According to the survey, 94.87% of the

Table 1. Survey from 39 total responses

Question	Responses
1.What post-graduate year are you?	PGY1:41.03% PGY2: 35.90% PGY3: 9%
2. Are you comfortable/confident with knee arthrocentesis/injection during residency?	Not Comfortable/confident: 69.23% Somewhat comfortable/confident: 28.21% Quite comfortable/confident: 2.56%
3. Do you think you have adequate exposure to knee procedures in residency?	Strongly Agree: 0% Agree: 0% Undecided: 5.13% Disagree: 51.28% Strongly Disagree: 43.59%
4. How many knee aspirations/injections have you done during residency?	0: 73.68% 1-4: 26.32% 5-10: 0% >10: 0%
5. Do you think our residency program is preparing you to do knee aspirations/ injections?	Strongly Agree: 0% Agree: 0% Undecided: 17.95% Disagree: 35.90% Strongly Disagree: 46.15%
6. Would you be interested in doing more knee aspirations/injections?	Yes: 94.87% No: 5.13%
7. Having exposure to arthrocentesis is very important for me to have in my residency program	Strongly Agree: 33.33% Agree: 35.90% Undecided: 23.08% Disagree: 5.13% Strongly Disagree: 2.56%

residents would be interested in learning to do knee procedures. Having exposure to knee arthrocentesis during residency was important to 36.84% and very important to 34.21% of the trainees.

Conclusion: The survey results demonstrate that most of the IM residents had no prior exposure and are uncomfortable with knee arthrocentesis. However we proved that there is high interest in learning this procedure. Literature review shows that structured training sessions have a long-term effect in competency and confidence with similar procedures. This survey provides us data to set up a system to improve the quality of joint procedures teaching in RWMC.

AB1504 WILL YOU CHOOSE RHEUMATOLOGY? SURVEY ON THE ATTRACTIVENESS OF RHEUMATOLOGY AMONG MOROCCAN STUDENTS, INTERNS AND FRESHLY GRADUATED DOCTORS.

A. Anass[1], T. Fatima Zahrae[1], H. Fouzia[1], B. Khadija[1], F. Abourazzak[1].
[1]Université Abdelmalek Essaidi - Faculté de Médecine et de Pharmacie de Tanger, Rheumatology - CHU Tangier,Tangier, Morocco

Background: In several countries, studies have shown that fewer medical students choose rheumatology as specialty. In Morocco no study has yet focused on this subject.

Objectives: The aim of our study is to assess the attractiveness of rheumatology as a specialty among Moroccan medical students, recently graduates and interns, and to analyze the factors that may be associated with it.

Methods: An online survey was sent to 297 medical students who had started their hospital practice, to 100 medical interns (students in 6th and 7th year who successfully passed the internship competition) and to 280 freshly graduated doctors (residency program candidates before choosing a medical or surgical specialty). The survey covered three areas: anonymous social and demographic informations, data on clinical trainee in a rheumatology department, and the attitude toward rheumatology as a specialty. Descriptive data were collected and Chi 2 Tests were used to assess differences between groups, Logistic regression was performed to investigate associations between demographic and exposure variables and the choice of rheumatology as a career.

Results: We collected responses from 161 students (response rate: 54%), 68 interns (68%) and 89 freshly graduated doctors (32%). The demographic characteristics are presented in Table 1.

Table 1.

	Medical students (N=161)	Interns (N=68)	Freshly graduated doctors (N=89)
Age*	21.5 ±1	24.2 ±1.1	28.62.3
Gender (females) (%)+	93 (57.8)	30 (44.1)	64 (71.9)
level (%)+	Third year: 44 (27.3) Fourth year: 53 (32.9) Fifth year:64 (39.8)	First year: 44 (64.7) Second year: 24 (35.3)	-
Training in a rheumatology departement (%)+	118 (73.3)	28 (41.2)	37 (41.6)
Dduration of training (weeks)*	3.4 ± 0.7	5.3 ±1.4	6.3 ±2.6

(*) expressed as a number and percentage /(+) expressed as a mean and standard deviation

73% of students, 41.2% of interns and 41.6% of graduates said they had already completed a clinical trainee in a rheumatology department. While 41.6% of students and 43.8% of graduates consider the possibility of choosing rheumatology as their specialty, only 11.2% of students, 5.9% of interns and 7.9% of graduates said that rheumatology is their dream career specialty. In uni and multivariate analysis, clinical exposure to rheumatology is retained as the main statistically significant factor predicting the choice of rheumatology in all categories (Odds ratio (95% CI) = 0.191 (0.07- 0.497; p= 0.02)), to this is added the female sex among freshly graduated doctors (Odds ratio (95% CI) = 4.02 (1.251- 12.918; p= 0.001).

Conclusion: Our study showed that rheumatology is considered a fascinating specialty by Moroccan medical students and freshly graduated doctors. Clinical exposure to rheumatology is the strongest predictor factor for choosing rheumatology as a future career.

AB1505 MOROCCAN MEDICAL STUDENTS SURVEY: WHAT ARE THE MOTIVATIONS AND BARRIERS TO CHOOSE RHEUMATOLOGY AS A CAREER?

A. Anass[1], T. Fatima Zahrae[1], N. Takhrifa[1], B. Khadija[1], F. Abourazzak[1].
[1]Université Abdelmalek Essaidi - Faculté de Médecine et de Pharmacie de Tanger, Rheumatology - CHU Tangier,Tangier, Morocco

Background: Rheumatology has experienced a genuine progress in recent decades, especially with the development of new treatments and the use of ultrasound as a mean of exploring the musculoskeletal system, which has contributed to its attractiveness for medical students.

Objectives: The objective of this survey is to study the factors that motivate or discourage medical students to choose rheumatology as a career.

Methods: Web-based questionnaire was sent to 297 medical students who had begun their Hospital training, 100 medical interns, and 280 general practice graduates after passing the residency program's examinations and before choosing their specialty. This questionnaire covered three areas: anonymous demographic information, attitudes toward rheumatology as a specialty, and reasons behind choosing or not choosing rheumatology (multiple choice and open-ended questions).

Results: We collected responses from 161 students (answer rate: 54%), 68 interns (68%), and 89 (32%) medical school graduates. 41.6% of students and 43.8% of graduates consider that they can choose rheumatology as a specialty, whereas 11.2% of students, 5.9% of interns and 7.9% of graduates considered rheumatology as their dream career. The main motivation for students to choose rheumatology is "the diversity of the musculoskeletal pathology". According to interns and graduates, the benefit of choosing rheumatology is the quality of life

Table 1. Main motivations and barriers to choose rheumatology according to Moroccan medical students, interns and medical graduates.

	Students	Interns	Graduates
Motivations	N=67	N=4	N=39
-Wide-ranging specialty with diversity of musculoskeletal pathologies	48 (71,6 %) 24 (35,8 %) 19 (28,4 %)	2 (50 %) 2 (50 %) 3 (75 %)	11 (28,2 %) 10 (25,6 %) 28 (71,8 %)2
- - -Interventional aspect of rheumatology: ultrasound guided injections, biopsy, Hydrodilatation. - - -Relatively less time-consuming specialty			
Barriers	N=88	N=62	N=50
-I am interested in surgical specialties	44 (50 %) 21 (23,9 %) 22 (25 %)	32 (49,2 %) 12 (18,5 %) 18 (27,7 %)	23 (46 %) 21 (42 %) 26 (52 %)
- -Monotonous specialty - -Limited therapeutic aspects			

it can offer, given that it is a "relatively less time consuming specialty». The main barrier to choose rheumatology is "the interest in surgical specialties" for students and interns and "the limited therapeutic aspects" for graduates. Other commonly reported reasons are shown in Table 1.

Conclusion: Our study has shown that rheumatology fascinates Moroccan medical students by its clinical abundance and the diversity of musculoskeletal pathology and also by the quality of life it can offer. According to the students, the main barriers to choose rheumatology are the interest in a surgical specialty, and the limited therapeutic aspects of the specialty.

AB1506 RHEUMATOLOGY TRAINING EXPERIENCE: ARE RHEUMATOLOGY RESIDENTS WELL-PREPARED NOWADAYS? A SELF-APPRAISAL

R. Dos-Santos[1], E. Perez-Pampín[1], A. Souto Vilas[1], A. Mera Varela[1]. [1]*Clinical University Hospital in Santiago de Compostela, Spain, Rheumatology Department, Santiago de Compostela, Spain*

Background: Rheumatology residence in Europe is a 4-year training program where Medical Doctors (MD) purchase all capacities for turning into Rheumatologists at each Hospital. European guidelines concerning which contents should be acquired and recommendations for its obtaining are available (UEMS, Union Européenne des Médecins Spécialistes).[1] Several researches have proven high self-reported abilities, but some deficiencies are displayed in deepen investigations: musculoskeletal ultrasound sonography, poorly crystal identification by optic microscopy and injection skills. As well, low clinical experience remains as one of the most self-reported deficiencies.[2,3]

Objectives: To assess the quality of one-year rheumatology trainee consultation at the outpatient clinic in a Spanish Hospital.

Methods: The last year during outpatient consultation of a resident training in Rheumatology in one Spanish hospital was assessed, from May 2021 to May 2022. All patients visited by the trainee were included, absent patients in the consultation date were excluded from the study. Main variables were collected, such as gender, main diagnosis, biological or targeted synthetic treatments and supplementary tests. The final resident's opinion about his training was also checked.

Results: During one-year period of the Resident's consultation, 1419 visits were performed. From those, 470 were the first visit of the patient and 119 of them were solved in the first visit and no follow-up was needed. 60.7% of patients were woman. Most frequent diagnosis were arthropaties: 21.8% psoriatic arthritis, 16.9% rheumatoid arthritis and 8.4% axial spondyloarthritis. Regarding collagenopathies, 3.4% of patients were diagnosed of systemic erythematosus lupus, 1.3% antiphospholipid syndrome, 2.3% systemic sclerosis and 1.3% myopathies. Bone-related diseases as Paget's disease and osteoporosis were also frequent (21 and 132 patients). The most prevalent vasculitis was giant cell arteritis with 51 patients, although patients with Behçet's disease, Takayasu artheritis and polyarteritis nodosa were also followed. A total of 207 musculoskeletal ultrasonography were made during daily clinical practice. As well, 67 articular injections were performed. Capillaroscopy and salivary gland biopsy were the least frequent procedures (21 and 18, respectively). Biological therapies most supervised by the resident were anti-TNF (76.9%), followed by anti-IL-6 (12.8%) and anti-IL-17 (10.3%).

Conclusion: Most of rheumatic diseases can be diagnosed and followed during one-year period in the resident's training program. Also, ultrasonography and injection skills are granted during this time. The most important self-reported deficiency is the low number of patients under biological/targeted synthetic treatments.

AB1507 ATTRIBUTES INFLUENCING THE SELECTION OF FELLOWSHIP PROGRAMS BY RHEUMATOLOGY APPLICANTS: A PILOT WEB-BASED SURVEY

V. Kesarwani[1], D. Feterman[2], S. Alexander[3], N. Singh[4]. [1]*University of Connecticut, Internal Medicine, Farmington, United States of America*; [2]*University of Connecticut, Internal Medicine, Farmington, United States of America*; [3]*University of Connecticut, Internal Medicine, Farmington, United States of America*; [4]*University of Washington, Division of Rheumatology, Seattle, United States of America*

Background: Recruitment of candidates is a cost- and effort-intensive aspect of rheumatology fellowship programs. For program leaders to efficiently use the available resources and improve recruitment outcomes, it is imperative to understand the attributes that influence the candidates' choice of a program. Previous studies have examined the type and relative importance of the factors that candidates use in selecting other fellowship programs (1, 2). However, no such studies have been conducted in the field of rheumatology.

Objectives: To examine the factors that influence the selection of fellowship programs by rheumatology applicants.

Methods: An anonymous, web-based survey comprised of 13 questions was shared with rheumatology fellowship applicants on messaging applications and online forums. The survey was open from 10/29/2021-11/06/2021. Participation was voluntary and informed consent was implied through the participants' response. Three reminders to complete the survey were sent. Four domains of the applicant's perception in relation to their preference of ranking rheumatology programs were assessed: (1) program prestige, (2) program structure, (3) interview day experience, and (4) career path of the alumni. The survey questions were devised in one of the following formats: (1) 5-point Likert scale, (2) rank order questions, (3) yes/no questions, (4) multiple choice questions, and (5) open-ended questions.

Results: Thirty-two rheumatology applicants responded to the survey. The prestige of the program was reported to be extremely important by 16%, very important by 19%, somewhat important by 44%, and little or not important by 21% responders. The opportunity to see a diverse patient population was reported to be important by 97% respondents. The call schedule and higher number of fellows were considered important by 88% of the respondents. 66% preferred programs with higher number of faculty members. 69% favored programs with an ultrasound curriculum. The availability of clinician-educator track (18%), MCR/MPH (14%), and T32 grand (4%) were considered less important. 69% reported that the opportunity to train at a Veterans Administration hospital did not influence their choice. Regarding interview day experience, interaction with the faculty (63%) and the fellows (17%) were considered important factors influencing program ranking. Respondents preferred programs with alumni in academic clinician track (45%) and private practice (43%) compared to programs with alumni in academic research (13%) or industry pathway (4%). The geographical location of the program including the cost of living and location of significant others also influenced the applicants' choice.

Conclusion: To the best of our knowledge, this is the first survey to assess the attributes that influence a candidate's choice of a rheumatology fellowship program. Our survey demonstrated that a positive interview day experience and program attributes including the opportunity to interact with a diverse patient population, relaxed call schedule, higher number of fellows and faculty, the presence of an ultrasound curriculum, and the location were the dominant factors influencing applicants' choice of a program. The main limitation of our study is the lack of generalizability due to selection bias. Understanding the factors involved in decision making of the rheumatology fellowship applicants can provide valuable information for both the applicants and the programs and therefore lead to a better match.

AB1508 A NOVEL PATHOGENIC VARIANT IN ZNF462 GENE ASSOCIATED WITH WEISS-KRUSZKA SYNDROME AND SLE

M. Constantinou[1], M. Lampi[1], V. Neocleous[2], P. Fanis[2], L. A. Phylactou[2], S. Psarelis[3], K. Parperis[4]. [1]*University of Cyprus, Medical School, Nicosia, Cyprus*; [2]*The Cyprus Institute of Neurology and Genetics, Molecular Genetics, Function and Therapy, Nicosia, Cyprus*; [3]*Nicosia General Hospital, Division of Rheumatology, Nicosia, Cyprus*; [4]*University of Cyprus Medical School, Department of Internal Medicine, Division of Rheumatology, Nicosia, Cyprus*

Background: Weiss-Kruszka syndrome (WSKA) is an autosomal dominant congenital anomaly syndrome due to mutations in the *ZNF462* gene and manifests with developmental delay and multiple craniofacial abnormalities with variable expressivity[1]. It is also characterized by cognitive impairment, whilst about a third of the affected individuals belong to the autism spectrum. Although the disease is inherited with the autosomal dominant manner, most of the described subjects (95%) had *de novo* variants with no affected family members[1]. WSKA has been recently described and only 26 (including our patient) affected individuals have been classified to date[2]. Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by the presence of autoantibodies and multi-organ inflammation. Genetic factors might play an important role in disease pathogenesis in patients with childhood-onset SLE.

Objectives: To describe the case of a SLE patient who was found to have WSKA related to a novel pathogenic autosomal dominant (AD) variant in the ZNF462 gene, and inform clinicians of a possible association between the 2 conditions.
Methods: A 25-year-old Caucasian female with a history of SLE, diagnosed at the age of 14, manifested with malar rash, Raynaud's phenomenon, arthritis, thrombocytopenia, positive ANA, ds-DNA antibody and hypocomplementemia. At the age of 17, she developed renal dysfunction due to lupus nephritis class IV, and she was treated with glucocorticoids (GCs), cyclophosphamide and hydroxychloroquine. In Oct 2020, she was admitted to the hospital for thrombotic thrombocytopenic purpura due to lupus exacerbation. She was successfully treated with GCs, plasma exchange and rituximab. During her hospitalization, the presence of various clinical features raised the suspicion of a genetic syndrome. First, the patient exhibited dysmorphic features such as hypertelorism, prognathism, arched eyebrows, flattened nasal bridge, small upper lip, mild intellectual disability, and a history of childhood-onset SLE. Whole exome sequencing (WES) by NGS was used for the genetic investigation of the patient.

Figure 1.

Results: The patient underwent genetic evaluation with WES and the novel heterozygous AD pathogenic variant c.4142delT (p.Ile1381ThrfsTer16) in *ZNF462* gene was identified. Confirmation of the identified variant was also verified by sanger sequencing. Pathogenic variants in the *ZNF462* gene were previously described in patients with the recently reported WSKA of which several characteristics are compatible with our patient's features. The ZFN462 encodes a zinc-finger transcription factor that plays a role in embryonic development, transcriptional regulation, and chromatin remodelling. Given that chromatin remodelling has been implicated in the pathogenesis of SLE, the association of this novel *ZNF462* variant in the development of SLE, needs to be determined[3].
Conclusion: This is the first report of a patient with coexisting SLE and WSKA due to a novel variant. It illustrates the need for further research in order to elucidate any possible pathophysiologic link among the 2 conditions.

AB1509 OVARIAN CARCINOMA MIMICKING SYSTEMIC SMALL VESSEL VASCULITIS: CASE REPORT

R. A. Elziaty[1]. [1]*Ain Shams University, Internal Medicine Department, Division of Rheumatology, Cairo, Egypt*

Background: Few cases of digital ischemia and gangrene associated with primary solid tumors have been described in literature[3]. The exact mechanism of severe occurrence has not been completely understood and the available treatment options have an extremely limited utility [1,2].In the most cases the patients were elderly women with adenocarcinomas of digestive or gynaecologic apparatuses [4].

Objectives: We describe a new case of digital gangrene as unusual presentation of ovarian cancer in a 36 years old woman.
Methods: 36 years old female was admitted to our Reheumatology deparment with blackish Blackish discoloration of the toes of one week duration. She had history of COVID -19 infection 8 months prior to the presentation then developed hemoptysis, picture suggestive of ILD, generalized anasarca and skin rash; accordingly an initial diagnosis of post COVID-19 vasculitis was made by dermatologist. The blood tests were ESR:21 mm/hr, CRP:25.7, D.Dimer:8.8, Ferritin:575 ng/ml, lymphopenia:0.9, S.Creatinine:2, 24 h urinary protein: 325 mg/24h and all autoimmune markers were negative except anti nuclear antibody (ANA) with titer:1/160. Further assessment revealed that she had multiple site coagulopathy; internal jugular vein thrombosis, bilateral lower limbs Deep Venous Thrombosis (DVT). Neck ultrasound surprisingly showed bilateral enlarged suspicious looking supraclavicular lymph node with lost hilum which was Biopsied for histopathological correlation which revealed focally necrotizing adenocarcinoma with significant signet ring differentiation. Searching for the primary malignancy, tumor markers were sent CA125: 584 u/ml (up to 35), Pelvi-abdominal Magnetic resonance imaging (MRI) revealed Left ovarian mass measuring 3.6 x 3.4 x 4.4 cm highly suspicious of malignant neoplastic growth for histopathological correlation, Suspicious looking pelviabdominal lymph nodes mostly representing malignant lymphadenopathy, Scattered peritoneal nodules suspicious of metastatic deposits.
Results: During admision the patient received full dose anticoagulation (Low Molecular Weight Heparin: 60 iu /12 h). Upon diagnosis we arrange the transferal to the oncology department to continue her management plan. Unfortunately; the case was terminal for palliative therapy and she died after 2 weeks.
Conclusion: Bluish discoloration of digits and toes may be a clue for diagnosis of many diseases not only vasculitis. Malignancy can disturb the immune system in a way that mimic any systemic connective tissue disease. Acute insult aggressive multiple site deep venous thrombosis (DVT) necessitate thinking outside the box and consider other causes of coagulopathy like visceral malignancy.

AB1510 INFLAMMATORY MYOSITIS – FINAL ANSWER?

M. Malik[1], E. E. P. Htut[1]. [1]*Basingstoke and North Hampshire Hospital, Rheumatology, Basingstoke, United Kingdom*

Background: Motor neurone disease may mimic inflammatory myositis. There is an overlap in clinical symptoms (such as muscle weakness, dysphagia and respiratory involvement) which may pose a diagnostic challenge. Careful history, thorough clinical examination and appropriate investigations can help to distinguish between the two. Monitoring the response to treatment is also crucial. We present a case that presented to rheumatology with progressive muscle weakness, she was investigated and treated for inflammatory myositis but was later diagnosed with motor neurone disease.

Objectives: To illustrate the need for thorough clinical assessment and investigations in patients with suspected inflammatory myositis and consider alternative diagnoses as clinical picture evolves.

Methods: A 68 year old lady, presented with 6 months history of progressive proximal muscle weakness. She also reported weakness of grip, affecting activities of daily life. She was finding it difficult to get up from chair. There was no swallowing difficulty, respiratory symptoms and skin rash. She had no weight loss or constitutional symptoms. She did not have any joint pain or features of connective tissue disease. She had history of hypertension. On clinical examination, she did not have any features of connective tissue disease. There was no evidence of joint synovitis or skin rash. Proximal power in upper and lower limbs noted to be 4/5 with intact reflexes. Initial investigations revealed mildly raised CPK at 287 with normal thyroid function and inflammatory markers. Immunological tests including ANA and myositis panel were requested alongside EMG, MRI thighs and CT chest/abdomen/pelvis. Myositis panel was positive for anti-MDA-5 antibodies (in the absence of any skin or respiratory symptoms). There was no evidence of malignancy on CT imaging. MRI thighs revealed fluid in the trochanteric bursae. She was trialled on oral prednisolone in view of her clinical features and positive anti-MDA5 antibody. However, there was no improvement in her symptoms or functional status. EMG revealed widespread neurogenic process affecting upper and lower limbs on both sides, without significant evidence of acute myopathy. The progressive nature of symptoms with the upper motor neurone signs raised the possibility of an evolving anterior horn cell disorder. She was referred to neurology and was subsequently diagnosed to have Motor Neurone Disease. The steroids were rapidly tapered off and stopped.

Results: Motor neurone disease is an important differential when considering inflammatory myopathy, particularly inclusion body myositis which causes more progressive muscle weakness. It is a neurological disorder characterised by degeneration of neurons. There is no clear cause identified. MND causes both upper and lower motor neurone signs. Symptoms include limb weakness, bulbar weakness that can affect speech and swallowing, muscle twitching and fasciculation. Respiratory weakness may occur. Thorough clinical examination and EMG findings help identify the diagnosis. Imaging may be needed. There is no cure. Management requires an MDT approach, primarily guided by neurology, including physiotherapy, occupational therapy, speech and language therapy and respiratory support.

Conclusion: This lady was initially treated for inflammatory myositis based on her symptoms, mildly raised CK and positive anti-MDA5 antibodies. On review of her clinical progress, we noted poor response to steroids and EMG results pointing at an alternative diagnosis of MND. This case highlights the importance of EMG in the assessment and management of patients with suspected inflammatory myositis as well as the need to closely monitor progress and re-evaluation where needed. Although she had anti-MDA-5 antibodies and mildly raised CK, she did not have any skin disease or other systemic features, inflammatory markers and muscle imaging was normal. Response to steroids was inadequate.

AB1511 SLE ONSET POST COVID-19 VACCINATION: COINCIDENTAL OR ASSOCIATION?

C. R. Ng[1], C. E. Goh[1]. [1]*Hospital Sultan Ismail, Rheumatology Unit, Department of Medicine, Johor Bahru, Malaysia*

Background: Numerous immune-mediated diseases flare or new disease onset after SARS-CoV2-vaccination have been reported. There were case reports showed the immune-mediated disease flare post vaccination but study on new disease occurs post Covid-19 vaccination is still lacking.

Objectives: To describe two SLE cases that diagnosed post Covid-19 vaccination.

Methods: Case report

Results: 14 years old girl, post Covid-19 vaccination 1st dose 3 weeks ago presented with 2 day history of giddiness, breathlessness, vomiting and diarrhea prior to admission. She also complained of frothy urine for the past 1 week associated with lower limbs swelling and facial puffiness. Clinical examination noted she had sparse hair, oral ulcers and discoid lupus at the ear concha. She also noted to have periorbital puffiness with pedal edema. Lung auscultation noted bi-basal crepitations. Blood investigation noted ANA positive (1:640, speckled) with low complement 3 (0.1g/L). Her full blood count showed leucopenia (3100 UL) with low lymphocyte count of 810UL. UFEME noted protein of 3 + and red blood cell of 2+ with normal renal profile. Her serum albumin was 22g/L. Chest x ray showed clear lung field with no cardiomegaly. Her 24-hour urine protein showed proteinuria of 2.345g/dl and her renal biopsy showed mesangial proliferative lupus nephritis class ii. She was given intravenous methylprednisolone 500mg OD for 3 days and discharged with tapering dose of prednisolone, hydroxychloroquine, calcium supplements, perindopril and frusemide. Another case was a 17 year-old female, post covid-19 vaccination 10 weeks, presented with 3 weeks history of bilateral lower limbs weakness with difficulty in getting up from chair. She also had fever on and off with cough for 1 week. There was no alopecia, oral ulcer, facial rash or photosensitivity. No joints pain. Clinical examination noted presence of proximal myopathy with stable vital signs. Other systemic examinations were unremarkable. Blood investigation noted ANA positive (1:640, homogenous and speckled) with low complements level (C3 0.19g/L and C4 0.049 g/L).Her creatine kinase was 2367U/L and EMG showed evidence of irritable myopathic process which is consistent with inflammatory myositis. Her TFT was normal. Myositis panel showed anti-Ku and anti-Ro 52 were positive. She was treated as SLE with myositis and intravenous methylprednisolone was given. She discharge well with tapering dose of prednisolone and azathioprine. Her creatine kinase showed improvement with immunosuppression therapy and she was advised on intensive physiotherapy.

Conclusion: The onset of these two SLE cases were occurred within the 2 month of post covid-19 vaccination. Whether Covid-19 vaccination direct contribute to the occurrence of SLE remained inconclusive. More studies are required to show its correlation between onset of SLE and Covid-19 vaccination.

AB1512 CENTRAL RETINAL ARTERY OCCLUSION (CRAO) LEADING TO BILATERAL BLINDNESS; DUE TO BOTH ARTERITIC AND NON-ARTERITIC ISCHEMIC OPTIC NEUROPATHY

S. Sunari.Subasinghe@gmail.com[1], C. Biyanwila[2], O. Temizsoylu[3], K. Ramesar[4]. [1]*Medway NHS Foundation Trust, Rheumatology, Gillingham, United Kingdom*; [2]*East Sussex NHS Health Care Trust, Stroke Medicine, Eastbourne, United Kingdom*; [3]*Moorfield Eye Hospital NHS Foundation Trust, Ophthalmology, London, United Kingdom*; [4]*East Sussex NHS Health Care Trust, Histopathology, Eastbourne, United Kingdom*

Background: Giant cell arteritis (GCA) is a large vessel vasculitis which is common in the elderly. It affects the cranial branches of the aorta, commonly superficial temporal, posterior ciliary and retinal arteries. Hence blindness can be one of the dreaded complications of the disease which makes prompt diagnosis and treatment of utmost importance. Sometimes atypical presentations and concurrent pathologies can make the timely diagnosis of the disease difficult. Therefore it is very important for clinicians to be vigilant of the varied presentations of the GCA and coexisting vascular risk factors.

Objectives: A 78-year-old Caucasian male was presented with acute onset blindness of the left eye. It started as few blotchy patches in the peripheral visual field and gradually became diffuse visual loss over a few days. He denied any headache, temporal tenderness, tongue or jaw claudication or symptoms of polymyalgia rheumatica. Following ophthalmology review he was diagnosed to have CRAO with marked disc pallor without any evidence of retinal emboli. He was in sinus rhythm, no carotid bruits or cardiac murmurs were noted. His comorbidities were hypertension and hypercholesterolemia. He was assessed in the transient ischemic attack clinic for screening for vascular risk factors and started on anti platelets.

Methods: Three months later he re-presented with visual loss in the right eye. Apart from the mild tenderness of the right temporal region noticed when trimming his hair he had no symptoms of GCA. He was started on dual antiplatelets and urgently referred to ophthalmologist who diagnosed central retinal artery occlusion of right eye with clear demonstration of emboli in all the arcades of the central retinal artery. A temporal arterial biopsy was performed.

Results: His CRP was 19mg/l & ESR was 18mm/hr initially. During the second presentation both ESR (35) and CRP (40) were further elevated. His carotid doppler did not show significant stenosis in internal carotid arteries. ECG at presentation was in sinus rhythm however 24 hour holter monitoring after involvement of both eyes showed paroxysmal atrial fibrillation (PAF). Transthoracic echocardiogram was normal. His temporal arterial biopsy showed destruction of the internal elastic lamina with lymphohistiocytic infiltration and occasional giant cells in keeping with a diagnosis of GCA. Patient was started on prednisolone 60 mg daily followed by a tailing off regime and antiplatelets were changed to anticoagulation due to PAF. His vision improved mildly, only in the right eye in the way of perception of hand movements.

Conclusion: CRAO is an ocular emergency and is the ocular manifestation of a stroke. The usual presentation is a painless unilateral visual loss leading to profound blindness and is commonly due to non arteritic causes like carotid artery stenosis, cardiogenic embolism, small vessel disease and rarely due to arteritic causes like GCA. Accurate identification of the aetiology is very important to avoid further recurrence. By consensus multiple retinal emboli usually excludes a diagnosis of GCA[(1).] However considering, the patient's age and recurrence of CRAO while on antiplatelets led us to consider occult GCA. 21.2% of patients with GCA induced vision loss do not have any systemic symptoms of the disease[(2)]. Hence there should be a high index of suspicion when an elderly person presents with ischaemic ocular manifestations especially optic nerve and retinal ischaemia even in the presence of another plausible explanation like PAF.

AB1513 SIROLIMUS INDUCED INFLAMMATORY ARTHROPATHY

K. Beharry[1], S. Srirangan[1]. *[1]Medway Maritime Hospital, Rheumatology, Gillingham, United Kingdom*

Background: Sirolimus is a non-calcineurin immunosuppressant commonly used in patients with organ transplantation to prevent rejection. While various inflammatory syndromes have been described post-sirolimus use, it is uncommon to have inflammatory arthritis to sirolimus[1]. We present a patient who developed significant joint inflammation following sirolimus use.

Results: Our patient is a 39 year old gentleman who had a heart transplant in 1992 following dilated cardiomyopathy. He was switched to sirolimus after concerns about chronic kidney disease and graft vascular disease. Six weeks later, he developed bilateral foot pain and swelling which prevented him from weight bearing. He had an MRI which showed significant bone marrow oedema in the midfoot tarsal bone and basal metatarsals. He then had a nuclear scan which showed highly increased and symmetrical uptake in both mid feet affecting the cuneiform and second, third and fourth bases of the metatarsals. The appearances showed increased osteoblastic activity with increased vascularity which was more in keeping with bone inflammation/infection and no osteonecrosis. His C-reactive protein was elevated at 148. This improved to 30 after cessation of the sirolimus. Blood cultures were negative. Of significance in his history, he also suffers from gout and has had previous monoarthritic flares involving his wrist, elbow and index finger. However, he was placed on febuxostat 80 mg in 2018 with excellent response. His serology was negative for anti-CCP and Rheumatoid factor. His urate levels were controlled at 374. He was also found to be HLA-B27 positive, but there was no evidence of inflammatory back pain.

He was placed on a tapering course of prednisolone and coupled with the cessation of the Sirolimus, his pain and swelling resolved. In follow-up clinic appointments, he remained in remission from his inflammatory arthritis and did not require any additional treatment but continued on Mycophenolate Mofetil and Ciclosporin for his cardiac transplant.

Conclusion: There are many studies investigating the use of sirolimus as an anti-inflammatory agent in autoimmune conditions such as rheumatoid arthritis[2] and inflammatory bowel disease[3]. The mechanisms include down regulation of IL-17 and IL-6[3]. However, the induction of an inflammatory arthritis by sirolimus can paradoxically occur as sirolimus causes a reduction in the STAT 3 and the anti-inflammatory cytokine IL-10[3]. There has been raised levels of IL-6 and TNFα in serum of patients with inflammatory sequelae post sirolimus therapy[1]. This disequilibrium of inflammatory cascade is related to the ability of Sirolimus to inhibit mammalian target of rapamycin (mTOR) which then subsequently modulates these effects[4]. In general, these pro-inflammatory sequelae are mild and tend to resolve after cessation of the drug[1]. Although our patient had severe arthritic manifestations which required steroid therapy, his symptoms were transient after removal of Sirolimus.

AB1514 AN UNUSUAL ASSOCIATION BETWEEN THROMBOTIC THROMBOCYTOPENIC PURPURA AND PRIMARY ANTIPHOSPHOLIPID SYNDROME

R. Santangeli[1], G. Montozzi[1], L. Gamba[1], S. Salvucci[1], L. Manfredi[2], G. Moroncini[1,2]. *[1]Ospedali Riuniti Ancona University Hospital, Internal Medicine Residency Program, Anocna, Italy*; *[2]Ospedali Riuniti Ancona, Internal Medicine, Ancona, Italy*

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare and life-threatening thrombotic microangiopathy characterized by microangiopathic haemolytic anemia, consumption thrombocytopenia and organ injury, particularly kidney failure and neurological manifestation[1]. Two forms are distinguished: the hereditary one, caused by a deficit of the metalloprotease ADAMTS13, and the idiopathic one characterized by the presence of antibodies directed against ADAMTS13. The second one is the most common. There are various subgroups of acquired TTP associated with HIV infection, sepsis, pregnancy, autoimmune disease, disseminated malignancies and drugs. Antiphospholipid syndrome (APS) is a clinical immunological condition characterized by thromboembolic events, repetead miscarriages or stillbirth and thrombocytopenia; it can be a primary disorder or due to connective tissue disease, in particular systemic lupus erythematosus[2].

Objectives: We describe a case of TTP associated with a primary APS. The real clinical challenge lies in the differential diagnosis between TTP and anti-phospholipid antibody syndrome.

Methods: A 37-year-old man presented to the emergency department for short-term episodes of anesthesia of the right upper limb and face with spontaneous resolution. In his past medical history, he suffered of antiphospholipid syndrome treated with warfarin. Upon admission, blood tests revealed severe thrombocytopenia, haemolytic anemia with schistocytes on peripheral blood smear, low thrombin time and prolongation in the prothrombin time. Neurological symptoms were assessed by electroencephalogram and CT brain, resulted negative, while a brain MRI revealed acute-subacute ischemic stroke. Based on these findings we suspected a diagnosis of TTP, subsequently confirmed by reduced activity of ADAMTS-13 with borderline ADAMTS-13 inhibitory antibodies. Immunological testing confirmed positivity of antiphospholipid antibodies and antinuclear antibodies.

Results: According to the last guidelines3 about management of acute episode of TTP, immediate therapy with high-dose corticosteroids (prednisone 1 mg/kg) and plasmapheresis was started and then we added infusion of rituximab (375 mg/m2/week for 4 times). Efficacy of treatment was evaluated by weekly dosage of ADAMTS13 activity, with a gradual rise in values (3 → 78%) and improvement in symptoms and laboratory examination. After persistent remission, we gradually reduced steroid therapy. Few months later, in February 2021, patient developed a bilateral comunitary pneumonia, that required hospitalization, oxygen - therapy (also with C-PAP) and endovenous antibiotics. After two weeks patient was discharged from hospital in good clinical health and he was subjected to periodic outpatients visits. Disease activity was in remission, so steroid therapy was reduced and recently we added hydroxychloroquine for APS. Some days ago patient developed covid – 19 infection, despite vaccination, and he was treated with monoclonal antibodies, with good clinical response.

Conclusion: We have described a rare clinical case of TTP, despite concomitant warfarin treatment for primary anti-phospholipid syndrome. A careful follow-up of these medical conditions is recommended for patient's fragility and for the risk of related serious clinical complications.

AB1515 ANCA-NEGATIVE PAUCI-IMMUNE GLOMERULONEPHRITIS AS A PARANEOPLASTIC MANIFESTATION OF SARCOMATOID MALIGNANCY

M. Ehtesham[1], S. H. B. Waqar[2], L. Farrukh[1], M. A. Shabbir[1], R. Peredo-Wende[3]. [1]*Albany Medical Center, Internal Medicine, Albany, United States of America*; [2]*SUNY Downstate Medical Center, Internal Medicine, Brooklyn, United States of America*; [3]*Albany Stratton VA Medical Center, Rheumatology, Albany, United States of America*

Background: Pauci-immune glomerulonephritis (PIGN) is a type of small vessel vasculitis associated with anti-neutrophilic cytoplasmic antibodies (ANCA). However, about 10-20% of PIGN patients have negative ANCA serologies. PIGN as a paraneoplastic syndrome is rarely described in literature with a few cases reporting an association with lung cancer.

Objectives: We describe a case of ANCA negative glomerulonephritis in a patient with underlying malignant sarcoma responsive to rituximab.

Methods: An 80-year-old female was admitted with complaints of upper abdominal pain and new onset hematuria for 2 days. Vital signs were stable, and physical exam was remarkable for mild tenderness on deep epigastric palpation. Initial laboratory workup was significant for acute kidney injury with serum creatinine of 2.1 mg/dl (creatinine two months ago at outpatient visit was 1.0 mg/dl). Urinalysis showed 4+ proteinuria and dysmorphic red blood cells. CT scan of the abdomen revealed a soft tissue mass surrounding celiac artery and a right adrenal hypodense mass. Further serologies to elucidate the cause of kidney injury revealed normal perinuclear-ANCA and cytoplasmic-ANCA levels. Renal biopsy was positive for focal segmental necrotizing and crescentic glomerulonephritis consistent with pauci-immune vasculitis. She also underwent right adrenal and celiac mass biopsy; both revealing malignant spindle and epithelioid cell neoplasm consistent with undifferentiated pleomorphic sarcoma (UPS). Our patient was treated with four rounds of plasmapheresis followed by 600mg rituximab infusion which decreased her creatinine to 1.7 mg/dl and resolved hematuria within 10 days of admission. She was followed up in rheumatology clinic two weeks later where she denied further hematuria and was given another round of 600mg rituximab infusion.

Results: UPS is a rare soft tissue cancer with a 5-year survival rate as low as 15% in metastatic disease. Paraneoplastic manifestations of UPS are seldom described in literature due to poor prognosis of the disease and low annual incidence. PIGN is scarcely reported in association with lung carcinoma in a few case reports[1, 2]. It is interesting to note that in these cases there was antecedent chemotherapy raising suspicion of vasculitis induced by adjuvant agents. As our patient did not receive chemotherapy, PIGN was deemed to be a paraneoplastic phenomenon secondary to malignant sarcoma.

Conclusion: This case underscores the importance of recognizing sarcoma as a possible etiology of paraneoplastic ANCA-negative PIGN. We also explain how plasmapheresis and rituximab may play a role in the treatment of renal dysfunction in these patients.

AB1516 A CASE OF SEVERE ANCA ASSOCIATED VASCULITIS AFTER COVID-19 VACCINATION

I. Qaisar[1], K. Sunmboye[2]. [1]*Leicester Royal Infirmary, Rheumatology, Leicester, United Kingdom*; [2]*Leicester Royal Infirmary, Rheumatology, Leicester, United Kingdom*

Background: The world is currently rocking to and fro in the midst of the COVID-19 viral storm and vaccinations have played a pivotal role in calming this.Although COVID-19 vaccines have been thoroughly assessed and studied before being rolled out to the general population, there have been reports of post vaccination complications in limited number of subjects strongly associated with COVID-19 vaccinations[1].

Objectives: To report a case of severe ANCA associated vasculitis after COVID-19 vaccination.

Methods: A case report and discussion.

Results: In view of this, we report the case of a 77 year old caucasian male who developed severe ANCA associated vasculitis (AAV) after two doses of Astra-Zeneca vaccine and one booster dose of Pfizer COVID-19 booster. He presented with acute onset inflammatory arthritis with mononeuritis multiplex with bilateral foot drop and left radial and ulnar nerve forearm weakness in typical asymmetrical pattern two weeks after the Pfizer vaccination. He had a raised MPO-ANCA titre of 66 IU/ml, C-reactive protein of 131mg/L and reactive thrombocytosis of 458 X 10 ^{9}/L. Nerve conduction study confirmed mononeuritis multiplex in the bilateral peroneal nerves and left radial and ulnar nerve. A total body CT had excluded malignancy and paraneoplastic associations and Gullian-Barre diagnosis was also excluded. The patient was treated with 3 days of intravenous methylprednisolone 1g daily then given intravenous Rituximab 1g, two weeks apart. He is currently undergoing rehabilitation in view of the vasculitic neuropathy from his diagnosis.

Conclusion: Diagnosis of AAV is often delayed or missed by other medical specialties due to its varied presentation. AAV should be suspected in a patient with paraesthesia/weakness in keeping with mononeuritis multiplex or other peripheral neuropathy in the absence of an alternative explanation (e.g. diabetes,B12 deficiency) and in particular with a wrist or foot drop.Exposure to certain drugs and substances of abuse such as cocaine, hydralazine and propylthiouracil has been implicated with AAV.While short-term side effects of COVID-19 vaccine resemble those of other vaccines, long-term side effects remain unknown[2]. Rare side effects continue to surface as millions of people receive COVID-19 vaccines around the world.

AB1517 SYNOVITIS COMPLICATING THE COURSE OF COMMON VARIABLE IMMUNODEFICIENCY: CAUSAL OR COINCIDENTAL?

M. Yasmine[1], S. Miladi[1], A. Fazaa[1], H. Bousaa[1], L. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Common variable immunodeficiency (CVID) is a heterogeneous disorder characterized by hypogammaglobulinemia and an increased susceptibility to recurrent bacterial infections. Even though several immunological defects are involved in the pathogenesis of CVID, the genetic background of the disease

remains unidentified [1]. Autoimmunity in CVID is not restricted to hematologic cells, as rheumatologic complications occur in perhaps 10% of patients, with females being more affected [1].

Objectives: Here by we report a case of a CVID complicated with RF negative synovitis.

Methods: We report a case of a 36-year-old woman who was referred to our department for oligoarthritis. She had a history of primary immune deficiency revealed at the age of 30 with recurrent pulmonary infections. The disease was complicated with type 1 diabetes and bronchiectasis and was treated with annual infusion of immunoglobulin. The patient presented with pain and swelling in both knees evolving for two months. On physical examination, she had synovitis in both knees. Laboratory investigations revealed normal blood count with elevated C-reactive protein (CRP) and erythrocyte sedimentation rate: 36.2mg/l, and 32 mm/h respectively. Synovial fluid aspiration analysis of the knee revealed an inflammatory liquid without crystals. Bacterial culture was negative. Her serum was negative for Rheumatoid Factor (RF), anti-cyclic citrullinated peptide (anti-CCP) antibody and antinuclear Antibodies (ANA). Knee ultrasound revealed synovitis in both knees with Doppler signal. The Magnetic resonance imaging (MRI) of the knees showed active synovitis without any erosion. Ophthalmological assessment showed severe dry eye syndrome. As Sjögren's syndrome was suspected, we performed a salivary gland biopsy that was normal.

Results: The patient did not fulfill criteria for auto-immune rheumatic related disease. She was treated with intraarticular glucocorticoids injections, with complete resolution of symptoms and disappearance of effusion on ultrasound. A follow-up was scheduled after one month. The synovitis has been attributed to rheumatologic involvement in the context of immune deficiency.

Conclusion: We report a rare case of RF negative synovitis complicating the course of CVID. Even though the symptoms could be mild compared to a typical RF+RA, it is important to educate clinicians as to the importance of maintaining a high index of suspicion about this rare, yet potentially treatable disease. Future research is indicated to understand the etiopathogenesis of rheumatologic manifestations in CVID.

AB1518 CASE REPORT OF A HARD TO TREAT DERMATOMYOSITIS AFTER A COVID-19 INFECTION AND SUBSEQUENT VACCINATION

P. Peteva[1], L. Marinchev[1]. [1]*UMHAT Sofimed, Sofia, Bulgaria, Rheumatology Department, Sofia, Bulgaria*

Background: A 50 years old woman, a medical doctor, came to our department with symmetrical proximal muscular weakness, several months after Covid-19 infection and three weeks after a second dose of Covid-19 mRNA vaccine. The patient had no prior or family history of autoimmune diseases and take no medicines. In the past she undergone an operation for double-kidney with frequent urinary infections. Objective findings have shown symmetrical proximal muscular weakness and classic sings of dermatomyositis - Gottron's papules, shawl and holster signs, periungual vasculitis.

Objectives: We present a case of a 50 old woman with clinical and laboratory proven dermatomyositis, starting three weeks after a second dose of a Covid1-19 mRNA vaccine without other reasons.

Methods: The laboratory tests showed elevated CPK, lactate dehydrogenase, aspartate aminotransferase and alanine aminotransferase, high ANA – 1:1280 and myositis specific autoantibodies- anti-NXP2 and anti-Mi-2-beta. The electromyography showed myopathic changes and the muscle MRI – symmetrical edema of mm.obturator and mm.adductor brevis. We exclude diseases that may mimic inflammatory myopathies. We made a cancer screening – whole body MRI, colonoscopy, gastroscopy, mammography and gynecological exam, immunoblot for detection of paraneoplastic syndrome-associated neuronal antibodies, with no detection of cancer. Muscle biopsy of m.vastus lateralis showed attenuating muscle inflammation with advancing muscle atrophy and fibrosis.

Results: The diagnose dermatomyositis was made according Bohan and Peter criteria and we start a high dose (1mg/kg/day) glucocorticoid therapy with good initial clinical and laboratory effect. Two months after starting a therapy muscle weakness worsened together with difficulty of swallowing. We excluded steroid myopathy after second EMG and lack of improvement when tapering the GS dose. Methotrexate 20 mg/weekly was added as a steroid sparing drug with good response, but was stopped because flare of pyelonephritis. Accordning to the opinion of dermatologist hydroxychloroquine was started for a couple of weeks, because of active skin manifestations. Muscle weakness worsened on the background of treatment, which was stopped. We started a therapy with intravenous immunoglobulins and considered therapy with cyclophosphamide or azathioprine after urinary infection. Because the patient was infected for a second time with covid-19, although vaccine, we continued only with glucocorticoids and anti-osteoporotic therapy.

Conclusion: The etiology and pathogenesis of inflammatory myopathies are not fully clarified so far. We speculate that the infection with Covid-19 as well as mRNA vaccine trigger inflammatory myopathy and compromise the patient's immunity for poor treatment response with glucocorticoids and immunosuppressives. On the other hand advanced muscle atrophy and fibrosis within a short period show that suspected triggering factors could be a reason for difficult to treat such type of dermatomyiositis.

AB1519 STEROID FREE REMISSION IN ORGAN THREATENING ANCA ASSOCIATED VASCULITIS: WITHOUT AVACOPAN

A. C. Das[1], G. Ms[2], C. Kavadichanda[2], M. M. Thabah[2]. [1]*JIPMER, Clinical Immunology, Puducherry, India*; [2]*JIPMER, Clinical Immunology, Pondicherry, India*

Background: Steroid free remission in organ threatening ANCA associated vasculitis is currently described only with Avacopan, a C5a receptor inhibitor. However, this drug is not yet available for use in the third world.(1)

Objectives: To describe a clinical case of granulomatous polyangiitis with orbital pseudotumor right eye with optic atrophy, who developed steroid induced central serous retinopathy in the other eye, necessitating a steroid free treatment regime.

Methods: A 45year old man was admitted to the department of clinical immunology, JIPMER in January 2021 with Orbital pseudotumor Rt eye since 2019 causing optic atrophy, treated with high dose steroids for more than a year. He developed steroid induced central serous retinopathy of left eye, necessitating withdrawal of steroids, leading to disease flare in the form of painful right orbital inflammation, acute glomerulonephritis, vasculitic ulcers over leg and lung nodules. His PR3 ANCA titers were elevated at the time of disease flare. His sputum infectious workup was negative for bacteria/fungus/tuberculosis. He was treated with 10 cycles of radiotherapy to right eye for debulking followed by exenteration. As he had pseudomonal infection in the post operative orbital cavity at the time of flare, 2 monthly

Table 1. Investigations:

	Week 0	Week 28	Week 48
Hemoglobin(g/dl)	5.5	7.8	10.7
Creatine (mg/dl)	1.43	1.35	1.0
Albumin (mg/dl)	1.9	2.5	3.8
Urine analysis	Protein:2+ RBCs:50 -100/hpf	Protein:1+ RBCs: 10-15/hpf	Protein: trace RBCs: <10/hpf
CECT Thorax	Left upper lobe solitary nodule	Resolved	
MRI orbit	RT orbital pseudotumor with optic atrophy	S/P exenteration	
Renal Biopsy	Focal proliferative sclerosing glomerulonephritis; No crescents.		
Orbital tissue biopsy	Palisading granuloma		
PR3 ANCA(ELISA)	57.63		
MPO ANCA(ELISA)	negative		
ANA	Negative		
C3/C4	1.61/0.32 (normal)		
ACE levels	25.3 (normal)		
IgG4	2.73		
BVAS	20	5	0
VDI	3	3	3

Abbreviations: hpf: high power field, CECT: Contrast enhanced computed tomography, PR3: proteinase3, MPO: Myeloperoxidase, ANA: Antinuclear antibodies, ACE: Angiotensin converting enzyme, BVAS: Birmingham vasculitis activity score, VDI: Vasculitis damage index

doses of IVIG 2g/kg was given; infection treated with antibiotics and regular dressing. After resolution of infection 6 doses of cyclophosphamide as per EUVAS protocol and Rituximab 2 gm was given along with the first dose of Cyclophosphamide.

Results: At 48 weeks of follow up, he continues to be in sustained clinical remission without steroids. He has received additional 500 mg of rituximab at 28 weeks. His lung nodules and vasculitic ulcers of leg healed over 34 weeks. He has developed saddle nose deformity for which reconstruction is planned.

Conclusion: Steroid free remission in GPA may be possible without Avacopan.

AB1520 EFFECTIVE TREATMENT OF TOCILIZUMAB IN PATIENTS WITH REFRACTORY ADULT-ONSET STILL'S DISEASE

T. Cheng[1], Z. Chen[2], J. Tan[1], Y. Jiang[2], Z. Liao[2]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Rheumatology and Immunology Department, Guangzhou, China*; [2]*Third Affiliated Hospital of Sun Yat-sen University, Rheumatology and Immunology, Guangzhou, China*

Background: Pro-inflammatory cytokines such as interleukin 6 (IL-6) are involved in the pathogenesis of adult-onset Still's disease (AOSD). Anti-IL-6 agents such as tocilizumab have been tried to treat AOSD successfully.

Objectives: To access the efficacy of tocilizumab in the treatment of AOSD patient refractory to,or with initial treatment.

Methods: We reviewed three cases with refractory AOSD treated with tocilizumab. All patients fulfill the Cush criteria for AOSD. All patients performed blood culture, auto-antibodies test and bone marrow test to exclude infectious diseases, other rheumatic diseases and tumors. All patients received broad-spectrum antibiotics and had no response. All patients received glucocorticoid therapy and at least one kind of anti-cytokine therapies but didn't have full response. Then the three patients received intravenous tocilizumab treatment of 8mg/kg every 2 weeks or 4 weeks.

Results: The first patient, a 21-year-old woman, performed positron emission tomography (PET-CT) and lymphoglandula pathology in addition to routine tests. She received high dose methylprednisolone (500mg per day for 3 days and followed by 80mg per day), gamma globulin injection (20g per day for 3 days) and baricitinib 4mg per day for 12 days, but had no response to the treatment. Then she received tocilizumab of 8mg/kg every 2 weeks and stopped baricitinib. And the symptoms and blood tests improved gradually, and the methylprednisolone dose reduced to 16mg per day at the last follow-up. The second patient is a 52-year-old man, and performed bone marrow cytology and PET-CT to excluded hematological diseases. He received methylprednisolone 80mg per day, adalimumab and tofacitinib treatment. But the patients still got recurrent fever, high ESR, CRP and serum ferritin. Then he stopped adalimumab and tofacitinib, and received tocilizumab of 8mg/kg every 2 weeks and reduced to 8mg/kg every 4 weeks because of economic factors. The patient did not develop fever and the inflammatory indexes such as ESR/CRP gradually decreased to normal range. And methylprednisolone dose reduced to 32mg nowadays.

The third patient is a 30-year-old woman and has recurrent AOSD for 15 years. She had tried glucocorticoids, methotrexate, iguratimod, baritinib and entanercept successively. Yet she still had recurrent arthritis on hand and knee, and elevated ESR/CRP/serum ferritin. Additionally she suffered femoral head necrosis because of excessive doses of glucocorticoid. The patient received tocilizumab 8mg/kg every 4 weeks, then joint symptoms and inflammatory indicators improved significantly. The methylprednisolone dose was also successfully reduced to 4mg/d.

The Figure 1 showed the main course of disease evolution.

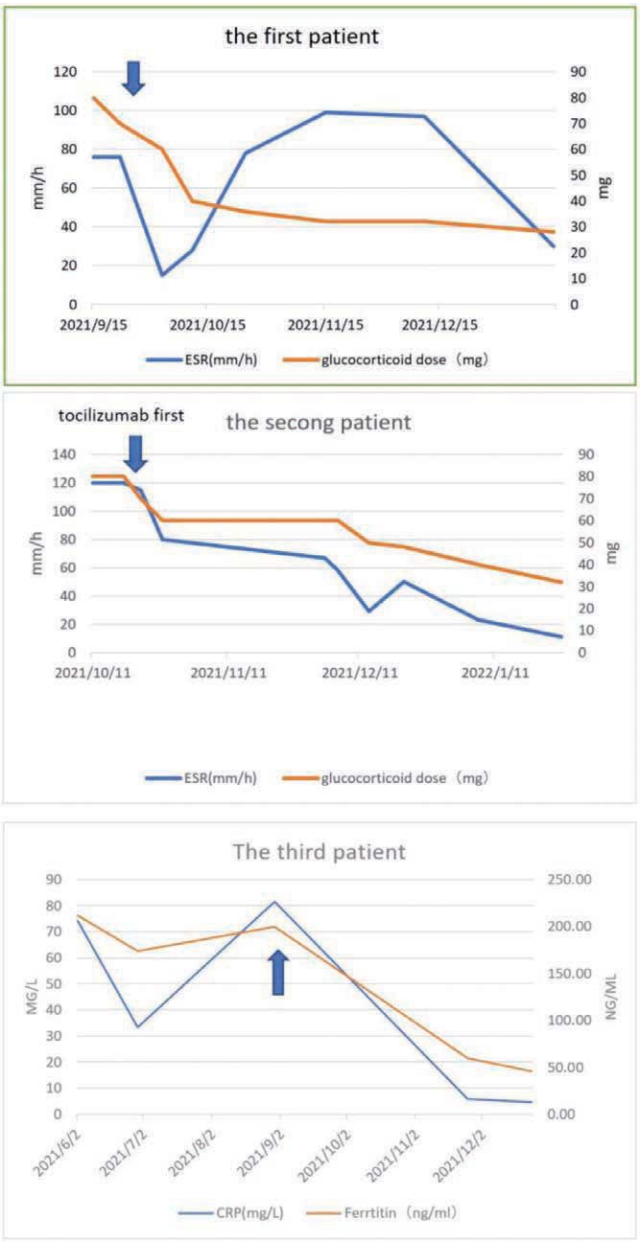

Figure 1.

Conclusion: Tocilizumab may be an effective candidate in refractory AOSD despite no response to other treatments.

AB1521 IGG4-RD AND SLE: COEXISTENCE IN THE KIDNEYS

O. Mena Mirands[1], C. Chao[2], M. Vukelic[3]. [1]*Albert Einstein College of Medicine, Rheumatology, Montefiore Medical Center, New York, United States of America*; [2]*Icahn School of Medicine at Mount Sinai, Internal Medicine, New York, United*

States of America; [3]*Albert Einstein College of Medicine, Rheumatology, New York, United States of America*

Background: IgG4 related disease (IgG4-RD) is an immune-mediated fibro-inflammatory condition that can mimic malignant, infectious and inflammatory diseases (1). Systemic lupus erythematosus (SLE) is a chronic autoimmune condition characterized by multisystem inflammation and autoantibody generation (2). Overlap of IgG4-RD and SLE is not frequent, however there have been few cases reported with kidney involvement secondary to both conditions (2,3). We present a case of an elderly male with a new diagnosis of IgG4-RD and SLE with kidney involvement.

Objectives: To present a case with a new concomitant diagnosis of IgG4-RD and SLE.

Methods: Case report.

Results: A 67-year-old man with longstanding history of cervical lymphadenopathy (LAD) presented to the Rheumatology Clinic due to intermittent lower extremity rash, anemia, worsening fatigue for the past 2 years. Prior history includes controlled DM type 2 and HTN treated with amlodipine. Denied photosensitivity, oral ulcers, sicca symptoms, Raynaud's phenomenon, weight loss, fever, chills, joint pain. Physical examination revealed bilateral cervical LAD and a non-blanching purpuric rash on lower extremities consistent with leukocytoclastic vasculitis, later confirmed with biopsy. Further workup revealed, normocytic anemia (Hgb 9.9 mg/dl), positive ANA (>1:2560, homogeneous pattern), positive dsDNA (211 IU/ml), positive histone Ab (413 IU/ml), low C3 (28 mg/dl), low C4 (1 mg/dl), increased IgG4 level (2787 mg/dl) and proteinuria 1100 mg/g with microalbuminuria, no urine casts. ANCA serologies were negative. Pan-CT showed mild cervical, retroperitoneal, pelvic LAD bilaterally. Kidney biopsy was performed and revealed severe diffuse tubulointerstitial nephritis, plasma cell rich (more than 40 IgG4 + cells seen per 40X hpf), with moderate to severe chronicity in addition to diffuse mesangial IgG and IgM staining with focal tubular basement membrane IgG and C1 staining consistent with mesangial proliferative class II lupus nephritis. Patient was started on moderate dose steroids (due to DM), hydroxychloroquine and azathioprine with resolution of LCV rash, anemia, LAD, improvement in dsDNA, proteinuria, complement levels.

Conclusion: SLE and IgG4-RDs are autoimmune diseases that cause damage to several organs, including lymph nodes and kidneys. Both are associated with hypocomplementemia and involvement of autoantibody-producing B cells and plasma cells. Patients with SLE present with positive antibodies such as anti-dsDNA and anti-Sm antibodies. On the other hand, IgG4-RD lack a specific antibody and the IgG4 is thought to be the result of the pathogenic process and not pathogenic by itself (1,2). Histologically, SLE presents with inflammatory cell infiltration in organs, whereas IgG4-RD is associated with fibrosis and organ enlargement (1-3). Lupus nephritis causes wide spectrum renal involvement whereas IgG4-RD most common presentation is tubulointerstitial nephritis (TIN), although other glomerular lesions, such as membranous nephropathy, have been reported (1-2). Our patient presented with proteinuria, positive antibodies for SLE, low complements and high levels of IgG4 which makes us consider that both diseases were active at time of diagnosis. This was confirmed by renal biopsy showing chronicity of IgG4-RD and lupus nephritis as a consenquence of progression of autoimmunity. The treatment of both conditions is immunosupression with medium to high doses of steroids and a steroid sparing agent. Due to patient preference he was started on azatioprine along with medium dose steroids with adequate clinical response. This case highlights the fact that SLE and IgG4-RD can coexist and it should be supected in elderly patients with lympadenopathy and renal disease.

AB1522

THE ASSESSMENT OF KNOWLEDGE OF NURSES BEFORE AND AFTER TRAINING ABOUT SPONDYLOARTHRITIS AND RHEUMATOID ARTHRITIS

A. Fazaa[1], A. Mahbouli[1], S. Miladi[1], O. M. Kmar[1], L. Souabni[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Nurses' education programs play an important role in the management of chronic diseases in rheumatology clinics. They can assume their own patient case-loads and provide an educative role to promote health.

Objectives: In order to foster educational programs, the present study aimed to assess the level of knowledge of nurses before and after targeted training sessions.

Methods: The nurses of the rheumatology department of Mongi Slim Hospital have been included initially during the month of September 2021, then later, after having followed a training during the month of January 2022. Data were collected by two self-administrated tests. The rheumatoid arthritis knowledge assessment scale (RAKAS) (1) which consisted of 13 items, defined knowledge as awareness about the disease, its risk factors, symptoms and treatment and categorized it into four levels namely, excellent, adequate, low and poor knowledge. The tool had a maximum of 14 points. A nurse was designed to have excellent knowledge if the score was 11 and above, adequately knowledgeable if the score was between 8 and 10, low knowledge if the score was between 5 and 7 and poor knowledge if it was 4 or less. Spondyloarthritis knowledge assessment questionnaire (SPAKE) (2) with 14 questions and 72 possible responses, divided into four areas, (A) general knowledge, comprising etiology, symptoms, blood tests (score range 0-8), (B) immunogenetic test (B27 antigen) and inheritance (score range 0-3), (C) general management, including drug treatment and physical therapy (score range 0-9), (D) joint protection, pacing and priorities (score range 0-5) The Wilcoxon signed rank test was used to assess the difference between test results before and after training. The level of statistical significance was set at $p<0.05$.

Results: Ten nurses were included with a sex ratio (M/F) of 0.3. Initially, the average RAKAS score was 11.7 ± 1.2. Almost two thirds of the nurses had excellent knowledge (n= 7, 70%) and the rest (n= 3, 30%) had adequate knowledge. The average SPAKE score was low (12.9±3.7). For the nurses interviewed in domain A, the maximum score was not reached and the average score was 5±1.6. For domain B, the maximum score was reached only once and the average score was 1.2±0.9. For domain C, the maximum possible score was not reached and the average score was 5.1±2.2. For domain D, the maximum score was not reached and the average score was low at 1.6±0.6. For the post-training test, the average RAKAS score was 12.6±0.5 and all nurses had excellent knowledge (n= 10, 100%). The average SPAKE score has risen (20.1±1.6). For the nurses interviewed in domain A, the maximum score was reached two times and the average score was 6.9±0.8. For domain B, the maximum score was reached four times and the average score was 2±0.9. For domain C, more than half of nurses have reached the maximum score (n=6, 60%) and the average score was 8.4±0.8. For domain D; the maximum score was not reached and the average score was 3.2±0.9. Differences between pre- and post-training test scores were found to be statistically significant for the SPAKE questionnaire ($p=0.005$) but not for the RAKAS ($p=0.077$).

Conclusion: The nurses' knowledge of rheumatoid arthritis was initially adequate, but not of spondyloarthritis, which improved significantly through the targeted training sessions.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

AB1523-HPR USABILITY AND ACCEPTABILITY OF A NEW AUTOINJECTOR DEVICE AND ITS ASSOCIATED APP IN AUSTRALIAN, FRENCH, GERMANY AND JAPANESE RHEUMATOLOGY PATIENTS

R. Alten[1], M. Latymer[2], D. C. Gruben[3], L. Gunther-Lavergne[4], S. Moss[5], H. Kameda[6]. [1]*Schlosspark-Klinik University Medicine, Internal Medicine, Rheumatology, Berlin, Germany*; [2]*Pfizer Ltd, I&I Medical Affairs, Sandwich, United Kingdom*; [3]*Pfizer, Global Biostatistics and Data Management, Groton, United States of America*; [4]*Farm Design, A Flex Company, Human Factors Engineering, Hollis, United States of America*; [5]*Pfizer R&D UK, Devices Centre of Excellence, Cambridge, United Kingdom*; [6]*Toho University (Ohashi Medical Center), Division of Rheumatology, Tokyo, Japan*

Background: Smartclic/ClicWise is a new reusable autoinjector with a dose-dispensing cartridge for subcutaneous self-administration of biotherapeutics in development for patients with rheumatoid arthritis (RA) and other diseases. The device can connect to an optional mobile phone app (Smartclic, or ClicNote in Japan) to aid in tracking injections and other treatment or symptom data.
Objectives: The study objective was to collect ease of use and usability data on the Smartclic injector and companion app from experienced patients.
Methods: After completing a patient profiling questionnaire, adult patients (≥18 yrs) from Australia, France, Germany, and Japan with RA, psoriatic arthritis, or an original diagnosis of juvenile idiopathic arthritis who were prescribed an injectable biologic were enrolled in this study. For Japan, only patients with RA were enrolled. Each patient received training individually on the use of the Smartclic injector device and insertable cartridge and gained experience by performing simulated injections. Participants completed a questionnaire with evaluations of the device categories (number of questions): 'ease of use' (14), 'usability effectiveness' (11), 'benefit of features' (8), and 'form factor' (7). Participants also separately received a storyboard presentation summarizing the key features of the app, during which patients could explore the app (on a phone with either an android or iOS operating system), and completed 16 questions on the connectivity, usability, and benefit. Responses were recorded as Likert scale ratings from 1 ('extremely negative') to 7 ('extremely positive'). Respondents also provided an estimate of patient training time for the device. Mean values were reported. The percentage of negative (Likert scale rating 1-2), neutral (3-5), and positive (6-7) responses for each category were determined.
Results: A total of 139 patients (mean age [range], 52 [18-84] yrs; 73% female) participated in the study (Table 1). Mean scores (percentage of positive responses) for the device were: ease of use 6.43 (86.2%), usability effectiveness 6.39 (86.5%), benefit of features 6.46 (89.4%), form factor 6.10 (77.2%); and 6.06 (74.2%) for connectivity and benefit of the app (Figure 1). Mean estimated time for training a patient to effectively use the device/cartridge was just under 9.5 min (range, 0-30 min).

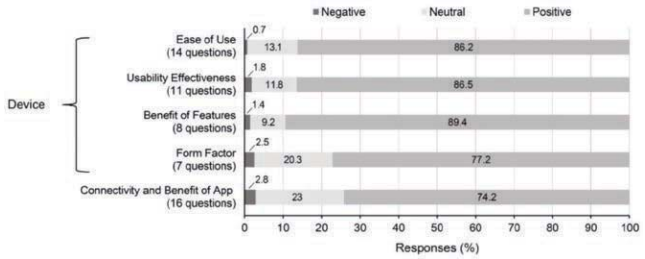
Table 1. Participant characteristics

Characteristic	Patients (N=139)
Sex, n (%)	
Male	38 (27)
Female	101 (73)
Mean age (range), yrs	52 (18-84)
Age groups, n (%)	
18-30 yrs	11 (8)
31-59 yrs	85 (61)
>60 yrs	43 (31)
Diagnosis, n (%)	
Rheumatoid arthritis	104 (75)
Psoriatic arthritis	34 (24)
Juvenile idiopathic arthritis*	1 (1)
Handedness, n (%)	
Right-handed	128 (92)
Left-handed	9 (6)
Ambidextrous	2 (1)

*Originally diagnosed with juvenile idiopathic arthritis, but now aged ≥18 yrs.

Conclusion: Rheumatology patients responded positively on the new autoinjector device and app across all categories, indicating its suitability for self-administration of biotherapeutics.

Figure. Summary of patient survey responses across all device and app questions*



*The percentages for each question were based on the Likert scale rating response: negative (1-2), neutral (3-5), and positive (6-7).

AB1524-HPR THERAPEUTIC RESULTS AND QUALITY OF LIFE CHANGES OF PATIENTS WITH RHEUMATOID ARTHRITIS IN PROSPECTIVE REAL LIFE CLINICAL SETTINGS

V. Boyadzhieva[1], K. Tachkov[2], N. Stoilov[1], K. Mitov[2], G. Petrova[2], R. Stoilov[1]. [1]*Medical University of Sofia, University Hospital "Sv. Iv. Rilski", Department of Rheumatology, Sofia, Bulgaria*; [2]*Medical University of Sofia, Faculty of Pharmacy, Department of Social Pharmacy and Pharmacoeconomics, Sofia, Bulgaria*

Background: Rheumatoid arthritis (RA) as a chronic inflammatory disease significantly deteriorating the physical functioning and the quality of life (QoL) of the patients. The introduction of biological therapy in its management significantly improves both the physical functioning and QoL. Many biological medicines are already available on the market claiming higher effectiveness and high cost of therapy but the difference in real clinical setting is not well studied.
Objectives: The aim of this study is to analyze the therapeutic results of RA therapy with different biologicals and the first JAK inhibitor in real life clinical settings.
Methods: This study was performed like a prospective, observational, longitudinal study at the biggest rheumatology clinic in Bulgaria during the period 2012 – 2020. Written informed consent was obtained by the recruited 197 patients, out of which 174 remain at the end of the observation. Patients naïve to biological therapy were assigned on the available at that moment biologic DMARDs (infliximab, etanercept, adalimumab, rituximab, golimumab, cetrolizumab, tocilizumab), and the first JAK inhibitor (tofacitinib). The clinically proven RA according ACR (1987) and / or ACR/EULAR (2010) criteria, previous therapy with DMARDs, and/or methotrexate, suitable for therapy with biological medicines or JAK inhibitors were formulated as inclusion criteria, while infectious diseases, cardiac insufficiency (NYHA III and IV grade), malignant hypertension, any neoplasms or proliferative lymph diseases within the previous 5 years were the exclusion criteria. We evaluate DAS28-CRP, HAQ and Short form 36 measured at the initiation of biological therapy, after 6, and 12 months of follow up. We analyze the changes in the two major subgroups of SF36 - physical (MCS) and mental health (PCS). Descriptive statistic, Dispersion analysis with non-parametric Kruskal-Wallis test comparing the effect of different therapies between first and third measurement was performed. Linear correlation and regression analysis (Pearson type) comparing the effect of different therapies was also performed.
Results: The age and gender distribution were similar between the groups on bDMARDs and tsDMARD. Number of patients per therapeutic DMARD vary between 20 to 30, with prevailing part of the female and average age between 53.2 (SD 9.13) and 57.15 (SD 9.05) years. Average length of the disease is also similar between the groups with highest value of patients assigned to tocilizumab (14.13 (SD 8.38) years) and lowest for infliximab (6.4 (SD 2.92) years), respectively. All observed indicators for disease control and QoL improve after the initiation of the biological or JAK inhibitor therapy. We also analyse the effect of therapies on DAS-28, HAQ, SF-36 (PCS, MCS). Dispersion analysis for the effect

of therapy measured through DAS28 between 1st and 3rd measurement shows a statically significant difference in between the average effect of therapies (P = 0.005141). The most effective is the golimumab (Median difference = 2.745), followed by rituximab (median = 2.305) and etanercept (median = 2.070). The difference in effect measured with HAQ is higher with tofacitinib (median 0,563). Followed rituximab and infliximab (median 0.500 for both). Less effective appears to be etanercept (median difference 0,250). All differences are statistically significant (p = 0,012589). Regarding the changes in the QoL measured with SF-36 MCS and PCS there is no statistically significant differences in the average effect of different therapeutic agents. The medical effect of different therapeutic agents regarding physical group of SF-36 (PCS) is similar and changes are not statistically significant. The same is valid for SF36 psychological components (MCS).
Conclusion: Tofacitinib and bDMARDs improve both clinical results and QoL of patients with RA naïve to biological therapy. The difference between tofacitinib and bDMARDs is not statistically significant for both clinical and QoL results.

AB1525-HPR EXAMINATION OF PHYSICAL FITNESS IN CHILDREN AND ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: A COMPARATIVE STUDY

S. Bozcuk[1], B. Basakci Calik[1], E. Gur Kabul[2], Z. Ekici Tekin[3], S. Yuksel[4]. *[1]Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey*; *[2]Uşak University Faculty of Health Sciences, Physiotherapy and Rehabilitation, Denizli, Turkey*; *[3]Ankara City Hospital, Pediatric Rheumatology, Ankara, Turkey*; *[4]Pamukkale University Faculty of Medicine, Pediatric Rheumatology, Denizli, Turkey*

Background: Juvenile Idiopathic Arthritis (JIA) is the most common rheumatic disease of childhood. Although its etiology is not known exactly; Immunological susceptibility and environmental factors (infections, stress, trauma) are emphasized (1). These children have low activity levels since a young age, and significant problems are observed in the realization of daily living activities (2).
Objectives: This study aims to compare the physical fitness of children/adolescents with Juvenile Idiopathic Arthritis (JIA) and their healthy peers.
Methods: Seventy children/adolescents (mean age: 13.40±2.31 years 35 JIA; mean age: 12.94±2.31 years 35 healthy) were included in the study. After recording demographic data, the functionality levels of the children/adolescents with JIA were evaluated by CHAQ (Childhood Health Assessment Questionnaire), all lower extremity muscle strengths were evaluated by the manual muscle test device, and the physical fitness levels were evaluated by the Brockport physical fitness test battery which is grip strength, push-up test, curl-up test, trunk lift test, shoulder stretch, back saver sit-reach test, calf, triceps, subscapular skinfold thickness and PACER 20 meter test. While the disease activities of children/adolescents with JIA were evaluated with JADAS-27 (Juvenile Arthritis Disease Activity Score); quality of life were evaluated with the PedsQL 3.0 Arthritis Module (Pediatric Quality of Life Inventory).
Results: As a result of the comparative analysis; In terms of functionality which is CHAQ dressing (p=0.008), eating (p=0.011), reaching (p=0.001), rising (p=0.001), walking (p=0.001), holding (p=0.016), hygiene (p=0.011), activity (p=0.00), total score (p=0.00), pain (p=0.00), general well-being (p=0.00) in terms of all sub-parameters, there was found to be significant in favor of healthy children/adolescents (p<0,05). In terms of physical fitness which is grip strength (p=0,041), PACER 20 meter test (p=0,00), trunk lift test (p=0.018) and curl-up (p=0.00) tests, there was a significant difference in favor of the healthy group (p<0,05). There was no significant difference between the groups in terms of other physical fitness tests (p>0.05). When all lower extremity muscle strengths were compared, only right hip external rotation (p=0.023) showed a difference in muscle strength. There was no correlation between JADAS-27 score and physical fitness scores (p>0.05) of children/adolescents with JIA, except for the push-up test (p=0.01). In terms of JADAS-27 score and some PedsQL child form which is pain, total score and activities of daily living of children/adolescents with JIA; there was a significant relationship. In terms of JADAS-27 score and some PedsQL parent form which is pain and total score of children/adolescents with JIA; there was a significant relationship. However there was no relationship in terms of the other parameters (p>0.05).
Conclusion: According to the results of our study, it was observed that the functionality and physical fitness levels of children/adolescents with JIA were lower than their healthy peers, and physical fitness was not affected by disease activity. However, it has been observed that the disease ability of children/adolescents with JIA affects the quality of life of both themselves and their families. For all these reasons, it is very important to encourage children/adolescents with JIA in terms of participation in physical activity and exercise, with informative training aimed at improving their physical fitness.

AB1526-HPR AWARENESS ASSESSMENT IN PATIENTS USING SUBCUTANEOUSLY ADMINISTERED BIOLOGICAL AGENTS ABOUT DRUG UTILIZATION

F. Tuncer[1], O. Ozdemir Isik[1], A. Yazici[1], A. Cefle[1]. *[1]Kocaeli University, Faculty of Medicine, Rheumatology, Kocaeli, Turkey, Rheumatology, Kocaeli, Turkey*

Background: Subcutaneous biological agents (SCBA) are commonly used in rheumatologic disorders, their storage in appropriate conditions and correct administration have importance. Informing the patient adequately and correctly is essential. Storing the drug in inappropriate conditions reduces its effectiveness, and affects the response to treatment (1). When these treatments are initiated, information on all the mentioned topics is provided to the patients, and they undergo hands-on training. Finally, the patients is requestioned in outpatient follow-up about whether a problem has occurred or not (2).
Objectives: This study aimed to investigate the awareness of patients using SCBA about the drug's utilization and storage conditions.
Methods: Demographic data of 100 patients diagnosed with rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis, using SCBA who presented to our outpatient clinic between January 2021 and June 2021,were recorded, and survey questions were asked.
Results: One hundred patients (46 females-54 males) were included in the study. Sixty-one patients were diagnosed with ankylosing spondylitis, 20 patients with rheumatoid arthritis, and 19 with psoriatic arthritis. The patients' mean age was 44.6±11.07 years. The mean duration of SCBA use was 74.5 (2-222) months. The patients' replies to the survey questions are summarized in Table 1. Most patients performed the injection themselves in both genders, whereas some women received help from paramedics (p=0.041). Forty percent of the patients with education level of high school or higher had a concern regarding drug use, whereas this rate was 21% in patients with education level of primary school. It was determined that the anxiety level decreased with decreasing level of education (p=0.032).

Table 1. The patients' replies to the survey questions

N=100	n (%)
Rate of patients who read the patient consent form before starting the drug	88 (88)
Concern regarding drug use	23 (23)
Malignancy	7 (7)
Increase in infection	7 (7)
Tuberculosis	70 (70)
Not worried	
The person who informing patients on drug use	88 (88)
Nurse	18 (18)
Doctor	7 (7)
Nurseanddoctor	
Patients who were informed about when to interrupt drug use	86 (86)
Situations where drug use is suspended	84 (95,3)
Flu and febril infection	68 (79,1)
Use of antibiotics	39 (45,3)
Herpes simplex virus infection	
Drug storage	65 (65)
Refrigerator shelf	31 (31)
Refrigerator door	4 (4)
Pharmacy	
State of waiting before administering the drug	17 (17)
Don't wait	71 (71)
20-30 minutes at room temperature	6 (6)
>30 minutes at room temperature	5 (5)
Hand warming and then administration	1 (1)
Soak in hot water	
Rate of controlling the expiration date before administering the drug	64 (64)
Rate of patients who control the clarity of the drug	75 (75)
Rate of hand washing before administering the drug	83 (83)
Injection site cleaning	6 (6)
Don't clean	66 (66)
With the swab from the drug box	24 (24)
With alcohol	3 (3)
With a wet wipe	1 (1)
With soap	
The person performing the injection	84 (84)
The person	11 (11)
Person's relative	5 (5)
Health personel	
The patients who carry their medication in accordance with the cold chain rules during travel	71 (100)

It was observed that in patients who used multiple SCBA for a long time, taking the drug out of the refrigerator and applying it after waiting for the optimum time,

controlling the expiration date of the drug and hand washing before the application decreased over time.

Conclusion: Evaluating the patient's SCBA treatment background is essential for correct treatment practice. Our study revealed that in forming patients on drug use not only initially but also at certain intervals is essential.

AB1527-HPR FUNCTIONAL SOMATIC SYNDROMES AND INSOMNIA IN PATIENTS WITH FIBROMYALGIA, RELATIONSHIP WITH THE INTENSITY OF THE PAIN SYNDROME

V. Bykov[1], V. Khomenko[1], L. Shvets[1], L. Perebetiuk[1], O. Ostapchuk[1], I. Shapoval[1], M. Stanislavchuk[1]. [1]*National Pirogov Memorial Medical University, Rheumatology, Vinnytsia, Ukraine*

Background: Fibromyalgia (FM) is a chronic diffuse musculoskeletal pain manifested by numbers of functional somatic syndromes (1). The pathogenesis and pathophysiology of fibromyalgia includes changes of autonomic nervous system, which can be realized in the abnormal functioning of many organs and systems.

Objectives: Analyze the frequency and spectrum of functional somatic syndromes and insomnia in patients with fibromyalgia, relationship with the intensity of pain.

Methods: We examined 102 women with FM according criteria ACR (1990), mACR (2010) with mean age 41.7±9.4 years (M±σ), duration of the disease was 8.4 ± 6.28 years. The severity of pain, fatigue, sleep disorders was assessed with a visual analog scale (VAS).

Results: The severity of pain (VAS) in patients with FM ranged from 2.1 to 8.5 and averaged 5.1±1.5. The severity of fatigue was estimated at 6.5 ± 1.7, sleep disorders - 6.3 ± 2.7. In the examined group of patients with FM, in addition to typical clinical manifestations, significant numbers of functional disorders were diagnosed: insomnia - 86.3%, irritable bowel syndrome – 59,8%, postural tachycardia syndrome - 53.9%, hyperventilation syndrome - 52.9%, bladder pain syndrome – 50,0%. According to the intensity of pain, patients were divided into 3 groups. The 1th group included patients with pain less than 4 points (<25th percentile, n = 21), the 2nd - with the pain severity 4-6 points (25-75th percentile, n = 58), the third group - patients with pain more than 6 points (>75th percentile, n = 23). According to the study, the frequency of functional somatic syndromes was not related to the intensity of pain. There was a positive correlation between the severity of insomnia and the intensity of pain ($r=0.36$; $p<0.05$). The same relationship was revealed between fatigue and pain ($r=0.41$; $p<0.05$).

Conclusion: Patients with FM have a wide spectrum of functional somatic syndromes. The changes described were not related to the severity of the pain syndrome. The presence of correlations between the severity of insomnia and the intensity of pain requires further research to develop algorithms for comprehensive treatment of identified disorders.

AB1528-HPR FULL BODY HAPTIC BODYSUIT - AN INSTRUMENT TO MEASURE THE RANGE AND SPEED OF MOTION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS (AXSPA) - PRELIMINARY RESULTS

N. Weber[1], R. Lennartz[1], J. Knitza[2,3], S. Bayat[2,3], M. Sadeghi[1], A. A. Ibrahim[1], C. Karatastan[1], A. Sudhakar[1], N. Ramzezanzadegan[1], S. Kahali[1], A. Mirzayev[1], L. Background: Movement of the spine is restricted in axial spondyloarthritis (axSpA) [1]. Spine function is usually assessed by the Bath Ankylosing Spondylitis Metrology Index (BASMI), which is based on a limited set of defined motions that are measured semiquantitatively in the spatial dimension but not in the temporal dimension. Sensor-based measurement of spine function in axSpA patients is in its infancy but may provide a deeper and more detailed understanding of the impact of axSpA on the impairment of spine function [2,3]. In theory, unbiased full body assessment of spine motion may open a new dimension in function analysis in axSpA.

Objectives: To test if a of a full-body based haptic capturing of spine motion is technically feasible and can pick up the measurements of BASMI items 1-5. Furthermore, we aimed to investigate whether such measurements are accurate and reproducible comparing to BASMI scores done by rheumatologists. Lastly, we sought to measure velocity of spine movements to allow spatiotemporal analysis of motion.

Methods: For full-body haptic assessment of spine motion a full-body haptic suit (Teslasuit; VR Electronics Ltd, London) was used that consists of a smart textile two-piece bodysuit that not only captures range and speed of motion but also provides biometric and haptic feedback. This device is currently tested in clinical trials (https://teslasuit.io/rehabilitation/) but has not been tested in rheumatic diseases such as axSpA [4]. Since there is no pre-defined technical solution for measuring BASMI, we used the integrated inertial measurement units (IMUs) of the suit (Figure 1a). The suit is recording the position and rotations of its IMUs and is transforming the raw data to position coordinates and joint angle of the bones. We implemented an algorithm that is accessing the sensor data and is calculating the BASMI measurements as well as velocity. Assessment were done in healthy individuals. BASMI was obtained 3 times by teslasuit followed by standard BASMI measurement by 2 independent rheumatologists. In addition, rotational movements with their maximum torso speed to evaluate angular velocity were performed (Figure 1b). Measurements were compared using absolute values and relative standard deviation (which is the standard deviation normalized by the mean).

Results: Five healthy individuals (all males, age: 27.6 ± 1.8 years, height: 178 ± 5 cm; weight 70.0 ± 8.0 kg) were assessed. Teslasuit measurements were well tolerated. Technically, we were able to calculate BASMI item 3 and 5, finger-to-floor distance and the velocity of the spine movement using the position data of hand, talus and upper back sensors (Figure 1a, b). Due to absence of sensors at the head and the required back areas, BASMI 1, 2, 4 could only partially be captured and require further programming, which is currently performed. Only marginal differences were detected regarding the relative standard deviations of measurements between teslasuit and rheumatologists (BASMI 3: rheumatologists 8,5%: suit 10%; BASMI 5: rheumatologists 5,4%: suit 4,9%) (Figure 1c). The speed of spinal motion could be measured with an average angular velocity of 172.2 degrees/sec over the entire rotation motion and an average maximum angular velocity of 417.2 degrees/sec.

Conclusion: This study shows that full-body haptic-suits can capture spinal motion including parts of the BASMI score. In addition, they allow to measure the speed of spinal movement, which might be an important and so far unrecognized factor to test the impact of axSpA on spinal function. Based on these results, full-body haptic-suits will be tested in axSpA patients in the future. Furthermore, technical solutions are currently developed to implement the remaining BASMI scores into the suit as well as connections from the suit to virtual reality devices for patients and doctors.

AB1529-HPR CROSS-CULTURAL ADAPTATION, RELIABILITY AND CONVERGENT VALIDITY OF THE TURKISH VERSION OF THE PRIMARY SJOGREN'S SYNDROME QUALITY OF LIFE QUESTIONNAIRE

S. Bayram[1], F. Sarİ[1], G. G. Pala[1], B. Özkızıltaş[2], A. Tufan[2], D. Oskay[1]. *[1]Gazi University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara, Turkey*; *[2]Gazi University, Faculty of Medicine, Department of Internal Medicine-Rheumatology, Ankara, Turkey*

Background: To completely comprehend the burden of an illness and the success of its treatment, it is essential to analyze the patients' perspective on health-related quality of life. Because of this, the Primary Sjögren's Syndrome-Quality of Life questionnaire (PSS-QoL) was developed, which evaluates the disease's physical and psychosocial effects in PSS patients.
Objectives: In the literature, there is no Turkish questionnaire evaluating quality of life in patients with PSS. Therefore, the aim of this study was to translate and evaluate cross-culturally adaptation the PSS-QoL into the Turkish language and investigate its convergent validity and reliability in Turkish-speaking population with PSS.
Methods: Patients completed PSS-QoL questionnaire, the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) and Euro-QoL 5D (EQ-5D). To test the convergent validity of PSS-QoL, correlation between PSS-QoL and EQ-5D and ESSPRI were assessed with Pearson correlation test. In order to investigate the internal consistency and test-retest reliability, Cronbach's alpha and Intra-class Correlation Coefficient (ICC) values interpreted, respectively.
Results: Seventy-nine patients with PSS (53.30+11.98 years, 74F/5M) were enrolled in the study. Good and moderate correlations were found between the PSS-QoL and ESSPRI (r: 0.818, p<0.001) and EQ-5D-pain/ discomfort (r:0.589, p<0.001). Correlations of subscales of PSS-QoL with subscales of ESSPRI and EQ-5D ranged from fair to strong (Table 1). Cronbach's alpha and ICC values of the PSS-QoL total score were found to be as 0.955 and 0.914, respectively, indicating excellent reliability.

Table 1. Correlations of PSS-QoL and EQ-5D, ESSPRI

	PSS-QoL	Physical	Discomfort	Dryness	Psychosocial
	total score	PSS-QoL	PSS-QoL	PSS-QoL	PSS-QoL
EQ-5D-mobility	0.543**	0.514**	0.678**	0.761**	0.891**
EQ-5D-usual activities	0.466**	0.342*	0.371**	0.233*	0.460**
EQ-5D-pain/discomfort	0.589**	0.651**	0.710**	0.442**	0.394**
EQ-5D-anxiety/depression	0.574**	0.570**	0.557**	0.436**	0.439**
EQ-5D-HS	-0.625**	-0.540**	-0.495**	-0.437**	-0.547**
ESSPRI-dryness	0.589**	0.706**	0.448**	0.722**	0.348*
ESSPRI-pain	0.673**	0.694**	0.824**	0.421**	0.494**
ESSPRI-fatigue	0.780**	0.668**	0.669**	0.497**	0.690**

EQ-5D, Euro-QoL-5 dimension; ESSPRI, EULAR Sjögren's Syndrome Patient Reported Index; HS, health state; PSS-QoL, Quality of Life in Primary Sjögren's Syndrome. *p<0.05, **p<0.001.

Conclusion: This study demonstrated that Turkish version of PSS-QoL is reliable and valid tool to assess quality of life in PSS patients. Therefore, PSS-QoL can be used to assess quality of life in Turkish-speaking PSS patients.

AB1530-HPR INVESTIGATION OF FUNCTIONAL MUSCLE PERFORMANCE AND STRENGTH AND BALANCE IN CHILDREN WITH FAMILIAL MEDITERRANEAN FEVER: A COMPARATIVE PRELIMINARY STUDY

S. Y. Cetin[1], O. Kaya Kara[1], D. S. Kara[1], E. Çomak[2], S. Akman[3]. *[1]Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey*; *[2]Akdeniz University, Pediatric Nephrology, Antalya, Turkey*; *[3]Akdeniz University, Pediatric Nephrology, Antalya, Turkey*

Background: Familial Mediterranean fever (FMF) is a hereditary, systemic auto-inflammatory disease characterized by recurrent fever, peritonitis, pleuritis, arthritis, or erysipelas-like skin (1). Colchicine treatment is frequently used in Familial Mediterranean Fever (2). Nausea, vomiting, abdominal pain and diarrhea are the most common side effects of colchicine, neuropathy and muscle damage can also be observed (2). Musculoskeletal features are common in children with FMF (3). Arthritis, arthralgia, myalgia and erysipelas-like erythema symptoms can be frequently observed in those patients whose disease onset age is younger than 18 years (4). Decreased functional performance and Quadriceps muscle strength were observed in children with FMF compared to healthy children. (5). It has been reported that the decrease in muscle strength and functional capacity is also associated with the quality of life in children. (5). In the light of all this information, although there is muscle weakness in children, it is thought that endurance, balance and functionality may decrease. There has been no study in the literature examining whole body muscle strength, endurance, balance and functionality in these children.
Objectives: The aim of the study was to assess muscle strenght, endurance, balance and functionality in children with FMF and comparison with healthy children matched the same age and gender.
Methods: 12 children with FMF and 12 healthy children between the ages of 7-17 were included in the study. 10 Meter Walk Test (10MWT) was used to evaluate walking speed in meters per second over a short duration; The 1 Minute Walking Test (1MWT) was used to evaluate functional capacity; Time Up and Go (TUG) was used to evaluate of functional mobility and dynamic balance; Functional Reach Test (FRT) was used evaluate dynamic balance; Muscle Power Sprint Test (MPST) was used to evaluate functional muscle strength and muscle performance short-term muscle strength; 10x5 Spring Test was used to evaulate agility; 30s Repetition Maximum Test was used to evaluate functional muscle strength; Vertical Jump Test used to evaluate explosive strength of the lower extremity; Standing Long Jump Test was used to evaluate muscular endurance of the upper body and the functional muscle strength of the lower extremities; Hand Dynamometer was used to evaluate general muscle strength.
Results: When the groups were compared, a significant difference was found in favor of healthy children in the 10MWT, 1-minute walking test, TUG, FUT, 30 s Repetition Maximum Test (p:0.00- 0.04).
Conclusion: According to the results of the study, children with FMF have low functional muscle performance and strength and balance compared with healthly children. There is a need for studies in which there are more children with FMF and assessmnet of muscle function. Therefore, in which we present the preliminary results, the functional muscle performance and strength and balance children with FMF should be routinely assessed and treatment and rehabilitation programs should be arranged according to these findings.

Department, Strasbourg, France; *[10]CHU de Kremlin-Bicêtre, Rheumatology Department, Paris, France*

Background: Primary Sjögren's syndrome (pSS) is a rare systemic autoimmune disease with no specific treatment at present. To better assess patient symptoms, we have developed a web application (WebApp) to collect patient symptom intensity on a regular basis.
Objectives: To measure the daily variability of symptoms using the WebApp. We also evaluated its ease of use.
Methods: 45 consecutive patients with pSS were included in 3 referral centers. Symptoms were assessed during the baseline and 3 month visits. We collected the VAS relating to fatigue, dryness and pain as well as the ESSPRI score. Patients used the WebApp daily for 3 months. The variability of symptoms over time was assessed by the predicted median error. This value was determined using a linear regression model, in order to predict the value at the 3rd month, then this value was compared to the actual value collected at the 3rd month during the clinical visit. The ease of use of the WebApp was assessed using a satisfaction score (SUS score).
Results: Of the 45 patients included, 91.1% were women with an average age of 57 years, and low systemic disease activity (84.4% had an ESSDAI score below 5). The intensity of the symptoms collected during the clinical visits was similar at baseline and at 3 months. The values of the median error for each measurement are between 0.5 and 0.8. The 3-month predicted median error values ranged from 2 to -3. The patients all used the web application for 3 months with good attendance (80% of data completion) and were satisfied with this tool (median SUS score = 90).
Conclusion: Symptoms of pSS fluctuate from day to day in the majority of patients, making a point measurement imprecise. The developed WebApp is easy to use, and could allow more sensitive detection of the effect of a therapeutic intervention. This tool will soon be evaluated during prospective interventional clinical trials.

AB1532-HPR GERIATRIC/GENERAL ORAL HEALTH ASSESSMENT INDEX AS EARLY DETECTION TEST OF ORAL DISEASES IN RHEUMATOLOGY.

B. T. Chavarín Argüello[1], J. C. Riegatorres[1], A. Cárdenas[1], D. C. Rubio Torres[1], L. R. Aguilar Rivera[1], L. G. Espinosa Banuelos[1], D. Á. Galarza-Delgado[1].
[1]Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico

Background: The oral health in patients with rheumatologic diseases is frequently affected because of chronic inflammation, slow rate of saliva production and poor self-care. These factors affect the life quality and psychosocial wellness, causing pain, difficulty biting and chewing, even malnutrition. The Geriatric/General Oral Health Assessment Index Spanish Version (GOHAI-SP) consists in 12 items and values self-perception in oral health and wellness (1), validated and applied to young adults (2).
Objectives: to describe the oral health measured by the GOHAI-SP in patients with rheumatic diseases.
Methods: a cross-sectional and observational study was conducted of January to May 2021 in rheumatology service of Hospital Universitario "Dr. José Eleuterio González" at Monterrey, Mexico. Patients with rheumatologic diseases was assessed with GOHAI-SP during their control consult, each item is valuated like a Likert ordinal scale from 1 to 5, the best and worst possible score is 60-12 respectively, patients whit score <45 is classified as poor oral health and >50 as good oral health(3). This assessment is divided in self-perception of mechanical function, pain and discomfort in mouth, gums, teeth and psychosocial function (4).
Results: 316 patients were included, 289 (91.5%) were women, the mean age was 46.23 years (SD: 15.49), the general mean score was 51.88 classified as good oral health. 24 (7.52%) patients was classified with moderate oral health and 63 (19.74%) as poor oral health. The most frequent diagnoses with poor oral health were rheumatoid arthritis 26 cases (8.22%), systemic lupus erythematosus 11 cases (3.48%) and psoriasic arthritis 4 cases(1.2%).
Conclusion: The prevalence of poor or moderated self-perceived oral health in patients with rheumatologic diseases was 27.53%. The primary prevention and early detection plays a fundamental roll to avoid oral disease in this population.

AB1533-HPR ASSOCIATED FACTORS OF FALL OR FRACTURE REPORTED BY RHEUMATOID ARTHRITIS PATIENTS IN ELECTRONIC MDHAQ DURING COVID-19 PANDEMIC

I. Lineburger[1], C. V. Brenol[2], V. Naomi Hirakata[1]on behalf of Rheumatology Service. *[1]Hospital de Clínicas de Porto Alegre, Mestrado Profissional de Pesquisa Clínica, Porto Alegre, Brazil*; *[2]Hospital de Clínicas de Porto Alegre, Rheumatology Service, Porto Alegre, Brazil*

Background: The COVID-19 pandemic accelerated the use telemedicine for rheumatologic patients. Patient reported outcomes (PRO) can provide prioritization criteria for the form of face-to-face care in situations of social restriction, and optimization of early care by identifying high-risk patients.
Objectives: Our aim was to demonstrate the main associated factors for a fall or fracture reported by rheumatoid arthritis (RA) patients in an electronic MDHAQ (Multidimensional Health Assessment Questionnaire) during this period.
Methods: Patients with RA according to 2010 ACR/EULAR and access to digital platforms were enrolled in the study, from January to august 2021. A weblink was sent to MDHAQ in electronic platform. The study was approved by the ethics committee of Hospital de Clínicas de Porto Alegre – Brazil and all patients agreed with a Term of Informed Consent.
Results: A total of 129 RA patients completed the electronic MDHAQ, mean age was 60 years (S.D. 14) and 83% were female. The mean DAS28, SDAI and HAQ were 3.8 (S.D. 1.6), 14.2 (S.D. 11.0) and 1.2 (S.D. 0.7). Of those 129 patients, 14 reported a fall or fracture in the last 6 months of response and only 16 patients were physically active. Relevant symptoms known as factors associated with risk of fall and its prevalence in this study were: pain (82%), followed by articular pain (68%), fatigue (43%), muscle weakness (37%) and weight gain (22%). Among patients who reported a fall or fracture, 83% had a RADAI ≥ 16 and mean FAST3 (Fibromyalgia Assessment Screening Test) index of 19 (IC95 % 17-21). FAST3 based on MDHAQ and independent RADAI showed positively association with a reported fall or fracture for these patients, with a p value of 0.023 and 0.025, respectively. Other factors, such as high disease activity based on DAS28 or MDHAQ, obesity and age were not statistically significant with the reported episode.
Conclusion: Maintaining PRO is aligned with patient-centered care, allowing relevant data source and identification of high-risk patients - in our study: patients in pain, sedentary and in major risk of fracture. Also, use of combined in like FAST3 or independent articular pain scores such as RADAI, might be helpful to identify those high-risk patients in need for orientation for reinforcement of physical activity, prioritization for in person visits and early clinical adjustments.

HPR Epidemiology and public health (including prevention)

AB1534-HPR ASSESSMENT OF BACK PAIN IN NURSES WORKING IN HOSPITALS AND OUTPATIENT CLINICS

B. Nieradko-Iwanicka[1]. [1]*Medical University of Lublin, Chair and Department of Hygiene and Epidemiology, Lublin, Poland*

Background: Back pain in a common health problem in nurses affecting 70-78% of them [1,2,3]. The risk of back pain in nurses increases by 35% for each additional working hour per day [2].
Objectives: The aim of the study was to find out if nurses working in hospital wards suffer more from back pain than their counterparts employed in the outpatient clinics.
Methods: An online survey was conducted with use of an questionnaire containing questions about body mass index (BMI), Revised Oswestry Low Back Pain Disability Scale (ROLBPDS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Numeric Rating Scale (NRS) for pain. Questions about seniority and working hours were included.It was uploaded and shared on the Google online survey platform. Participation was anonymous and voluntary. An invitation was mailed to the members of The Lublin Chamber of Nurses and Midwives. A total of 163 nurses (161women and 2 men) aged 21-70 years filled in the questionnaire in February and March 2021.Of the group 82 were nurses from hospitals (NHs) and 81 from outpatient clinics (NOCs).
Results: The mean BMI of participants was 26.4kg/m^2. In NHs the mean BMI was 25kg/m^2 and in NOCs 27.8kg/m^2.Seventy five percent of HNs looked after lying patients.Ninety nine percent of NHs and 75% of NOCs suffered from back pain. In the NH group 73% reported pain in lumbar, 13% in thoracic and 14% in cervical spine. In the NOC group 15% complained about neck pain and the rest about low back pain. The mean ROLBPDS rating was 15 which means moderate disability. In NOCs it was 13 and in HNs it was 17. The mean back pain NRS was 6. In NOCs it was 3 and in NHs it was 9 ($p<0.05$). There was a positive correlation between shift length and back pain measured with the NRS. As many as 5 participants had diagnosed seronegative spondyloarthropathy. In those mean BASDAI was 5.6±1 which means active disease.
Conclusion: Nurses working in hospital wards experience significantly more back pain than their counterparts working in outpatient clinics. Long working hours increase the risk for the ailment.

HPR Interventions (educational, physical, social and psychological)

AB1535-HPR COURSE WITH GROUP SESSIONS TO START SELF-INJECTION OF BIOLOGICAL MEDICINE (ADALIMUMAB)

J. Schjerbech Bech[1], B. A. Esbensen[2], S. Skalsted Rasmussen[1].
[1]*Rigshospitalet, Center for Rheumatology and Spine Diseases, Hellerup, Denmark*; [2]*Rigshospitalet, Glostrup, Glostrup, Denmark*

Background: Denmark decided in 2018 that Adalimumab should be the first-line biological of patients with inflammatory arthritis. Consequently, a higher number of patients needed to be given information about Adalimumab and learn how to do self-injections. The department focused on making optimum use of its resources while at the same time ensuring a high medical standard for this new task.
Objectives: To examine whether group instructions with a structured approach will provide the medical standard required to enable the patients to perform their own treatment at home. And also to examine whether participation in group sessions where the patients will have an opportunity to exchange experience with other people in a similar situation would be beneficial for them.
Methods: *Design:* An anonymous questionnaire survey. *Setting:* The training sessions took place at the Center for Rheumatology and Spine Diseases, Rigshospitalet, Gentofte, Denmark, and involved patients who were already consulting the outpatient clinic. *Participants:* Patients, ≥ 18 year, due to start on their therapy with Adalimumab, were referred to the group sessions irrespective of previous diagnosis, previous experience with other forms of biological therapy and/or experience with self-injection. A group consisted of between two and six participants. *Course structure:* Initially the participants were given group instructions in subjects such as effect, adverse effects, storage and precautions to be taken in the event of an infection. The patients were also given theoretic instructions in the administration of injections and an introduction to the injection pen (test model). Following this, the patients administered self-injections individually in private under guidance. *Material:* The questionnaire asked about whether the participants felt capable of managing their therapy at home and whether they had benefited from being instructed in a group. In addition to this, the patients were asked about background data such as gender and previous experience with injection techniques and biological therapy. The questionnaire also left room to offer more detailed comments. *Analysis:* Descriptive data analysis, including also the more detailed comments from the questionnaires.
Results: A total of twenty-five patients with inflammatory arthritis divided onto seven groups. Female: 15; male: 10
Bionaïve, no experience with self-injection: 13
Bionaïve, experience with self-injection: 6
Previous biological therapy, no experience with self-injection: 2
Previous biological therapy, experience with self-injection: 4

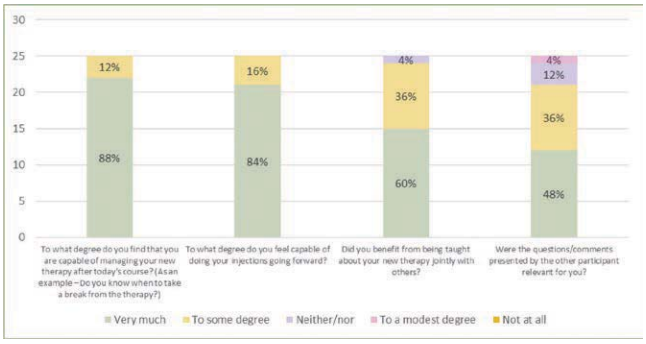

Figure 1.

After the group sessions, all of the patients felt they were capable of managing their own therapy and administering their own injections going forward. The patients were very much or to some degree happy that they were taught in groups and most replied that the questions/comments presented by the other participants were very relevant or relevant to some degree. Gender and previous experience with injection techniques and/or biological medicine did not affect patient satisfaction. Selected comments made by the patients:

"Found the group approach to be really good. Good to hear what the others said"; *"It was really good to be part of a group. I would never have thought of asking the question that the other patients raised and it was relevant for me too"*; *"Nice to listen to other people's experience because it makes you realize that things may not be all that bad for you"*; *"It was really good talking to others"*; *"Always good to meet others in the same boat"*

Conclusion: Group instructions with a structured approach are found to provide a medical standard which enables the patients to perform their own treatment at home. Participation in group sessions with others in the same situation as oneself is also found to be beneficial for the patients since this approach creates a space for dialogue and knowledge sharing by the participant.

AB1536-HPR DEVELOPING WORK-ON - VOCATIONAL REHABILITATION FOR PATIENTS WITH INFLAMMATORY ARTHRITIS

C. M. T. Madsen[1,2], J. Primdahl[1,2,3], A. Bremander[1,2,4], L. Eggen[1], J. Reffstrup Christensen[5,6,7]. *[1]Danish Hospital for Rheumatic Diseases, University Hospital of Southern Denmark, Sønderborg, Denmark*; *[2]Department of Regional Health Research, University of Southern Denmark, Odense, Denmark*; *[3]Hospital of Southern Jutland, University Hospital of Southern Denmark, Aabenraa, Denmark*; *[4]Section of Rheumatology, Department of Clinical Sciences, Lund University, Lund, Sweden*; *[5]Research Unit of General Practice, Department of Public Health, University of Southern Denmark, Odense, Denmark*; *[6]User Perspectives and Community-Based Interventions, Department of Public Health, University of Southern Denmark, Odense, Denmark*; *[7]Research Unit of General Practice, Aarhus University, Aarhus, Denmark*

Background: Patients with inflammatory arthritis (IA), i.e. rheumatoid arthritis, axial spondyloarthritis and psoriatic arthritis, experience low work ability, an increased risk of long-term sickness absence and up to 38% lose their job in the first years after diagnosis. This affects the patients' identity and has economic consequences for the individual as well as for the society. Patients with IA need vocational rehabilitation (VR) to increase their work ability, decrease their sickness absence, and risk of losing their job. Positive results from VR for patients with IA are limited (1).

Objectives: To describe the development of a VR, WORK-ON.

Methods: The development process was based on the Medical Research Council's framework for Complex Interventions and ran in two phases (2). Phase 1, the evidence base: identifying existing evidence through a scoping review and theories (occupational balance, self-management and shared decision making) considered useful for VR. In addition, interviews with 15 patients with IA and 21 health professionals were performed and analysed (3). Phase 2, program development: a workshop was held with patient research partners, researchers, health professionals from a hospital specialised in rheumatological rehabilitation, and from a municipal job center. By repetitive feedback from the stakeholders, the WORK-ON was modelled, remodeled, and described in a manual. Patient research partners were involved throughout the process.

Results: The duration of WORK-ON will be eight months and includes 6 - 11 meetings (30-60 minutes) depending on the patients' needs. The WORK-ON intervention consists of four parts: 1) Initial assessment and goalsetting by an occupational therapist, 2) Coordination by an occupational therapist throughout the VR and assistance in navigation across primary and secondary health and social care including follow up.The coordinator is responsible for individual support concerning issues such as energy management, coping with the disease and concerns related to work. 3) Group sessions together with other patients with IA for peer support, and 4) Individually tailored VR consultations with physiotherapists, nurses, or social workers. Multidisciplinary team discussions will be held with the patient, relatives and all involved partners from the patients' municipality and the hospital to evaluate the VR and decide the next step after eight months. Suggested primary outcome measures are the Occupational Balance Questionnaire (OBQ) and the Work Productivity and Activity Impairment questionnaire (WPAI). Secondary outcomes are health related quality of life (EQ-5D-5L), number of days of sickness absence over a year, VAS pain, fatigue, and global assessment.

Conclusion: WORK-ON was developed with input from various stakeholders and is ready to be tested in a feasibility study after training of the health professionals, who will deliver the VR. Depending on feasibility and indications of efficacy, the primary outcome will be selected and the effect of WORK-ON will be tested in a subsequent RCT study on IA patients in Denmark or further developed in a second feasibility study. Furthermore, a realistic evaluation will be conducted by interviews with patients and health professionals to determine the quality of implementation, contextual factors, and mechanisms.

AB1537-HPR INFLUENCE OF SEGMENTAL STABILIZATION AND PILATES ON NON-SPECIFIC CHRONIC LOW BACK PAIN IN BRAZILIAN ELDERLY: A PRELIMINARY STUDY.

A. Torres Cruz[1], P. De Oliveira Januário[1], I. Coelho Baptista[2], A. Da Rocha Rodrigues[2], B. Libanio de Souza Castro[2], G. Bezerra Oliveira[2], I. Da Silva Palmeira[2], T. De Fátima Cabral Dos Santos[2], A. Pasqual Marques[1]. *[1]Universidade de São Paulo – USP, Medical School, Department of, Speech Therapy, Physiotherapy and Occupational Therapy, São Paulo, Brazil., São Paulo, Brazil*; *[2]Centro Universitário de Barra Mansa - UBM, Department of Physiotherapy, Barra Mansa, Brazil*

Background: Low back pain is the second most common health condition in Brazilian elderly, after arterial hypertension, and can be defined as any pain between the last ribs and the lower gluteal folds, with or without pain in the lower limbs, manifesting itself acutely, subacutely or chronically.

Objectives: To analyze the effect of segmental stabilization in comparison with the Pilates method in elderly patients with chronic non-specific low back pain.

Methods: 9 elderly people with chronic low back pain participated in the study, randomized into two groups: Segmental Stabilization Group (SG n=9; age 66.11±4.78; Body Mass Index - BMI 28.21±4.05) and Pilates Group (PG n=13; age 67.46 ±4.89; BMI 28.18±3.48). Both groups performed 16 individual 60-minute sessions twice a week and evaluated before and at the end of treatment. Pain was assessed using the Visual Numerical Pain Scale; functional disability, by the Oswestry disability index; excessive fear of movement and physical activity, by the Tampa Kinesiophobia Scale; level of confidence in balance for specific activities, by the Activities-specific Balance Confidence (ABC) scale and; activation of the transversus abdominis muscle, by the pressure biofeedback unit Stabilizer of the brand Chatanooga. The allocation and assessments of participants were performed by a blinded examiner. Data were analyzed using Student's t test with the level of significance ($p \leq 0.05$).

Results: Pain intensity had a greater reduction in the SG when compared to the PG ($p=0.0015$), as well as a reduction in functional disability ($p=0.0043$). The activation of the transversus abdominis was greater in the PG ($p=0.0213$). There was no difference in kinesiophobia and the level of confidence in balance for specific activities.

Conclusion: Segmental stabilization and Pilates were effective in improving pain and functional disability, with SG showing a better effect for these variables. The

PG obtained better results when compared to the SG regarding the activation of the transversus abdominis muscle. It is suggested to carry out studies with a greater number of participants, a longer treatment and follow-up time to complement these findings.

AB1538-HPR AMIGOS DE FIBRO (FIBRO FRIENDS): VALIDATION OF AN EDUCATIONAL PROGRAM TO PROMOTE THE HEALTH OF PATIENTS WITH FIBROMYALGIA IN BRAZIL.

M. Antunes[1], A. Schmitt[1], A. Pasqual Marques[1]. [1]*University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy, São Paulo - SP, Brazil*

Background: Health education is a very important tool in the treatment of people with fibromyalgia. Health education acts as an excellent non-pharmacological treatment to promote health in fibromyalgia.
Objectives: To validate a multidisciplinary educational program to promote the health of people with fibromyalgia in Brazil, called Amigos de Fibro.
Methods: This is a methodological research with 45 individuals with fibromyalgia (target audience) and 23 health professionals (expert judges). Both groups used an instrument to assess the objectives, themes and proposed actions, relevance, writing style and structure of the program using the Delphi technique. The Content Validity Index (CVI) ≥ 0.78 and Kappa Coefficient ≥ 0.61 were used to analyze and validate the data.
Results: All items evaluated in both groups had a considerable minimum CVI and Kappa Coefficient to be valid. In the global assessment of Amigos de Fibro, the CVI of the target audience judges was 0.95, while the expert judges presented a value of 0.90. The Kappa Coefficient of the target audience judges was 0.85 and that of the expert judges was 0.90. Therefore, the instrument proved to be validated.
Conclusion: Amigos de Fibro was considered valid for its content and internal consistency, therefore, valid to be used by health professionals with the target audience in Primary Health Care in Brazil, allowing them to act as promoters of their health.

AB1539-HPR AMIGOS DE FIBRO (FIBRO FRIENDS): VALIDATION OF AN EDUCATIONAL E-BOOK TO PROMOTE THE HEALTH OF PEOPLE LIVING WITH FIBROMYALGIA IN BRAZIL

M. Antunes[1], A. Schmitt[1], A. Pasqual Marques[1]. [1]*University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy, São Paulo - SP, Brazil*

Background: In the optimal treatment of fibromyalgia, international recommendations highlight non-pharmacological treatment as the key to success. Health education is one of the main tools to promote the health of patients with fibromyalgia. Educational strategies are essential for the care of patients with fibromyalgia.
Objectives: Develop and validate an e-book to promote the health of people with fibromyalgia who live in Brazil.
Methods: This is a methodological study, initially, through a bibliographic survey, the available publications on the subject were analyzed. Then, this knowledge was used to build the theoretical content addressed and the art and layout of the e-book was elaborated. Finally, the validation of the constructed material was carried out with three groups of specialists: content specialists (n=23), technicians (n=23) and design specialists (n=23). In addition, it was also decided to validate the e-book with individuals who have fibromyalgia (n=45. The e-book was evaluated by specific instruments through the Delphi technique. The data were analyzed, and the reliability was evaluated by the Alpha of Cronbach (αC) and agreement, using the Content Validity Index (CVI).
Results: In the global evaluation, all the judges agreed with the items evaluated in the e-book, presented a considerable minimum of the CVI, being: content (0.79), technical (0.89), design (0.92), and target audience (0.97). Regarding reliability, all groups also had an αC within the acceptable range: content (0.960), technical (0.963), design (0.977), and target audience (1.08).
Conclusion: E-book was prepared and validated in terms of content and relevance, and can be used in Brazil to promote the health of individuals with fibromyalgia, mainly as a complement to treatments already carried out for fibromyalgia. In the future, this e-book may be translated and adapted into new languages.

AB1540-HPR NURSING INTERVENTIONS FOR RHEUMATIC MUSCULOSKELETAL DISEASES (RMDS) PATIENTS ON BIOLOGIC THERAPY: A SYSTEMATIC LITERATURE REVIEW (SLR)

M. R. Melis[1], K. El Aoufy[2], C. Bruni[2], F. Bartoli[1], G. Fiori[1], S. Guiducci[1], S. Bellando Randone[1], S. Bambi[3], L. Rasero[3], M. Matucci-Cerinic[2]. [1]*Careggi Hospital, Department of Experimental and Clinical Medicine, University of Florence, Rheumatology Unit, Florence, Italy*; [2]*University of Florence, Department of Experimental and Clinical Medicine, Rheumatology Unit, Florence, Italy*; [3]*University of Florence, Department of Health Sciences, Florence, Italy*

Background: The support of the Rheumatology nurse to the management of patients who are affected by RMDs, characterized by remission and recrudescence and chronicity, may be strengthened by the investigation of their unmet needs and the identification of the necessary interventions to the continuity and quality of care.
Objectives: The aim of the present SLR is to identify the main nursing interventions to assure quality care in RMDs patients on biologic therapy.
Methods: Study design: a systematic search was conducted from 1990 to 2020 (01/01/1990- 2020/05/07). Inclusion criteria consisted of 1) patients with RMDs in accordance with American College of Rheumatology classification criteria and the American College of Rheumatology/European League against Rheumatism (ACR/EULAR); 2) in therapy with bDMARDS; 3) adult population > 18 years; 4) primary research only; 6) English language; 7) abstract available; and 8) relative quantitative studies; 9) nursing interventions and/or outcomes. Data sources: Medline, CINAHL, PsycINFO and EMBASE databases were used to search for relevant studies. Review methods: using the predetermined inclusion/exclusion criteria, two independent reviewers (MRM, KEA) screened records selected for eligibility based on titles and abstracts. Records meeting the inclusion criteria were retrieved and full texts were further assessed. Critical Appraisal Skills

Program (CASP) tools were used to evaluate the quality of the included studies. Data from 8 studies were extracted independently by the reviewers.
Results: 1805 articles were retrieved: after the review process, 8 articles met the inclusion criteria resulting in 1 randomized trial, 1 quasi-experimental study and 6 observational studies. The RMDs patient needs emerged concerning the psychosocial domain, the relationship with healthcare facilities and disease follow up to monitor symptoms. Moreover, three major nursing interventions related to these areas were identified: education, patient-centered care and data assessment.
Conclusion: Rheumatology nurses are part of a multidisciplinary team caring for patients on biologic therapy. Starting with accurate initial and ongoing data collection, rheumatology nurses can plan their interventions focusing primarily on patient education and tailored care based on actual needs. Further studies are necessary for research on aspects of patient-centered nursing care, including tele-nursing and Nursing Sensitive Outcomes in RMDs.

AB1541-HPR IMPACT OF COUNSELLING, TELEPHONE-BASED SYMPTOMS TREATMENT TITRATION AND REMINDER CALL ON REGULAR FOLLOW UP AMONG COMMON RHEUMATOLOGIC DISORDERS; A PROSPECTIVE COHORT STUDY

V. Kattel[1], N. Gupta[2], S. Malviya[3]. [1]*BP Koirala Institute of Health Sciences, Internal Medicine, Dharan, Nepal*; [2]*MGM Medical College, Anaesthesiology, Indore, India*; [3]*Medanta Superspeciality Hospital, Rheumatology and Clinical Immunology, Indore, India*

Background: Poor adherence to rheumatologic diseases exist for various reasons.
Objectives: The objective of the study was to measure adherence with interventions.
Methods: It was a prospective cohort study for 52 weeks. Assuming adherence of 30%, power of the study as 90% and confidence interval 95% sample size was calculated as 323. Common rheumatologic disorders (Rheumatoid arthritis (RA), Spondyloarthropathy (SpA), Primary Sjogren's Syndrome (PSS) and Systemic Lupus Erythematosus (SLE)) patients with at least 15% from each group who presented first time in our clinic were followed up. The interventions were two separate sessions of face-to-face counselling during first initial visits, telephone-based titration of drugs if there was poor control of the presenting symptoms and two-day prior reminder phone call for next follow up.
Results: Among 323 enrolled patients 27% were compliant with previous treatment. The relative ratio of compliant groups under follow up with the rheumatologist verses other clinicians was 2.2. Median duration of diagnosis of the 60% previously diagnosed verses 40% newly diagnosed at our clinic was 18 months verses 7 days. Among 64 cases of PSS 86% were undiagnosed with median duration of symptoms of 4 years. Knowledge about consequences of poor treatment between pre verses post counselling was 40% and 78% respectively. (Table 1) Symptom controlled with telephone-based drug titration was achieved among 84% of cases (30%, 44%, 10% partial, nearly complete and complete improvement respectively). With the reminder call the adherence weans off to 85% at first follow up, 77% at third month and 53% at the end of year. By 52 weeks PSS had maximum adherence (78%) followed by SLE (58%), RA (42%) and SpA (42%). (Figure 1)

Table 1. Comparison between pre and post intervention

Variables	RA (N=116)	ax-SpA (N= 72)	SLE (N=71)	PSS (N=64)
Before intervention	3.5	2.5	3	4
•Median duration of diagnosis (years)	25	9	34	19
•Number of adherence (87)	9	4	7	3
•Insight about the disease conditions	17	17	16	16
a.I don't have disease	30	17	16	31
b.I have disease due to external factors	28	23	25	11
c.I have disease due to internal factors	22	11	7	3
d:'c' + I need medication for some time	<1	2	<1	2
e:'c' + I need medication per rheumatologist	49	30	41	50
After intervention	5	4	5	1
•Median duration of diagnosis (weeks)	9	4	4	4
•Number of adherence at 52 weeks (170)	14	9	8	11
•Insight about the disease conditions	31	21	17	11
a.I don't have disease	57	34	37	32
b.I have disease due to external factors				
c.I have disease due to internal factor				
d:'c' + I need medication for some time				
e:'c' + I need medication per rheumatologist				

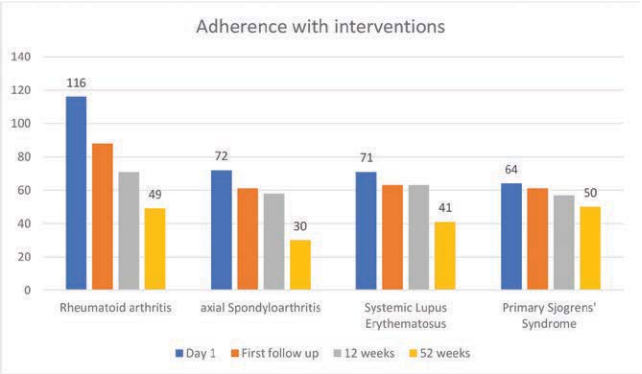

Figure 1. Adherence proportion with consequent follow up

Conclusion: Early diagnosis, separate counselling sessions, effective control of symptoms and reminder to follow up significantly increases the adherence in rheumatological disorder.

AB1542-HPR USING SOCIAL NETWORKS AS A SOURCE OF INFORMATION FOR RHEUMATOLOGICAL PATIENTS

A. Sarapulova[1], O. Teplyakova[2]. [1]*USMU, Outpatient Therapy, Yekaterinburg, Russian Federation*; [1]*USMU, Outpatient Therapy, Yekaterinburg, Russian Federation*

Background: The COVID-19 pandemic has brought significant changes to the work of healthcare professionals around the world. Technologies of telemedicine counseling and education of patients have become widespread. The largest platforms for informing patients are social networks such as Facebook, Instagram, Twitter.
Objectives: to study the possibilities and impact of the social network as a digital medical tool on the education and management of rheumatological patients
Methods: The study was conducted in the form of a survey in the social network Instagram in the blog @revmatologg_sarapulova, dedicated to the rheumatological diseases, and was dedicated to the level of information. At the time of the survey, the number of subscribers to the blog was 4895 people, 223 people answered the questions submitted. The survey was conducted in a Google form and was anonymous.
Results: 86% of respondents lived in Russian Federation, 17.5% - in the survey region, 14% of patients were from other countries. 72% indicated the presence of rheumatic disease as the reason for reading the blog, 7% - disease in relatives, 14% are guided by the desire to know more about rheumatological diseases. 68.5% of the respondents rated the information presented in the blog as very interesting (10 points on a scale from 0 to 10), 13.3% - 9 points and 9.1% - 8 points. It should be noted that none of the participants in the study gave less than 5 points.

The most interesting in the blog, the majority calls information posts (88.8%) and answers the questions (77.6%). 2 out of 3 patients (64.5%) after getting acquainted with the information provided began to know more about their disease, 14% began to lead a healthier lifestyle, 9.8% realized the need to visit a doctor. 83.3% of participants rated the information on the blog as more detailed than what they get at their doctor's appointment, and 81% would seek advice from a blogger. When answering the question "Do you share the information you get from the blog with your healthcare provider?" 47.2% noted that they prefer not to report, 28% - report, while 44.9% of respondents indicated that the doctor is neutral about the information received, 22.9% - positively, 7.6% - negatively. In general, 86% agreed that social networks are an important source of medical information, and as other sources they noted self-search for information in the Internet and visiting a doctor. 65.7% of the respondents asked the question to the author of the blog and received a response that was helpful in 90.6% of cases. 36.8% previously applied for telemedicine counseling through any messengers/systems, and 20.1% plan to do so. In 57.8% of cases, the opinion of the attending physician coincided with the result of a telemedicine counseling, in 12.8% it did not, and 17.8% of patients consulted only online.

Conclusion: social networks are an important source of information for patients and a means of choosing a medical specialist. However, it is alarming that in about half of the cases, patients do not share the information received with the attending physician, which can be explained both by lack of time and the lack of an adequate level of trust.

AB1543-HPR WAITING ROOM PROJECT: IMPROVING HEALTHCARE OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

F. Moura[1], S. Brito[2], D. Amaral Mota[2], L. Diniz[2], J. Monção[2], V. Nunes[3], V. Gonçalves[2], J. Lacerda de Oliveira Campos[2], P. Fradico[2], M. Baldini[2], U. Hasparyk[2], D. Calderaro[2], C. C. Lanna[2], R. Weiss Teles[2]. [1]*UFMG Faculty of Medicine, Locomotor, Belo Horizonte, Brazil*; [2]*UFMG Faculty of Medicine, Locomotor, Belo Horizonte, Brazil*; [3]*UFMG Faculty of Medicine, Locomotor, Belo horizonte, Brazil*

Background: Systemic lupus erythematosus (SLE) prognosis is determined by a wide range of factors, such as the severity of the disease manifestations, the psychosocial aspects of patients, the proper management of comorbidities, adoption of a healthy lifestyle and adherence to treatment. Studies on chronic diseases highlight the value of patient education to foster treatment adherence and improve prognosis.

Objectives: To promote health education to SLE patients and their families providing accessible and comprehensive scientific information, in order to improve adherence to treatment and the patient's prognosis.

Methods: The Waiting Room Project is linked to the Extension Health Care Program for SLE patients and their families of Universidade Federal de Minas Gerais, Brazil, since 2011. A total of 700 patients under SLE treatment at the Rheumatology Unit of the University Hospital are involved. Medical students and rheumatology fellows, altogether, developed high-quality informative texts, with clear content and layman language appropriate for the patient, under the supervision of the rheumatology professors. The texts are illustrated by the team of the Communication Department of the Medical School and medical students, and are printed in a leaflet format. The material is handed out to the patients, while they wait for their medical appointment, by the students and the care team. The content of the leaflets is discussed, making sure that all the concerns and doubts are properly addressed

Results: The Waiting Room Project has produced 17 leaflets, addressing different aspects of SLE, comorbidities, and treatment. The texts approach the traditional cardiovascular risk factors (Smoking, Arterial Hypertension, Diabetes, Obesity, Physical Activity), and some medical conditions related to general health and SLE treatment (Sun Protection, Healthy Food, Oral Care, Vaccination, Pregnancy, Osteoporosis). In 2020 and 2021, two leaflets about Covid-19 were produced in order to clarify important aspects of this disease, its impact on lupus patients and to solve questions about SLE medications: one regarding the association between Lupus and Covid-19 and another about the treatment of lupus and Covid-19. Other four leaflets were produced concerning SLE treatment, including Adherence to Treatment, the use of Antimalarials, Corticosteroids, and Immunosuppressants. Information about the drugs, general importance on lupus treatment, recommendations and possible adverse events were described. Futhermore, additional content is currently in production with themes such as Intravenous Corticosteroid and Cyclophosphamide, Human Papillomavirus Infection, Malignant Neoplasm, and specific cancers frequently affecting women, such as Colorectal Cancer, Cervical Cancer, and Breast Cancer. The leaflets are also available online on the Medical School website in Portuguese and in English (medicina.ufmg.br/alo/material-didatico/), on the Minas Gerais Rheumatology Society website (reumatologia.org.br/orientacoes-ao-paciente/), and on the Instagram page @lupusufmg

Conclusion: The leaflets have been an important source of information and health education for SLE patients and their families, improving student/physician-patient communication. Despite the adversities caused by the coronavirus pandemic, the Waiting Room Project has kept its purpose to make each patient with SLE an agent of their healthcare. Improving the patients' access to evidence-based information must be a goal of healthcare professionals that treat patients with SLE

AB1544-HPR CLINICAL COMORBIDITY PHENOTYPE IN KNEE OSTEOARTHRITIS IS ASSOCIATED WITH HIGHER INTENSITY SCORES

A. Ben Tekaya[1], O. Hamdi[2], L. Rouached[1], S. Bouden[1], R. Tekaya[1], O. Saidane[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Charles Nicole Hospital, Rheumatology, Tunisia, Tunisia*; [2]*La Rabta Hospital, Rheumatology, Tunisia, Tunisia*

Background: Knee osteoarthritis (OA) is a common osteoarticular disease. Its prevalence increases with age as well as the coexistence of other chronic diseases. Recent researches have revealed an association between OA and cardiovascular diseases. However, association between knee OA and comorbidities has not been fully studied.

Objectives: The purpose of this study was to investigate the association between knee OA and comorbidities.

Methods: In this cross-sectional study, patients with knee OA were enrolled. Sociodemographic data as well as comorbidities were collected. Grading of knee OA was performed using the Kellgren-Lawrence (KL) grading system. Functional impact of knee OA was assessed by KOOS-Physical Function Shortform (KOOS-PS).

Results: This study assessed 104 patients with knee OA (10 men and 94 women). Mean age was 65.83 ±11.08 years. Mean VAS pain was 6.56 ± 1.72. Mean KOOS-PS was 15.58 ± 6.73. Up to 81 patients (77.9%) had severe knee OA according to the KL grading system. Comorbidity was noted in 92 cases (88%). The most frequent comorbidities were obesity (62.5%), hypertension (61.5%) and dyslipidemia (43.3%). Comorbidities in knee OA were associated with age (p=0.04), neuropathic pain component (p=0.02) and VAS pain (p=0.04). Our study also showed a significant correlation between comorbidities and structural grading of knee OA (p=0.04). However, comorbidities were not correlated with KOOS-PS score (p=0.06).

Conclusion: The accumulation of comorbidities is significantly associated with higher intensity scores in knee OA. Physicians should additionally pay close attention to the prevention and the treatment of comorbidities in the management of OA.

AB1545-HPR MALNUTRITION IN PATIENTS WITH RHEUMATOID ARTHRITIS OVER 65 YEARS OF AGE

L. Cano Garcia[1], D. Ruiz[2], P. Armenteros[2], C. Dominguez[3], N. Al Mashhadani[1], N. Mena-Vázquez[1]. [1]*Instituto de Investigación Biomédica de Málaga (IBIMA); Hospital Regional Universitario de Málaga, Rheumatology, Málaga, Spain*; [2]*Hospital Universitario Reina Sofía, Instituto Maimónides de Investigación Biomédica (IMIBIC), Universidad de Córdoba, Rheumatology, Córdoba, Spain*; [3]*Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*

Background: Malnutrition is one of the most important geriatric syndrome and fragility factor in older people. In adittion to being a disease sign, its presence is related with increasing of morbility, longer hospitalizations, institucionalization and mortality due to concomitant diseases.

Objectives: Describe prevalence of malnutrition risk and associated factor in patients with rheumatoid arthritis (RA) over 65 years of age.

Methods:

Design: A case-controls study.

Participants:

Cases: Recruitment was performed by random sampling between patients over 65 years of age with RA (ACR/EULAR 2010 criteria) attended at 4 Spanish

University Hospitals. Controls: Recruitment of subjects without rheumatoid disease was performed asking for case patients who attended to medical center with a similar-age (age of range +/- 5 years) and same-gender person from same social or family environment. Variables y measures: The main variable was malnutrition risk, measured by screening of Mini Nutritional Assessment. Other variables were: presence of sarcopenia, defined according to European Working Group on Sarcopenia in Older People (EWGSOP) 2019, economic status, dual-energy x-ray absorptiometry (DEXA) in spine and hip to osteoporose screening, toxic habits, comorbidities and Charlson index, physical activity measured with Global physical activity questionnaire (GPAQ) and Short Physical Performance Battery (SPPB), haemoglobin, calcium, D and B12 vitamins, total proteins, albumin, C reactive protein, body mass index (BMI), polimedication, quality of life measured with EQ-5D and RA related factors, activity disease measured with DAS28, SDAI and CDAI; physical function measured with HAQ (Health assessment questionnaire) and global functional status according ACR criteria. Statistical analysis: Descriptive and multivariative analysis was performed to identify factors associated to sarcopenia in RA.

Results: 152 subjects were included in the study, 76 RA and 76 controls.More patients than controls with malnutrition risk were found, although there were no significative difference (24 [31,6%] vs 17 [22,4%]; p=0,136). More women with RA were included (78,9%), with media ± SD of age 74,7 ± 3,78., sarcopenia was presented in 9/24 (37,5%) and Charlson index was 3 points in 11/24 patients (45,8%) and 4 points in 8/24 patients (33,3%). According to the treatment, almost a 40%, no DMARDs were taken and neither 25% biological DMARD. 58,3 % of patients received corticosteroids and mayority of them (95,8%) were polimedicated. RA patients who presented desnutrition risk, in comparison with the rest of patients, had a media of upper age (p=0,007), more frequency of sarcopenia (p=0,006), right tricipital skinfold thickness (p=0,043). Also, higher values were found in activity index like physical function and quality of life: DAS28 (p=0,003), HAQ (p=0,044), Vitamin D (p=0,035), IPAQ (p=0,003), SPPB (p=0,018), EQ5D (p=0,01), VAS EQ5D (p=0,044), SDAI (p= 0,006), CDAI (p=0,008). In multivariative análisis, factors associated by independent way to malnutrition risk were age (OR [CI 95%], 1,148 [1,020-1,291]; p=0,022) and inflammatory disease by DAS28 (OR [CI 95%], 2,043 [1,198-3,483]; p=0,009) (R2=0,252).

Conclusion: Even though frequency of malnutrition was similar in cases and controls, in RA was associated with inflammatory activity and older age. It´s important monitoring malnutrition risk in this kind of patients to perform correct interventions to prevent and improve nutrition.

AB1546-HPR LOCUS OF CONTROL IN RHEUMATIC DISEASES

R. Grekhoff[1,2]. [1]*Zborovsky Research Institute for Clinical and Experimental Rheumatology, Laboratory of Functional Research Methods, Ultrasound Diagnostics and Rehabilitation Therapy, Volgograd, Russian Federation*; [2]*Volgograd State Medical University, Chair of General and Clinical Psychology, Volgograd, Russian Federation*

Background: Locus of control as a theoretical construct derives from Julian B. Rotter's [1] social learning theory of personality. Locus of control is the person's trait to attribute their successes or failures only to internal or only external factors; it refers to an individual's perception about the underlying main causes of events in his/her life.

Objectives: The aim of the study was to investigate the level of locus of control in patients with systemic lupus erythematosus, primary fibromyalgia syndrome, and osteoarthritis.

Methods: The level of locus of control was studied in 87 patients with systemic lupus erythematosus (SLE), 100 patients with fibromyalgia (F) and 27 patients with osteoarthritis (OA), using the Subjective Control Level (SCL) questionnaire [2].

Results: Patients with SLE show a pronounced tendency to externality in the general sphere, as well as in the sphere of failure (3.63±0.34), work related sphere (3.42±0.21), interpersonal relations, and especially in relation to health (3.31 ±0.32). The study of SCL in patients with F allowed to note a significant decrease of scales in the spheres of general internality (2.98±0.31), internality in the field of achievements (3.08±0.34) and failures (3.42±0.30), interpersonal relations (3.54±0.25) and health (2.87±0.32), that indicates the externality of the F patients' attitudes according to these scales. Patients with OA has a pronounced tendency to externality in the general sphere (3.81 + 1.387), as well as on the scales of internality in the area of failures (3.51 + 0.64), family relationships (4.18 + 0.55), work related sphere (2.74 + 0.98) and in relation to health (4.66 + 1.94). In the sphere of interpersonal relations and on the scale of internality in the field of achievements, internal tendencies are observed (5.14 + 0.71 and 5.0 + 1.24, respectively). Thus, the role of the sick man, that is assimilated to some extent by most patients with rheumatic diseases, and the symptoms of the disease form a feeling of helplessness in the patients, the need for sympathy and care from others, the hope that the improvement in the condition will be the result of external factors that do not depend on the patient himself. These changes may make it difficult to carry out effective therapy measures and, in turn, are the target of psychology intervention.

Conclusion: Thus, the successful treatment of rheumatic diseases requires the active involvement of a patients in the therapy process, as well as changes in their attitudes and lifestyles. The condition of the majority of patients can be significantly improved if the patient and the doctor can form a working partnership and the patient becomes an active participant in the treatment process, gains experience in controlling the situation, takes responsibility for strict adherence to the treatment and rehabilitation regimen. Some psychotherapy methods can be used in order to achieve these goals.

AB1547-HPR CAN A NURSE REPLACE THE DOCTOR IN AN UNCOMPLICATED PATIENT COURSE IN A PMR CLINIC? WHAT DO THE PATIENTS SAY?

S. Højmark Jakobsen[1]. [1]*University Hospital Svendborg Hospital, Rheumatology, Svendborg, Denmark*

Background: Since 2020 the Rheumatology Outpatient Clinic of OUH, Svendborg Hospital has offered telephone consultations for patients diagnosed with muscular arthritis (PMR) treated with prednisolone. Since 2021 has the course for the non-complexed patients been run by nurses. Initially patients only see a rheumatologist at the time of admission and the rheumatologist is only involved again if complications occur in the course e.g. that the patient can´t reduce Prednisolone as agreed without getting symptoms. At same day the patients are diagnosed by a rheumatologist they have a conversation with the nurse. The nurse gives both oral and written information about the disease and a Prednisolone reduction schedule is handed out to the patients. Afterwards the patients are followed by nurses and by telephone contact only. The telephone contact with the patients take place after 2, 10 and 17 weeks. When the patients are down to 7.5 mg of prednisolone daily, the nurse discharge the patient in our out-patient clinic to their own GP, who then takes care of the rest of the treatment and reduction of prednisolone to zero. There are more literature reviews about PMR and outpatient clinics led by nurses and patient satisfaction, but we have not found anything about the patient satisfaction when they only have contact to nurses during their course.

Objectives: The aim of this qualitative study was to examine the impact on patient satisfaction when they only have contact to nurses during their course and at the same time examine whether the patients have missed talking to a rheumatologist. In addition to this, we were interested in the understanding and degree of application of the written reduction schedule.

Methods: All PMR patients completed in the outpatient clinic between December 2021 and January 2022 where asked to participate in a telephone interview at the end of their treatment. They were asked about their satisfaction with nurse consultations during their course on a scale from 0-10: 0= not satisfied and 10= high satisfaction. The patients were also asked if they had missed not to talk to a rheumatologist and finally they were asked about the Prednisolone reduction schedule.

Results: 20 patients participated in the telephone interviews. 55% of the patients responded 10 on a scale from 0-10 in satisfaction talking with the nurses. 25% responded 9 on the scale, 15% mentioned 8 on the scale and 5% mentioned 7 on the scale. All of the patients answered no regarding the need to talk with a rheumatologist. None of the 20 patients has been re-admitted to our outpatient clinic afterwards. 75% of the patients have no problem in following the Prednisolone reduction schedule and found it easy to read and understand.

Conclusion: With the limited number of participants, it is not possible to conclude anything definitive, but the answers indicate that the patients are satisfied with nurse consultations only during their course in the outpatient clinic and the answers also indicate that they have no need to talk to a rheumatologist. Our research could therefore indicate that nurses with a specific protocol in hand are capable of managing a course for non complex PMR patients including discharging the patients from the outpatient clinic. The answers regarding the reduction schedule reassured us, that it is understandable which should reduce the possibility of errors in the treatment.

PATIENT-REPORTED ADVERSE DRUG REACTIONS ATTRIBUTED TO THE USE OF ADALIMUMAB: DISTINCTION BASED ON NATURE, FREQUENCY AND BURDEN

L. Van Boxem[1], H. Gosselt[1], J. Van Lint[1], S. Tas[2], B. Van den Bemt[3], H. Vonkeman[4], F. Hoentjen[5], M. Nurmohamed[6], M. Van Doorn[7], N. Jessurun[1]. *[1]Netherlands Pharmacovigilance Centre Lareb, Dutch Biologic Monitor, 's-Hertogenbosch, Netherlands*; *[2]Amsterdam UMC, Locatie AMC, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[3]Sint Maartenskliniek, Pharmacy, Research and Innovation, Ubbergen, Netherlands*; *[4]Medisch spectrum Twente, Rheumatology and Clinical Immunology, Enschede, Netherlands*; *[5]University of Alberta Hospital, Division of Gastroenterology, Edmonton, Canada*; *[6]Reade, Locatie Dr. Jan Van Breemenstraat, Rheumatology and Clinical Immunology, Amsterdam, Netherlands*; *[7]Erasmus MC, Dermatology, Rotterdam, Netherlands*

Background: Research regarding adverse drug reactions (ADRs) associated with the use of adalimumab in patients with inflammatory rheumatic diseases (IRDs) usually focuses on the nature and frequency of ADRs without considering the burden of the ADRs. However, not every ADR causes the same burden for patients. Information is lacking about the degree of experienced burden per ADR by patients with IRDs.
Objectives: First, to describe ADRs of adalimumab based on nature, frequency and burden, and second to propose a new model for identification of relevant ADRs for health care professionals.
Methods: Data of the Dutch Biologic Monitor (DBM) was used to categorize patient-reported ADRs into high and low burden. In this prospective cohort event monitoring system patients were asked to fill out bimonthly questionnaires on experienced ADRs that they attributed to the use of a biological. The questionnaire included a quantification of the burden of the reported ADRs using a five-point Likert scale ranging from 1 (no burden) to 5 (very high burden). The nature of the reported ADRs were grouped into preferred terms (PTs) according to the Medical Dictionary for Regulatory Activities (MedDRA). Inclusion criteria for this study were patients with IRDs using adalimumab and the reporting of an ADR with at least one burden score. For every patient, the mean burden scores per ADR (MedDRA PT) were analyzed. The burden was classified in two categories: 'high' when the mean burden score was equal to or more than 2.5, and 'low' when it was less than 2.5. Text analytics of the reported ADRs (MedDRA PTs) and a comparison word cloud were used to visualize ADRs that were more often reported with high burden or more often reported with a low burden. For this, the relative ADR frequencies of the low burden classes were subtracted from the relative frequencies of the high burden class, resulting in a percentual difference between the high and low burden class for every ADR. Therefore, the highest percentual difference corresponds to the ADRs that are experienced as most burdensome.
Results: A total of 170 patients (68% female) met the inclusion criteria and reported 671 ADRs, of which 271 (40%) were reported with high burden (see Table 1). The word cloud (Figure 1) visualizes which ADRs were more often reported with high or low burden. These ADRs correspond to the greatest difference in relative class frequency. Patients experienced the burden of respiratory tract infections and increased infection susceptibility mainly as high, and the burden of injection site pruritus and injection site pain as low.

Table 1. Characteristics of patients and reported adverse drug reactions (ADRs)

Characteristics	Total		
Patients (n = 170)			
Gender (female, %)	116 (68)		
Age (years) (mean ± SD)	55.4 ± 12.8		
Indication[a]			
Rheumatoid arthritis (%)	91 (54)		
Ankylosing spondylitis/axial spondyloarthritis (%)	31 (18)		
Psoriatic arthritis (%)	48 (28)		
Adverse drug reactions	Total	High burden	Low burden
Adverse drug reactions (ADRs) (%)	671 (100)	271 (40)	400 (60)
Drug-induced ADR burden (mean ± SD)	2.5 ± 1.0	3.4 ± 0.7	1.8 ± 0.4
High burden ADRs:			
Respiratory tract infections	12	11	1
Infection susceptibilityincreased	20	14	6
Headache	13	9	4
Therapeutic product effectdecreases	14	9	5

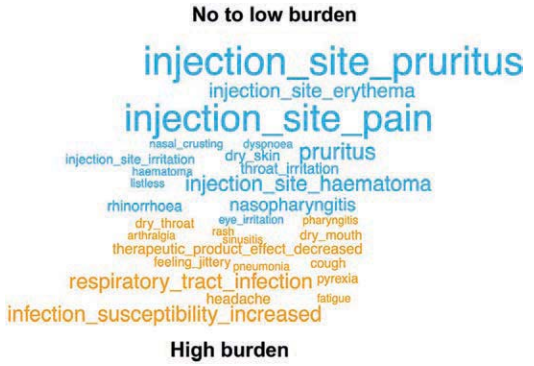

Figure 1. Comparison word cloud visualizing adverse drug reactions that patients reported more often with high burden (orange) and with no to low burden (blue). An ADR increases in size if the relative difference in frequency between classes increases.

Conclusion: The outcomes of the word cloud reveal that infections are more often experienced as burdensome, whereas injections site reactions impose low to no burden. Visualizing the nature, the frequency and the burden of ADRs in one picture, provides simple guidance to the degree of relevance for the reported ADRs in clinical practice.
Disclosure of Interests: Larissa van Boxem: None declared, Helen Gosselt: None declared, Jette van Lint: None declared, Sander Tas Consultant of: Gebro, GSK, AbbVie, Galvani, Arthrogen/MeiraGTx, Galapagos, Grant/research support from: Pfizer, GSK, Celgene, BMS, Sanofi, AstraZeneca, Bart van den Bemt Speakers bureau: paid as speaker for UCB, Pfizer, Sanofi-Aventis, Galapagos, Amgen en Eli Lilly, Harald Vonkeman Speakers bureau: Amgen, BMS, Celgene, Galapagos, GSK, Janssen-Cilag, Lilly, Novartis, Pfizer, Roche, Sanofi-Genzyme, UCB, Grant/research support from: Abbvie, Sanofi-Genzyme, Frank Hoentjen Speakers bureau: Frank Hoentjen has served on advisory boards or as speaker for Abbvie, Janssen-Cilag, MSD, Takeda, Celltrion, Teva, Sandoz and Dr Falk, Michael Nurmohamed Speakers bureau: Abbvie, Janssen, Celgene, Consultant of: Abbvie, Grant/research support from: Abbvie, Amgen, Pfizer, Galapagos, BMS, Martijn van Doorn Speakers bureau: Janssen, LEO Pharma, Pfizer, Novartis, Paid instructor for: LEO Pharma, Consultant of: AbbVie, Janssen, LEO Pharma, Pfizer, Celgene, Novartis, TEVA, MSD, Sanofi, AstraZeneca, Grant/research support from: Novartis, Janssen, Naomi Jessurun: None declared

AB1549-HPR

SOCIAL ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH THE ARTICULAR FORM OF RHEUMATOID ARTHRITIS

N. Shuvalova[1], S. Lezhenina[2], E. Guryanova[3]. *[1]I.Ya.Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation*; *[2]I. N. Ulianov Chuvash State University, Department of Healthcare Management and Economics, Cheboksary, Russian Federation*; *[3]I. N. Ulianov Chuvash State University, Department Internal Diseases, Cheboksary, Russian Federation*

Background: Patients with rheumatoid arthritis (RA) often experience persistent, prolonged pain. This requires taking pain medications (most often non-steroidal anti-inflammatory drugs) every day for many years or decades. Pain can lead to decreased social activity and emotional changes. Therefore, the quality of life of patients with rheumatoid arthritis may decrease.
Objectives: The purpose of the study: to determine the quality of life in patients with rheumatoid arthritis.
Methods: A survey was conducted using a questionnaire that included aspects of Health-related quality of life (HRQOL). The study was conducted from September 2020 to September 2021, in the Chuvash Republic, Cheboksary. The study involved 75 patients (n = 75) with articular form of RA, aged 25 to 70 years (mean age 52.2±4.63), 82% women. In 24 (32%) respondents, 1 degree of inflammatory activity was verified, in 36 (48%) - the second, in 15 (20%) - the third degree. The first stage was diagnosed in 9 (12%) patients (according to Steinbroker), in 42 (56%) cases stage 2 of RA development was diagnosed, in 18 (24%) cases - the third stage, 6 (8%) patients had stage 4. The diagnosis of RA was based on the criteria (ACR). Statistical processing of the results was carried out in MS Office Excel programs.
Results: More than half of the patients (55.87%) experienced daily pain in the peripheral joints, which worsened their mood and well-being. When assessing the degree of pain, 68.45% of patients assessed their pain according to VAS as moderate (7.2±0.96 points). When assessing physical activity (PF) in 33.17% of patients, its decrease was noted as "significant". When assessing social activity (SF), a decrease in this indicator was revealed: 56.32% of the surveyed noted a "moderate" decrease, 33.16% as "significant". 23.94% of the surveyed noted the

decrease in the indicator of general health (GH) as "moderate". When assessing mental health (MH), a decrease in the indicator was found in 43.67% of patients as "moderate". When assessing emotional problems in disability (RE), there was a "significant" decrease in the indicator in 54% of respondents. 62.24% of the surveyed patients consider the loss of freedom of movement to be the biggest problem in RA. 56.24% of patients rated their satisfaction with their lives as "average degree of satisfaction"; 43.76% of patients as "low satisfaction".

Conclusion: As a result of the survey, it can be stated that 43.76% of respondents have a "low degree of satisfaction" with life. In order for the doctor to have all the objective information, it is necessary to adequately and timely evaluate changes in HRQOL for the purpose of early diagnosis and timely treatment of RA.

AB1550-HPR CORRELATIONS BETWEEN PAIN AND EMOTIONAL STATUS IN PATIENTS WITH FIBROMYALGIA

R. Grekhoff[1,2]. [1]*Zborovsky' Research Institute for Clinical and Experimental Rheumatology, Rehabilitation Department, Volgograd, Russian Federation*; [2]*Volgograd State Medical University, Chair of General and Clinical Psychology, Volgograd, Russian Federation*

Objectives: The aim of the study was to investigate the correlations between pain syndrome and psychological status of patients with fibromyalgia (F).

Methods: The group we investigated consisted of 100 people. All patients were women of 43.85±0.79 years old in average. The diagnosis was made in accordance with the diagnostic criteria for fibromyalgia (ACR, 2010) [1]. The intensity of the pain syndrome was ranked using a visual analogue scale (VAS) and expressed in points: 0-3 points - the absence or slight severity of muscle pain, 4-7 points – moderate, and more than 7 points - intense, almost constant muscle pain. The average pain syndrome was 7.2±0.16 points, diagnostic pain points - 14.27±0.25 points. The psychological status was studied using standardized psychodiagnostics methods adapted in the laboratory of clinical psychology of the St. Petersburg Bekhterev's PsychoNeurological Institute: "Type of attitude towards the disease" - "TOBOL" (Wasserman L.I., et al., 2005) [2]; questionnaire "Life Style Index" - "LSI" (Wasserman L.I., et al., 2005) [3]; method of formalized assessment of neurotic manifestations "NL" (Wasserman L.I., et al., 1999) [4].

Results: According to the severity of pain in the muscles, patients with F were divided into two groups: 1st group (57 people) - intensity of muscle pain = 0-7 points and 2nd group (43 people) - intensity of muscle pain = 8-10 points. The study of the correlations between the intensity of muscle pain and the types of personal response to the disease, the intensity of psychological defenses showed that F patients from 1st group were characterized by a significant formation of an ergopathic type of attitude towards the disease and intense use of the psychological defense "Intellectualization" ($p<0.05$). Patients of 2nd group had neurasthenic, sensitive and egocentric types of attitudes to the disease, intense use of psychological defenses such as "Repression" and "Regression", and the decrease in the tension of using the "Intellectualization" ($p<0.05$). It was also noted that in 1st group of F patients, there was already a significantly significant clinical increase in such neurotic traits as depression (6.17±0.16 points), asthenia (6.37±0.21 points) and, especially, anxiety (8 .16±0.69 points) ($p<0.05$). With an increase in the intensity of muscle pain up to 8-10 points (2nd group), indicators on the scales of depression (7.3±0.20 points), asthenia (7.29±0.20 points) and hypochondria (6.16±0.30 points) significantly increased ($p<0.05$).

Conclusion: Thus, the increase in pain sensations in patients with F leads to the formation of maladaptive variants of attitudes towards the disease (neurasthenic, sensitive and egocentric); accompanied by a significant increase in asthenic and depressive tendencies; as well as a limited range of use of less mature and adaptive defenses mechanisms ("Repression" and "Regression"), which may indicate the maladaptive nature of the personality's attempts to cope with the disease The data obtained can be useful and taken into account in the development of individual tactics of treatment and rehabilitation measures in order to improve the quality of the treatment.

AB1551-HPR BODY COMPOSITION AND NUTRITIONAL STATUS IN PATIENTS WITH RHEUMATIC DISEASES

D. C. Rubio Torres[1], A. Cárdenas[1], J. C. Riegatorres[1], L. R. Aguilar Rivera[1], B. T. Chavarín Argüello[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma de Nuevo León, Rheumatology, Monterrey, Mexico*

Background: An adequate nutritional status and a balanced diet are essential for a functional immune system, especially in chronic diseases that condition a catabolic state. The increase in adipose tissue and the proinflammatory environment that it generates influences rheumatic diseases.[1.] This translates to increased disease activity, morbidity and mortality.

Objectives: To describe body composition and nutritional status alterations in patients with rheumatological diseases in a 3rd level center in northern Mexico.

Methods: A prospective observational study was conducted in a third level center in northern Mexico. Anthropometric measurements were made by electrical bioimpedance analysis with the InnerScan TANITA BC-533 equipment (Yesod, S.A de C.V. Japan). Descriptive statistics were performed for categorical variables and measures of central tendency and dispersion were used for quantitative variables.

Results: A total of 1,666 evaluations of 1,218 individual patients were included: 1,098 (90.14%) women and 119 (9.77%) men. The mean age was 50 (±13). The most frequent diagnoses were rheumatoid arthritis 556 (45.64%), systemic lupus erythematosus 164 (13.46%), osteoarthritis 106 (8.7%) and fibromyalgia 48 (3.9%). The means of the anthropometric measurements were weight 69.78. kg (±15.53), height 1.57 m (±.07), percentage of total fat 35.17% (±9.3), percentage of body water 45.15% (±6.42), visceral fat 8.32(±.3.9), kg muscle 41.84kg (6.4), bone mass 2.35 (±.0.75), metabolic age 50(±13), BMI 28.22(±.6.04), waist circumference 92.85(±.15.38), hip circumference 106.8, (±.12.94) waist-hip ratio 0.87 (±.0.08). A total of 431 (35.38%) patients were overweight, 407 (33.41%) had some degree of obesity, 338 (27.75%) had a normal BMI, and only 41 (3.36%) were underweight. 1,013 (83.16%) patients had low lean mass, 719 (59.03%) had low body water percentage, 680 (55.82%) had high levels of total fat, and 163 (13.38%) had visceral fat; 672 (55.17%) sarcopenic obesity and 320 (26.27%) a metabolic age greater than the chronological age.

Conclusion: The nutritional status of rheumatology patients in northern Mexico is inadequate with a high prevalence of obesity, overweight, and low lean mass. Nutritional intervention is of paramount importance in the comprehensive management of patients with rheumatologic diseases.

AB1552-HPR HEALTH PERCEPTION OF PATIENTS WITH FIBROMYALGIA IN BRAZIL

M. Antunes[1], A. Torres Cruz[1], P. De Oliveira Januário[1], A. Pasqual Marques[1]. [1]*Universidade de São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy, São Paulo - SP, Brazil*

Background: Fibromyalgia is a rheumatologic syndrome characterized by chronic pain and symptoms such as fatigue, morning stiffness, sleep disturbances and depression. Health perception is a global assessment of health based on an analysis of the objective and also subjective aspects of each person. Health self-assessment is increasingly researched and shows the health status of the population, considering the individual's personal perspective and that this information can be useful to propose health promotion strategies.

Objectives: To identify the health perception of patients with fibromyalgia who live in Brazil.

Methods: This is a cross-sectional study that was carried out in Brazil in 2021. They were invited to participate in the research. Individuals with fibromyalgia were invited to participate in the study through the Brazilian Association of

Fibromyalgia Patients (ABRAFIBRO) in August 2021. The invitation was sent via email to all people registered with this association in the country. Self-perception of health was questioned through the following response options: bad, fair, good or very good. Data were analyzed using descriptive statistics.

Results: The study consisted of 243 people with fibromyalgia living in different states of Brazil. Most were female (97.5%), married or living with a partner (63.7%), of white race/color (58%), receiving 1 to 2 minimum wages (60.4%), with complete higher education (46.5%) and who administer more than 2 medications per day (65.8%). Regarding the perception of health, the majority reported that their health was regular (42.4%), followed by bad (38.3%), good (16%) and very good (3.3%).

Conclusion: The most prevalent health perception in people with fibromyalgia in Brazil was: "regular", followed by "bad", "good" and "very good". In view of the findings of this study, measures to control and prevent health risks in people with fibromyalgia become necessary. In order to implement policies to promote a healthy life for this population, it is necessary to know the determinants of these indicators of self-reported health morbidity in Brazil. It is also suggested that the results of this investigation be monitored by periodic population-based surveys, in order to verify the determination of the observed associations, being able, in the future, to detect an association with other variables. In addition, these data can guide and evaluate education and health promotion strategies in fibromyalgia.

AB1553-HPR PATIENT'S EXPERIENCES ATTENDING AN EDUCATIONAL PROGRAM IN A RHEUMATOLOGY OUTPATIENT CLINIC IN COLOMBIA

R. A. Castiblanco Montañez[1], F. Rodriguez[2], G. Sánchez[1], D. Buitrago-Garcia[1], P. Santos-Moreno[3]. [1]*Fundación Universitaria de Ciencias de la Salud - FUCS, Epidemiology, Bogotá, Colombia*; [2]*Biomab IPS, Patients Education, Bogotá, Colombia*; [3]*Biomab IPS, Rheumatology, Bogotá, Colombia*

Background: An educational program has been recommended as an integral component of the standard care for rheumatoid arthritis (RA). Studies have demonstrated that education in patients with RA improves the overall outcome of treatment and positively impacts patients' lives. In addition, it is always relevant to understand the effects of these interventions from the patient perspective by using qualitative research methods (1, 2).

Objectives: To explore the experiences of patients attending a structured educational program specific to rheumatoid arthritis.

Methods: We conducted a qualitative study; data were collected in two focal groups; The information was transcribed and coded according to the leading emerging categories.

Results: 23 participants attended the focal groups; most were women (90%). The mean age was 61 years ± 5. We identified fourth categories. First, the experiences in the program. Second, sharing their experience with other patients with rheumatoid arthritis. Third, the knowledge acquired during the program. Finally, the fourth category was applying the new knowledge in everyday life. Figure 1.

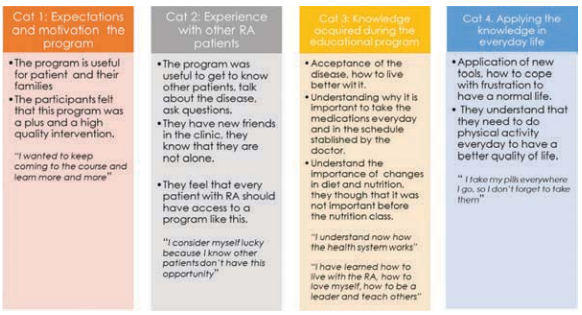

Figure 1. Emerging categories in the qualitative analysis

Conclusion: Patients who attend an educational program report positive and fulfilling experiences. An educational activity improves how the patient sees the disease and the pharmacological and nonpharmacological treatment. Our findings are similar to other studies, where involving an educational component can improve self-efficacy and might improve clinical outcomes (3, 4).

AB1554-HPR DRUG-RELATED PROBLEMS EXPERIENCED BY PATIENTS WITH RHEUMATIC DISEASES: A LONGITUDINAL OBSERVATIONAL STUDY

L. Haegens[1], V. Huiskes[2], E. M. Smale[3], C. Bekker[3], B. Van den Bemt[2,3]. [1]*Sint Maartenskliniek, Department of Research, Ubbergen, Netherlands*; [2]*Sint Maartenskliniek, Department of Pharmacy, Ubbergen, Netherlands*; [3]*Radboud University Medical Center, Department of Pharmacy, Nijmegen, Netherlands*

Background: Patients with rheumatic diseases can experience multiple drug-related problems (DRPs) along their patient journey.[1] Insight into patients' experience of DRPs over time might aid in timely identifying and preventing DRPs.[2,3]

Objectives: To longitudinally identify DRPs experienced by patients with rheumatic diseases.

Methods: A prospective observational study was conducted in a Dutch outpatient pharmacy. Adult patients with rheumatic diseases that were prescribed medication by a rheumatologist were questioned about experienced DRPs by telephone 4 times in 8 weeks using a structured interview-guide. Unique DRPs (i.e. DRPs not reported in earlier interviews by individuals) were categorized using a classification for patient-reported DRPs and analysed descriptively.

Results: In total, 52 participants (median age 68 years (interquartile range (IQR) 62-74), 52% male) completed 192 interviews with 45 (87%) participants completing all 4 interviews. The majority of patients (65%) were diagnosed with rheumatoid arthritis. Patients reported a median number of 3 (IQR 2-5) unique DRPs during interview 1. In subsequent interviews, patients reported median numbers of 1 (IQR 0-2), 1 (IQR 0-2) and 0 (IQR 0-1) unique DRPs for interview 2 to 4 respectively. Participants reported a median number of 5 (IQR 3-9) unique DRPs over all completed interviews. Unique patient-reported DRPs were most frequently categorized into (suspected) side effects (28%), medication management (e.g. medication administering or adherence) (26%), medication concerns (e.g. concerns regarding long-term side-effects or effectiveness) (19%) and medication effectiveness (17%).

Conclusion: Patients with rheumatic diseases experience various DRPs over time. These patients might benefit from continuous support during their patient journey.

HPR Service developments, innovation and economics in healthcare

AB1555-HPR PRELIMINARY DESCRIPTION OF PATIENTS PARTICIPATING IN A MHEALTH OA MANAGEMENT PROGRAM – BASELINE DATA FROM A RANDOMIZED CONTROLLED TRIAL

L. Martinsen[1], N. Østerås[1], T. Moseng[1], A. T. Tveter[1]. [1]*Diakonhjemmet Hospital/ Division of Rheumatology and Research, Norwegian National Advisory Unit on Rehabilitaion in Rheumatology, Oslo, Norway*

Background: As the prevalence and costs related to osteoarthritis (OA) are expected to rise in the coming years, actions have to be taken to ensure access to effective and economical sustainable recommended treatment for this patient population. Digital tools, such as the use of mobile health applications (mHealth), could serve as a solution. Though, little is known about characteristics of patients participating in a mHealth osteoarthritis management program (OAMP) in physiotherapy practice.
Objectives: To describe demographic and disease-related characteristics of patients with hip and/or knee OA recruited to a mHealth OAMP and compare these characteristics to those of other OAMPs.
Methods: The Digital Osteoarthritis Care-study (DigiOA) is a two-armed non-inferiority RCT currently running in primary health care in Norway. In total 156 participants with hip and/or knee OA seeking physiotherapy in primary care will be asked to participate. Consenting patients will receive 1-2 hours of education before randomization to 6 weeks of either exercise therapy via the Virtual Training mobile health application or supervised exercise therapy. Inclusion rate is reported as frequency and percentage. To describe patient characteristics, we have included baseline data on patients currently included in the study. These characteristics are compared to baseline data from a web-based OAMP (1) and a standard OAMP in physiotherapy care (2).
Results: Of 39 eligible patients, 25 (64%) have to date consented to participate in the study. An overweight of the included patients are presented with knee OA, have had symptoms for five years or less, and have higher education (Table 1).

Table 1. Demographic and disease-related characteristics of patients with hip and/or knee OA recruited to a mHealth OA management program (n=25)

Age years, n=24, mean (SD)	63.2 (10.4)
Female, n (%)	17 (70.8)
BMI, mean (SD)	27.3 (5.4)
Education, n (%)	10 (40)
-Upper secondary	15 (60)
-College/university	
Non-Smoking, n (%)	23 (92)
Work status, n (%)	12 (48)
-Employed	4 (16)
-Sick leave/receiving disability benefits	11 (44)
-Retired	
Primary joint affected, n (%)	17 (68)
-Knee	8 (32)
-Hip	
Other joints affected, n (%)	21 (84)
Other chronic conditions, n (%)	15 (60)
Symptom duration years, n (%)	5 (20)
-Less than a year	15 (60)
-1-5 years	5 (20)
-More than 10 years	
OA medication use last 3 months, n (%)	19 (76)
Pain last week[a], mean (SD)	4.7 (2.3)
HOOS/KOOS[b], mean (SD)	59.4 (18.5)
-Pain	48.4 (10.2)
-Symptoms	67.2 (19.1)
-ADL	39.7 (19.7)
-Sport/Rec	46.5 (14.2)
-QOL	
ASES[c], mean (SD)	2.2 (0.8)
-Pain	2.5 (0.7)
-Other symptoms	
Exercise self-efficacy scale[d], mean (SD)	40.2 (3.4)

[a]= NRS 0-10 (10=most pain) [b]= (HOOS: Hip disability and Osteoarthritis Outcome Score/ KOOS: Knee injury and Osteoarthritis Outcome Score (0-100, 100=no problems) [c]= Arthritis Self-Efficacy scale (0-4, 4=most certain) [d]= (20-100, 100=most certain)

The study sample report high impact of symptoms, and decreased function. Self-efficacy related to pain and symptoms are relatively high, but the patients report lower exercise self-efficacy. The study sample is comparable to patients included in both standard and web-based OAMPs, except from lower impact of pain and higher usage of pain medication in DigiOA.

Conclusion: Preliminary results show that baseline characteristics are comparable to patients included in other OAMPs, but with only two third of eligible patients consenting to participate in a mHealth OAMP there is a need for more in-depth knowledge on patients' attitude towards mHealth OAMPs.

AB1556-HPR IDENTIFYING BARRIERS IN EARLY RECOGNITION AND MANAGEMENT OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A RETROSPECTIVE REVIEW

A. Nandagudi[1], M. Dare[2,3], D. Laila[4], A. Bharadwaj[1]. [1]*Basildon University Hospital, Rheumatology, Basildon, United Kingdom*; [2]*Orsett Hospital, Community Rheumatology, Orsett, United Kingdom*; [3]*Connect Health, Community Rheumatology, Newcastle upon Tyne, United Kingdom*; [4]*Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom*

Background: Axial spondyloarthritis are immune and genetically mediated inflammatory arthritis where there is significant delay in diagnosis and management of roughly 8.5 years; leading to poorer outcome and quality of life for a patient.
Objectives: This aim of audit was to improve the identification and referral pathways for patients with axial spondyloarthritis in South West Essex United Kingdom as per agreed NICE & EULAR criteria.
Methods: This was a retrospective audit of 35 patients diagnosed as Axial Spondyloarthritis in secondary care and those which was referred to secondary care by community triage MSK service (Connect) as Axial Spondyloarthritis, between January 2019 and March 2020. Data was extracted to look at demographics, diagnostic investigations performed, duration from symptom onset to diagnosis and the patient journey to secondary care.
Results: Out of total 35 patients, 63% were males with a median age of 35 years. Of all the GP referrals 17% were directly to secondary care and 71% were via triage service. Twelve percent of referrals came from other specialties. The average timeframe from symptoms onset to referral by GP was 7.7 years. Average time before a patient was seen by a rheumatologist after referral was 4.4 months. After evaluation in clinic, 30 cases (85.7%) were finally diagnosed as AxSpA after rheumatologist's review. Rest were mechanical back pain. Inflammatory back pain was mentioned in 18% of referrals by GP and 80% of referrals letters by triage service. Base line investigations included: CRP was in 39% of cases under GP care and 100% cases under triage service. Additionally, HLAB27, X ray and MRI tests were done in 22%, 17% and 22% of GP cases respectively and 86%, 80% and 80% of cases from triage service. After specialist review, HLAB27 was positive in 49% of patients, X ray positive sacroileitis in 54.5% patients and rest had MRI positive sacroileitis and spinal features. Some had both X ray and MRI investigations.
Conclusion: Lack of education and awareness about spondyloarthropathy remains the most prominent factor behind delay to diagnosis. Lack of important information and clinical features on referral letters are also a contributing factor. It is evident that early referral to rheumatologist care and early triaging during reviews are crucial to diagnose AxSpA. We are piloting use of SPADE tool in suspected AxSpA cases to guide clinical reasoning and early referrral.

AB1557-HPR DEVELOPING THE GUIDELINE FOR OUTPATIENT APPOINTMENT OF A CLINICAL NURSE SPECIALIST AT THE EAST-TALLINN CENTRAL HOSPITAL RHEUMATOLOGY CENTER. DEVELOPMENT PROJECT.

D. Batšinskaja[1], K. Korve[1], K. Rannus[2]. [1]*East-Tallinn Central Hospital, Rheumatology Center, Tallinn, Estonia*; [2]*Tallinn Healthcare College, Health Science Curriculum, Tallinn,*

Background: Rheumatic diseases can increase the economic and social burden on the individual and their relatives' ones, as well as on the health care system and society. Based on international empirical experience, it can be stated that in an exemplary Rheumatology center, both the outpatient appointment of a (general)

nurse and the outpatient appointment of a clinical nurse specialist work as a team. The Rheumatology Center of East Tallinn Central Hospital is the only center in Estonia that specializes in rheumatic patients, where (general) nurses are proceed, but the extent to which the current health care service meets the needs of rheumatic patients has not yet been assessed. In addition, the health insurance fund launched a pilot project to clarify the difference between outpatient appointment of a clinical nurse specialist and independent appointment of a (general) nurse. However, there is no evidence-based guideline for outpatient appointments for rheumatic patients.

Objectives: The aim of the development project was to develop the guideline for outpatient appointment of a clinical nurse specialist for rheumatology based on evidence-based literature and expert opinions at the Rheumatology Center of East-Tallinn Central Hospital.

Methods: The development project process took place as a plan-do-study-act cycle, using the method of systematic review of the literature to develop the guideline and the method of written survey to obtain an expert opinion on it. Verbal responses from experts for organizational diagnostics and the guideline feedback was analyzed using content analysis. Quantitative or numerical responses were analyzed using descriptive statistics to calculate the frequency distributions (n and %) for each response.

Results: The guideline developed as part of the development project supports the implementation of a new clinical nurse specialist care service for rheumatic patients.

Conclusion: Based on previous research analyzed and surveys conducted by experts at the Rheumatology Center, it can be argued that the clinical nurse specialist service differs significantly from the (general) nurse outpatient appointment and is more responsive to the needs of rheumatic patients. There are potential benefits for the clinical nurse specialist of the outpatient appointment to the organization and to society, as this service increases the level of reliability, efficiency, and availability of all nursing care.

AB1558-HPR TELERHEUMATOLOGY WITH PRIMARY CARE CENTERS: FEEDBACK FROM AN EXPERIMENTAL TELEMEDICINE PROJECT IN BURGUNDY (2019-2021)

E. Staszewski[1], A. Vaillant[2], C. Piroth[1], A. Patte[3], A. Arbault[1], C. Vazzano[4], A. Ramon[1], P. Ornetti[1]. *[1]University Hospital F.mitterand Dijon-Bourgogne, Rheumatology, Dijon (21000), France*; *[2]Maison Medicale Seurroise, Family Medicine, Seurre, France*; *[3]ARS Bourgogne-Franche-Comté,Telemedicine, Dijon (21000), France*; *[4]GRADES,Telemedicine, Chalon, France*

Background: Telemedicine could be an innovative and sustainable response for rheumatologic advice in areas with low medical density. Improving coordination of investigations, access to allied health members and dedicated telehealth platform may improve the management of many rheumatologic patients.

Methods: This French TeleRheumatology project with multidisciplinary primary care centres was set up in 2019, specifically targeting the Burgundy region in Eastern France and was financed by the Regional Health Agency. Four rheumatologists from the Dijon University Hospital took turns to respond to the various requests for telemedicine (teleconsultation, teleexpertises) on a dedicated digital platform integrating a medical imaging viewer. In addition to the activity (number and type of procedures performed) and the distances avoided for the patient for rheumatology consultation, feasibility of this colaborative digital project was assessed on the basis of a participant satisfaction questionnaire (rheumatologists, general practitioners and patients).

Results: From October 2019 to january 2022, this TeleRheumatology project allowed the progressive integration of 23 primary care centres despite the concomitant COVID-19 crisis which slowed down the deployment. 212 procedures were performed (96% teleexpertises): 76% for mechanical disorders (spine 31%, osteoporosis 19%, osteoarthritis 15%), 18% for inflammatory rheumatism, 53% advice for diagnosis, 41% for management and/or therapy, 89% with imaging (X-Rays, CT- Scan, MRI) to be reviewed. The average response time was 16 hours and the average number of round-trip kilometers avoided was 216. Only 15% of the rheumatologic advices led to a face-to-face consultation or hospitalization at the University Rheumatology Department and 6% to other specialists. 97% of the patients would like to use this Telerheumatology program again (Satisfaction score: 9.1/10). 100% of the expert rheumatologists (satisfaction score 9.25/10) and the general practitioners (satisfaction score: 9.0/10) wanted to continue this digital health partnership in their daily practice.

Conclusion: Despite the inherent limitations of telemedicine (absence of clinical examination, technical barriers of interoperability, etc.), this french innovative TeleRheumatology project with primary care centres has shown encouraging results in terms of acceptability and satisfaction thanks to the coordination of the Regional Health agency and physicians' motivations. Telerexpertise seems to be the preferred modality given its better practical feasibility. Approval and acceptance are increasing in the Rheumatology community because telemedicine appears to be an effective tool for improving health care access as demonstrated by its rapid expansion, especially during the COVID-19 pandemic.

AB1559-HPR ESTABLISHING A MULTIDISCIPLINARY CLINIC TO IMPROVE THE QUALITY OF CARE FOR PATIENTS WITH INTERSTITIAL LUNG DISEASE.

A. Bankole[1], T. Kazmi,[2], A. Strazanac[3], W. Scheuing[2], J. Fleming[2]. *[1]Virginia Tech Carilion School of Medicine, IM, Roanoke, United States of America*; *[2]Carilion Roanoke Memorial Hospital, IM, Roanoke, United States of America*; *[3]Wake Forest, IM, Wake Forest, United States of America*

Background: Patients with interstitial lung disease related to rheumatic disease (ILD-RD) often need to see multiple specialties to establish the diagnosis and for management. Suh care is better provided in a multidisciplinary clinic (MDC) and setting up such a MDC involves significant cost, time and buy in from stakeholders. In our center, we approached starting a MDC as a multiple phased project. Phase 1: confirm improved patient outcomes when multiple specialties are involved in providing care to these patients. Phase 2: application for an internal grant for a prospective pilot clinic and phase 3: the establishment of a permeant MDC. We report the results of our phase 1 analysis.

Objectives: The primary aim of this study was to determine if involvement of our pulmonary and cardiology colleagues in the care of patients with ILD-RD seen in the rheumatology clinic results in improvement in the evaluation and treatment of these patients.

Methods: This is a retrospective, single center, hospital-affiliated outpatient study. All patients seen in the rheumatology clinic with a diagnosis of ILD-RD between January 1 2018 and December 31 2019 were eligible for enrollment. A list of patients was generated by the technology service group using relevant international classification of diseases codes. These records were reviewed and those meeting the inclusion and exclusion criteria were enrolled.

A review of the 1574 charts generated confirmed 41 patients with ILD-RD. Demographic data, as well as disease related data including serological testing, disease manifestation and treatment choices was obtained. Continuous variables were analyzed using T-test or Mann-Whitney U test. Categorical variables were analyzed using Chi-square Tests or Fisher's exact tests. Statistical analysis was performed using SAS9.4, and p value <0.05 was considered statistically significant.

Results: Patients seen by more than one specialty were more likely to have had a more extensive evaluation for ILD and its complications. The cause of the ILD-RD did not have an impact on the tests performed or the number of specialist seen.

There was a significantly more glucocorticoids monotherapy use in scleroderma related ILD, but disease-modifying antirheumatic drugs were more commonly used in non-scleroderma ILD patients.

Table 1. Demographics

	Non-scleroderma ILD (N = 27)	Scleroderma ILD (N = 14)	p-value
Age at diagnosis	72.8 (10.2)	70.5 (13.7)	0.55
Female	70.4% (19/27)	71.4% (10/24)	0.99
Race			0.69
Caucasian	77.8% (21)	85.7% (12)	
African American	22.2% (6)	14.3% (14)	
PAH	17.4% (4/23)	23.1% (3/13)	0.69
PFT	87.5% (21/24)	92.9% (13/14)	0.99
CT Chest	100% (24/24)	100% (14/14)	
Right HCC	30.4% (7/23)	21.4% (3/14)	0.71
Number of specialists			0.31
1	8.3% (2)	14.3% (2)	
2	37.5% (9)	57.1% (8)	
3	4.2% (13)	28.6% (4)	
Medication			<0.01
None	0% (0)	14.3% (2)	
GC	7.4% (2)	42.9% (6)	
GC + DMARDs	88.9% (24)	42.9% (6)	
DMARDs	3.7% (1)	0% (0)	

Conclusion: Our data suggests that a MDC for RD-ILD results in a more thorough investigation and treatment, and this will likely lead to improvements in patient outcomes. Based on these findings, our rheumatology group is seeking internal funding for a pilot clinic evaluating prospectively the benefits of an ILD MDC.

AB1560-HPR NURSE-DRIVEN DIAGNOSTIC PROCESS OF PATIENTS WITH SJÖGREN'S SYNDROME (SS) A CLINICAL DEVELOPMENT PROJECT

M. T. Poder[1], G. M. Colding[1], K. Frödin[1], M. B. T. Pedersen[1], M. S. Andersen[1], L. S. Timm[1], A. Vibe[1], K. N. Sørensen[1], L. Lindgren[1], A. Svensson[1], M. Pfeiffer-Jensen[1], V. Fana[1], J. J. Lykkegaard[1], G. Thamsborg[1]. [1]*Rigshospitalet Glostrup, Afdeling for Rygkirurgi, Led- og Bindevævssygdomme, Glostrup, Denmark*

Background: Sjögren's Syndrome (SS) is a chronic autoimmune disease that affects the body's glandular functions, especially the lacrimal and salivary glands, causing the mucous membranes to dry out (1). There are no diagnostic criteria, and classification criteria are often used to support the diagnosis (2). We identified a need to unify and consolidate the diagnostic process of patients with SS in the Capital Region of Denmark. A medical working group supervised the nurse-driven diagnostic process at Rigshospitalet, Glostrup. Here an interdisciplinary working group with physicians, nurses, and secretaries developed a diagnostic process and logistic based on the American-European Consensus Group Classification Criteria 2002 (3). The nurse's took medical history and performed sicca tests and made sure that the patient received adequate guidance. With input from three patients, the nurses at the outpatient clinic developed - written material on eye and mouth dryness. We developed a "smart phrase" for our documentation platform in the interdisciplinary working group. The purpose of the 'smart phrase", was to unify the documentation and ensure continuity in the conversation with the patient. The Rheumatologists task was to disprove or confirm the diagnosis and perform a risk stratification especially in relation to the development of lymphoma, but also interstitial lung disease.

Objectives: The aim of this project was to examine and evaluate the patients' experience of nurse-driven diagnostic process.

Methods: To evaluate the new patient course, we performed a survey. The questions selected for the survey were primarily based on the patients experience of meaning and coherence in the diagnostic process. The questions were developed by the nurses in the Outpatient Clinic; "Do you feel safe going home after the consultation today?" "Did you get answers to the questions you asked while you were in the consultation?" "Did the staff take the time to listen to you?". Also, the patients could add comments.

Results: A total of 34 consecutives responded to the questionnaire. 88% felt safe when returning home from the Outpatient Clinic, 85% received answers to their questions during the consultation. Altogether, 94% answered that the health care professionals were present and listened to them. The patients had the following comments: "The diagnostic process contained a lot of unresolved waiting time " and "There has been some confusion about the division of tasks in the different hospital wards".

Conclusion: We found that the patients were satisfied with the nurse-driven diagnostic process. The diagnostic process created a feeling of safety in the patients and the patients found that they were listened to and allowed to ask questions. In addition, by evaluating the process investigation, we could change practice and further unify the diagnostic process. The result of the questionnaire supports the justification of the nurse competencies, by preforming a high level of information and guidance as well as the need for recognition of the patient's symptoms. Therefore, the working group chose to meet again and evaluate. We decided that the nurse and rheumatologist consultation should be performed on the same day. Such consultation made it possible for the nurse to ensure continuity in the process, as the same nurse could follow the patient throughout the day. This optimized the opportunity for the nurse to guide the patient in the symptomatic treatment of eye and mouth dryness. Also, the nurse had the opportunity to guide in oral hygiene, fatigue, and lifestyle factors.

The next step in our development project is to evaluate our revised nurse-led diagnostic process. In addition, the working group is currently working on material for a course in SS, where 4-6 patients and relatives can have the opportunity to participate.

AB1561-HPR PHYSIOTHERAPY FOR RHEUMATOID ARTHRITIS (RA) – PAST, PRESENT AND A POSSIBLE FUTURE?

A. M. Mengshoel[1]. [1]*University of Oslo, Department of Interdisciplinary Health Sciences, Oslo, Norway*

Background: Physiotherapy has a long tradition providing services to patients with RA. The main aim of physiotherapy is to improve patients' abilities to perform movements and physical activities through exercises and educating patients in self-management skills. For physiotherapy to proceed into future, it seems relevant to examine what shifts occurred in physiotherapy over time and why did they happen.

Objectives: Is to unpack the shifts in physiotherapy for patients with RA from 1980 until today.

Methods: Norwegian physiotherapy in rheumatology is used as case. The shifts are identified with help of literature about history of medicine and physiotherapy in rheumatology and empirical physiotherapy research since the 1980s. The author draw on own experiences first as a clinician and practice teacher for physiotherapy students in rheumatology, and later as a scientist and advisor for a multidisciplinary team in rheumatology.

Results: Physiotherapy focuses on movement and function, which over time have consistently been understood in relationship to disease-induced alterations and biomechanics. Shifts in physiotherapists' remedial exercises have occurred over time as better disease control occurred and evidence showed that physical activities and exercise programmes had disease modifying effects and improved patients' functional capacity. In the 1980s, a move from earlier passive, joint protective movements with little weight load to cautious weight-bearing movements occurred, mostly as a response to improved disease-modifying drugs and joint surgery. In the 1990s, physiotherapy shifted from cautious weight-bearing movements to safely performed physical activity as a response to scientific findings showing beneficial effects on radiological, immunological, and physical function measures. In the 21. century, RA is identified earlier and increasing number of patients reach disease remission before irreversible occurs in the musculoskeletal system. Presently, a new shift in Norwegian physiotherapy is on the way. Adherence to EULAR guidelines 2018 on physical activity[1] is moving physiotherapy from promoting exercises through engagement in self-determined physical activities into educating patients in performing structured intensive physical fitness training programmes for preventing future comorbidities.

Conclusion: At the moment, it is a dilemma that the raising rate of patients successfully treated to disease remission is not accompanied with more patients remaining in volitional work in Norway[2]. Thus, there is a need in physiotherapy to critically scrutinize the meaning and significance of movements and functioning for the individual patient's own life purpose and the society's wish that people stay in paid work.

AB1562-HPR COMPARING THE PROVISION OF SUBCUTANEOUS METHOTREXATE BETWEEN HOMECARE AND OUTPATIENT PHARMACY; WHAT DO PATIENTS PREFER AND IS ONE ROUTE QUICKER?

R. Heaton[1], J. Nasralla[1], C. Filer[1], E. Appleby[1], M. Myintzu[2]. [1]*Stepping Hill Hospital, Rheumatology, Hazel Grove, United Kingdom*; [2]*Macclesfield District General Hospital, Rheumatology, Macclesfield, United Kingdom*

Background: The provision of subcutaneous methotrexate has historically been through homecare who provide injection training and delivery. In July 2018, subcutaneous methotrexate was accepted for shared care in the Trust's locality to reduce medication costs but to also improve safety, reducing the risk of concomitant trimethoprim prescribing.
When suitable for shared care, initial injection training is provided by outpatient pharmacists and prescribing and monitoring during the stabilisation period is the responsibility of the rheumatology pharmacy team.
Objectives: The primary aim of this audit was to compare patient satisfaction between these two different routes of injection training and prescription provision. Additionally, the time it took for a patient to receive their first dose following a decision to start treatment, was also compared.
Methods: Patients were identified from databases held within the department, contacted retrospectively via telephone and asked to complete a short questionnaire. Clinic letters and the homecare company provided dates of treatment decision and initiation.
Results: 40 patients were contacted, 20 had received treatment via outpatient pharmacy and 20 via homecare.

Table 1. Patient reported satisfaction following receipt of injection training and prescription provision via outpatient pharmacy and homecare

	Outpatient Pharmacy (20)			Homecare (20)		
	Not satisfied	Satisfied	Very satisfied	Not satisfied	Satisfied	Very satisfied
Time taken to start treatment	2	5	13	2	6	12
Injection training	0	4	16	3	5	12
Method for delivery of injection training and initial prescription	1	8	11	3	4	13
Process of receiving repeat prescriptions	1	4	15	1	3	16

The mean time taken to start treatment was 30 days in the homecare group and 13 days in the outpatient group. 7 patients (35%) within the outpatient group started treatment within 7 days. The shortest time within the homecare group was 15 days (3 patients).
Conclusion: Reported patient satisfaction between the two routes of treatment provision was similar. Patients commenced treatment significantly quicker via outpatient pharmacy, reporting a high degree of satisfaction with the injection training provided by outpatient pharmacists. This audit has confirmed that shared care provision of methotrexate initially via outpatient pharmacy is a safe, efficient and viable option.

HPR Professional education, training and competencies

AB1563-HPR TRAINING AND ASSESSMENT OF MUSCULOSKELETAL ULTRASOUND AND INJECTION SKILLS - A SYSTEMATIC REVIEW

S. M. D. Carstensen[1,2], M. Velander[3], L. Konge[2,4], M. Østergaard[1,2], M. Pfeiffer-Jensen[1], S. A. Just[3], L. Terslev[1,2]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, University Hospital of Copenhagen, Rigshospitalet, Glostrup, Denmark*; *[2]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*; *[3]Section of Rheumatology, Department of Medicine, Svendborg, Denmark*; *[4]Copenhagen Academy for Medical Education and Simulation, The Capital Region of Denmark, Copenhagen, Denmark*

Background: The importance of international harmonization regarding education of rheumatologists in musculoskeletal ultrasound (MSUS) and injection skills have been highlighted in several studies, including the need for standardized training programs containing competency-based education using validated assessment tools [1-2].
Objectives: To examine how residents are trained and assessed in MSUS, MSUS-guided and landmark-guided joint aspiration and injection. Additionally, to present the available assessment tools and examine their supporting validity evidence.
Methods: A systematic search of PubMed, Cochrane Library, and Embase was conducted in accordance with the PRISMA guidelines and studies published from January 1, 2000 to May 31, 2021 were included. Two independent reviewers performed the search and data extraction. The studies were evaluated using the Medical Education Research Quality Instrument (MERSQI).
Results: 9,884 articles were screened and 43 were included; 3 randomized studies, 21 pre- and post-test studies, 16 descriptive studies (Table 1), and 3 studies developing assessment tools. The studies used various theoretical training modalities e.g. lectures, anatomical quizzes, and e-learning. The practical training models varied from mannequins and cadavers to healthy volunteers and patients. Most studies used subjective "comfort level" as assessment, others used practical examination and/or theoretical examination. All training programs increased trainees' self-confidence, theoretical knowledge, and/or practical performance, however few used validated assessment tools to measure the effect. Only one study met the MERSQI high methodical quality cut-off score of 14.

Table 1. Description of included studies examining training of MSUS, MSUS-guided or landmark-guided joint aspiration and injection skills.

Study characteristics	MSUS	MSUS-guided	Landmark-guided
No. of studies[a]	14	3	23
Study design	0	0	3
Randomized	2	2	17

AB1564-HPR ULTRASOUND EXAMINATION AND INTRA-ARTICULAR INJECTIONS BY A RHEUMATOLOGY NURSE SPECIALIST.

A. Brink Walling[1]. *[1]University Hospital Svendborg Hospital, Rheumatology, Svendborg, Denmark*

Background: At The Department of Medicine, section of Rheumatology, Odense University Hospital (OUH) Svendborg, we consult patients with rheumatoid arthritis, psoriatic arthritis and gout. The patients can have joint inflammation. Therefor need joint assessment by ultrasound, arthrocentesis and / or IA injection. Ultrasound examination, arthrocentesis and administration of intra-articular (IA) injections for rheumatic disease represent an expansion of the nurse's role.

A previous study has shown, that trained nurses can perform satisfying and safe IA injections at least as well as those administered by doctors (1). High availability to adequate treatment will have a positive effect. For the patient and on a socio-economic level, as patients who have severe arthritis could be forced to stay home from work and leisure activities (2). It was decided to educate a nurse, who showed interest in ultrasound and IA injections and who showed the technical skills.

Objectives: To educate and develop competence in the nursing staff regarding ability to perform joint ultrasound, arthrocentesis and IA injection. In order to offer immediate arthritis treatment and free up doctor time to be able to see other patients.

Methods: At first, the nurse watched the ultrasound, arthrocentesis and injection on the knee performed by a rheumatologist a couple of times. Then she performed the procedure under supervision and then she independently performed the ultrasound, arthrocentesis and injection on the knee with the opportunity for supervision. The nurse completed a two-day muscular/skeletal ultrasound course at university hospital Skejby. The course was both theory and hands-on training in an auditorium and was held by a radiologist and a rheumatologist. The nurse has furthermore participated in a course at Esbjerg hospital for doctors and nurses about ultrasound on upper extremities. This was a hands-on course. In conjunction with arthrocentesis, the nurse learned to identify urate crystals in synovial fluid through microscopy.

Results: See Table 1 for which joints where the nurse performed ultrasound, arthrocentesis and injection during the first and second year.

Table 1.

Year 1

Joint	*Ultrasound*	*Arthrocentesis*	*IA injection*
PIP	10		4
MCP	9		7
WRIST	23		15
ELBOW	1		1
KNEE	50	41	50
ANKEL	7		9
MTP	5		4
In all	102	41	90
Year 2			
Joint	***Ultrasound***	***Arthrocentesis***	***IA injection***
PIP	10		9
MCP	35		37
WRIST	32		35
ELBOW	12	3	12
KNEE	69	66	80
ANKEL	18	1	17
MTP	28	2	23
In all	203	72	204

One year after the procedure was implemented the joints that the nurse perform ultrasound and injections on, had increased. Starting with only knees to PIP, MCP, wrist, elbow, knees, ankles and MTP joints. After the first year, the nurse grew independent and confident with the new task, as the table beneath shows. Since the nurse started to perform ultrasound, arthrocentesis and IA injections, there has been no reports of adverse events.

Conclusion: Nurses can be trained to perform ultrasound, arthrocentesis and injections, in a wide range of joints. Patients and staff express satisfaction with the availability of treatment. There has been no reports of adverse events.

AB1565-HPR REHABILITATION NURSES KNOWLEDGE ABOUT OSTEOPOROSIS AND FRAGILITY FRACTURES IN PORTUGAL

G. Pimentel[1,2], A. Cruz[3], M. Loureiro[4], S. Fernandes[5], C. Baixinho[6], A. Marques[2,3]on behalf of Master's Thesis. [1]*Higher School of Nursing of Coimbra, Rehabilitation Nursing, Coimbra, Portugal*; [2]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [3]*Higher School of Nursing of Coimbra, Health Sciences Research Unit Nursing, Coimbra, Portugal*; [4]*Nurses' Regulatory Board, Royal Colleague of Nursings, Coimbra, Portugal*; [5]*Nurses' Regulatory Board, Section Regional South, Lisboa, Portugal*; [6]*Nursing School of Lisbon,Train4Health, Lisboa, Portugal*

Background: Scientific evidence reveals gaps in health professionals' knowledge about osteoporosis and fragility fractures, which impairs and influences the quality of care, namely in preventive actions.

Objectives: To analyse knowledge of Rehabilitation Nurses about osteoporosis and fragility fractures to identify training needs of Rehabilitation Nurses.

Methods: A cross-sectional study, integrated in a larger project, using an adapted questionnaire, made available online and disseminated by mailing list of "Ordem dos Enfermeiros" (Royal Colleague of Nursings) to all Portuguese Rehabilitation Nurses.

Results: There were include 452 participants(10.3% of the 4 397 Rehabilitation Nurses), 17% perform functions in orthopaedics and traumatology service, 4.5% physical medicine and rehabilitation and 78.6% in other services, majority, 74.6% women. On average, 69.6% correct answers were identified regarding osteoporosis and fragility fractures. Results reveal that the main areas of knowledge deficit, in this study, are related to the concept and epidemiology of osteoporosis and fragility fractures and about the most appropriate diet. Nurses with higher academic degree (master's degree) revealed more knowledge (p=0.01).

Conclusion: This study reveals that the knowledge about osteoporosis and fragility fractures is low (<70% correct answers), thus there is an opportunity to improve the knowledge related to osteoporosis and fragility fractures among Specialist Nurses in Rehabilitation Nursing.

AB1566-HPR SHIFTING THE MINDSET: USING A HEALTH COACHING APPROACH FOR HEALTH PROMOTING CONSULTATION IN ADOLESCENT RHEUMATOLOGY

A. Bouraoui[1], P. Newman[2], C. Fisher[1], S. Mavrommatis[1], A. Mcdowell[3], D. Sen[1]. [1]*University College Hospital, Adolescent and Young Adult Rheumatology, London, United Kingdom*; [2]*HaelanCoaching, Coaching, London, United Kingdom*; [3]*TPC HEALTH, Health Coaching, London, United Kingdom*

Background: Juvenile rheumatic diseases have a significant negative impact on health early in life which may affect later health outcomes. The Adolescent and Young Adult Rheumatology Department (AYAD) at University College London Hospitals (UCLH) looks after over 2,000 young people with a variety of rheumatological conditions and provides developmentally appropriate interdisciplinary (ID) approach to healthcare. Health coaching (HC) is "a behavioural intervention that facilitates participants in establishing and attaining health promoting goals in order to change lifestyle-related behaviour, with the intent of reducing health risks, improving self-management of chronic conditions, and increasing health related quality of life".[1] Evidence shows that health coaching can improve health related behaviours including medication adherence, patient activation, and use of healthcare resources. [2-4]

Objectives: The aim of this project is to enable young people attending the AYAD to establish and achieve their own health-promoting goals and thereby change behaviour and increase confidence in self-management. As a first stage the aim was to develop health coaching capabilities within our ID Team by March 2022.

Methods: The strategy to deliver this project included commissioning a recognised core skills health coaching course for multidisciplinary team (MDT) members. Pre and post course surveys were completed by participants.

Results: All the AYA team members comprising 3 physiotherapists, 2 nurse specialists, a transition pathway coordinator, 4 consultants and 2 senior registrars took part in the health coaching workshops. A pre course survey (10/ 12 responded) revealed that 70% of MDT members felt their consultations focused solely on young people's medical/clinical care. 80% reported they discuss lifestyle choices such as sleep, and weight management. 40 % felt that their consultation times were long enough to discuss resources that would support long-term management. 30% reported they felt effective

in facilitating Young people and their families to self-manage and/or had sufficient health coaching awareness to facilitate behaviour change. The course was delivered over 2 separate days, one week apart, and included educational material, presentations, group discussion and skills development delivered in a coaching style. A post course survey (11/12 responses) demonstrated 100% of participants were satisfied with the course content, delivery, facilitation and opportunities to work and learn with colleagues, and felt that the skills were applicable to their work. They reported that the skills learned could be applied beyond healthcare, for example, with colleagues or in leadership roles, the course helped to raise self-awareness of behaviours that can negatively and positively impact patient and family engagement in their care, and that using some techniques and small changes to practice could potentially have a big impact on quality of care and outcomes as well as patient and staff experience.

Conclusion: Health coaching skills were considered as a useful tool by all AYAD team members. Skills gained on the course were considered useful in managing young people and applicable in settings beyond clinical care. The next stage of this project will include embedding the techniques learned into clinical practice and measuring qualitative and quantitative outcomes over time

HPR Interdisciplinary research

AB1567-HPR SOCIAL WORKERS: DESCRIBING SOCIOECONOMIC CHARACTERISTICS DURING PRENATAL CARE IN PATIENTS FROM A PREGNANCY AND AUTOIMMUNE RHEUMATIC DISEASES CLINIC.

M. E. Corral Trujillo[1], F. R. Arevalo Nieto[1], L. G. Espinosa Banuelos[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], A. Y. Lujano Negrete[1], D. Á. Galarza-Delgado[1]. *[1]Hospital Universitario Dr. José Eleuterio González, Rheumatology Department, Monterrey, Mexico*

Background: Social workers (SW) interventions are fundamental in health care; the main objective is to identify and mitigate social determinants of the patient's health. The socioeconomic study (SES) is the core assessment of SW; it analyzes the demographic structure and population dynamics.

Objectives: Describe the sociodemographic and social security characteristics in pregnant patients with autoimmune rheumatic diseases.

Methods: A cross-sectional and retrospective study was conducted in a pregnancy and rheumatic diseases outpatient clinic from the university hospital in Monterrey, México. The data from the SES database was collected. The sociodemographic information, family's monthly income and expenses, expenditures related to healthcare, type of social security, family nucleus (FN) and socioeconomic level (SL) were analized. The rheumatic diagnosis was retrieved from the medical records. The SL is classified in 7 levels (according to the score obtained in the SES); each level represents a percentage of the total cost of the healthcare received. Level 1 to 3 correspond to 0 - 28% percentage while levels 4 to 7 go from 53 to 100% of total payment that is due. To evaluate the health expenditure, the monthly limit expenditure per Mexican family is 98.39 dollars (the limit expenditure was taken from the Organization for Economic Co-operation and Development "OECD" 2019 report). For statistical analysis, the sociodemographic and clinical characteristics of the sample are presented as frequencies and percentages.

Results: From 2019 to 2021, 54 patients were interviewed. The mean age was 28.46 years(SD=6.69). The rheumatic diagnoses can be found in Table 1. The most common occupation was unemployment(n=34, 62.96%) and only completed basic levels of education(n=37,68.51%).

Table 1. Sociodemographic characteristics

	n=54
Demographic Data	
Age, mean(SD)	28.46(6.69)
Occupation, n(%)	
Unemployed	34(62.96)
Employed	17(31.48)
Self-Employed	3(5.55)
Marital Status, n(%)	
Married/Cohabitating	38(70.37)
Single	16(29.62)
Level of Education, n(%)	
Basic education	37(68.51)
Higher education	17(31.48)
Family Structure	
Family members, n(%)	
0-5	36(66.66)
6-11	18(33.32)
Number of children, n(%)	
1	36(66.66)
2	13(24.07)
3	5(9.25)
Family Nucleus, n(%)	
Nuclear	27(50)
Multi-nuclear	26(48.14)
Extended	1(1.85)
Rheumatic Disease, n (%)	
Rheumatoid arthritis	29(53.7)
Lupus	9(16.66)
Antiphospholipid syndrome	8(14.81)
Sjögren syndrome	1(1.85)
Health Expenditure, n(%)	
Active health insurance	
None	39(72.22)
Public health services (governmental and state workers)	8(14.81)
Private health insurance	7(12.96)
Average monthly family income (USD)	$614.23
Average monthly health expenditure (USD)	$105.71
Percentage of expenses in patient's health	16.21%

SD:Standard deviation

The most frequent SL was level 3 (46.29%) and the predominant FN was the nuclear family (50%) (couple and their dependent children). Most of them were not under any health coverage(n=39, 72.22%). The average family income was $614.23 USD and the average health expenditure was 105.71 USD; which represents 16.21% of the family income (per month).

Conclusion: SW play a key role understanding basic needs and identifying health determinants that decreases the odds of access of healthcare. Women with autoimmune rheumatic diseases have an important burden of the main determinants of health like low income, unemployment, basic education, and poor health coverage. In addition, the average health expenditure is higher than the recommended by OECD. Different strategies are needed for childbearing age patients with rheumatic diseases to decrease the impact of health determinants.

Patient information and education

AB1568-PARE LIVED EXPERIENCES OF POSTMENOPAUSAL OMANI WOMEN WITH OSTEOPOROSIS

F. Zadjali[1], E. Stanmore[2], J. Brooks[2], T. O'Neill[3]. *[1]The University of Manchester, School of Health Sciences, Manchester, United Kingdom*; *[2]The University of Manchester, School of Health Sciences, Manchester, United Kingdom*; *[3]The University of Manchester, Department of Rheumatology, Manchester, United Kingdom*

Background: Osteoporosis is a globally significant clinical public health problem associated with age-related fractures [1,2]. Most research on the impact of the disease has been based on quantitative survey data. There are relatively few qualitative studies exploring women's lived experience with osteoporosis. Furthermore, most data are from Western countries, with no data from the Middle

East. Direct access to lived experiences is a powerful tool for gaining insights into a disease [3]. This study aimed to determine the lived experience of postmenopausal Omani women with osteoporosis.
Objectives: This study sought to answer three questions:
1.What does living with osteoporosis mean for postmenopausal Omani women?
2.How does culture impact the lives of postmenopausal Omani women with osteoporosis?
3.How do postmenopausal Omani women with osteoporosis perceive the support and care provided by healthcare professionals?
Methods: An interpretive phenomenology design was used with a purposive sample of 15 postmenopausal Omani women with osteoporosis and fragility fractures from primary and secondary care facilities in Muscat, Oman. Audio recorded, semi-structured, one-on-one interviews were held by Zoom and telephone; Crist and Tanner's framework was used to analyze data and identify key themes.
Results: The mean age of the participants was 63 years. Five (33.3%) reported a previous fracture. Just over half (53%) were illiterate; three (20%) had studied in college. Key themes related to their lived experience emerged from the data analysis: culture and religion; health care professionals' attitudes; and services and treatment regimen. The subjects' social and cultural lives were negatively impacted by osteoporosis and fragility fractures, which prevented some from attending celebrations such as close family marriages and religious gatherings. Participants played significant care-giving roles as wives, mothers and grandmothers but many were unable to perform many household chores, such as cooking, due to the osteoporosis and fractures. They perceived healthcare professionals through the professionals' communication styles and information they provided. Participants satisfied with their doctor's communication style described it as humanistic, with humour added, noting they provide health information and understand patients' needs. Those not satisfied indicated their doctors had poor communication styles, showed insufficient interest in them, and asked few questions during their appointments. Professionals at in-patient clinics were perceived as more caring and empathetic than those at out-patient clinics. Treatment abroad was preferred by these women, though some were highly satisfied with their treatment from Omani hospitals. Beliefs about and usage of traditional herbal remedies for the management of fragility fractures differed between educated and non-educated women.
Conclusion: This study explored postmenopausal Omani women's experiences of living with osteoporosis and fragility fractures including the impact of the disease on social and cultural life. It contributes also to our understanding of the experience of the disease in non-western settings.

AB1569-PARE WHAT DO PATIENTS KNOW ABOUT RHEUMATOID ARTHRITIS?

S. Lezhenina[1], N. Shuvalova[2], E. Guryanova[3]. [1]*I. N. Ulianov Chuvash State University, Departament of Healthcare Management and Economics, Cheboksary, Russian Federation*; [2]*I.Ya.Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation*; [3]*I. N. Ulianov Chuvash State University, Department Internal Diseases, Cheboksary, Russian Federation*

Background: Patient awareness of rheumatoid arthritis (RA) contributes to more effective prevention of this disease. It is necessary to study the initial level of knowledge of patients about rheumatoid arthritis and analyze which sections of the educational program need to be studied carefully.
Objectives: To analyze what patients know about rheumatoid arthritis, and do patients with this nosology want to be trained in various educational programs?
Methods: A survey of 86 patients with RA of varying severity was conducted. The diagnosis of RA was established according to the (EULAR)/ACR criteria. Patients were divided into 2 groups by age: group 1 - 18-44 years old (young patients, N= 43), group 2 - 45-65 years old (middle-aged patients, N= 43. The study was conducted in the Central District Hospital of the city of Kanash. Questioning was conducted from January to December 2021. The questionnaire consisted of 2 parts: the first part (part A) included 20 questions (2 points were awarded for each correct answer). Questions related to the relationship between the onset of the disease and hypothermia, infection, stress, injuries of the musculoskeletal the presence of rheumatoid arthritis in close relatives. The knowledge of one's own role in the process of treatment and prevention of RA was assessed. The second part of the questionnaire (part B) consisted of 6 questions. The need for obtaining information about RA and the desire of patients to be trained in various educational programs was studied. It was studied in what format they would like to study (remote or full-time) Survey data was processed in Statistical Analysis Software 15.0. Statistical significance was handled using Analysis of Variation analysis of variance.
Results: 43.7% of group 1 and 56.8% of group 2 correctly classified rheumatoid arthritis as a disease that occurs predominantly in women. 14.6% of young respondents knew about the role of infection in the occurrence of RA, 32.8% - middle-aged. 52.2% of middle-aged patients, 22.8% of young patients knew about the influence of heredity in the occurrence of the disease. 28.0% of young respondents knew about the negative impact of stress on the onset and course of RA, middle-aged respondents - 58.2%. 21.6% of young respondents were aware of the impact of injuries of the musculoskeletal system on the occurrence of RA compared to 55.3% of middle-aged respondents. The awareness of patients about their own role in the treatment process in group 1 was 4.2%, in group 2 - 5.4%. 10.6% of young respondents and 14.8% of middle-aged respondents consider it possible to prevent RA relapses. 92.1% of group 1 and 89.1% of group 2 expressed the need for additional information about RA. Distance learning was preferred by 80.1% of young patients and 65.7% of middle-aged respondents. 56.9% were not aware of the negative impact of stress on the course of RA. 62.5% did not know about the influence of hereditary factors. 95.2% of respondents underestimate their own role in the treatment of rheumatoid arthritis and 87.3% consider it impossible to prevent RA exacerbations. A positive factor was that 90.6% of the respondents report a need to obtain additional information about the disease.
Conclusion: It is necessary to actively implement various educational programs, in which more attention should be paid to the prevention of RA and the participation of the patient himself in the treatment process. Training for patients is preferable to be carried out in a distance learning format.

AB1570-PARE PROFILING LOW BACK PAIN PATIENTS FOR THE DEVELOPMENT OF A PERSONALIZED COACHING APPLICATION

F. Debackere[1,2], J. C. Martin[1,2], A. Roren[3], V. T. Tran[4,5], G. Snoubra[6], Y. Messaï[6], F. Rannou[3,7,8], C. Nguyen[3,7,8], C. Clavel[1,9]. [1]*CNRS, LISN, Orsay, France*; [2]*Université Paris-Saclay, Informatique, Paris, France*; [3]*AP-HP - Hôpital Cochin, Rééducation et Réadaptation de l'Appareil Locomoteur et des Pathologies du Rachis, Paris, France*; [4]*AP-HP - Hôpital Hôtel-Dieu, Epidémiologie Clinique, Paris, France*; [5]*Inserm, UMR-1153, Paris, France*; [6]*Fondation Arthritis/Arthritis R&D, Scientific Department, Paris, France*; [7]*Université de Paris, Faculté de Santé - UFR Médecine, Paris, France*; [8]*Inserm, UMRS-1124, Paris, France*; [9]*Université Paris-Saclay, Psychologie, Paris, France*

Background: Low back pain is a major public health problem that is increasing with the aging of the population. It is the leading cause of disability in most countries [1]. The recommendations of Inserm (2019) include personalized physical activity programs according to the individual characteristics (motivation, preferences, attitude towards physical activity) and life context of each patient (family and professional load, socioeconomic level, living place) [2]. However, the current management of chronic low back pain includes rehabilitation programs that are costly and/or not always personalized, which reduces their effectiveness.
Objectives: The objective of this research is to better understand the characteristics of people with chronic low back pain to identify main motivational profiles that will allow us to offer personalized coaching via a mobile application.
Methods: After a review of the literature and following advice from experts in the management of chronic low back pain, we selected 8 scales to characterize patients: General Health Status (MYMOP), Treatment Burden (TBQ), Quality of Life (EQ-5D-5L), Level (IPAQ), Fears and Beliefs (FABQ-AP), and Motivation (EMAPS) for physical activity, Emotional Status (PHQ-9), and Sense of Self-Efficacy (FC-CPSES). These questionnaires were administered online to participants in the ComPaRe (Community of Patients for Research) chronic low back pain cohort. An initial descriptive analysis of the results allowed us to describe our sample. In order to distinguish different motivational profiles of patients towards physical activity, we performed a Agglomerative Hierarchical Clustering (AHC) and a principal component analysis (PCA) of the results of the EMAPS, PHQ-9, FABQ-AP and FC-CPSES scales.
Results: A total of 193 patients with chronic low back pain were included (m ≃ 54years, s ≃ 13years; majority women (74%); duration of low back pain: m ≃

15years, s ≃ 12years; occupational status: 44% employed, 22% on disability, 19% retired). Clustering analysis allowed us to distinguish 4 main profiles that we named as follows: (1) "Amotivated," characterized by the lowest motivation and highest amotivation toward physical activity (i.e. they do not understand why it is useful), (2) "Cautious" with low motivation and having the highest fears and beliefs toward physical activity, (3) "Depressed" with good intrinsic motivation but also a significant level of depressive symptoms, and (4) "Confident" also showing good intrinsic motivation and having the highest sense of self-efficacy.

Conclusion: The main novelty of this research is a new classification of 4 motivational profiles in the low back pain population determined by a clustering method. This typology is in line with the HAPA model of behavior change [3]. It will allow us to make recommendations for the design of a personalized mobile coaching application. Future work will aim to test and evaluate the personalization of e-coaching according to these profiles.

AB1571-PARE SELF-HEALING CONCEPT: AN INTEGRATIVE MEDICINE APPROACH TO PATIENT SELF-MANAGEMENT OF MUSCULOSKELETAL PAIN

N. Betteridge[1]. [1]*Neil Betteridge Associates Ltd, Patient Advocacy, London, United Kingdom*

Background: Musculoskeletal (MSK) pain affects bones, muscles, ligaments, tendons, fascia and nerves. The pain can occur suddenly (acute) and can become recurrent. The cause is not always clear but triggers can include obesity, trauma and injury, overuse, ageing, inflammation, and mental disorders. Conventional therapies such as rehabilitation, drugs and surgery treat the symptoms of MSK pain but often not the underlying cause. Integrative medicine (IM) is an alternative to conventional therapies as it focuses on the whole person, making use of all therapeutic approaches to promote healing and is being used more world-wide by both patients and healthcare professionals (HCPs). Connected to IM is the concept of self-healing, an intrinsic ability of the whole body that has developed throughout evolution. A recent publication describes the 'self-healing concept' as the innate ability of the body and mind to promote body networks to return the body to equilibrium and relieve pain.[1] There are five body networks thought to be essential, the nervous system, microcirculation, immune modulation, muscular relaxation/contraction and psychological balance. Integral to the self-healing concept is that the body networks can be boosted and optimised by the use of IM which can act simultaneously through more than one body network (multi-modal). The use of IM is amenable to patients managing their own care (self-management) however, there is a need for both HCPs and patients to be educated on the self-healing concept.

Objectives: A global survey will be conducted to further understand the perception of patient and HCPs about the self-healing concept and its multi-modal IM approaches.

Methods: The multi-modal IM approaches of the self-healing concept are described here as well as the global survey which will inform and request feedback from HCPs and patients on the role of self-healing in supported self-management of MSK pain.

Results: Multi-modal IM approaches that boost and optimise body networks to reduce MSK pain within the self-healing concept include a variety of techniques. The innate ability of both the body and mind are integral to self-healing and psychological techniques such as yoga, mindfulness meditation, cognitive behavioural therapy and hypnosis are therapies that make use the strength of the mind. Regards the body, muscle strengthening through moderate exercise and physiotherapy is linked to an increase in microcirculation associated with muscle contraction/relaxation. Dietary patterns also have an important role in musculoskeletal well-being, as high intakes of protein, fat, and sugar are associated with a lower pain threshold. The use of traditional Chinese medicine has been shown to be effective, along with other natural therapies such as melatonin, menthol and cannabidiol and heat therapy which can be used to relieve pain and muscle cramps, increase blood flow and facilitate tissue healing. An increasing number of devices are being introduced to patients such as transcutaneous electrical nerve stimulation, which provides localised strong yet comfortable muscle contractions to ease musculoskeletal pain, and infra-red technology, which can potentially help enhance blood circulation and metabolism. The self-healing global survey is being developed for release in mid-2022. Around 15–20 simple questions will be asked of patients and HCPs via a digital platform/app. The insights generated will address unmet need, quality of life, importance of new innovative therapies, impact of treatment options and the impact of self-management, self-healing and sustainability on the healthcare system.

Conclusion: The use of integrative medicine can boost and optimise the body networks within the self-healing concept and there are many options available for patient self-management of MSK. Results from the survey will identify current treatment gaps and what is needed to improve patient outcomes.

This study was funded by Sanofi.

AB1572-PARE VIEWPOINTS OF YOUNG TUNISIAN WOMEN WITH RHEUMATOID ARTHRITIS REGARDING THE IMPACT OF THE DISEASE ON FERTILITY: ARE THEY AWARE ENOUGH?

S. Nouicer[1], S. Jemmali[1], S. Boussaid[1], S. Rahmouni[1], S. Rekik[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta, Rheumatology, Tunis, Tunisia*

Background: Rheumatoid Arthritis (RA) is one of the most common chronic inflammatory disease in women in reproductive age. It seems difficult to acheive parenthood in RA, therefore, reproductive health in these patients is an important issue. Many factors may interfere with procreation such as high disease activity and medication. Female perception and behavior towards fertility are not often assessed.

Objectives: We aimed to evaluate the fertility perceptions and related behavior among young women with RA.

Methods: We conducted a cross sectional study involving young female patients with RA (2010 ACR-EULAR criteria). Sociodemographic data and the following disease-related parameters were collected: diseases activity score (DAS28CRP) and NSAID (Non steroidal Anti-inflammatory Drugs), prednisone and DMARDs being used. We asked the patients about their knowledge about the risk of infertility due to the disease itself, the activity of RA and medication.

Results: Sixty-two females patients were included. The average age was 26.1 ±2.1 years [20-35]. The majority of patients, 54 women, live in rural enviroment and 8 women live in urban enviroment. Forty-two women (67%) were illiterate, ten women (16%) had primary or secondary school level and ten women (16%) had university school level. Only twenty percent (20%) were employed. There were no smokers included. Sixty-six percent (66%) were married. Forty-one women (66%) aimed to have children: 35 women got pregnant and 6 still didn't get pregnant. The average of gestity was 1.6 [0-4]. The average of parity was of 1.2 [0-3]. The average of time to pregnancy (TTP) was 12 months ± 2 [6-24]. Pregnancy resulted in a live-born baby in 30 women (73%), 4 women (9%) miscarried and there was one intra-uterine fetal death (2%). Ten pregnant women had had fertility treatment to get pregnant. The mean duration of the RA was 3.1 years ± 1.2 [2-10]. The mean DAS28CRP were 3.1 ± 1.25[2-3.9]. Both rheumatoid factor and anti-citrullinated peptides antibodies were positive in 58 women (93%). RA was erosive in 48 cases (76.1%) and deformed in 2 cases (3%). Half of patient were using NSAID daily and 60% were using prednisone with an average daily dose of 5.1 mg/day [2.5-7.5]. Sixty-one percent (61%) of patients were using Methotrexate with an average weekly dose of 15.1 mg/week [10-22.5], 10% Leflunomide, 10% Sulfasalazine, and 45% biotherapy. About half of patient think that RA may cause fertility problems, infertility in 60% and abortion in 40% and they had this information in 60% from media, 30% from siblings and only 10.1% from their rheumatologist. None of patients think that disease activity may interfere with pregnancy and that they should strive low disease activity before trying to conceive. None of patients think that NSAID or COX2 inhibitor or prednisone may interfere with fertility and about 10 women used NSAID in pregnancy. About 24% think that DMARDs may interfere with procreation especially infertility (100%) with respectively: MTX (70%), Leflunomide (3%), Sulfasalazine (5%), biotherapy (20%). Women who didn't get pregnant accused their impaired fertility to their DMARDs and eight women stopped their DMARDs in pregnancy for fear that it affected their baby. Only 5 women (8%) saw a rheumatologist in the preconception period.

Conclusion: The relationship between RA and fertility seems to be misunderstood in young women with RA. Clinicians must routinely discuss this issue with these young patients to preserve their fertility by learning them the mechanisms by which RA may affects their fertility: the disease itself and medication. Appropriate information about fertility can help women in productive age reach and carry a healthy pregnancy.

AB1573-PARE WHAT DO OSTEOPOROTIC PATIENTS KNOW ABOUT THEIR DISEASE?

F. Idrissi Zaki[1], H. Arabi[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Rheumatology, Marrakech, Morocco*

Background: Osteoporosis (OP) is a systemic skeletal disorder characterized by low bone mass responsible of fracture. It is a major public health problem. knowledge assessment is an essential step in therapeutic education which could improve the management of osteoporosis.

Objectives: The objective of this study is to assess the degree of knowledge of osteoporotic patients regarding their disease as part of therapeutic education in order to improve management and develop a shared decision with the patient.

Methods: This is a cross-sectional epidemiological study conducted on osteoporotic patients at the rheumatology department of the university hospital center Mohamed VI Marrakech. Descriptive data, knowledge evaluation, patient expectations and therapeutic adherence were collected and analysed by SPSS 20. The comparison was made by the Chi-square test for qualitative variables.

Results: 137 patients were included with an average age of 63.7 years, with a female predominance (94.9% female vs 5.1% male), 70.1% were illiterate, 58.4% had postmenopausal OP, 36.5% secondary OP and 5.1 % (n=7) male OP. 14.6% of the patients had diabetes, 9.5% had arterial hypertension, 5.8% had breast cancer under aromatase-inhibitors, 13.9% had rheumatoid arthritis and 9.5% had other chronic diseases, 16.1% were on long-term corticosteroids, 98.5% were on oral bisphosphonate and only 2 patients were on Intravenous zoledronate, 51.1% had osteoporosis for less than 2 years, 9.5% had a history of fracture with 2.9% major fractures. 9.5% of patients answered that osteoporosis was linked to bone fragility, 29.2% thought it was age-related, 26.3% had a confusion between osteoporosis and osteoarthritis, 16.8% believed it was an inflammatory rheumatism. 81% supposed it was a female pathology, 92% presumed that their rheumatological manifestations were linked to osteoporosis, 58.4% didn't know OP's risk factors, 14.6% and 8.8% had recognized aging and menopause as OP's risk factors respectively. 59.1% and 61.3% didn't know any fall nor fracture related factors respectively. Concerning the clinical manifestations of osteoporosis, 48.2% thought OP manifested by arthralgia, 21.2% by myalgia, 2.2% by bone pain and only 5% assumed that it is a silent disease. 95.6% assumed that physical activity is harmful and 32.1% had made environmental modifications. 52.6% were convinced by their anti-osteoporotic treatment, 32.8% said they trusted the doctor's decision and 14.6% were not convinced of the treatment but took it anyway. In bivariate analysis, there was a statistically significant correlation (p=0.008) between non-adherence to treatment and poor knowledge of OP's risk factors.

Conclusion: The knowledge evaluation being the first step of therapeutic education, it is necessary to encourage OP's knowledge improvement and consequently increase therapeutic adherence.

AB1574-PARE "ABITARE" PROJECT – HOME FOR PATIENTS WITH RHEUMATIC DISEASES

L. S. Martin[1], S. Middei[2], R. Convertino[2], A. Celano[2]. [1]*ASL ROMA 6, Operative Unit of Internal Medicine and Rheumatology, Rome, Italy*; [2]*APMARR APS - Italian National Association of People With Rheumatological and Rare Diseases, Rheumatology, Lecce, Italy*

Background: Talking about home means talking about ourselves. Our home represents the "movie set" where the film of our lives is shot, and we can choose whether to be simple actors or the directors of it. The house expresses our personality, it identifies us in a unique way, like a fingerprint. Talking about our home means understanding how the way we relate to it can create well-being or discomfort.

Objectives: The goal of this project is to promote the empowerment of people with disabilities and chronic diseases. We aim to do that starting from a greater awareness of their living needs and the quality of life and self-esteem enhancements that derives from a tailor-made home.

Methods: 308 people participated in the survey and were distributed anonymous questionnaires regarding their experience at home.

DEMOGRAPHIC PARAMETERS:

Gender: 72 males and 236 females

Age: 24 (18-25); 44 (26-34); 32 (35-42); 88 (43-50); 44 (51-58); 44 (59-66); 32 (67-75)

Percentage of disability: 36 do not know their own percentage; <25%: 52; >25<50: 44; >50<75: 60; >75<100: 112

Pathologies found: Psoriatic arthritis: 52; Rheumatoid arthritis: 116; Connectivitis: 44; Fibromyalgia: 16; Ankylosing spondylitis: 16; Muscle diseases: 64

We found the highest number of severely disabled people (>75<100) among patients with muscle diseases (93,7%), followed by patients with connectivitis (45%) and Rheumatoid arthritis (44%).

Results: 92% of the participants agree "*very/very much*" with the phrase "*An accessible home ...* (**question 12**)", **6%** "*fairly*" agree and only **1.2%** "*do not agree*". **43%** of people like their home "*a lot/very much*" (**question 4**), another **43%** "*quite*" and only **13%** (40 people) "*don't like it at all/like it a little*". Curiously, **90%** of those who do not like it perceive their home as "*not very/not at all welcoming*"; **70**% feel "*little /not at all autonomous*" and **100%** report that the house "*reflects them only a little/not at all*"; therefore **80%** think that the house should "*change fairly/a lot*", (but only **10**% have done renovations). **82%** of the people who carried out renovations (**question 9**), were aware of tax breaks, while only **36%** of those who did not carry out renovations knew about the tax breaks. **Males** who have done renovations represent **25%** of this population and all of them had a great disability (**100%**); a particular degree of disability was not prevalent among women. **65%** of those who have done renovations report that the improvement in their quality of life as a result of the work is "*fairly*" (**question 11**), and for the remaining **45%** the quality of life has improved "*a lot*". The most necessary and reported renovation works are not "**frivolous requests**" or "**whims**", but practical needs for the daily life: *removal of architectural barriers, stair lifts, mobile wall units and adaptation of toilets.* All this is essential and necessary for people with reduced mobility and /or disabilities. The most interesting part of the survey concerns the "*more intimate and personal*" question (**question 16**): "*What does your home represent for you*". The concept that is most expressed is "**Refuge**" or others like that such as "**Safe Harbor**", "**Nest**", "**Freedom**" ... concepts that go far beyond the "**architectural**" and "**material**" sense of the house.

Conclusion: The home represents, for the general population, but above all people with disabilities, *a place to take refuge from the dangers/anxieties/ worries of everyday life*. Therefore, every effort to inform patients about the possible facilities to make their home more comfortable is fundamental, as well as those to raise the awareness of governments in order to increase the facilities for patients who will need them.

AB1575-PARE DIETS AND JOINT SYMPTOMS: SURVEY OF MOROCCAN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM

N. Takhrifa[1], T. Fatima Zahrae[1], I. Berrichi[1], A. Anass[1], K. Berrada[1], F. Abourazzak[1]. [1]*Tangier, Department of Rheumatology, Tangier, Morocco*

Background: The role of diet in triggering or aggravating chronic diseases, in particular chronic inflammatory rheumatism (CIR), is a question frequently asked by patients.

Objectives: The objective of our study is to investigate whether Moroccan patients report a relationship between certain diets or foods and the symptoms of the disease and also to study whether patients adopt specific eating behaviors in order to relieve their symptoms.

Methods: This is a survey based on a questionnaire that included any patient followed for CIR who presents to the rheumatology department. The questionnaire

has 3 parts: 1) Sociodemographic data, comorbidities, and information on the CIR (type, duration of evolution, activity, functional impact and treatments), 2) beliefs and attitudes of patients in this regarding diet in relation to their CIRs 3) a list of 24 foods for which patients are asked whether they worsen, improve or leave their joint symptoms unchanged.

Results: To date we have included 120 patients. The average age was 45.3 ± 13.4, 73.3% of the patients were women, 39.3% had comorbidities, 50% were illiterate, 57.5% were followed for RA and 42.5% for SPA. The median duration of evolution of the RIC was 7 years [3; 15], for the treatments 45% of the patients in our study were on corticosteroid therapy, 3.3% used a biological treatement while 7.5% received no treatment. 25% of patients think that the diet influences the activity and/or the evolution of the rheumatism. 26% of subjects said food had an effect on their CIR, with 11.7% reporting improvement and 25% worsening. Honey (6.7%), garlic (5%) and olive oil (4.2%) were the foods most often cited as improving CIR symptoms, while red meat (18.3%), fish (6.7%) and legumes (3.3%) were most often cited as aggravating symptoms. 20.8% of patients declare that they have avoidance behaviors vis-à-vis certain foods while 7.5% adopt certain diets and 3.3% have already tried fasting in order to relieve joint symptoms. In uni and multivariate analysis no factor, only the duration of evolution was associated with the fact of declaring that food has an influence on the symptoms of the CIR (OR: 0.947, IC95%: [0.901-0.996], p=0.03).

Conclusion: The results of our investigation suggest a possible link between certain foods and joint pain in patients followed for CIR.

AB1576-PARE RHEUMATOID ARTHRITIS ASSESSMENT KNOWLEDGE QUESTIONNAIRE (RAKE) IN TUNISIAN POPULATION

S. Rekik[1], Z. Zeineb[1], S. Jemmali[1], S. Boussaid[1], S. Rahmouni[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta University Hospital, Rheumatology, Tunis, Tunisia*

Background: Rheumatoid arthritis (RA) is a chronic, systemic, inflammatory disease that has a very high burden on patients their families, and society. So that it is important that RA patients receive education about their disease. The knowledge of RA patients in Tunisia regarding their disease has not yet been assessed.

Objectives: The purpose of the study was to evaluate disease-specific knowledge of patients with rheumatoid arthritis by using the RAKE questionnaire (Rheumatoid Arthritis assessment Knowledge Questionnaire).

Methods: This was a cross-sectional study. Adults with RA fulfilling the ACR/EULAR criteria were asked to participate by responding to RAKE Questionnaire in the short version.

Results: A total of 28 RA patients were included: 23 females (82%) 5 mens (18%). The mean age was 58.5 years with a range of 31 to 79 years. The mean disease duration was 9.8 years. The disease duration was 0-5 years in 5 (17.8%) patients, and more than 5 years in 23 (82.2%) cases. Twenty patients were housewives. Thirteen (46.4%) patients were from rural areas. Almost all of the patients didn't follow education programs for their RA. Twenty-two (78.5%) patients obtained information's RA from their rheumatologist. Six patients (21.5%) from other sources (neighbors, nurses, other RA patients, social media). The mean time for answering the questionnaire was11.6 min (9-15 min). The RAKE total score was11.8/32 [3-22]. For the initial part of the questionnaire, related to the general aspects of RA, the mean score was 4.3/8 [0-6]. The mean score of the second component of the questionnaire concerning medications and non-pharmacological management, was respectively 4.3/11 [0-7] and 2.3/5 [0-4]. For comorbidities, the mean score was 0.6/1. The fourth component includes auto-management, pain, and tiredness the mean score was1.4/3 [0-3]. The last component covers psychosocial, occupational, and health system coping skills. Its mean score was 2.1/4. The mean score of unknown answers was 6.7/32 [4-16].

Conclusion: In our study, the knowledge patients of RA was low in all domains of RAKE questionnaire at various degrees. These findings can be used for improving current patient education programs and better disease control.

AB1577-PARE DO MOROCCAN PATIENTS DISCUSS WITH THEIR RHEUMATOLOGISTS ABOUT DIET AS PART OF THE MANAGEMENT OF THEIR OSTEOARTHRITIS?

N. El Mansouri[1], T. Fatima Zahrae[1], R. Bensaid[1], N. Takhrifa[1], H. Fouzia[1], B. Khadija[1], F. Abourazzak[1]. [1]*Tangier, Depatment of Rheumatology CHU Tangier Tetouan Al Hoceima, Tangier, Morocco*

Background: The question of diet is frequently asked by patients with osteoarthritis. Beyond the effect of weight on the worsening of their symptoms, patients often ask whether certain foods, labelled as inflammatory or anti-inflammatory, can improve or worsen their disease.

Objectives: The aim of our study is to find out whether patients with osteoarthritis discuss diet during their medical visits and to investigate the association between patients's reported dietary beliefs and practices and their willingness to discuss them.

Methods: This is a survey based on a questionnaire that included all patients followed for osteoarthritis who presented to the rheumatology department. The questionnaire consists of 3 parts:

1) Socio-demographic data, co-morbidities, and information on osteoarthritis (location, duration of evolution, functional impact and treatments),

2) Patients's beliefs and attitudes about diet in relation to osteoarthritis

3) Discussions about diet during medical visits and whether there is any patient interest in such discussions.

Results: At that time we included 120 patients. The average age was 57.1 ± 11.8, 88.3% of the patients were women, 41.2% had comorbidities, 62.5% were illiterate. The median duration of evolution of osteoarthritis was 4 years [2; 7]. 64.2% of the patients were followed for Gonarthrosis, 25% for Discarthrosis and 10.8% for Digital osteoarthritis. The average BMI was 27.8 ± 5.2. 8.3% of the patients thought that diet influenced their osteoarthritis. 9.5% of the subjects stated that food had an effect on their symptoms, with 9.2% reporting an improvement and 8.3% an aggravation. 6.7% of patients reported food avoidance behaviours, while 10.8% adopted certain diets in order to relieve joint symptoms. Only 2.5% of the patients reported having ever had discussions about diet with their rheumatologists while 99.2% showed interest in such discussions. For those who had never done so, the main reason was that the rheumatologist had never broached the subject. In uni and multi-variate analysis, the experience of a food that improves symptoms (OR: 13; 95% CI [1,258-134,333]; p=0.019) and the adoption of dietary practices (OR: 13; 95% CI [1,258-134,333]; p=0.019) were associated with discussing diet.

Conclusion: Discussions about diet are reported by a minority of osteoarthritis patients and seem to be mainly related to patients's experiences with certain foods that improve their symptomatology and also to patients' adoption of certain diets. This situation needs to be improved as nutritional advice should be an integral part of the management of our patients.

AB1578-PARE A PATIENT-REPORTED OUTCOME SCALE: RASQ FOR MEASURING SYMPTOMS OF RHEUMATOID ARTHRITIS

S. Rekik[1], Z. Zeineb[1], S. Boussaid[1], S. Rahmouni[1], S. Jemmali[1], K. Zouaoui[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta University Hospital, Rheumatology, Tunis, Tunisia*

Background: Patient-reported outcome (PRO) instruments are used to assess the patient experience of rheumatoid arthritis (RA) symptoms and impacts and can capture RA treatments effects. Also, there are often discrepancies between patient and physician perspectives.

Objectives: The objective of our study was to proceed with a psychometric evaluation of patients with RA using the Rheumatoid Arthritis Symptom Questionnaire (RASQ).

Methods: Adults with clinically confirmed RA, as defined by the ACR/EULAR criteria, were recruited for this cross-sectional study, and then completed the RASQ. Medical records were reviewed, clinical features, treatments, and outcomes were analyzed.

Results: In total 28subjects (82% females) with RA were included. The meanagewas58.5years (31-79 years). Comorbiditieswerepresentin86 %, diabetes (50%), high blood pressure (32,1%), dyslipidemia (25%), thyroid disease (3,7%), Depression (7.1%).The mean duration since RA diagnosiswas9,8 years. Almost all the patients had at least one of the disease severity criteria, high level of CRP (76%), radiographic erosion (96%), C1-C2 involvement (18%), or hip involvement (14,2%). All of the patients received CsDMARDs and biological therapy. Disease activity evaluated by the DAS28 score was in remission or very low disease activity in 38%, moderate (46%), and high (16%). Functional impact evaluated by the Health Assessment Questionnaire (HAQ)was an average of 1.1 (0.2–3). The RASQ total symptomwas6.6 (2-10). The mean of each item was joint pain (5.4), joint swelling (5.5), joint stiffness (6.1), joint tenderness (4.1), joint warmth (4.3), muscle pain (6), tiredness (5.7). The RASQ total symptom was statistically significantly different (p=0.01) across the DAS28severityrankings but only the first two single items of the RASQ were not statistically significantly different (p=0.9 and p=1,6). A medium positive correlation was found between subjects' HAQ score and the total symptom score of the RASQ (r=0,38).

Conclusion: The primary goal of treating patients with RA is to maximize the long-term health-related quality of life. In this order, measurement of all of the signs and symptoms of RA that are significant and relevant to patients living with the disease is important to achieve this main objective.

AB1579-PARE THE EFFECTS OF A HEALTH EDUCATION PROGRAMME ON PATIENTS' SYMPTOMS AND LIFESTYLE CHANGES IN PATIENTS WITH KNEE OSTEOARTHRITIS ATTENDING A TERTIARY CARE CLINIC IN SRI LANKA

S. Janagan[1], R. M. Wickramarachchi[1], M. De Silva[1]. [1]*National Hospital of Sri Lanka, Rheumatology, Colombo, Sri Lanka*

Background: Osteoarthritis is the major cause of joint pain and disability among middle aged and elderly with no disease specific treatment. Management includes analgesics, lifestyle changes and physical therapy.
Objectives: We aimed to study the demographics of the patients and knowledge regarding osteoarthritis among those who attended our clinic with mechanical knee pain and the effects of a health education programme.
Methods: Patients complaining of mechanical knee pain who were found to have examination findings suggestive of knee joint osteoarthritis were enrolled in this study (N-150). Where available diagnosis was confirmed by radiography. Data was collected when they attended a health education programme which focused on lifestyle changes in osteoarthritis including diet and exercise (n-76). An interviewer administered questionnaire regarding disease, dietary changes for reduction of weight and exercise was used to obtain data before and 3 months after the health education programme. Anthropometric measurements were taken using validated instruments. Data was analyzed using SPSS software.
Results: Response rate was 50.67 %.The average age of the study population was 54.8 years and constituted of 92.1 % females. About one fifth of them had received only primary school and 50 percent were unemployed. The average BMI was 29.68 (SD-5) and average WOMAC score was 44.1 (SD -19.4).
Their knowledge of healthy dietary habits, primarily to lose weight and exercises for knees were assessed before the health education programme and 3 months later.

Table 1.

	Before health education	3 months after health education
n	76	20
BMI (average)	29.68	30.2
Not aware of disease	90%	50%
Aware of diet to reduce weight	32%	65%
Aware of exercises	5 %	35%
WOMAC score	44.1	36.7

There was no statistically significant correlation between WOMAC score and age, educational level or BMI.Though the knowledge regarding disease and lifestyle measures improved significantly($p < 0.05$) following the health education program, there was no significant difference in the WOMAC score.
Conclusion: Health education was seen to improve the knowledge regarding disease and lifestyle measures despite no significant improvement in the pain or disability scores.Further studies are needed to see the long term effects of health education.

AB1580-PARE REMISSION: IS IT UNKNOWN?

S. Tonolo[1,2,3], A. Verducci[2], F. Padovani[4], P. Grossi[5], G. Mussi[6], S. Severoni[7]. [1]*ANMAR Italia, Anmar, Rome, Italy*; [2]*ANMAR Italia, Umbria, Assisi, Italy*; [3]*ANMAR Italia, Veneto, Rome, Italy*; [4]*ANMAR Italia, Abruzzo, Pescara, Italy*; [5]*ANMAR Italia, Toscana, Firenze, Italy*; [6]*ANMAR Italia, Liguria, Genova, Italy*; [7]*ANMAR Italia, Lazio, Rieti, Italy*

Background: Remission is the alleviation or disappearance of the symptoms of a pathology. It may be due to the cessation of a pathogenic action, its overcoming by the body's defense mechanisms, the implementation of adequate therapy. The term is used when the phenomenon is transitory and can have variable duration, even very long (months or years). However, the morbid process persists in the body and then fatally returns to recur. But how much do patients with chronic rheumatological diseases know? How many of them know this word and, among those who know it, how many correctly understand its full meaning? Here is the objective of the campaign: to verify the level of awareness among rheumatological patients with respect to the concept of remission of the pathology.
Objectives: The objective of the Association, in collaboration with SIR (which has already granted the patronage to the campaign) is to verify, in 3 years, how and how much awareness has improved on the concept of remission between patients and if, and how much, doctor-patient communication will be improved on the subject.
Methods: This awareness campaign is on the concept of remission will start, implemented with different tools: 1 – Informative booklet on the concept of remission, on what it is and how it can be achieved. And to maintain, both from the point of view of the rheumatologist and from the patient's point of view. The booklet will be accompanied by the results of the questionnaire mentioned above. 2- Ideation, creation and realization of a Facebook page: https://www.facebook.com/ObiettivoRemissione/ which will be used as a vehicle for a series of informative contents on the concept of remission and for an emotional video intended for the target of patients and their family:
Results: Started in 2020, the campaign is still ongoing and the first preliminary results will be delivered in the last quarter of 2022
Conclusion: A survey conducted on 1,300 respondents, of which 93% were patients or family members of patients, shows that 26% do not know the concept of remission and only half report having heard about it from their referring physician. From an SEO survey conducted on the main search engines, then, it is clear that the concept of remission in the context of rheumatic diseases is totally absent from the Internet which is, unfortunately or fortunately, at this moment, the first research outpost by of patients or potential patients on health issues.

AB1581-PARE ATTITUDES TOWARDS MEDICATIONS AND COMMONLY REPORTED SIDE EFFECTS TO DMARDS IN RHEUMATOID ARTHRITIS PATIENTS ATTENDING A TERTIARY CARE HOSPITAL IN SRI LANKA

S. Janagan[1], M. De Silva[1]. [1]*National Hospital of Sri Lanka, Rheumatology, Colombo, Sri Lanka*

Background: Rheumatoid arthritis(RA) is a chronic multisystem disease which can be controlled with disease modifying anti-rheumatic drugs (DMARDs). Compliance to treatment can be affected by attitudes to medicines and side effects of drugs.
Objectives: To identify attitudes towards medicines in patients with rheumatoid arthritis and its relationship to disease characteristics and identify the side effect profile of commonly used DMARDs in a Sri lankan population.
Methods: A cross sectional study was carried out on patients attending a rheumatology clinic at National hospital of Sri Lanka between August to November 2018. Patients diagnosed with RA based on standard criteria and on DMARDS for more than 3 months were administered an interviewer administered questionnaire regarding sociodemographic and beliefs about medicines questionnaire (BMQ) assessing patients' attitudes to the necessity of prescribed medication for controlling their disease and their concerns about potential adverse consequences of taking it. Further questions about commonly reported side effects were also asked. Data was analysed using SPSS software.
Results: 160 patients fulfilled our inclusion criteria and the response rate was 75%. The study population consisted of 84% females with an average age of 52 years. They were predominantly Sinhalese (82 %) with a median duration of disease of 10 years (interquartile range-1.6-18.4 years). Three fourths of them were seropositive. The mean disease activity (DAS-28) was 4.03 (SD-1.29). Respondents indicated their degree of agreement with each statement in the BMQ on a five-point Likert scale, ranging from 1 = strongly disagree to 5 = strongly agree. The first ten questions specifically asked regarding arthritis medication.

Table 1.

	Percentage agreeing or strongly agreeing
Necessity scale	
My health at present depends on my arthritis medicines	77.5
My life would be impossible without my arthritis medication	72.5
Without my arthritis medication I would be very ill	68.3
My health in the future will depend on my arthritis medication	66.7
My arthritis medication protects me from becoming worse.	59.2
Concern scale	
Having to take arthritis medication worries me	40
I sometimes worry about the long-term effects of my arthritis medication	62.5
My arthritis medication is a mystery to me	28.3
My arthritis medication disrupts my life	38.3
I sometimes worry about becoming too dependent on my arthritis medication	57.5

The overall necessity scale score (mean 19.2, S.D. 3.21) was higher than the concerns scale score (mean 14.86, S.D. 3.89; *P*<0.01) but was not statistically significant. The overall necessity scale score was found to be significantly correlated with duration of disease (p<0.05) but not with age, sex, seropositivity or disease activity. 59.2 %, 13.4 %, 8.2 %, 6.1 % of the patients were on monotherapy with Methotrexate, Leflunomide, Sulphasalazine, HCQ respectively. 12.8 % were on combination methotrexate and leflunomide and remainder were on biologics. The commonest side effects noted on methotrexate were leucopenia, loss of appetite,raised liver enzymes, oral ulcers, hair loss which were 30 %, 21 %, 8 %, 7% and 11% respectively. Patients on leflunomide reported raised BP, raised liver enzymes, loss of appetite and leucopenia in 30 %, 14 %, 8 % and 6 % respectively. Patients on both reported raised liver enzymes, leucopenia, loss of appetite in 78 %, 60 %,11 % respectively. Sulphasalazine caused anaemia,leucopenia and insomnia in 23 %, 17 %, 8 % respectively.HCQ caused pigmentation and maculopathy at 17 % and 9 % respectively.

Conclusion: Though a positive attitude towards their medication was seen in most patients with rheumatoid arthritis, they had concerns regarding potential long-term effects and dependency. This was found to be significantly correlated to duration of disease. Educating patients about their medication and clarifying misconceptions will improve compliance and disease outcomes. Side effects noted were similar to western population but GI side effects were notably less.

Building patient led organisations

AB1582-PARE **ASSIGNING A VALUE TO THE 'PASS' CONCEPT IN PSORIATIC ARTHRITIS PATIENTS: A SINGLE CENTER DATA.**

R. Reji[1], S. K. C.[1], S. Joemo C.[1], R. R.[1], P. Shenoy[1], A. J. Mathew[2]. [1]*Centre for Arthritis & Rheumatism Excellence, Rheumatology, Ernakulam, India*; [2]*Christian Medical College, Department of Clinical Immunology and Rheumatology, Vellore, India*

Background: Psoriatic arthritis (PsA), a chronic, heterogeneous disease, needs long-term management. The concept of 'Patient acceptable symptom state' (PASS), evaluated with a dichotomized question on patients' overall satisfaction with their current state of symptoms, represents the overall health state at which patients consider themselves well. Therapeutic compliance improves when the patient's perspective of wellness is recognized while modifying treatment.

Objectives: To identify cut-off points for composite disease activity scores (DAS) and patient reported outcomes (PROs) that can reciprocate the PASS status of a patient with PsA.

Methods: A cross sectional study was conducted in patients with PsA attending a rheumatology centre in Kerala between March 2020 and Aug 2021. Baseline demographics, clinical characteristics, composite DAS [disease activity index for PsA (DAPSA), clinical (c) DAPSA] and PROs [PsA impact of disease (PsAID), patient pain visual analogue scale (VAS), patient global assessment (PGA), 12-item short-form survey (SF-12)] were compared in patients who responded 'yes' and 'no' to the 'PASS' question. Cut-off values for PASS in composite DAS and PROs were quantified using the Receiver Operator characteristic curve (ROC) curve. Regression models assessed the impact of different variables on the PASS status.

Results: From a total of 314 patients, 302 who fulfilled the inclusion, exclusion criteria were chosen for analysis. Of them, 171 (56.62%) patients were males. Mean age (S.D) and median disease duration (range) were found to be 50.50 ±11.77 years and 8 (4-14) years respectively. Among the study patients, 215 (70.46%) had acceptable PASS status. Median values for composite scores and patient reported characters in patients who accepted their symptoms and in patients who did not accept their symptoms, are represented in Table 1. Cut-off values for patient pain VAS, Pat GA, DAPSA, cDAPSA and PsAID, with the best tradeoffs between sensitivity and specificity, were found to be 17.5, 25, 10.95, 4.75 and 1.95, respectively (Figure 1A and B). Patients with active psoriatic lesions indicated by higher PASI score, presence of nail involvement, and moderate to high disease activity DAPSA value tended not to attain PASS (OR: 0.793; 95% CI: 0.67-0.93, OR: 0.438; 95% CI: 0.22-0.87, OR:0.168; 95% CI: 0.081-0.349).

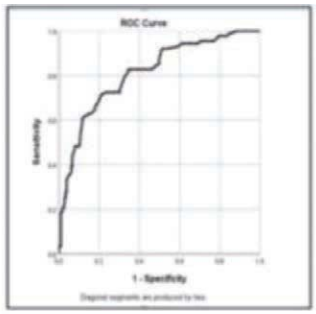

Fig 1 A: PSAID

ROC cut off (sensitivity, specificity) 1.95 (0.724, 0.233)

AUC: 0.812

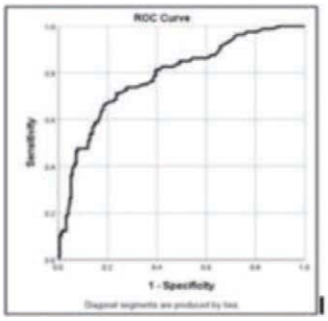

Fig 1 B: DAPSA:

ROC cut off (sensitivity, specificity): 10.95 (0.725, 0.272)

AUC: 0.786

Figure 1.

Table 1. Patient characteristics according to PASS status

parameters (median (IQR)	PASS+ve N=215	PASS –ve N= 87	p value
DAPSA	6.7 (3.54 -11.10)	13 (7.15-18.85)	0.00
cDAPSA	3 (1-7)	11(6-15)	0.00
Dactylitis	0 (0-0)	0 (0-1)	0.00
HAQ	0.25 (0-0.5)	0.5 (0.13-0.88)	0.00
PsAID	1 (0.5-1.9)	2.55 (1.6 -4.3)	0.00
VAS (0-100)	10 (0-20)	40 (10-50)	0.00
Pat GA (0-10)	1 (1-2)	3 (2-5)	0.00
SF 12 PCS (physical component score)	49.67 (42.99-54.31)	40.77 (34.58)-50.12)	0.00
SF12MCS (mental component score)	58.82 (53.96-60.73)	47.16 (39.65-54.83)	0.00
Physician global assessment (1-10)	1 (0-2)	3 (2-4)	0.00
PASI	0.30 (0-0.8)	1 (0.2-4.9)	

P<0.05 is considered as significant

Conclusion: The determined cut-off values for PASS lay in the low disease activity range. A significant number of patients who did not attain PASS, received treatment intensification. Patients with increased PASI, presence of nail dystrophy, and moderate to high disease activity DAPSA value tended to not accept their state.

Arthritis research

AB1583-PARE QUALITATIVE INTERVIEWS OF SYMPTOMS, IMPACTS AND SELECTED PROMIS SHORT FORMS: A STUDY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

A. Findley[1], J. Middlehurst[1], C. Howse[1], M. Clifford[1], W. Neill[1], S. Tatlock[1], W. H. Chen[2], M. Bracher[3], D. Patel[4]. *[1]Adelphi Values, Patient-Centred Outcomes, Bollington, United Kingdom*; *[2]GlaxoSmithKline, Specialty Care, General Medicines & Vaccines, Collegeville, United States of America*; *[3]GlaxoSmithKline, Global Value Evidence & Outcomes, Stevenage, United Kingdom*; *[4]GlaxoSmithKline, Global Value Evidence & Outcomes, Collegeville, United States of America*

Background: Axial spondyloarthritis (axSpA) is characterised by inflammation of the sacroiliac joints and spine. Sleep disturbance, pain and fatigue are reported in the literature to be key symptoms and impacts of axSpA. Three customised Patient-Reported Outcomes Measurement Information System (PROMIS) Short Forms (Sleep Disturbance, Pain Interference and Fatigue), previously developed for use in rheumatoid arthritis, have been proposed for use in patients with axSpA to assess the key concepts.
Objectives: To conduct in-depth qualitative interviews to further understand the patient experience of axSpA and evaluate the content validity of the three PROMIS Short Forms to support their use as endpoints in axSpA clinical trials.
Methods: A non-interventional, cross-sectional qualitative (concept elicitation [CE] and cognitive debriefing [CD]) study was conducted in 28 adult patients with diagnosed axSpA, including radiographic axSpA (r-axSpA), also known as ankylosing spondylitis (AS, n=12), and non-radiographic axSpA (nr-axSpA, n=16). Patients took part in 90-minute telephone interviews. A semi-structured interview guide was used to assist discussions. The CE section used broad, open-ended questions to elicit information about symptoms and impact experienced by patients. The CD section involved a 'think-aloud' exercise in which patients read out each instruction, item and response option for the three PROMIS Short Forms and shared their feedback. Patients were also asked detailed questions about the relevance of the items, response options and recall period. Verbatim interview transcripts were subject to thematic and content analysis.
Results: Patients were from the United States (n=20) and Germany (n=8), mean age was 52.8 years, and 57% (n=16) were male; mean time since diagnosis of axSpA was 9.5 years (range 0.3–31.3 years). The CE section identified 12 distinct signs and symptoms that characterised patients' experience of axSpA: pain, sleep problems, fatigue/tiredness, stiffness, swelling, vision/eye issues, restricted body movements, headache/migraine, spasms, change in posture/stature, balance/coordination problems and numbness. Pain, sleep problems and fatigue/tiredness were all reported to be experienced by ≥90% of patients, occurring simultaneously and exacerbating one another. 78% (n=21/27) of patients reported pain to be the most bothersome symptom, and 88% (n=23/26) described it as the symptom they would most like treatment to improve. Patients reported axSpA to impact their lives across six health-related quality of life (HRQoL) domains: physical functioning (100%), emotional wellbeing (89%), work/volunteering (79%), social functioning (75%), activities of daily living (61%) and cognitive functioning (54%). Impacts were most frequently described as being associated with pain, stiffness and fatigue. The experiences of symptoms and impacts were consistent between the AS and nr-axSpA patients. CD showed all three PROMIS instruments are conceptually comprehensive and well understood by patients with axSpA. No patients reported misunderstanding of instructions and/or items of the sleep disturbance instrument, and only one and four items had a small number of instances of misunderstanding for the fatigue and pain interference instruments, respectively. Across each instrument, all items were relevant to at least half of patients, and almost all patients reported the instruments to be appropriate for measuring their experience of sleep problems, pain and fatigue due to axSpA. Both AS and nr-axSpA patients confirmed the three PROMIS Short Forms to be relevant and appropriate for assessing their disease experience.
Conclusion: Pain, sleep problems and fatigue are pivotal symptoms of axSpA and associated with HRQoL impacts. Interpretability and content validity of the PROMIS customised Short Forms have been confirmed, with each deemed to adequately assess key impacts associated with axSpA, making them suitable for use in clinical trials of patients with axSpA.

AB1584-PARE UNDERSTANDING HETEROGENEITY IN PATIENTS' CONCEPTUALIZATION OF TREATMENT FOR RHEUMATOID ARTHRITIS: A CLUSTER ANALYSIS

B. Hsiao[1], J. Downs[2], M. Lanyon[2], J. R. Curtis[3], S. Blalock[4], C. Wiedmeyer[5], S. Venkatachalam[5], W. B. Nowell[5], L. Fraenkel[6,7]. *[1]Yale-New Haven Medical Center, Rheumatology, New Haven, United States of America*; *[2]Carnegie Mellon, Social and Decision Sciences, Pittsburgh, United States of America*; *[3]University of Alabama at Birmingham, Division of Clinical Immunology & Rheumatology, Birmingham, United States of America*; *[4]University of North Carolina, Chapel Hill, Division of Pharmaceutical Outcomes and Policy, Chapel Hill, United States of America*; *[5]Global Healthy Living Foundation, Patient-Centered Research, Upper Nyack, United States of America*; *[6]Berkshire Medical Center, Rheumatology, Lenox, United States of America*; *[7]Yale University, School of Medicine, New Haven, United States of America*

Background: Uptake of treat to target strategies for the management of rheumatoid arthritis (RA) is low. System-related barriers to accessing treatment are known, but poor adherence to starting and continuing treatment are prevalent causes of suboptimal care.
Objectives: To better understand heterogeneity in patients' conceptualization of RA treatment to inform interventions aimed at improving appropriate utilization of disease modifying antirheumatic drugs (DMARDs).
Methods: Participants (pts) were recruited from the ArthritisPower US online research registry. Pts who met eligibility criteria [physician diagnosed RA currently being treated with DMARD(s)] rated 56 items (coded on 5-point scales) reflecting concepts raised during in-depth patient interviews. To combine similar items for ease of analysis and interpretation, we conducted a principal components analysis using Varimax rotation. We then entered mean scores, weighted by how heavily each item loaded onto each factor, into a k-means cluster analysis. We examined whether demographic characteristics differed across clusters using ANOVA for continuous and chi-square for categorical variables.
Results: Pts (N= 621) ranged in age from 22 to 93, with a mean of 57 years (SD= 11.5). Most (89%) were female and reported as non-Hispanic white (89%); 27% reported having a post-graduate degree. A scree plot revealed that a 4-factor solution explaining 36.8% of the variance would provide desirable interpretability, with a discontinuous drop in eigenvalues for additional factors slowly tapering and adding little discriminability between later solutions. The four factors (% variance explained, number of items) were: 1) Access to high quality care and support (12.10%, n= 21); 2) Comfortable adding/switching DMARDs (9.73%, n= 14); 3) Perceived favorable DMARD risk/benefit ratio (8.74%, n= 15); and 4) Confidence that testing reflects disease activity (6.20%, n= 6). A 5-cluster solution showed the most stable convergence of cluster centers after 10 iterations. Figure 1 shows the weighted mean scores for each factor across clusters. The largest group (31.7%) is characterized by mean scores on each of the four factors toward the high end of mean responses for the sample, reflecting positive experiences; we labeled this group "Successfully Engaged in Care" to indicate a positive rheumatologist relationship, feeling well-informed and active participation in care. The next group (24.3%) also had high scores for Factor 1 (access to high quality care/support) and Factor 3 (perceived favorable DMARD risk/benefit ratio), but were less comfortable adding/switching DMARDs (Factor 2) and had less confidence in testing reflecting their disease activity (Factor 4); we labeled this group "Worried About Medication." The three remaining clusters are smaller. The third cluster (16.4%), labeled "Skeptical of Testing," had a favorable view of DMARDs (Factor 3) despite lower scores related to access and quality of care (Factor 1) and confidence in testing (Factor 4). The fourth cluster (14.3%) expressed low perceived value of DMARDs as well as reduced scores for DMARD risk/benefit and confidence in testing; we labeled this group "Resistant to DMARDs." The last cluster (13.2%) scored lowest on their rating of access to high quality care and support, indicating less access to, and satisfaction with, information needed to

support decision making. Their perceived risk/benefit ratio for DMARDs was still favorable, so we labeled this group "Dissatisfied with Care."
Conclusion: Patients' conceptualization of RA treatment varies, but discomfort with adding/switching DMARDs appears to be ubiquitous regardless of perceived benefits associated with DMARDs and access to high quality care/support. Interventions outside of the traditional physician-patient relationship are needed to facilitate treatment escalation in patients with RA. Further research is required to understand residual variance not explained by our model.

AB1585-PARE

DO PATIENT AND PHYSICIAN ASSESSMENTS OF A HEALTH CARE VISIT MATCH FOR HISPANIC/LATINX PATIENTS WITH RHEUMATOID ARTHRITIS IN THE UNITED STATES AND PUERTO RICO?

D. Hernandez[1], J. Bravo[2], J. J. Maya[3], O. Soto-Raíces[4], A. Tapia[1], G. Valenzuela[5], W. B. Nowell[1], S. Venkatachalam[1]. *[1]Global Healthy Living Foundation, Medical Affairs and Hispanic Outreach, Nyack, United States of America*; *[2]Novant Health Westbrook, Rheumatology & Arthritis, Winston-Salem, United States of America*; *[3]Rheumatology Center of Palm Beach, PLLC., Rheumatology, Lake Worth, United States of America*; *[4]Soto-Raices Mindful Rheumatix and Medical Research Group, Rheumatology, San Juan, Puerto Rico*; *[5]Integral Rheumatology and Immunology Specialists, Rheumatology, Plantation, United States of America*

Background: Nonlinear associations in rheumatoid arthritis (RA) prevalence and sociodemographic indices suggest social determinants of health affect RA.[1] RA screening tools have lower sensitivity and specificity for Hispanic/Latinx individuals compared with white individuals (77% vs 85% sensitivity and 45% vs 87% specificity).[2] Hispanic/Latinx people also present to physicians later and with more severe RA.[3] There is little research in this population to explain these differences or how they can be addressed. Because it is known the Hispanic/Latinx population has lower English-language proficiency, we hypothesized this is in part because of the lack of validated Spanish-language educational materials and research tools for RA.
Objectives: To validate a Spanish-language patient-provider questionnaire (PPQ) for Hispanic/Latinx patients with RA that had previously been validated as concordant for primary care visits in Sweden.[4] To understand if rheumatologist and patient assessments for Hispanic/Latinx people with RA are concordant when using a Spanish-language digital PPQ. To determine if a Spanish-language rheumatologist-completed PPQ could be a proxy for patient impressions in a prospective clinical study.
Methods: A Spanish-language PPQ for RA was created by translating 9 of 13 questions previously validated in the Swedish study,[4] and adding a question about treating to target specific to RA. The survey was made available on tablet devices in 4 rheumatology clinics in the U.S. and Puerto Rico. Clinic staff obtained patient consent and gathered demographic information to generate a unique confidential identifier code for each visit, which was inputted into surveys on tablet devices. After the visit ended the patient and rheumatologist were each given the PPQ coded for that visit to complete independently of one another. The PPQs were submitted electronically to a secure database in which the visit code was the only identifier recorded.
Results: Across 114 clinical visits, 96.75% of possible answers were recorded and were almost invariably positive with scores of 5 (strongly agree; 88%), 4 (agree; 12%), or 3 (neither agree nor disagree; 0.09%). Physicians responded with 4 (agree) more often than patients (18% vs 6% of responses). Responses from both patient and physician were available for (96.64%) of answered questions. Within these paired answers, 80.67% were concordant (same answer from both patient and physician). Physicians answered 4 when patients answered 5 in 76.5% of discordant responses (different ratings from patient and physician). Most physician ratings of 4 came from 1 of the 4 physicians involved and only 12.5% of patients were responsible for 75% of the patient responses of 4.
Conclusion: Hispanic/Latinx patients with RA and their rheumatologist rated their communication, goal setting, and relationships extremely positively, making it difficult to evaluate true concordance and not possible to use rheumatologist-completed PPQs as proxy for patient assessments. Notably, ratings were substantially different from what is typically seen on Likert scales, which normally skew positively but with a normal distribution. This finding may reflect social determinants of health or cultural differences such as a social-desirability bias toward positive statements about physician-patient interactions. Heterogeneity within the participants is also a plausible explanation, considering that a distinct subset of respondents account for almost all responses below the 5 rating. Further research is needed to identify best practices for measuring treatment to target and patient-rheumatologist interactions in the Hispanic/Latinx population with RA.

Innovations in arthritis health care

AB1586-PARE

MULTI-CENTER, RANDOMIZED, OPEN-LABEL, 2-ARM PARALLEL STUDY TO COMPARE THE PHARMACOKINETICS, SAFETY AND TOLERABILITY OF AVT02 ADMINISTERED SUBCUTANEOUSLY VIA PREFILLED SYRINGE OR AUTOINJECTOR IN HEALTHY ADULT VOLUNTEERS

C. Wynne[1], H. Stroissnig[2], R. Dias[3], J. Sobierska[3], E. Guenzi[3], H. Otto[2], A. Sattar[4], H. N. Haliduola[2], E. Edwald[5], F. Berti[3]. *[1]New Zealand Clinical Research, Clinical Research, Christchurch, New Zealand*; *[2]Alvotech Germany GmbH, Clinical and Medical Affairs, Jülich, Germany*; *[3]Alvotech Swiss AG, Clinical and Medical Affairs, Zürich, Switzerland*; *[4]Alvotech UK Ltd, Clinical and Medical Affairs, London, United Kingdom*; *[5]Alvotech hf., Combination Products & Devices, Reykjavik, Iceland*

Background: AVT02 is an investigational biosimilar to adalimumab. It is approved in Europe, Canada, and the UK. It is not approved by the US Food and Drug Administration (FDA).
Objectives: To evaluate the pharmacokinetic similarity of 100 mg/mL AVT02, an investigational biosimilar of adalimumab, when administered either via a pre-filled syringe, or with a newly developed autoinjector in healthy adult subjects.
Methods: This was a Phase 1, randomized, open-label, parallel-group study in which 207 healthy adult subjects were randomized in a 1:1 ratio to receive 100 mg/mL AVT02 either via a pre-filled syringe, or with an autoinjector, stratified by body weight. Subjects received a single subcutaneous 40 mg dose on Day 1. Pharmacokinetics, immunogenicity, local injection site reactions, and adverse events were assessed prior to, and up to 64 days after, study drug administration.
Results: The results observed supported the assessment of pharmacokinetic similarity of investigational AVT02 administered by pre-filled syringe or with an autoinjector. The 90% CIs for the ratios of geometric least square means for the primary pharmacokinetic parameters C_{max}, AUC_{0-t}, and $AUC_{0-\infty}$ were contained within prespecified margins 80% and 125%, based on an analysis of variance model with treatment as a fixed effect. The mean serum concentration-time profile of adalimumab by treatment group is shown in Figure 1.

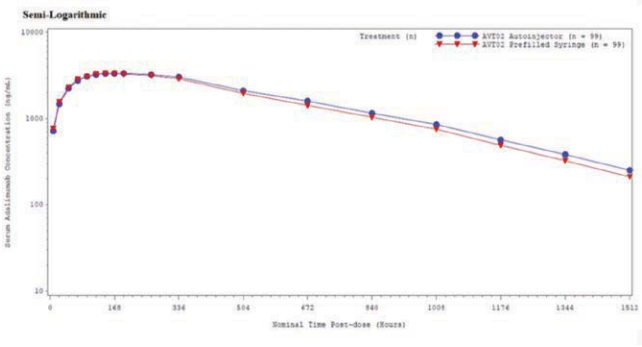

Figure 1. Mean Serum Concentration-Time Profile of Adalimumab by Treatment Group on Semilogarithmic Scale (Pharmacokinetic Population)

Binding anti-drug antibodies were detectable at the end of study visit on Day 64 in 100% and 97.0% of subjects in the pre-filled syringe administration and the autoinjector groups, respectively. Of those subjects positive for anti-drug antibodies, 85.7% and 86.5% further tested positive for neutralizing antibodies in the pre-filled syringe administration and autoinjector groups, respectively. The frequency of local administration site reactions was 11.8% overall and similar between treatment groups. The most frequently reported treatment-emergent adverse events in both treatment groups were under the SOC: Infections and infestations (56.0% in the AVT02-pre-filled syringe group and 45.2% in the AVT02-autoinjector group). The safety profiles were generally similar between treatment groups.
Conclusion: The results observed supported the assessment of pharmacokinetic similarity between the pre-filled syringe and autoinjector delivery systems after a single subcutaneous 40 mg dose. The autoinjector delivery system was generally well tolerated in healthy subjects, with a safety and immunogenicity profile similar to that observed with 100 mg/mL AVT02 administered using a pre-filled syringe. Work and rehabilitation

AB1587-PARE **INFLUENCE OF COMPLEX KINESIOTHERAPY ON METABOLISM IN CASES OF SARCOPENIC OBESITY**

V. Vasileva[1], L. Marchenkova[1]. [1]*National Medical Research Center of Rehabilitation and Balneology, Department of Somatic Rehabilitation, Reproductive Health and Active Longevity, Moscow, Russian Federation*

Background: exercise is one of the main factors for the successful treatment of obesity. It is known that with increasing age, muscle strength (sarcopenic obesity) decreases in an obese patient, which can lead to early disability. Regular exercise therapy increases the functional capacity of the metabolism, prevention of obesity among the population, as well as treatment for persons with sarcopenia and obesity. Therefore, it is relevant to study in metabolism obese patients while using kinesiotherapy.
Objectives: aim of the study was to estimate the effect of complex 3-week treatment with 4 kinesiotherapy methods on body weight loss and carbohydrate metabolism in patients with obesity.
Methods: 80 people were enrolled in the study. 40 people in the first group (G1) -26-69 years old with alimentary obesity (mean age 53.7 ± 11 years, weight 106.8 ± 25 kg, BMI 38.3 ± 7.4 kg/m2, waist circumference WC 110.6 ± 16 cm, hip circumference HC 121 ± 15.3 cm. 40 people in the second group (G2) 21-68 years old with alimentary obesity (mean age 51.3 ± 11 years, weight 112.7 ± 25 kg, BMI 41.8 ± 8.2 kg/m2, WC 113.6 ± 16 cm, HC 126.3 ± 15.1 cm. Complex kinesiotherapy administrered daily for 3 weeks and included interactive sensorimotor training on double platform, a special complex of physical exercises in the gym and ergocycle trainings. In addition, in 2 gr. patients additionally included kinesiohydrotherapy in a pool. Weight, WC, HC, carbohydrate tolerance test (TT HC), insulin last 3 weeks was measured at baseline and after the treatment was completed. Evaluation of the results were performed at baseline and in 3 weeks.
Results: there was a significant improve in body weight in two groups (110 ± 24 kg at baseline vs 107 ± 22.5 kg in 3 weeks; p = 0.000), BMI (40 ± 8 vs 39 ± 7.6 kg/m2; p = 0.000), WC (112 ± 15.9 vs 108.1 ± 15 cm; p = 0.000), HC (123.4 ± 15.4 vs 119 ± 14 cm; p = 0.000) in treated obese patients. After 3 weeks, we registered statistically significant elevation in insulin levels of G2 vs to G1. With Z = 2.63 in G1, p = 0.003 and Z = 1.96, p = 0.002 in G2, and Z = 2.87 when assessing the significance elevation between G1 and G2, p = 0.023. Significantly improved performance of TT HC in 1 g. Z = 2.02, p = 0.04, in 2 g. Z = 3.004, p = 0.002. When assessing the significance of differences between G1 and G2 after treatment, Z = 2.3, p = 0.017.
Conclusion: Complex treatment with 4 methods of kinesiotherapy helps to reduce body weight, reduce WC, HC, insulin, TT HC in obesity. However, patients who additionally received kinesiohydrotherapy in a pool showed more significant improvements in metabolism.
